  - Transparent Port UNI — a physical port maps to a Layer 2 VSN I-SID (all traffic through that port, 802.1Q tagged or untagged, ingress and egress is mapped to the I-SID). Note: All VLANs on a Transparent Port UNI interface now share the same single MAC learning table of the Transparent Port UNI I-SID.
- E-Tree UNI — it extends Private VLANs beyond one Switch to form a network-wide E-Tree service infrastructure. An E-Tree UNI is a Layer 2 VSN where broadcast traffic flows from Hub sites to Spokes sites, and from Spokes to Hubs, but not between Spoke sites. E-Tree Hubs can be formed with any VLAN UNI, while E-Tree Spokes must be configured as Private VLAN UNIs.
- Layer 3 VSN UNI — a device-specific VRF maps to an I-SID, and the control plane exchanges the Layer 3 routes belonging to the same I-SID. All VRFs in a network sharing the same Layer 3 I-SID effectively form an Layer 3 VPN. Layer 3 VSNs can be configured to simultaneously support both IP Unicast and IP Multicast.

Transparent Port UNI

Use a Transparent Port User-Network-Interface (Transparent Port UNI or T-UNI) to map an entire port or an MLT to an I-SID. CMAC learning is done against the I-SID. T-UNI configures a transparent port where all traffic is MAC switched on an internal virtual port using the assigned I-SID. No VLAN is involved in this process. Devices switch tagged and untagged traffic in the assigned I-SID regardless of the VLAN ID. The T-UNI port or MLT can be either static or LACP and is not a member of any VLAN or Spanning Tree Group (STG). The T-UNI port or MLT is always in the forwarding state.

You can map multiple ports to a T-UNI I-SID. Multiple ports on the same switch and on other BEBs can use the common I-SID to switch traffic.

T-UNI is a point to point service and all traffic that ingress the UNI egress from the remote UNI end-point

For information about QoS re-marking, see QoS re-marking on a Transparent Port UNI on page 2392.

Transparent

T-UNI is transparent because the MAC learning occurs within the I-SID, and packets that ingress from any CVLAN are processed in an identical manner. Devices switch tagged and untagged traffic in the assigned I-SID. Devices switch control protocols, such as BPDU, LACP, LLDP, and others, in the assigned I-SID, rather than forwarding to the CP.

The service classification of packets that are received on a T-UNI port, is independent of the VLAN ID values present in those packets. All data packets received on a T-UNI port are classified into the same service. When data packets enter and exit the T-UNI service, no VLAN tag modifications are performed on the data packets.

T-UNI based MAC learning

When a packet ingresses a port or MLT associated with a T-UNI I-SID, the system performs MAC lookup based on the I-SID. A packet that ingresses a T-UNI port on a BEB can transfer through the SPB network, or can egress out another T-UNI port configured to the same I-SID.

When a packet ingresses a network-to-network interface (NNI) port, before egressing a T-UNI port, the system performs a MAC Destination Address (DA) lookup based on the I-SID. If the DA lookup fails, the packet floods to all T-UNI ports.

Considerations

Consider the following design requirements when you configure a T-UNI:

- Only E-LAN based T-UNI is supported. All T-UNI I-SID end points for a given I-SID become members of the same shared E-LAN service. If an E-LINE type of service is required, provision T-UNI at the two end points comprising the point-to-point service.
- You cannot configure a T-UNI on the same I-SID as a C-VLAN.
- A port or MLT associated with a T-UNI I-SID cannot be part of any VLAN and does not belong to any STG.
- Ensure that you always associate a T-UNI LACP MLT with a VLAN (even if it is the default VLAN) before adding it to a T-UNI I-SID. Otherwise, traffic is not forwarded on the T-UNI LACP MLT.
- No Layer 3 processing takes place on packets ingressing on a T-UNI port.
- Pause frames do not switch through the T-UNI I-SID.
- Multiple ports or MLTs can be associated with same T-UNI I-SID.
- One port or MLT cannot be part of multiple T-UNI I-SIDs.
- An I-SID mapped to a T-UNI service must not be mapped to any other service, such as Layer 2 VSN and Layer 3 VSN, on any of the remote BEBs in the SPBM network.
- Any Spanning Tree Protocol implementation is disabled on the port or MLT associated with the T-UNI I-SID. The port will always be in a Forwarding state.
- No additional IS-IS TLVs are added to advertise or withdraw T-UNI I-SID services. Extreme Networks makes use of the existing IS-IS TLV-144 and sub TLV-3 to carry I-SID information.
- MACs are learned against the combination of the I-SID and port or MLT.
- The MAC address limit is supported on a per-I-SID basis. For example, the MAC addresses learned on the T-UNI I-SID can be limited.

  Note

  MAC learning limit for T-UNI service is not supported on all hardware platforms.

- Static MAC is not supported for a T-UNI port.
- IP traffic and control packets are transparently bridged over T-UNI endpoints.
- Untagged traffic ingressing on the T-UNI port will use COS 0. B-TAG and I-TAG priorities are derived from the best effort queue that is assigned. If the T-UNI port is set as a Layer 2 untrusted port, a best-effort queue is assigned.
- The 802.1p bits of the incoming traffic are used to derive the B-TAG and I-TAG priorities for tagged traffic.
- LACP, VLACP and LLDP PDUs are extracted to the CP and all other control packets are transparently bridged over the T-UNI port or MLT.

This feature handles control PDUs in the following manner:

All the Layer 2 and Layer 3 control packets are transparently bridged over the T-UNI port or MLT with the exception of LACP, VLACP and LLDP PDUs. LACP PDUs, VLACP PDUs and LLDP PDUs are not transparently bridged over the T-UNI port or MLT if LACP, VLACP or LLDP is enabled on the port or MLT.

- If an LACP MLT is associated with a T-UNI I-SID, LACP PDUs are extracted to CP and processed locally.
- If LACP is not enabled globally and LACP MLT is not associated with the T-UNI I-SID, LACP PDUs are transparently bridged across the T-UNI port or MLT.
- If a VLACP enabled port is added to a T-UNI I-SID, VLACP PDUs are extracted to the CP for local processing. If a port that is not VLACP enabled is added to the T-UNI I-SID, VLACP PDUs are transparently bridged across T-UNI port.
- If a LLDP enabled port is added to a T-UNI I-SID, LLDP PDUs are extracted to the CP for local processing.
- If LLDP is not enabled on the port or MLT interface associated to TUNI I-SID , LLDP PDUs are transparently bridged across the T-UNI port or MLT.

The following list of control packet types are transparently bridged across the T-UNI I-SID:

- SLPP
- VRRP
- OSPF
- RIP
- BGP
- ISIS
- CFM
- STP
- SONMP

Use T-UNI when either of the following apply:

- All tagged and untagged traffic on a port must be classified into the same broadcast domain.
- You want to offer a transparent provider solution.

An example of an application for T-UNI is a typical Ethernet provider deployment with port-based classification and transparent forwarding.

Transparent Port UNI over vIST

Virtual IST (vIST) provides the ability to dual-home hosts, servers and other network devices to a pair of Multi-Chassis Link Aggregation (MC-LAG) enabled devices. The system displays the MC-LAG nodes to the connected devices as one link-aggregated group. So, although the physical connection is spread between two individual network nodes, logically the system displays them as a single connection.

Transparent Port UNI (T-UNI) over vIST peers extends the capability of dual-home hosts on the SPB cloud to achieve higher network resiliency. The MACs learnt on the T-UNI interface of any one vIST peer is synchronized with the other peer through MAC synchronization.

In the following figure, the T-UNI access switch ACCESS-1 is dual-homed into vIST peer hosts VIST-PEER 1 and VIST-PEER 2. At ACCESS-1, a link aggregation is created to connect to the SPBM cluster. On the VIST peers, an SMLT is created towards ACCESS-1. Depending on the link aggregation hashing logic,

traffic is hashed on to VIST-PEER 1 and VIST-PEER 2. The MACs learnt on the T-UNI interfaces of either host is synchronized with the other host.

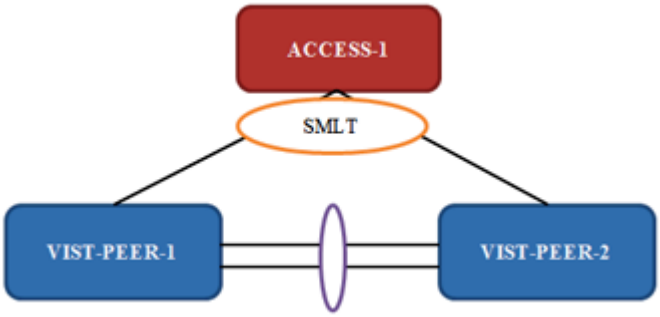

Figure 86: Example of Transparent Port UNI over vIST

If one of the links between ACCESS-1 and the vIST cluster goes down, all traffic is serviced through the other link. The same applies when any of the vIST peers go down. Since MAC learning on both peers are synchronized, both peers can switch traffic with the same efficiency.

Single-homed T-UNI service on a vIST-enabled node

If you configure a T-UNI service as a single-homed service on a vIST-enabled node, you must configure the same I-SID service without port/MLT being mapped to I-SID, on the other vIST peer node. Failure to perform this configuration on the vIST peer node can result in the loss of traffic to the single-homed T-UNI service in various scenarios.

Switched UNI

Switched User Network Interface (S-UNI) allows the association of local endpoints to I-SIDs based on local port and VLAN together. With Switched UNI, the same VLAN can be used on one port to create an endpoint to one I-SID, and on another port to create an endpoint to another I-SID.

Switched UNI summary:

- Switched UNI is a VLAN and ports associated with I-SIDs.
- Local significance on the ports.
- You can re-use the same VLAN to associate different ports with different I-SIDs.
- You can use a different VLAN to the same ports, or you can assign different ports to the same I-SID.
- Supports VLAN mapping on the local switch.
- To accept untagged traffic, the port needs to be configured as untagged-traffic in the I-SID.

Use Switched UNI when either of the following apply:

- Vlan ID (VID) reuse is required. The same VID is used on different broadcast domains (multi-tenant applications).
- Multiple VLANs must be part of the same broadcast domain.
- VID translation is required.

An example of an application for Switched UNI is a typical host and provider deployment, with a port and VID-based classification.

Switched UNI based MAC learning

MAC learning is done on I-SID MAC. When a packet ingresses on a port or MLT which is associated with Switched UNI I-SID, the system performs MAC look up based on the I-SID. Switched UNI operates on Any-To-Any (ELAN) mode, there can be one or more ports associated to a Switched UNI I-SID. A packet that ingresses to a Switched UNI port on a BEB can transfer through the SPBM cloud, or can egress out another Switched UNI port configured to the same I-SID.

When a packet ingresses an network-to-network interface (NNI) port, before egressing a Switched UNI port, the system performs a MAC Destination Address (DA) lookup based on the I-SID. If the DA lookup fails, the packet floods to all Switched UNI ports in the I-SID.

Considerations

Consider the following when you configure a Switched UNI:

- The VLAN tag is removed before the traffic egresses out on the untagged-traffic port or MLT.
- VLAN priority received on the packet is maintained across VLAN IDs.
- Spanning tree is disabled on all Switched UNI ports, and the ports remain in forwarding state.
- The Switched UNI I-SID is advertised to the SPBM cloud.
- The Broadcast and unknown Unicast packets are flooded to all ports in the I-SID.

Limitations

- You cannot change from one UNI type to another dynamically. The I-SID has to be deleted and created with new UNI type (Customer VLAN (C-VLAN), Transparent port user-network-interface (T-UNI), ELAN).
- I-SID cannot be used by IPVPN, MVPN, SPBM dynamic multicast range, or Transparent Port UNI.
- If the port is a member of MLT, the entire MLT has to be added to the VID.
- The port is always in the forwarding state.
- The same VID, port, or MLT cannot be member of more than one I-SID.
- Static MAC, Static ARP and static IGMP group are not supported on Switched UNI enabled ports.

BPDU handling on S-UNI port/MLT

The switch handles Bridge Protocol Data Units (BPDUs) according to whether or not you configure a platform VLAN.

- When you configure a platform VLAN:
  - BPDUs are forwarded to the CPU by default.
  - For both the ingress and egress ports, BPDUs are not flooded in the S-UNI I-SID associated with the platform VLAN.

  Note

  If the platform VLAN is configured for the S-UNI port, you cannot enable BDPU forwarding.

- When you DO NOT configure a platform VLAN:
  - BPDUs received on untagged-traffic ports are dropped by default.
  - To flood BPDUs in its I-SID, enable BPDU forwarding under S-UNI I-SID using the command **`untagged-traffic port <port no> bpdu enable`**.

SPBM sample operation—L2 VSN

The following section shows how a SPBM network is established, in this case, a Layer 2 VSN.

1. Discover network topology

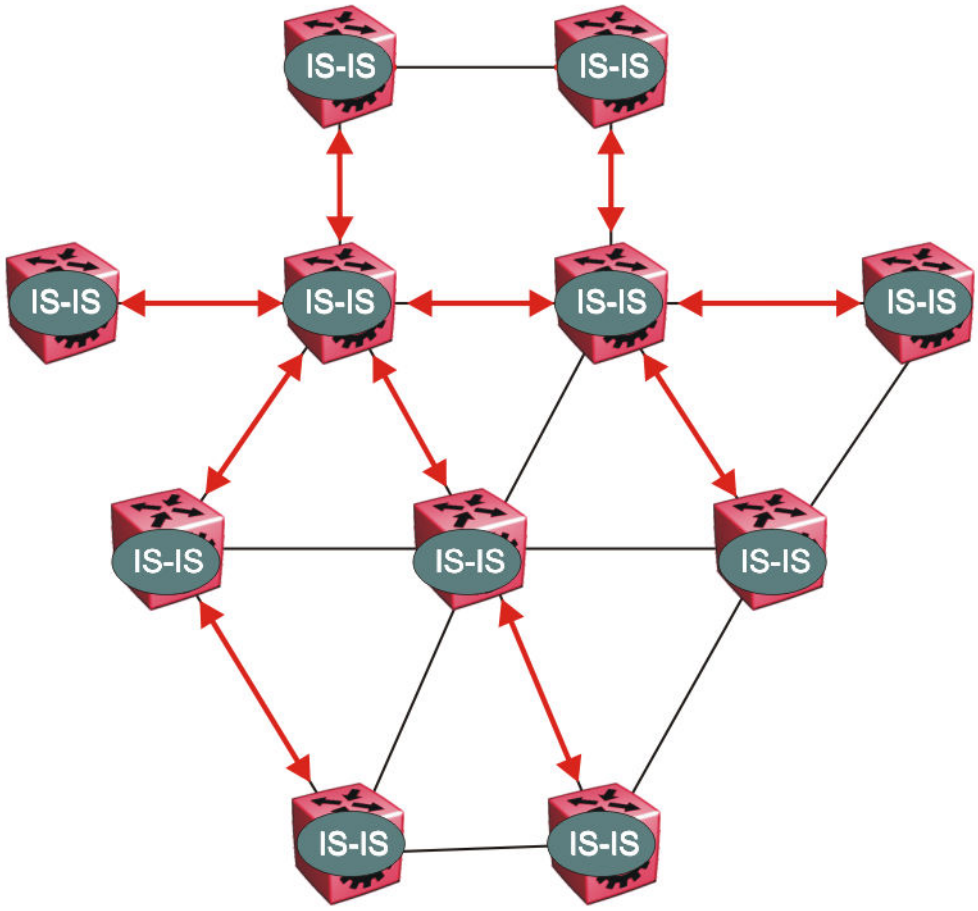

Figure 87: SPBM topology discover

IS-IS runs on all nodes of the SPBM domain. Since IS-IS is the basis of SPBM, the IS-IS adjacency must be formed first. After the neighboring nodes see hellos from each other they look for the same Level (Level 1) and the same area (for example, Area 2f.8700.0000.00). After the hellos are confirmed both nodes send Link State Protocol Data Units, which contain connectivity information for the SPBM node. These nodes also send copies of all other LSPs they have in their databases. This establishes a network of connectivity providing the necessary information for each node to find the best and proper path to all destinations in the network.

Each node has a system ID, which is used in the topology announcement. This same System ID also serves as the switch Backbone MAC address (B-MAC), which is used as the source and destination MAC address in the SPBM network.

2. Each IS-IS node automatically builds trees from itself to all other nodes

   When the network topology is discovered and stored in the IS-IS link state database (LSDB), each node calculates shortest path trees for each source node. A unicast path now exists from every node to every other node

   With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes. Multicast FIB is not produced until Layer 2 VSN services are configured and learned.

3. IS-IS advertises new service communities of interest

   When a new service is provisioned, its membership is flooded throughout the topology with an IS-IS advertisement.

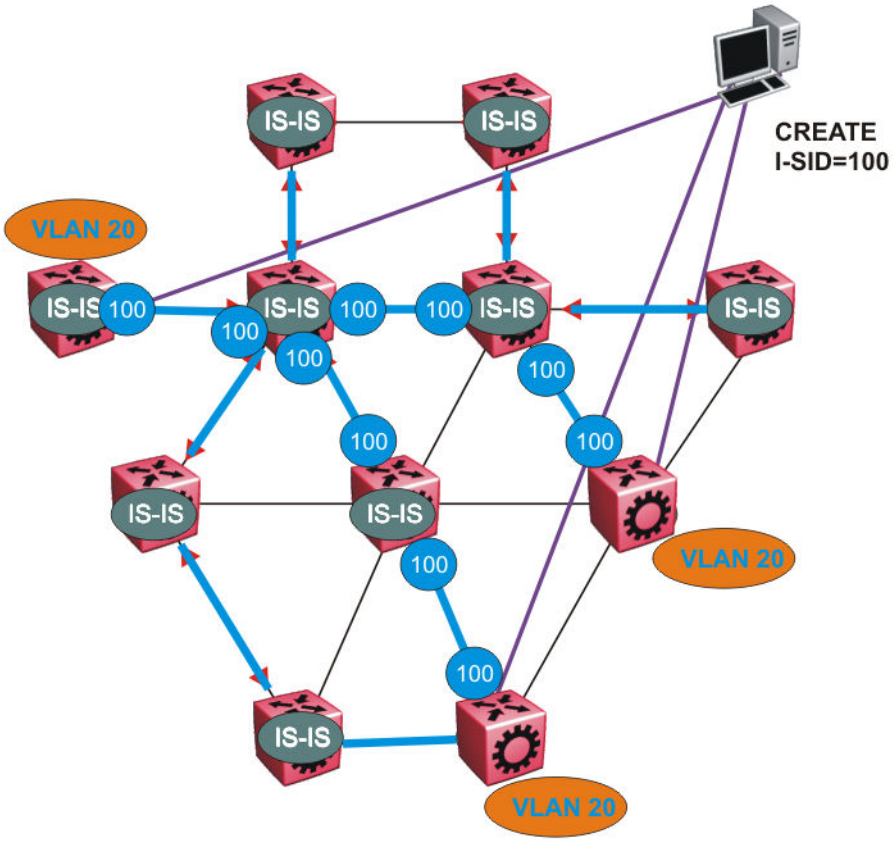

Figure 88: SPBM BMAC and I-SID population

BMAC and I-SID information is flooded throughout the network to announce new I-SID memberships. In this case, VLAN 20 is mapped to I-SID 100.

Note

I-SIDs are only used for virtual services (Layer 2 and Layer 3 VSNs). If IP Shortcuts only is enabled on the BEBs, I-SIDs are never exchanged in the network as IP Shortcuts allow for IP networks to be transported across IS-IS.

Each node populates its FDB with the BMAC information derived from the IS-IS shortest path tree calculations. Thus there is no traditional flooding and learning mechanism in place for the B-VLAN, but FDBs are programmed by the IS-IS protocol.

4. When a node receives notice of a new service AND is on the shortest path, it updates the FDB

   In this scenario, where there are three source nodes having a membership on I-SID 100, there are three shortest path trees calculated (not counting the Equal Cost Trees (ECTs).

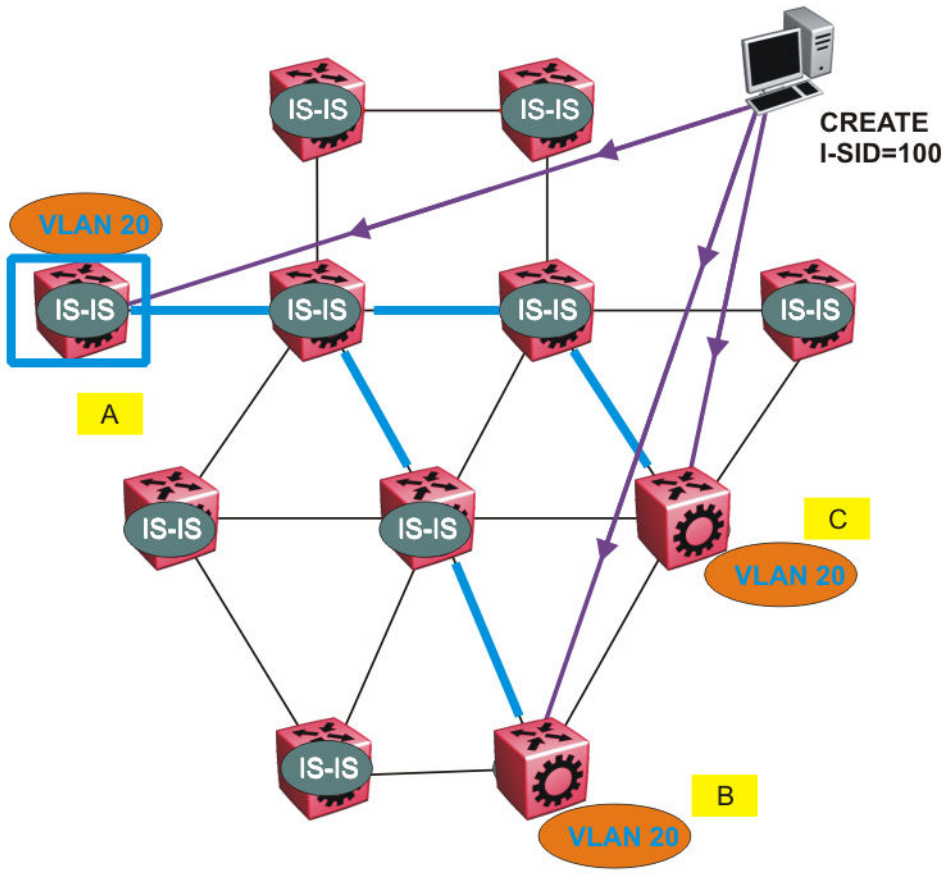

Figure 89: Shortest path tree for source node A

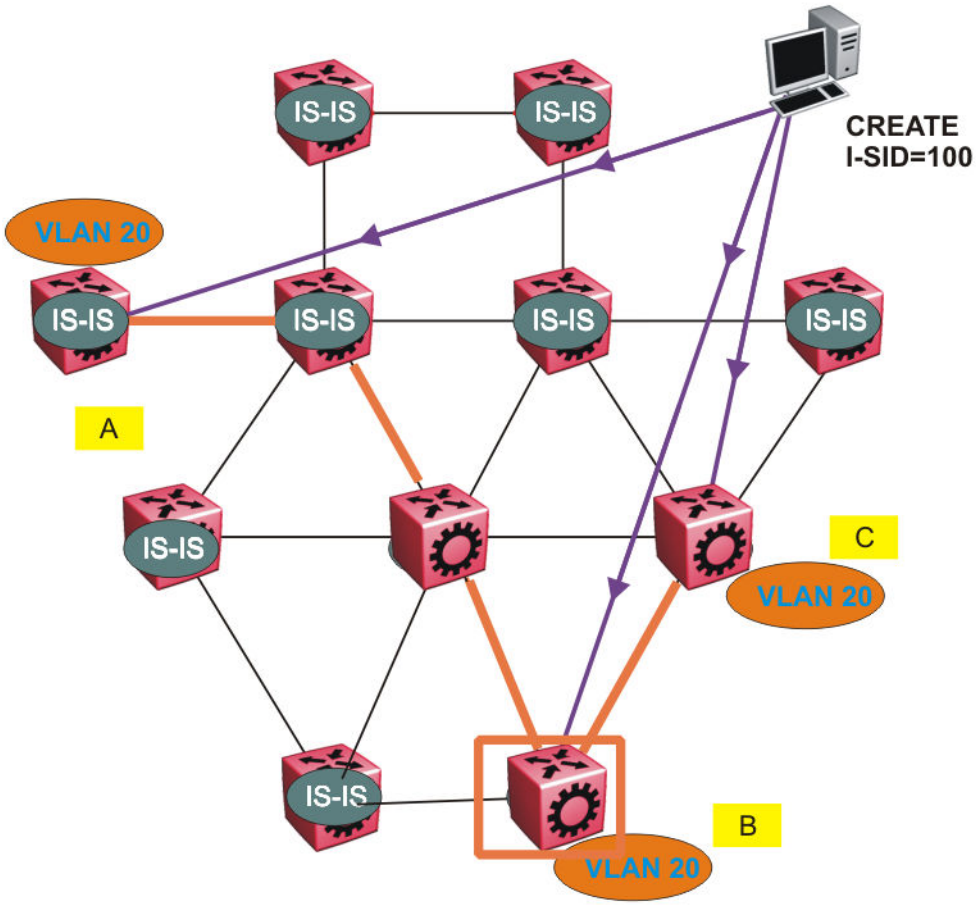

Figure 90: Shortest path tree for source node B

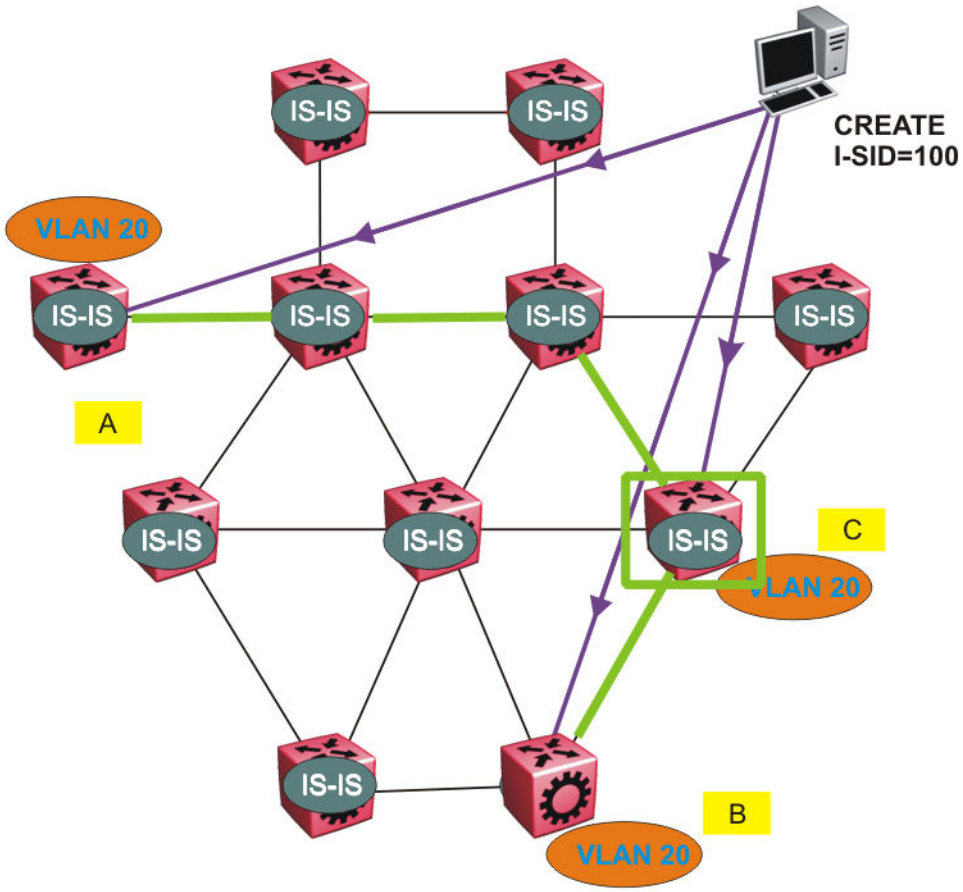

Figure 91: Shortest path tree for source node C

The paths between any two nodes are always the shortest paths. Also, the paths in either direction are congruent, thus a bidirectional communication stream can be monitored easily by mirroring ingress and egress on a link to a network analyzer.

VLAN traffic arriving on switch A and VLAN 20 is forwarded following the blue path, traffic arriving on switch B and VLAN 20 the orange path and on switch C VLAN 20 traffic is following the green path.

If the destination CMAC is unknown at the SPBM ingress node or the traffic is of type broadcast or multicast, then it is flooded to all members of the topology which spans VLAN 20. If the destination CMAC is already known, then the traffic is only forwarded as a unicast to the appropriate destination. In the SPBM domain, the traffic is switched on the BMAC header only. The bridge filtering database (FDB) at the VLAN to I-SID boundary (backbone edge bridge BEB), maintains a mapping between CMACs and corresponding BMACs.

For example, Switch B learns all CMACs which are on VLAN 20 connected to switch A with the BMAC of A in its FDB and the CMACs which are behind C are learned with the BMAC of C.

Layer 2 VSN configuration using the CLI

This section provides procedures to configure Layer 2 VSNs using the CLI.

Configure SPBM Layer 2 VSN

SPBM supports Layer 2 Virtual Service Network (VSN) functionality where customer VLANs (C-VLANs) are bridged over the SPBM core infrastructure.

At the BEBs, customer VLANs (C-VLAN) are mapped to I-SIDs based on the local service provisioning. Outgoing frames are encapsulated in a MAC-in-MAC header, and then forwarded across the core to the far-end BEB, which strips off the encapsulation and forwards the frame to the destination network based on the I-SID-to-C-VLAN provisioning.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Map a customer VLAN (C-VLAN) to a Service Instance Identifier (I-SID):

   ```
   vlan i-sid <1-4059> <0-16777215> [force]
   ```

   

   Important

   When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.

   The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in an SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.

3. Display C-VLAN information:

   ```
   show vlan i-sid
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#vlan i-sid 10 100
Switch:1(config)#show vlan i-sid

Switch:1>show vlan i-sid
================================================================================
                  Vlan I-SID
================================================================================
VLAN_ID      I-SID        I-SID NAME
--------------------------------------------------------------------------------
```

```
1
10           100          Hospital-Server-10
90           1000         ISID-1000

3 out of 3 Total Num of Vlans displayed
```

Variable Definitions

The following table defines parameters for the **vlan i-sid** command.

Variable	Value
<1-4059>	Specifies the primary VLAN ID. Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<0-16777215>	Specifies the service instance identifier (I-SID). Note: The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in an SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service. This value is the same for the primary and secondary VLANs.
force	Specifies the software must replace the existing VLAN-to-I-SID mapping, if one exists.

Configure a Global I-SID Name

Use this procedure to provide a descriptive name for the Service Identifier (I-SID).

You can configure a service name for I-SIDs, loopback interfaces, and static routes. You can configure the service name can before or after you create the I-SID for the following services:

- Layer 2 VSN
- Layer 3 VSN
- ELAN I-SID or Switched UNI I-SID
- ELAN transparent I-SID or Transparent UNI I-SID
- IPv4 and IPv6 static routes
- IPv4 and IPv6 loopback CLIP interface

Note

The service name for I-SIDs does not support the following special characters: “ ” # $ % ‘ / [\ ] ^ { | } ~ @.

By default, the service name is ISID-x, where x correlates to the I-SID number of the service.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enter a name for the global I-SID.

   ```
   i-sid name <1-6777215> WORD<1-64>
   ```

3. Display I-SID names for all configured I-SIDs.

   ```
   show i-sid name
   ```

4. Display I-SID name by I-SID.

   ```
   show i-sid name <1-6777215>
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#i-sid name 1 ExtremeServer1
Switch:1(config)#i-sid name 20 ExtremeServer7
```

View the configured I-SID names:

```
Switch:1(config)#show i-sid name
================================================================================
                          I-SID Name
================================================================================
I-SID           I-SID NAME                      TYPE
--------------------------------------------------------------------------------
1               ExtremeServer1                  adminName
2               ExtremeServer2                  adminName
3               ExtremeServer3                  config adminName
4               ISID-4                          config
23              ISID-23                         config
25              ExtremeServer4                  config adminName

Total number of I-SID Name entries: 6.
```

View the configured I-SID by number:

```
Switch:1#show i-sid name 1
================================================================================
                           I-SID Name
================================================================================
I-SID           I-SID NAME                TYPE
--------------------------------------------------------------------------------
1               ExtremeServer1            adminName

Switch:1#show i-sid name 20
================================================================================
                           I-SID Name
================================================================================
I-SID           I-SID NAME                TYPE
--------------------------------------------------------------------------------
20              ExtremeServer7            adminName
```

Variable Definitions

Use the data in the following table to use the **i-sid name** command.

Variable	Value
<1-6777215>	Specifies the I-SID number.
WORD<1-64>	Specifies the name of the I-SID. The I-SID can be named before or after the I-SID is created. By default, for an I-SID in use, the service is named ISID-x, where x correlates to the I-SID number of the service.

Displaying C-VLAN I-SID information

Use the following procedure to display C-VLAN I-SID information.

Procedure

1. Display the C-VLAN to I-SID associations:
   `show vlan i-sid <1-4059>`
2. Display the IS-IS SPBM multicast-FIB calculation results by I-SID:
   `show isis spbm i-sid {all|config|discover} [vlan <1-4059>] [id <1-16777215>] [nick-name <x.xx.xx>]`
3. Discover where entries are learned:
   `show vlan mac-address-entry [spbm-tunnel-as-mac]`
4. Display the VLAN remote MAC table for a C-VLAN:
   `show vlan remote-mac-table <1-4059>`

Example

```
Switch:1>show vlan i-sid
================================================================================
                    Vlan I-SID
================================================================================
VLAN_ID      I-SID        I-SID NAME

Variable definitions

The following table defines parameters for the **show vlan** commands.

Variable	Value
i-sid <1-4059>	Displays I-SID information for the specified C-VLAN.
mac-address-entry [spbm-tunnel-as-mac]	Displays the bridging forwarding database. Use the optional parameter, *spbm-tunnel-as-mac* to display the BMAC in the TUNNEL column. If you do not use this optional parameter, the TUNNEL column displays the host name. If an entry is not learned in the SPBM network, the *TUNNEL* column will be empty (-).
remote-mac-table <1-4059>	Displays C-VLAN remote-mac-table information.

The following table defines parameters for the **show isis** commands.

Variable	Value
spbm i-sid {all|config|discover}	• all: displays all I-SID entries • config: displays configured I-SID entries • discover: displayes discovered I-SID entries
vlan <1-4059>	Displays I-SID information for the specified SPBM VLAN.
id <1-16777215>	Displays I-SID information for the specified I-SID.
nick-name <x.xx.xx>	Displays I-SID information for the specified nickname.

Configuring an SPBM Layer 2 Transparent Port UNI

Use this procedure to configure a Transparent Port UNI or E-LAN Transparent service.

Note

If you are configuring a T-UNI to terminate on a port or MLT on a switch in a vIST switch cluster, you must also configure the T-UNI I-SID on the other switch of the vIST switch cluster. You must configure the T-UNI I-SID on both switches of a vIST pair. It is not necessary to assign an actual port or MLT to the T-UNI on the second switch.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes creating the SPBM B-VLANs.
- You must associate a T-UNI LACP MLT with a VLAN before mapping the LACP MLT to a T-UNI I-SID.

Caution

In the case of T-UNI LACP SMLT, before you configure SMLT on switch peers, ensure that the T-UNI LACP MLT on each peer is always associated with a VLAN, even if it is the default VLAN, and that it is added to a T-UNI I-SID. Otherwise, traffic is not forwarded on the T-UNI LACP MLT.

About This Task

You can configure Transparent Port UNI when either of the following apply:

- You want all tagged and untagged traffic on a port to be classified into the same broadcast domain.
- You want to offer a transparent provider solution.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure a Transparent Port UNI (Elan-Transparent based service). Enter:

   ```
   i-sid <1-16777215> elan-transparent
   ```

   This command automatically takes you to the Elan-Transparent I-SID Configuration mode.
3. Add ports to the Elan-Transparent based service. Enter:

   ```
   port {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```

   A warning message displays indicating that adding a port to a T-UNI I-SID removes the port from all VLANs. Click `y` when prompted, to continue.
4. Add an MLT to the Elan-Transparent based service. Enter:

   ```
   mlt <1-512>
   ```

   A warning message displays indicating that adding an MLT to a Transparent Port UNI I-SID removes the MLT from all VLANs. Click `y` when prompted, to continue.
5. To verify the Transparent Port UNI configuration, enter:

   ```
   show i-sid <1-16777215>
   ```

6. To remove ports or MLT from the Elan-Transparent based service, enter one of the following commands:

   ```
   no port {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```

   OR

   ```
   no mlt <1-512>
   ```

7. To delete the Elan-Transparent based service, enter:

   ```
   no i-sid <1-16777215>
   ```

Example

Configure a Transparent Port UNI I-SID (elan-transparent based service).

```
Switch:1(config)#i-sid 3 elan-transparent

Switch:1(elan-tp:3)#port 1/25
Adding Ports to Transparent UNI i-sid removes it from all VLANS.
Do you wish to continue (y/n) ? y
Switch:1(elan-tp:3)#

Switch:1(elan-tp:3)#mlt 1
Adding MLTs to Transparent UNI i-sid removes it from all VLANS.
Do you wish to continue (y/n) ? y
Switch:1(elan-tp:3)#
```

Verify Transparent Port UNI or Elan-Transparent based service configuration.

```
Switch:1(config)#show i-sid 3

```

Variable definitions

The following table defines parameters for the **i-sid** command.

Note

When SPB is enabled, I-SID IDs 16000000 (0xF42400) and greater, up to 16,777,215 (0xFFFFFF), are reserved for dynamic i-sid allocation and used to support IP Multicast traffic over SPB and other advanced Fabric services.

Variable	Value
i-sid <1-16777215> elan-transparent	Creates an Elan-Transparent based service. The service interface identifier (I-SID) range is 1 to 16777215.
port {slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Add ports to the Elan-Transparent based service.
mlt<1-512>	Add MLTs to the Elan-Transparent based service. The MLT range is 1 to 512.

View all Configured I-SIDs

Perform this procedure to view all the configured I-SIDs including their types, ports, and MLTs.

About This Task

View all configured I-SIDs (both CVLAN and T-UNI). View also the I-SID types and the ports or MLTs that are assigned to each I-SID.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. View all configured I-SIDs. This command displays both CVLAN and T-UNI based I-SIDs.

   ```
   show i-sid
   ```

3. View all T-UNI (Elan-Transparent) I-SIDs.

   ```
   show i-sid [elan-transparent]
   ```

4. View information for a particular T-UNI I-SID.

   ```
   show i-sid [<1-16777215>]
   ```

5. View all IS-IS SPBM I-SID information by I-SID ID:

   ```
   show isis spbm i-sid {all|config|discover} [vlan <2-4059>] [id <1-16777215>] [nick-name <x.xx.xx>]
   ```

Example

View all configured I-SIDs.

```
Switch:1(config)#show i-sid

Variable Definitions

Note

When SPB is enabled, I-SID IDs 16777216 and greater are reserved for internal I-SID and SPB multicast.

The following table defines parameters for the **`show i-sid`** command.

Variable	Value
<1–16777215>	Specifies the service interface identifier (I-SID).
elan-transparent	Displays only all the Elan-Transparent (T-UNI based) I-SIDs.

The following table defines parameters for the **show isis spbm i-sid** command.

Variable	Value
{all|config|discover}	• all: displays all I-SID entries • config: displays configured I-SID entries • discover: displayes discovered I-SID entries
vlan <2-4059>	Displays I-SID information for the specified SPBM VLAN.
id <1-16777215>	Displays I-SID information for the specified I-SID.
nick-name <x.xx.xx>	Displays I-SID information for the specified nickname.

View C-MACs Learned on T-UNI Ports for an I-SID

Perform this procedure to view the I-SID bridge forwarding database.

About This Task

The **show i-sid mac-address-entry** command displays the C-MACs learned on T-UNI I-SIDs. It also displays the C-MACs learned on T-UNI I-SIDs for a specific I-SID, MAC address, port or port list or remote MAC address.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View C-MACs learned on the T-UNI I-SIDs:

   ```
   show i-sid mac-address-entry [<1-16777215>] [home] [mac
   <0x00:0x00:0x00:0x00:0x00:0x00>] [non-local] [port {slot/port[/sub-
   port] [-slot/port[/sub-port]] [,...]}] [remote]
   ```

Example

View C-MACs learned on all T-UNI I-SIDs.

```
Switch:1#show i-sid mac-address-entry

```

Variable Definitions

The following table defines parameters for the **show i-sid mac-address-entry** command.

Variable	Value
<1-16777215>	Displays the MAC address learned on the service interface identifier (I-SID).
home	Filters the command output to show only MAC addresses learned in the home area.
mac <0x00:0x00:0x00:0x00:0x00:0x00>	Displays the I-SID FDB details for the specified MAC address.
non-local	Filters the command output to show only MAC addresses learned from other nodes; not local nodes.
port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Displays the MAC address learned on the specified port or port list.
remote	Filters the command output to show only MAC addresses learned in the remote area.

Configure an SPBM Layer 2 Switched UNI on an MLT

Shortest Path Bridging MAC (SPBM) supports Layer 2 Virtual Service Network (VSN) functionality where Switched UNIs are bridged over the SPBM core infrastructure.

Switched User Network Interface (S-UNI) allows the association of local endpoints to I-SIDs based on local port and VLAN together. With Switched UNI, the same VLAN can be used on one port to create an endpoint to one I-SID, and on another port to create an endpoint to another I-SID.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.

About This Task

To configure a Switched UNI on an MLT, you must create a Switched UNI I-SID, and map an MLT to the Switched UNI I-SID.

Note

When you configure Switched UNI, Spanning tree is disabled on all the Switched UNI ports.

Procedure

1. Enter MLT Interface Configuration mode:

   ```
   enable

   configure terminal

   interface mlt <1-512>
   ```

2. Enable S-UNI on MLT:

   ```
   flex-uni enable
   ```

   Note
   You cannot enable Switched UNI on EAPoL enabled interface.

3. Configure a Switched UNI Service Instance Identifier (I-SID):

   ```
   i-sid <1-16777215> [elan]
   ```

   This command automatically takes you to the Elan I-SID Configuration mode.

4. Add an MLT to a Switched UNI I-SID:

   ```
   c-vid <c-vid> mlt <1-512>
   ```

   Note
   You can run this command again to map a Switched UNI MLT to multiple I-SIDs.

5. Add untagged traffic to a Switched UNI I-SID:

   ```
   untagged-traffic mlt <1-512> [bpdu enable]
   ```

6. Display the Switched UNI information:

   ```
   show mlt i-sid
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#mlt 10
Switch:1(config)#interface mlt 10
Switch:1(config-mlt)#flex-uni enable
Switch:1(config-mlt)#i-sid 100
Switch:1(elan:100)#c-vid 20 mlt 10
Switch:1(elan:100)#untagged-traffic mlt 10 bpdu enable
Switch:1(elan:100)#show mlt i-sid

Variable definitions

The following table defines parameters for the **i-sid** command to configure a Switched UNI.

Variable	Value
i-sid <1–16777215> elan	Creates an Elan based service. The service interface identifier (I-SID) range is 1 to 16777215.
c-vid *<c-vid>* mlt <mlt-id>	Specifies the customer VLAN ID. Different hardware platforms support different customer VLAN ID ranges. Use the CLI Help to see the available range for the switch.
untagged-traffic mlt <mlt-id> [bpdu enable]	Add untagged traffic to the Elan-based service.

Configuring an SPBM Layer 2 Switched UNI on a Port

Shortest Path Bridging MAC (SPBM) supports Layer 2 Virtual Service Network (VSN) functionality where Switched UNIs are bridged over the SPBM core infrastructure.

Note

EAP and FA can coexist on the same port. EAP and FA can be enabled in any order; however, EAP must have Flex UNI enabled in order to function on an FA-enabled port. If EAP is currently enabled, FA can only be enabled if the port is a Flex UNI-enabled port.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.

About This Task

To configure a Switched UNI on a port, you must create a Switched UNI I-SID, and map the port to the Switched UNI I-SID.

Note

When you configure Switched UNI, Spanning tree is disabled on all the Switched UNI ports.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Switched UNI on a port:

   ```
   flex-uni enable
   ```

3. Configure a Switched UNI Service Instance Identifier (I-SID):

   `i-sid <1-16777215> [elan]`

   This command automatically takes you to the Elan I-SID Configuration mode.
4. Add ports to a Switched UNI I-SID:

   `c-vid <c-vid> port {slot/port[/sub-port][-slot/port[/sub-port]][,...]}`
5. Add untagged traffic to a Switched UNI I-SID:

   `untagged—traffic port {slot/port[/sub-port][-slot/port[/sub-port]][,...]} [bpdu enable]`
6. Display the Switched UNI information:

   `show interface gigabitethernet i-sid {slot/port[/sub-port][-slot/port[/sub-port]][,...]}`

Examples

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/1,1/2
Switch:1(config-if)#flex-uni enable
Switch:1(config-if)#i-sid 100
Switch:1(elan:100)#c-vid 10 port 1/1,1/2
Switch:1(elan:100)#untagged—traffic port 1/1,1/2 bpdu enable
```

```
Switch:1#show interface gigabitEthernet i-sid

Variable definitions

The following table defines parameters for the **i-sid** command to configure a Switched UNI.

Variable	Value
i-sid <1–16777215> elan	Creates an Elan based service. The service interface identifier (I-SID) range is 1 to 16777215.
c-vid *<c-vid>* port *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*	Specifies the customer VLAN ID. Different hardware platforms support different customer VLAN ID ranges. Use the CLI Help to see the available range for the switch.
untagged-traffic < port *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*> [bpdu enable]	Add untagged traffic to the Elan-based service.

View All Configured Switched UNI I-SIDs

Perform this procedure to view all the configured Switched UNI I-SIDs including their types, ports, and MLTs.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. View all configured CVLAN, T-UNI, and S-UNI based I-SIDs:

   ```
   show i-sid
   ```

3. View all S-UNI I-SIDs.

   ```
   show i-sid [elan]
   ```

4. View all associated MLT on the S-UNI I-SID.

   ```
   show mlt i-sid [MLT ID <1–512>]
   ```

5. View all associated ports on the S-UNI I-SID.

   ```
   show interface gigabitethernet i-sid {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```

6. View all IS-IS SPBM multicast FIB entries.

   ```
   show isis spbm multicast-fib detail
   ```

Examples

View all configured I-SIDs.

```
Switch:1#show i-sid

Variable Definitions

The following table defines parameters for the **i-sid** command.

Variable	Value
elan	Displays only all the Elan (S-UNI based) I-SIDs.
MLT ID <1–512>	Specifies the MLT associated with the Switched UNI I-SID.
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Specifies the ports associated with the Switched UNI I-SID.

Display C-VLAN and Switched UNI I-SID Information

Use the following procedure to display C-VLAN and Switched UNI (S-UNI) I-SID information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the C-VLAN to I-SID associations:

   ```
   show vlan i-sid <1-4059>
   ```
3. Display I-SID information and Switched UNI to I-SID associations:

   ```
   show i-sid <1-16777215>
   ```
4. Display the IS-IS SPBM multicast-FIB calculation results by I-SID:

   ```
   show isis spbm i-sid {all|config|discover} [vlan <1-4059>] [id <1-16777215>] [nick-name <x.xx.xx>]
   ```
5. Display all elan I-SID:
   - `show i-sid elan`
6. Display I-SID configured on MLT:
   - `show mlt i-sid`
7. Display I-SID configured on port:
   - `show interfaces gigabitethernet i-sid`

Examples

```
Switch# show isis spbm i-sid all

Variable Definitions

The following table defines parameters for the **show vlan i-sid** commands.

Variable	Value
<1-4059>	Displays I-SID information for the specified C-VLAN. You can specify the VLAN ID.

The following table defines parameters for the **show i-sid** commands.

Variable	Value
<1-16777215>	Displays I-SID information. You can specify the I-SID ID.

The following table defines parameters for the **show isis** commands.

Variable	Value
spbm i-sid {all|config|discover}	• all: displays all I-SID entries • config: displays configured I-SID entries • discover: displays discovered I-SID entries

Layer 2 VSN configuration using EDM

This section provides procedures to configure Layer 2 Virtual Services Networks (VSNs) using Enterprise Device Manager (EDM).

Configuring SPBM Layer 2 VSN

After you have configured the SPBM infrastructure, you can enable the SPBM Layer 2 Virtual Service Network (VSN) using the following procedure.

SPBM supports Layer 2 VSN functionality where customer VLANs (C-VLANs) are bridged over the SPBM core infrastructure.

At the BEBs, customer VLANs (C-VLAN) are mapped to I-SIDs based on the local service provisioning. Outgoing frames are encapsulated in a MAC-in-MAC header, and then forwarded across the core to the far-end BEB, which strips off the encapsulation and forwards the frame to the destination network based on the I-SID-to-C-VLAN provisioning.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.

Procedure

1. In the navigation pane, expand **Configuration** > **VLAN**.
2. Click **VLANs**.
3. Click the **Advanced** tab.

4. To map a C-VLAN to a Service instance identifier (I-SID), in the **I-sid** field, specify the I-SID to associate with the specified VLAN.
5. Click **Apply**.

Important

- When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.
- The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in an SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.

Displaying the remote MAC table for a C-VLAN

Use the following procedure to view a the remote MAC table for a C-VLAN.

Procedure

1. In the navigation pane, expand **Configuration** > **VLAN**.
2. Click **VLANs**.
3. Click the **Remote MAC** tab.

Remote MAC field descriptions

Use the data in the following table to use the **Remote MAC** tab.

Name	Description
VlanId	Indicates the VLAN ID for this MAC address.
Addr	Indicates the customer MAC address for which the bridge has forwarding and/or filtering information
DestAddr	Indicates the provider MAC address for which the bridge has forwarding and/or filtering information.
PrimaryBVlanId	Indicates the primary B-VLAN ID for this MAC address.
PrimaryDestSysName	Indicates the primary system name of the node where the MAC address entry comes from.
PrimaryPort	Either displays the value 0, or indicates the primary port on which a frame came from.
SecondaryBVlanId	Indicates the secondary B-VLAN ID for this MAC address
SecondaryDestSysName	Indicates the secondary system name of the node where the MAC address entry comes from.
SecondaryPort	Either displays the value 0, or indicates the secondary port on which a frame came from.

Name	Description
SmltRemote	Indicates the MAC address entry for the remote vIST peer.
Status	Indicates the status of this entry: • other • invalid • learned • self • mgmt

Configure UNI

Use the following procedure to configure a Transparent Port UNI or Switched UNI by mapping an I-SID to a port or MLT and VLAN together.

Note

If you are configuring a T-UNI to terminate on a port or MLT on a switch in a vIST switch cluster, you must also configure the T-UNI I-SID on the other switch of the vIST switch cluster. You must configure the T-UNI I-SID on both switches of a vIST pair. It is not necessary to assign an actual port or MLT to the T-UNI on the second switch.

Before You Begin

You must enable Flex UNI to create a Switched UNI service.

About This Task

You must first create a type of service instance identifier (I-SID) to create the different types of services available. After you create an I-SID you can add members (ports or MLTs) to the I-SID to create end-points for the service.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **ISID**.
3. Select the **Service** tab.
4. To create a Transparent Port UNI service:
   a. Select **Insert**.
   b. Select **elan Transparent** in the **Type** field.
   c. Enter the I-SID in the **Id** field.
5. To create a Switched UNI service:
   a. Select **Insert**.
   b. Select **elan** in the **Type** field.
   c. Enter the I-SID in the **Id** field.
6. Select **Insert**.

Service Field Descriptions

Use the data in the following table to use the **Service** tab.

Name	Description
ID	Specifies a unique value to identify the service associated with this entry.
Type	Specifies the type of service associated with this entry.
MacLimitEnable	Indicates whether the MAC limit is enabled (true) or disabled (false).
MaxMacLimit	Indicates the maximum learned value of the MAC address for each service I-SID.
Action	Specifies I-SID related actions.
OriginBitMap	Specifies the origin of the I-SID.
VnId	Identifies the VXLAN service associated with this I-SID.
Name	Specifies the name of the I-SID.

Associate a Port and MLT with an I-SID for Elan Transparent

Transparent Port UNI (T-UNI) maps a port or MLT to an I-SID. Transparent Port UNI configures a transparent port where all traffic is MAC switched on an internal virtual port using the assigned I-SID. Multiple ports on the same unit and on other Backbone Edge Bridges (BEBs) are switched on a common I-SID. No VLAN is involved in this process. The T-UNI port is not a member of any VLAN or STG.

Use the following procedure to associate a port and MLT with an I-SID.

Before You Begin

- You must configure Transparent Port UNI. For more information, see Configuring Transparent UNI.
- You must associate a T-UNI LACP MLT with a VLAN before mapping the LACP MLT to a T-UNI I-SID.

Caution

Ensure that a T-UNI LACP MLT is always associated with a VLAN (even if it is the default VLAN) before adding it to a T-UNI I-SID. Otherwise, traffic is not forwarded on the T-UNI LACP MLT.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **ISID**.
3. On the **Service** tab, select a row with the type configured as elanTransparent.
4. Select **ELAN**.
5. Select port members.
6. Select MLT Ids.
7. Select **Apply**.

Elan Transparent field descriptions

Use the data in the following table to use the Elan Transparent tab.

Name	Description
PortMembers	The set of ports that are members of the elanTransparent service type. From the ports available, you can select single or multiple ports.
MltIds	The set of bits that represent the MLT Ids. From the MLTs available, you can select any, or all of the MLTs to be a part of elan transparent i-sid .

Viewing the I-SID forwarding database

View the I-SID forwarding database (FDB).

Note

To view the T-UNI I-SID FDB entries filtered on a port that is part of an MLT, you must mention the MLT ID in the option for the port.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **ISID**.
3. Select the **FDB** tab.
4. (Optional) Select the **Filter** button to filter rows based on specific filter criteria.

FDB Field Descriptions

Use data in the following table to use the **FDB** tab.

Name	Description
IsidId	Specifies the service interface identifier (I-SID).
Address	Specifies the MAC address of the port assigned to the specific I-SID or C-MAC learned on the particular I-SID.
Status	Specifies the learning status of the associated MAC.
Port	Specifies the port on which the MAC is learned for the specific I-SID.
PortType	Specifies if the MAC address is learned locally or on an network-to-network interface (NNI) port from a remote destination.
RemoteMacDestAddr	Specifies the virtual BMAC address or system-ID of the remote destination.
RemoteMacBVlanId	Specifies the B-VLAN ID on which the remote destination was discovered.
RemoteMacDestSysName	Specifies the remote destination system name.
Cvid	Specifies the customer VLAN ID of the associated Switched UNI port.

Associate a Port and MLT with an I-SID for Elan

Shortest Path Bridging MAC (SPBM) supports Layer 2 Virtual Service Network (VSN) functionality where Switched UNIs are bridged over the SPBM core infrastructure.

Switched User Network Interface (S-UNI) allows the association of local endpoints to I-SIDs based on local port and VLAN together. With switched UNI, the same VLAN can be used on one port to create an endpoint to one I-SID, and on another port to create an endpoint to another I-SID.

Use the following procedure to associate a port and MLT with an I-SID.

About This Task

You must configure Switched UNI.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **ISID**.
3. On the **Service** tab, select a row with the type configured as elan.
4. Select **Switched Uni**.
5. Select **Insert**.
6. Enter the VLAN ID in the **Cvid** field.
7. Select **Port** or **Mlt** to update the interface index in the **IfIndex** field.
8. Select **Insert**.

Switched Uni field descriptions

Use the data in the following table to use the **Switched Uni** tab.

Name	Description
Isid	Displays the I-SID.
Cvid	Specifies the customer VLAN identifier.
IfIndex	Specifies the interface index of the Elan end point.
Bpdu	Enables or disables for an untagged end point. The default is disabled.
OriginBitmap	Specifies the origin information of the service associated with the I-SID Elan end point.
MacBased	Shows if the current entry is associated to a MAC-based Switched User Network Interface (S-UNI).

Viewing the I-SID interface

View the I-SID interface.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **ISID**.
3. Select the **Interface** tab.

   Select **Filter** to filter rows on specific filter criteria.

Interface field descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
IfIndex	Specifies the interface index
Isid	Specifies the service interface identifier (I-SID).
Isid Name	Specifies the service interface identifier name.
Vlan	Specifies the platform VLAN.
Cvid	Specifies the customer VID.
Type	Specifies the type of service associated with the I-SID interface.
OriginBitMap	Specifies the origin of the service associated with the I-SID interface.
Bpdu	Specifies the BPDU forward option for the untagged traffic port.
MacBased	Specifies the Switched UNI MAC address.

Modify Global I-SID Name

About This Task

Use this procedure to modify the assigned name for the Service Identifier (I-SID).

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **ISID**.
3. Select **Global Name**.
4. View the name of the I-SID in the **ISID Name** field. To modify, double-click the name of the I-SID and type a new name.
5. Select **Apply**.

Global Name Field Descriptions

Use the data in the following table to use the **Global Name** tab.

Name	Description
ISID Id	Specifies the index number that uniquely identifies the I-SID.
ISID Name	Specifies the name of the I-SID, which can be up to 64 characters.
UsedByType	Specifies the I-SIDs that are in use as services. An I-SID can have one base type or a combination of base types so that multiple services can use the same I-SID at the same time.

Layer 2 VSN configuration examples

This section provides configuration examples to configure Layer 2 VSNs.

Examples and network illustrations in this document may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

Layer 2 VSN Configuration Example

The following figure shows a sample Layer 2 VSN deployment.

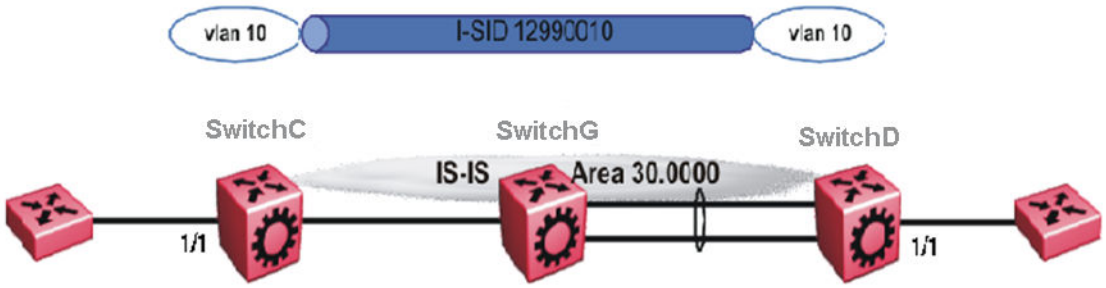

Figure 92: Layer 2 VSN

The following sections show the steps required to configure the Layer 2 VSN parameters in this example. You must first configure basic SPBM and IS-IS infrastructure. For more information, see: SPBM configuration examples on page 1034.

```

Inter-VSN Routing Configuration

Table 91: Inter-VSN Routing product support

Feature	Product	Release introduced
Inter-VSN routing (IPv4)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Inter-VSN routing (IPv6)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Inter-VSN routing configuration fundamentals

This section provides fundamental concepts on Inter-VSN Routing.

Inter-VSN routing

Inter-VSN routing with SPBM allows routing between Layer 2 VLANs with different I-SIDs.

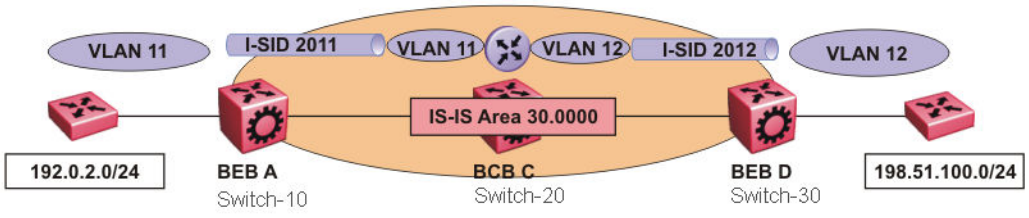

Figure 94: Inter-VSN routing

Inter-VSN routing provides a routing hub for Layer 2 Virtual Services Network edge devices, Layer 3 devices, routers, or hosts connected to the SPBM cloud using the SPBM Layer 2 VSN service. To go

between a routed network, a Layer 2 VSN termination point provides the routing services to hop onto another Layer 2 VSN, using I-SID.

Note

The Layer 2 VLANs must be in the same VRF. You cannot route traffic between two different VRFs with Inter-VSN routing.

In this example, the C-VLANs are associated with I-SIDs on the BEBs using SPBM Layer 2 VSN. With Inter-VSN routing enabled, BCB C can route traffic between VLAN 11 (I-SID 2011) and VLAN 12 (I-SID 2012).

IP interfaces are where the routing instance exists. In this case, on Switch-20.

Note

The switch does not support IP multicast over Fabric Connect routing on inter-VSN routing interfaces.

Inter-VSN routing configuration using the CLI

This section provides a procedure to configure Inter-VSN routing using the CLI.

Configure SPBM Inter-VSN Routing

Inter-VSN allows you to route between IP networks on Layer 2 VLANs with different I-SIDs. Inter-VSN routing is typically used only when you have to extend a VLAN as a Layer 2 Virtual Services Network (VSN) for applications such as vMotion. As a best practice, use IP Shortcuts or Layer 3 VSNs to route traffic. You must configure both the Backbone Edge Bridges (BEBs) and the Backbone Core Bridge (BCB).

Note

To enable inter-VSN routing, you must configure IP interface where the routing instance exists.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Follow the procedures below on the Backbone Edge Bridges (BEBs) containing the VSNs you want to route traffic between.
   a. Create a customer VLAN (C-VLAN) by port:
      ```
      vlan create <2-4059> type port-mstprstp <0-63>
      ```
   b. Add ports in the C-VLAN:
      ```
      vlan members add <1-4059> {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
      ```

c. Map a customer VLAN (C-VLAN) to a Service Instance Identifier (I-SID):

```
vlan i-sid <1-4059> <0-16777215> [force]
```

Important

When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.

3. On the Backbone Core Bridge (BCB), create a VRF and add a VLAN for each VSN:
   a. Create a VRF:

```
ip vrf WORD<1-16> vrfid <1-511>
```

   b. Create a VLAN to associate with each VSN:

```
vlan create <2-4059> type port-mstprstp <0-63>
```

   c. Enter VLAN Interface Configuration mode:

```
interface vlan <1-4059>
```

   d. Add a VLAN to the VRF you created in step a:

```
vrf WORD<1-16>
```

   e. Associate an I-SID with the VLAN:

```
vlan i-sid <1-4059> <0-16777215> [force]
```

Important

When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.

The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in an SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.

   f. Configure an IP address for the VLAN:

```
ip address {A.B.C.D/X}
```

   g. Repeat steps b to f for every VLAN you want to route traffic between.

Variable Definitions

The following table defines parameters for the **`vlan create`** command.

Variable	Value
<2-4059>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
type port-mstprstp <0-63> [color <0-32>]	Creates a VLAN by port: • *<0-63>* is the STP instance ID. • *color <0-32>* is the color of the VLAN.

The following table defines parameters for the **vlan members add** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

The following table defines parameters for the **vlan i-sid** command.

Variable	Value
<1-4059>	Specifies the primary VLAN ID. Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<0-16777215>	Specifies the service instance identifier (I-SID). You cannot use I-SID 0x00ffffff. The system reserves this I-SID to advertise the virtual BMAC in an SMLT dual-homing environment. This value is the same for the primary and secondary VLANs.
force	Specifies the software must replace the existing VLAN-to-I-SID mapping, if one exists.

The following table defines parameters for the **ip vrf** command.

Variable	Value
WORD <1–16>	Create the VRF and specify the name of the VRF instance.
vrfid <1–511>	Specifies the VRF instance by number.

The following table defines parameters for the **vrf** command.

Variable	Value
WORD <1–16>	Specifies the VRF name. Associates a port to a VRF.

The following table defines parameters for the **ip address** command.

Variable	Value
{A.B.C.D/X}	Configures an IP address for the VLAN.

Inter-VSN routing configuration using EDM

This section provides procedures to configure Inter-VSN routing using Enterprise Device Manager (EDM).

Configure BEBs for Inter-VSN Routing

Use Inter-VSN routing to route between IP networks on Layer 2 VLANs with different I-SIDs. Inter-VSN routing is typically used only to extend a VLAN as a Layer 2 Virtual Services Network (VSN) for applications such as vMotion. Use IP Shortcuts or Layer 3 VSNs to route traffic. You must configure both the Backbone Edge Bridges (BEBs) and the Backbone Core Bridge (BCB).

Note

To enable inter-VSN routing, you must configure the IP interface where the routing instance exists.

Before You Begin

You must configure the required SPBM and IS-IS infrastructure.

About This Task

Follow these steps on the BEBs that contain the VSNs you want to route traffic between.

Procedure

1. Create a customer VLAN (C-VLAN) by port and add ports in the C-VLAN:
   a. In the navigation pane, expand **Configuration** > **VLAN**.
   b. Select **VLANs**.
   c. On the **Basic** tab, select **Insert**.
   d. For **Id**, type an unused VLAN ID, or use the ID provided.

e. For **Name**, type the VLAN name, or use the name provided.
f. For **Color Identifier**, select a color from the list, or use the color provided.
g. For **Type**, select **byPort**.
h. For **PortMembers**, select the ellipsis **(...)**.
i. Select the ports to add as member ports.

   The ports that are selected are recessed, while the nonselected ports are not recessed. Port numbers that are dimmed cannot be selected as VLAN port members.
j. Select **OK**.
k. Select **Insert**.

2. Map a C-VLAN to an I-SID:
   a. From the same **Configuration** > **VLAN** > **VLANs** navigation path, select the **Advanced** tab.
   b. For **Isid**, specify the I-SID to associate with the specified VLAN.

      The switch reserves I-SID 0x00ffffff. The switch uses this I-SID to advertise the virtual B-MAC in a SMLT dual-homing environment. The platform clears the receive and transmit bit of this I-SID, therefore I-SID 0x00ffffff cannot be used for any other service.
   c. Select **Apply**.

Important

When a protocol VLAN is created, all ports are added to the VLAN including SPBM ports. To configure a protocol-based VLAN as a C-VLAN, you must first remove the SPBM-enabled ports from the protocol based VLAN, and then configure the protocol-based VLAN as a C-VLAN.

3. Configure the Backbone Core Bridge (BCB) for Inter-VSN Routing. For more information, see Configure BCBs for Inter-VSN Routing on page 1106.

Configure BCBs for Inter-VSN Routing

Inter-VSN allows you to route between IP networks on Layer 2 VLANs with different I-SIDs. Inter-VSN routing is typically used only when you have to extend a VLAN as a Layer 2 Virtual Services Network (VSN) for applications such as vMotion. Use IP Shortcuts to route traffic. You must configure both the Backbone Edge Bridges (BEBs) and the Backbone Core Bridge (BCB).

Note

To enable inter-VSN routing, you must configure the IP interface where the routing instance exists.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure.
- You must configure the BEBs that contain the VSNs you want to route traffic between. For more information, see Configure BEBs for Inter-VSN Routing on page 1105.

About This Task

Follow these steps to configure the BCB for inter-VSN routing.

Procedure

1. On the BCB, create a VRF:
   a. In the navigation pane, expand **Configuration** > **VRF**.
   b. Select **VRF**.
   c. Select **Insert**.
   d. For **Id**, specify the VRF ID.
   e. Name the VRF instance.
   f. Configure the other parameters as required.
   g. Select **Insert**.
2. Create a VLAN to associate with each VSN:
   a. In the navigation pane, expand **Configuration** > **VLAN**.
   b. Select **VLANs**.
   c. On the **Basic** tab, select **Insert**.
   d. For **Id**, type an unused VLAN ID, or use the ID provided.
   e. For **Name**, type the VLAN name, or use the name provided.
   f. For **Color Identifier**, select a color from the list, or use the color provided.
   g. For **Type**, select **byPort**.
   h. For **PortMembers**, select the ellipsis **(...)**.
   i. Select the ports to add as member ports.

      The ports that are selected are recessed, while the nonselected ports are not recessed. Port numbers that are dimmed cannot be selected as VLAN port members.
   j. Select **OK**.
   k. Select **Insert**.
3. Associate the VLAN with an I-SID:
   a. From the same **Configuration** > **VLAN** > **VLANs** navigation path, select the **Advanced** tab.
   b. For **Isid**, specify the I-SID to associate with the specified VLAN.
   c. Select **Apply**.
4. Configure a circuitless IP interface (CLIP):
   a. In the navigation pane, expand **Configuration** > **IP**.
   b. Select **IP**.
   c. Select the **Circuitless IP** tab.
   d. Select **Insert**.
   e. For **Interface**, type a CLIP interface number.
   f. Provide the IP address.
   g. Provide the network mask.
   h. Select **Insert**.

Inter-VSN Routing Configuration Example

The following topics provide a configuration example for Inter-VSN routing.

Examples and network illustrations in this document may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

Inter-VSN Routing with SPBM Configuration Example

The following figure shows a sample Inter-VSN deployment.

Figure 95: Inter-VSN routing configuration

The following sections show the steps required to configure the Inter-VSN parameters in this example. You must first configure basic SPBM and IS-IS infrastructure. For more information, see: SPBM configuration examples on page 1034.

Note that the IP interfaces are configured where the routing instance exists, namely, on SwitchG.

SBPM Reference Architectures

SPBM has a straightforward architecture that simply forwards encapsulated C-MACs across the backbone. Because the B-MAC header stays the same across the network, there is no need to swap a label or perform a route lookup at each node. This architecture allows the frame to follow the most efficient forwarding path from end to end.

The following reference architectures illustrate SPBM with multiple switches in a network.

The following figure shows the MAC-in-MAC SPBM domain with BEBs on the boundary and BCBs in the core.

The following figure illustrates an existing edge that connects to an SPBM core.

The boundary between the MAC-in-MAC SPBM domain and the 802.1Q domain is handled by the BEBs. At the BEBs, VLANs or VRFs are mapped into I-SIDs based on the local service provisioning. Services (whether Layer 2 or Layer 3 VSNs) only need to be configured at the edge of the SPBM backbone (on the BEBs). There is no provisioning needed on the core SPBM nodes.

Provisioning an SPBM core is as simple as enabling SPBM and IS-IS globally on all the nodes and on the core facing links. To migrate an existing edge configuration into an SPBM network is just as simple.

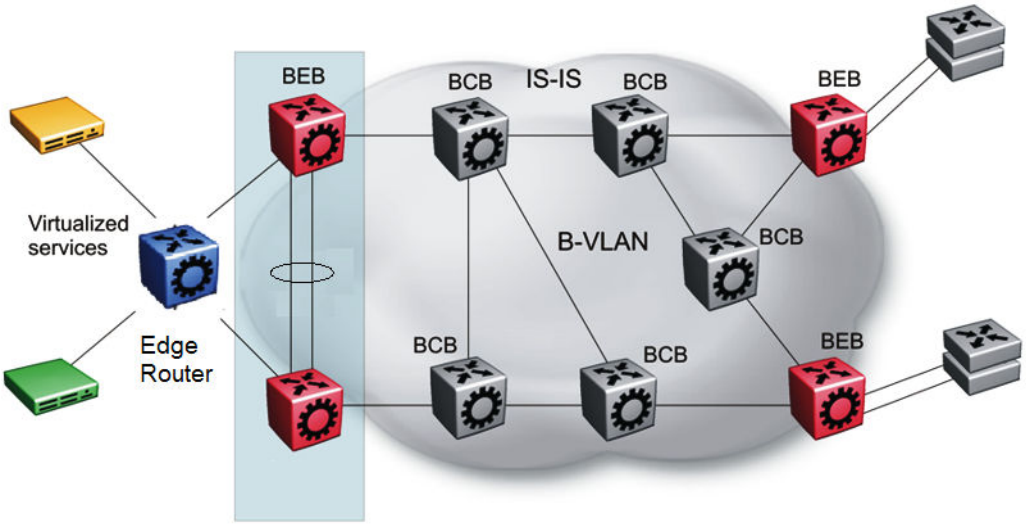

Figure 96: SPBM basic architecture

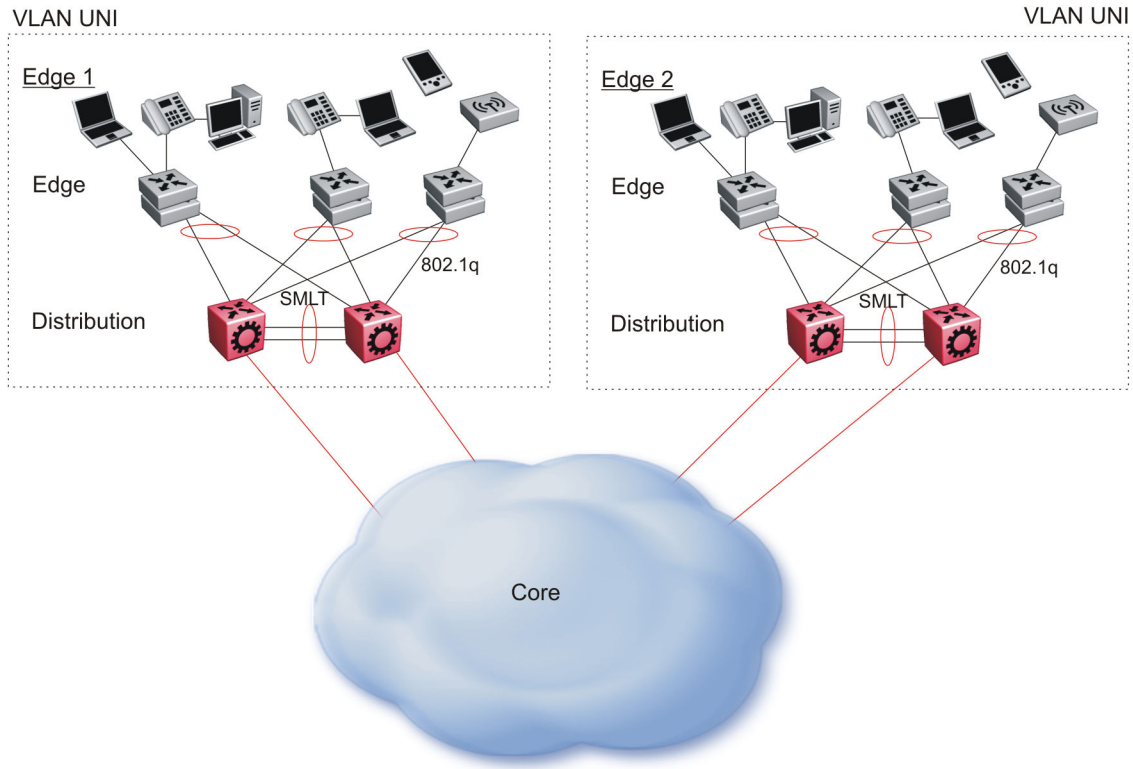

Figure 97: Access to the SPBM Core

All BEBs that have the same I-SID configured can participate in the same VSN. That completes the configuration part of the migration and all the traffic flows return to normal operation.

For Layer 3 virtualized routing (Layer 3 VSN), map IPv4-enabled VLANs to VRFs, create an IP VPN instance on the VRF, assign an I-SID to the VRF, and then configure the desired IP redistribution of IP routes into IS-IS.

For Layer 2 virtualized bridging (Layer 2 VSN), identify all the VLANs that you want to migrate into SPBM and assign them to an I-SID on the BEB.

Campus Architecture

For migration purposes, you can add SPBM to an existing network that has SMLT configured. In fact, if there are other protocols already running in the network, such as Open Shortest Path First (OSPF), you can leave them in place too. SPBM uses IS-IS, and operates independently from other protocols. However, as a best practice, eliminate SMLT in the core and eliminate other unnecessary protocols. This reduces the complexity of the network and makes it much simpler to maintain and troubleshoot.

Whether you configure SMLT in the core, the main point to remember is that SPBM separates services from the infrastructure. For example, in a large campus, a user may need access to other sites or data centers. With SPBM you can grant that access by associating the user to a specific I-SID. With this mechanism, the user can work without getting access to confidential information of another department.

The following figure depicts a topology where the BEBs in the edge and data center distribution nodes are configured in SMLT clusters. Prior to implementing SPBM, the core nodes would also have been configured as SMLT clusters. When migrating SPBM onto this network design, it is important to note that you can deploy SPBM over the existing SMLT topology without network interruption. After the SPBM infrastructure is in place, you can create VSN services over SPBM or migrate them from the previous end-to-end SMLT-based design.

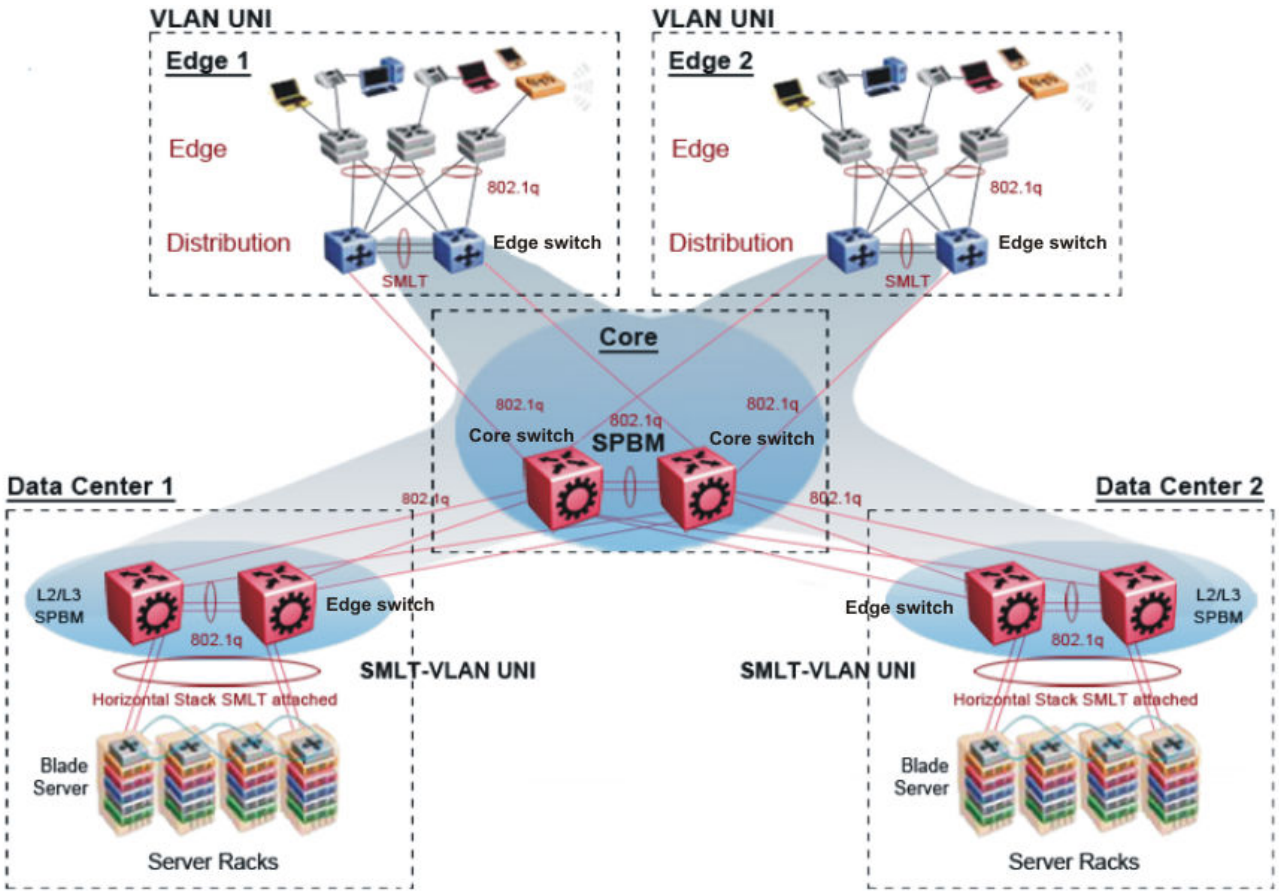

Figure 98: SPBM campus without SMLT

After you migrate all services to SPBM, the customer VLANs (C-VLANs) will exist only on the BEB SMLT clusters at the edge of the SPBM network. The C-VLANs will be assigned to an I-SID instance and then associated with either a VLAN in an Layer 2 VSN or terminated into a VRF in an Layer 3 VSN. You can also terminate the C-VLAN into the default router, which uses IP shortcuts to IP route over the SPBM core.

In an SPBM network design, the only nodes where it makes sense to have an SMLT cluster configuration is on the BEB nodes where VSN services terminate. These are the SPBM nodes where C-VLANs exist and these C-VLANs need to be redundantly extended to non-SPBM devices such as Layer 2 edge stackable switches. On the BCB core nodes where no VSNs are terminated and no Layer 2 edge stackables are connected, there is no longer any use for the SMLT clustering functionality. Therefore, in the depicted SPBM design, the SMLT/vIST configuration can be removed from the core nodes because they now act as pure BCBs that simply transport VSN traffic and the only control plane protocol they need to run is IS-IS.

Because SMLT BEB nodes exist in this design (the edge BEBs) and it is desirable to use equal cost paths to load balance VSN traffic across the SPBM core, all SPBM nodes in the network are configured with the same two B-VIDs.

Where the above figure shows the physical topology, the following two figures illustrate a logical rendition of the same topology. In both of the following figures, you can see that the core is almost identical. Because the SPBM core just serves as a transport mechanism that transmits traffic to the destination BEB, all the provisioning is performed at the edge.

In the data center, VLANs are attached to Inter-VSNs that transmit the traffic across the SPBM core between the data center on the left and the data center on the right. A common application of this service is VMotion moving VMs from one data center to another.

The following figure uses IP shortcuts that route VLANs. There is no I-SID configuration and no Layer 3 virtualization between the edge distribution and the core. This is normal IP forwarding to the BEB.

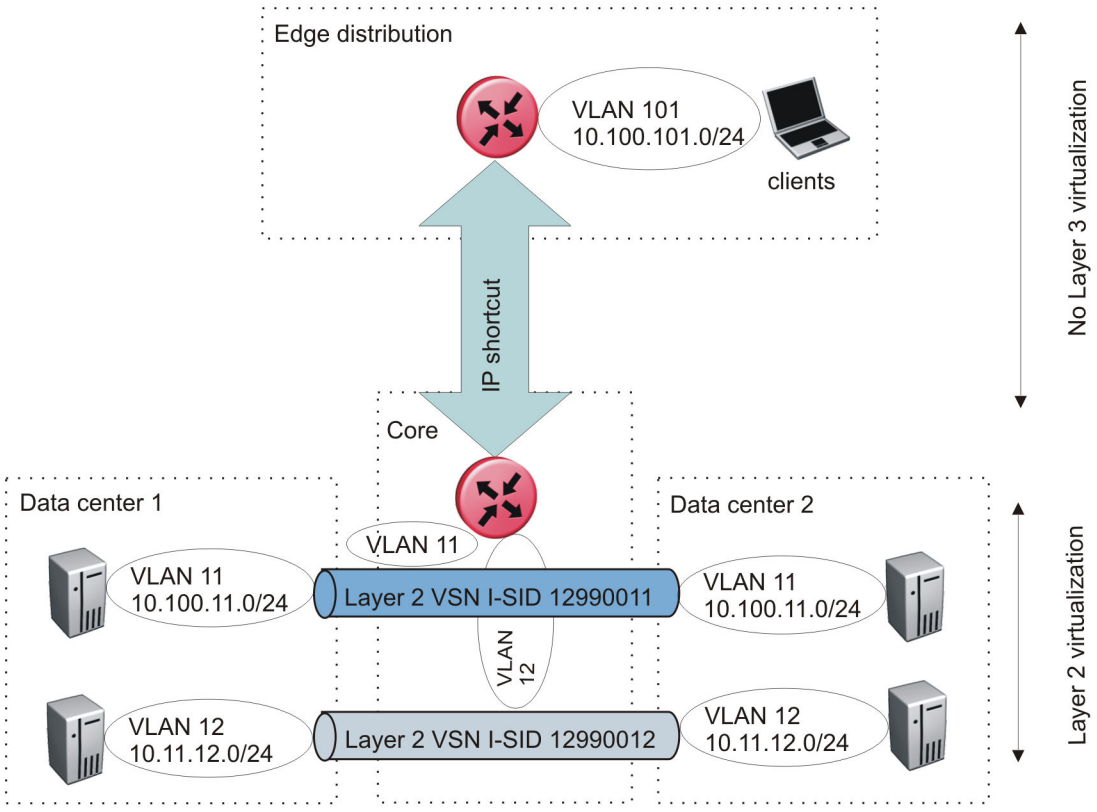

Figure 99: IP shortcut scenario to move traffic between data centers

The following figure uses Layer 3 VSNs to route VRFs between the edge distribution and the core. The VRFs are attached to I-SIDs and use Layer 3 virtualization.

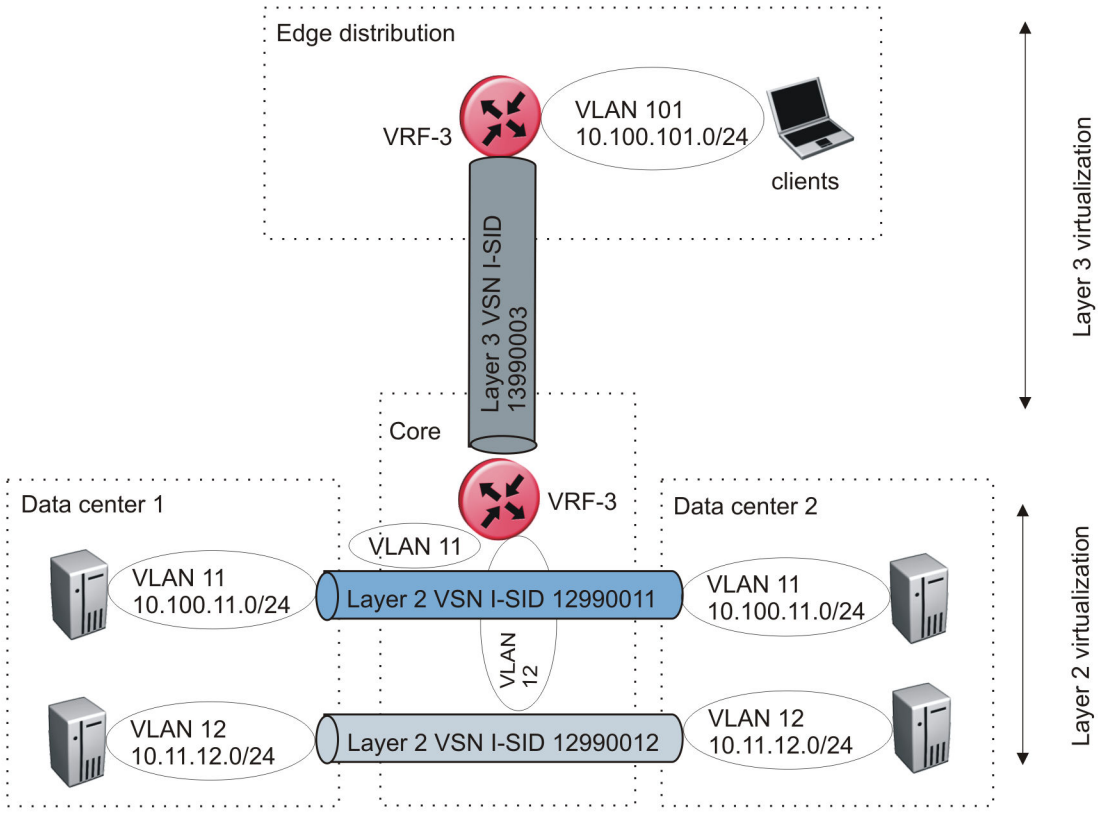

Figure 100: VRF scenario to move traffic between data centers

Large data center architecture

SPBM supports data centers with IP shortcuts, Layer 2 VSNs, or Layer 3 VSNs. If you use vMotion, you must use Layer 2 between data centers (Layer 2 VSN). With Layer 2 VSNs, you can add IP addresses to the VLAN on both data centers and run Virtual Router Redundancy Protocol (VRRP) between them to allow the ESX server to route to the rest of the network.

The following figure shows an SPBM topology of a large data center. This figure represents a full-mesh data center fabric using SPBM for storage over Ethernet. This topology is optimized for storage transport because traffic never travels more than two hops.

Note

As a best practice, use a two-tier, full-mesh topology for large data centers.

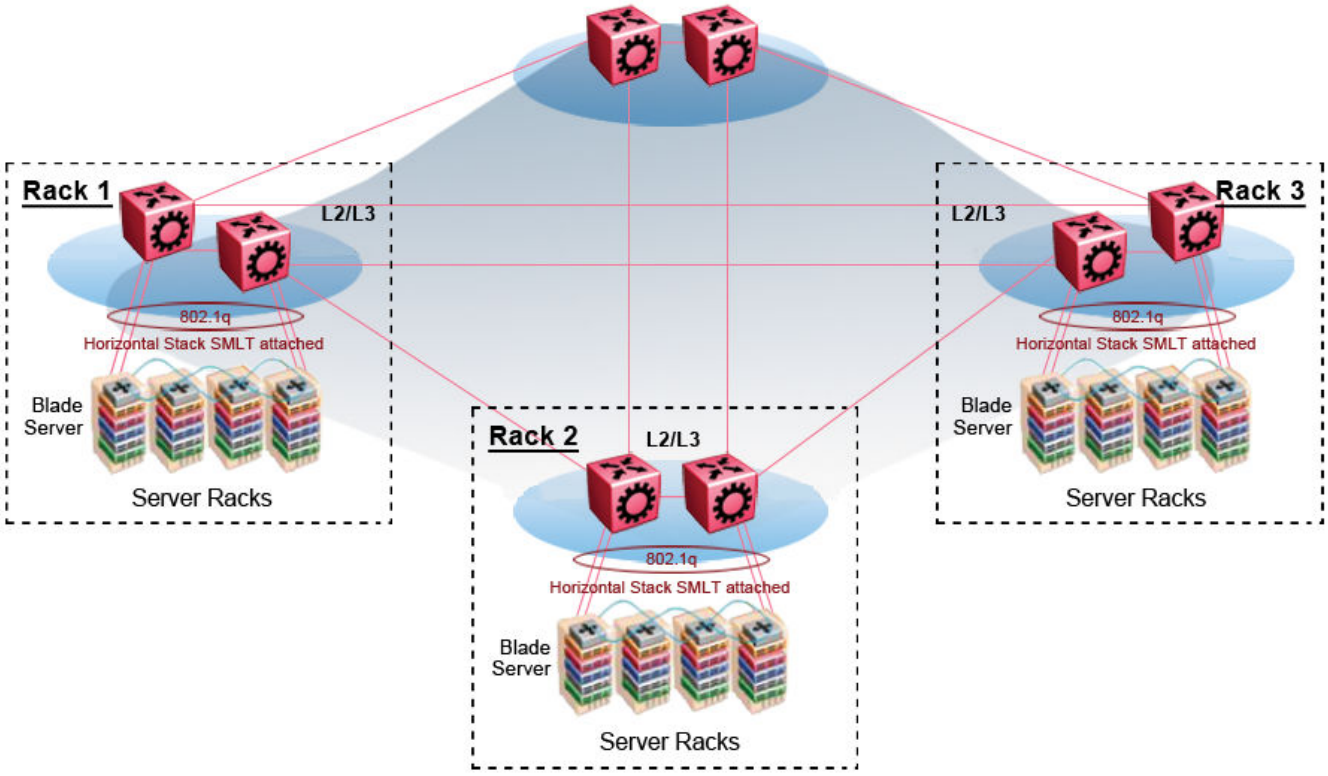

Figure 101: SPBM data center—full mesh

Traditional data center routing of VMs

In a traditional data center configuration, the traffic flows into the network to a VM and out of the network in almost a direct path.

The following figure shows an example of a traditional data center with VRRP configured. Because end stations are often configured with a static default gateway IP address, a loss of the default gateway router causes a loss of connectivity to the remote networks. VRRP eliminates the single point of failure that can occur when the single static default gateway router for an end station is lost.

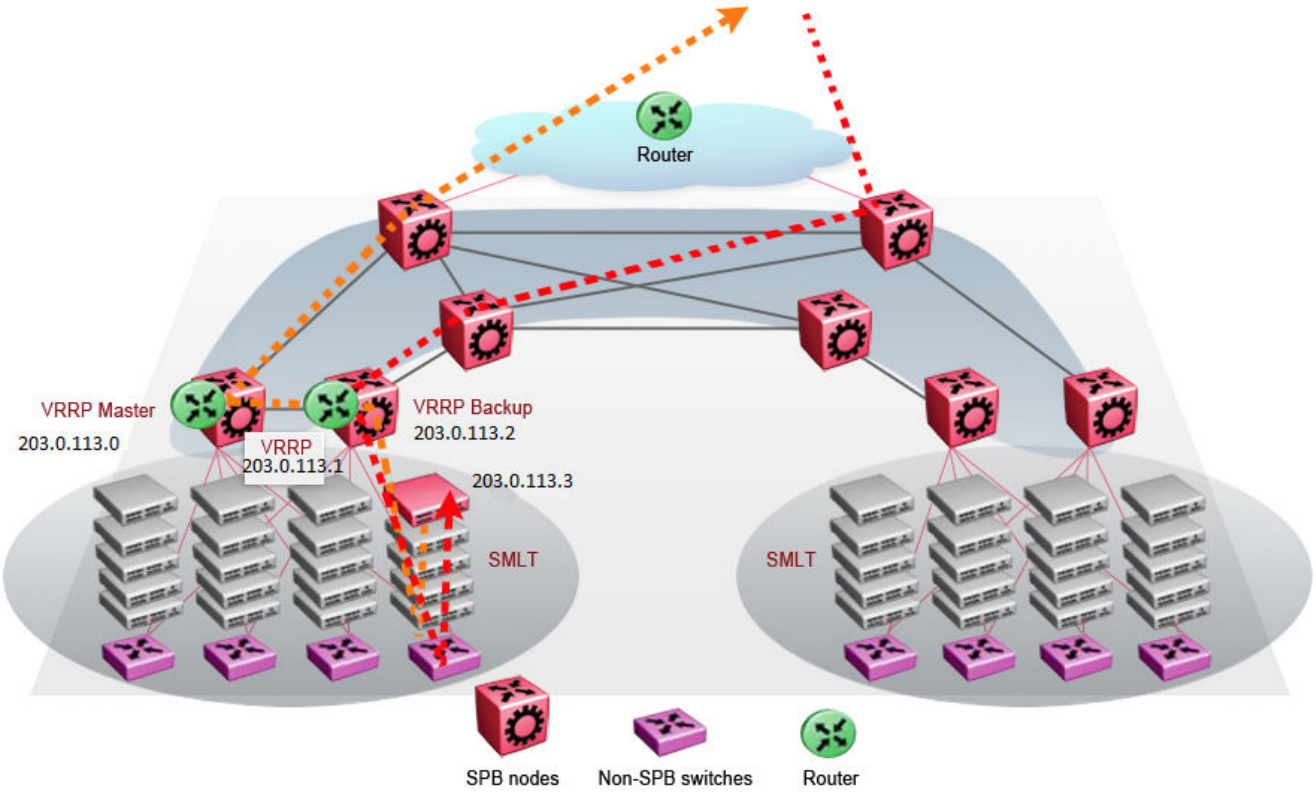

Figure 102: Traditional routing before moving VMs

A VM is a virtual server. When you move a VM, the virtual server is moved as is. This action means that the IP addresses of that server remain the same after the server is moved from one data center to the other. This in turn dictates that the same IP subnet (and hence VLAN) exist in both data centers.

In the following figure, the VM moved from the data center on the left to the data center on the right. To ensure a seamless transition that is transparent to the user, the VM retains its network connections through the default gateway. This method works, but it adds more hops to all traffic. As you can see in the figure, one VM move results in a complicated traffic path. Multiply this with many moves and soon the network look like a tangled mess that is very inefficient, difficult to maintain, and almost impossible to troubleshoot.

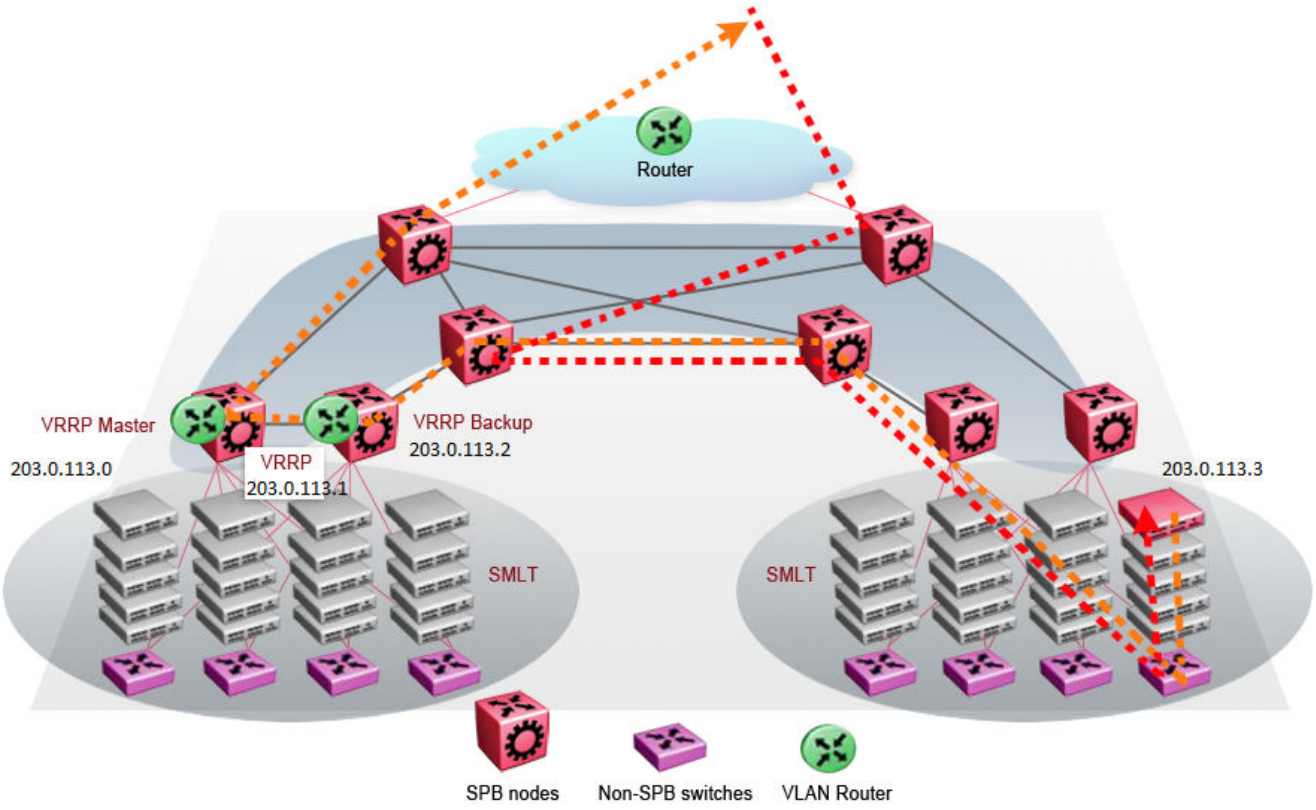

Figure 103: Traditional routing after moving VMs

Optimized data center routing of VMs

Two features make a data center optimized:

- VLAN routers in the Layer 2 domain (green icons)
- VRRP BackupMaster

The VLAN routers use lookup tables to determine the best path to route incoming traffic (red dots) to the destination VM.

VRRP BackupMaster solves the problem of traffic congestion on the vIST. Because there can be only one VRRP Master, all other interfaces are in backup mode. In this case, all traffic is forwarded over the vIST link towards the primary VRRP switch. All traffic that arrives at the VRRP backup interface is forwarded, so there is not enough bandwidth on the vIST link to carry all the aggregated riser traffic. VRRP BackupMaster overcomes this issue by ensuring that the vIST trunk is not used in such a case for primary data forwarding. The VRRP BackupMaster acts as an IP router for packets destined for the logical VRRP IP address. All traffic is directly routed to the destined subnetwork and not through Layer 2 switches to the VRRP Master. This avoids potential limitation in the available vIST bandwidth.

The following figure shows a solution that optimizes your network for bidirectional traffic flows. However, this solution turns two SPBM BCB nodes into BEBs where MAC and ARP learning will be enabled on the Inter-VSN routing interfaces. If you do not care about top-down traffic flows, you can omit the Inter-VSN routing interfaces on the SPBM BCB nodes. This makes the IP routed paths top-down less optimal, but the BCBs remain pure BCBs, thus simplifying core switch configurations.

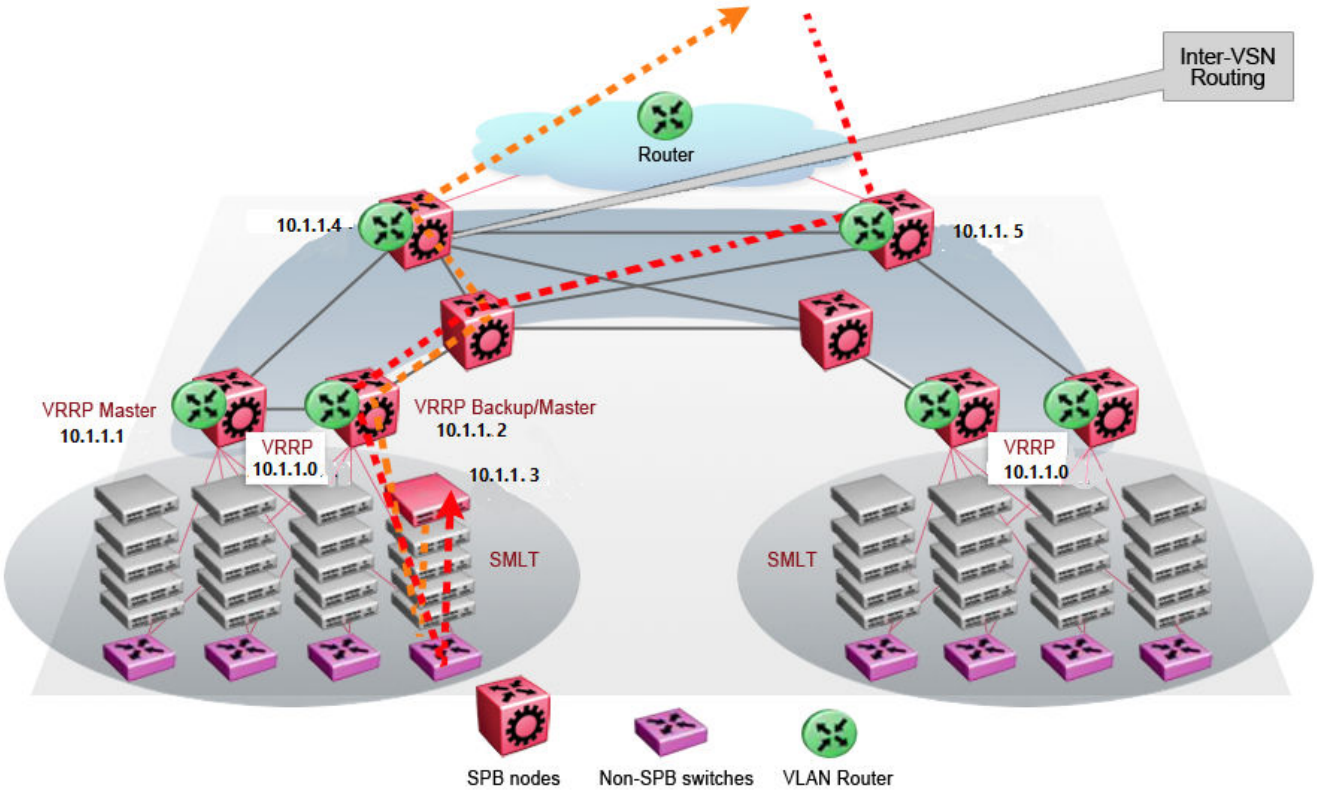

Figure 104: Optimized routing before moving VMs

In the traditional data center, chaos resulted after many VMs were moved. In an optimized data center as shown in the following figure, the incoming traffic enters the Layer 2 domain where an edge switch uses Inter-VSN routing to attach an I-SID to a VLAN. The I-SID bridges traffic directly to the destination. With VRRP BackupMaster, the traffic no longer goes through the default gateway; it takes the most direct route in and out of the network.

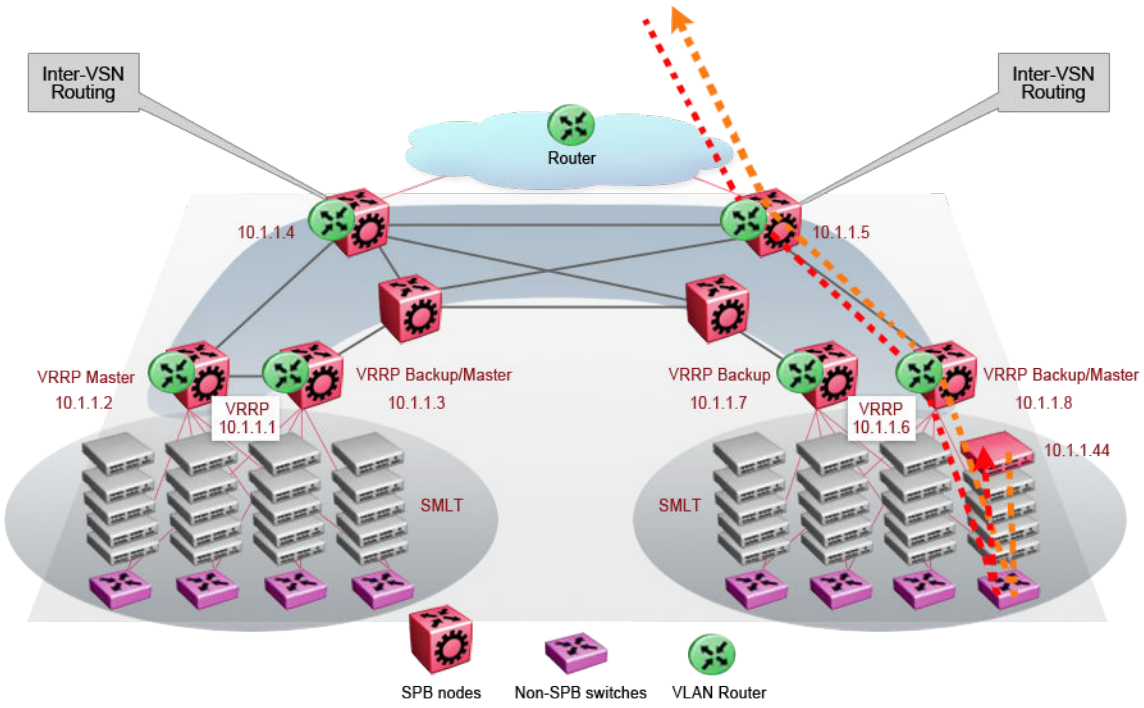

Figure 105: Optimized routing after moving VMs

Fabric Layer 3 Services

IP Shortcuts Configuration

Table 92: IP Shortcuts product support

Feature	Product	Release introduced
IP Shortcut routing including ECMP	5320 Series	Fabric Engine 8.6 Note: Only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration.

	5720 Series	Fabric Engine 8.7

IP Shortcuts configuration fundamentals

This section provides fundamental concepts for IP Shortcuts.

Fabric Connect supports both IPv4 Shortcuts and IPv6 Shortcuts. Because IPv6 Shortcuts depend on IPv4 Shortcuts, you should understand how IPv4 Shortcuts work (see SPBM IP shortcuts) before jumping to the IPv6 section.

SPBM IP Shortcuts

In addition to Layer 2 virtualization, the SPBM model is extended to also support Routed SPBM, otherwise called SPBM IP Shortcuts.

Unlike Layer 2 VSN, with SPBM IP shortcuts, no I-SID configuration is required. Instead, SPBM nodes propagate Layer 3 reachability as “leaf” information in the IS-IS LSPs using Extended IP reachability TLVs (TLV 135), which contain routing information such as neighbors and locally configured subnets. SPBM nodes receiving the reachability information can use this information to populate the routes to the announcing nodes. All TLVs announced in the IS-IS LSPs are grafted onto the shortest path tree (SPT) as leaf nodes.

The following figure shows a network running SPBM IP shortcuts.

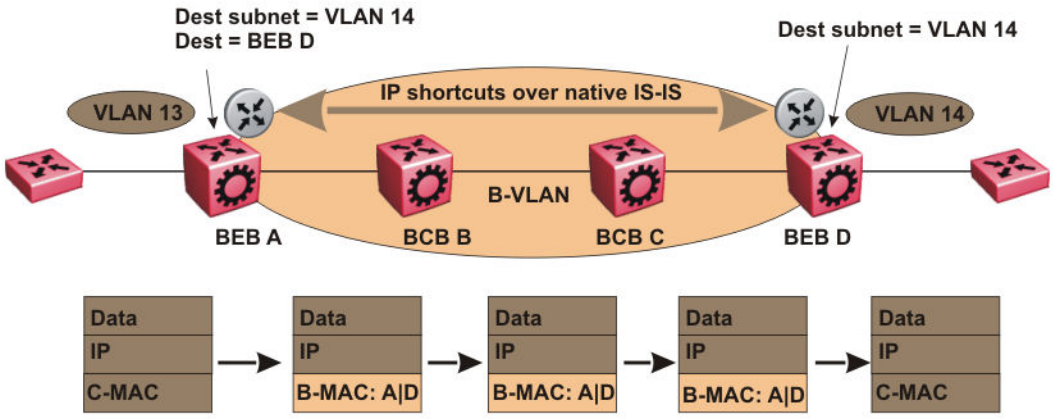

Figure 106: SPBM IP Shortcuts

In this example, BEB A receives a packet with a destination IP address in the subnet of VLAN 14 and knows to forward the packet to BEB D based on the IP route propagation within IS-IS. After a route lookup, BEB A knows that BEB D is the destination for the subnet and constructs a new B-MAC header with destination B-MAC: D. BCBs B and C need only perform normal Ethernet switching to forward the packet to BEB D. A route lookup is only required once, at the source BEB, to identify BEB D as the node that is closest to the destination subnet.

In contrast to IP routing or Multiprotocol Label Switching (MPLS), SPBM IP shortcuts provide a simpler method of forwarding IP packets in an Ethernet network using the preestablished Ethernet FIBs on the BEBs. SPBM allows a network to make the best use of routing and forwarding techniques, where only the BEBs perform an IP route lookup and all other nodes perform standard Ethernet switching based on the existing SPT. This allows for end to end IP-over-Ethernet forwarding without the need for ARP, flooding, or reverse learning.

In the above example, the SPBM nodes in the core that are not enabled with IP shortcuts can be involved in the forwarding of IP traffic. Since SPBM nodes only forward on the MAC addresses that comprise the B-MAC header, and since unknown TLVs in IS-IS are relayed to the next hop but ignored locally, SPBM nodes need not be aware of IP subnets to forward IP traffic.

With IP shortcuts, there is only one IP routing hop, as the SPBM backbone acts as a virtualized switching backplane.

The following figure shows a sample campus network implementing SPBM IP shortcuts.

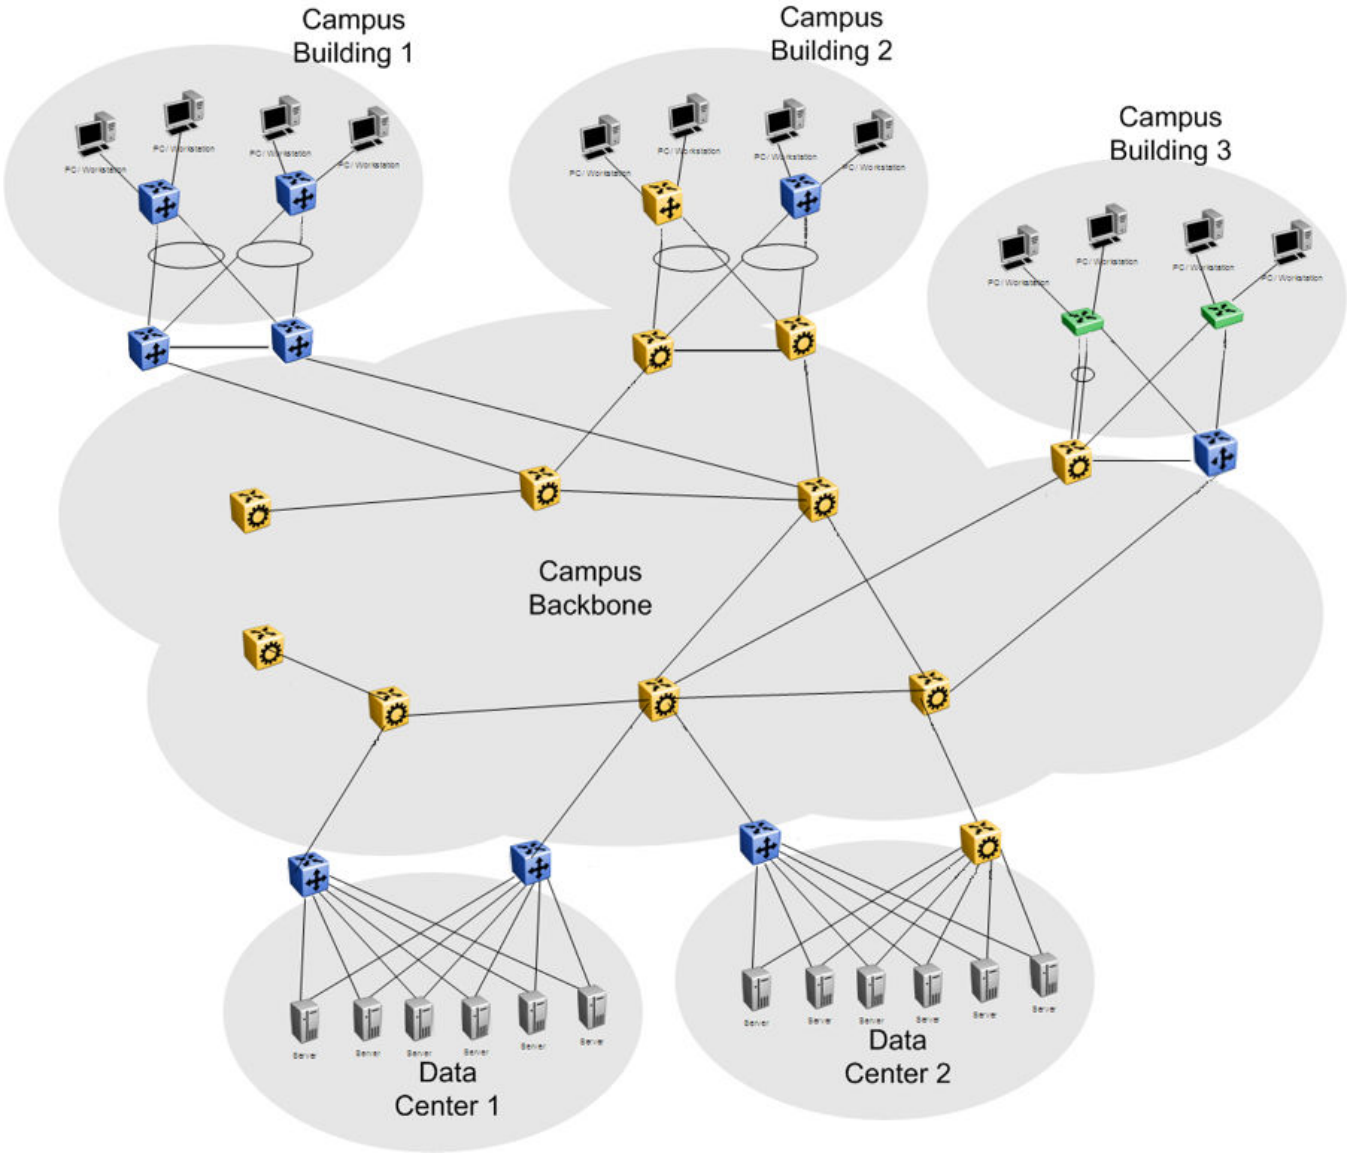

Figure 107: SPBM IP shortcuts in a campus

To enable IP shortcuts on the BEBs, you can configure a circuitless IP address (loopback address) and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 135.

In addition, to advertise routes from the BEBs into the SPBM network, you must enable route redistribution of direct, static, OSPF, RIP, or BGP routes into IS-IS. To advertise IPv6 routes from the BEBs into the SPBM network, you must enable route redistribution of IPv6 direct, IPv6 static, and OSPFv3 routes into IS-IS.

SPBM IPv6 Shortcuts

Both IPv4 and IPv6 Shortcuts use IS-IS as the Interior Gateway Protocol (IGP) and the link state packet (LSP) for reachability information. However, IPv4 Shortcuts use TLV 135 and IPv6 Shortcuts use TLV 236. All TLVs announced in the IS-IS LSPs are grafted onto the shortest path tree (SPT) as leaf nodes. IS-IS

transports the IPv6 reachability information to remote BEBs and uses the shortest path, calculated by SPBM, for data forwarding.

Note

You only configure the IPv6 address information on the edges. There is no IPv6 in the SPBM cloud.

IS-IS transports the IPv6 routes through TLV 236 in the LSP advertisements. These routes are installed in the Global Routing Table (GRT) with the node from which the LSPs carrying the IPv6 routes are received as the next hop.

IPv6 Shortcuts Dependency on IPv4 Shortcuts

IPv6 Shortcuts function in a very similar manner to IPv4 Shortcuts and depends on IPv4 Shortcuts for some functions. For example, IPv6 Shortcuts use the BMAC (local and remote) information created by IPv4 Shortcuts.

Important

IPv4 Shortcuts must be enabled before you enable IPv6 Shortcuts.

An error is displayed if you try to enable IPv6 Shortcuts but do not have IPv4 Shortcuts already enabled.

IPv6 Shortcuts alone can be disabled while leaving IPv4 Shortcuts enabled. When IPv4 Shortcuts is disabled without disabling IPv6 Shortcuts disabled first, a warning or error message is displayed indicating that IPv6 should be disabled first.

Circuitless IPv6 (CLIPv6)

To enable IPv6 Shortcuts on the BEBs and to advertise the local BEB to other IS-IS nodes, you must configure a circuitless IPv6 address (loopback address) and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 236.

IPv6 Shortcuts support Circuitless IPv6 (CLIPv6), which ensures uninterrupted connectivity to the switch as long as there is an actual path to reach it. This route always exists and the circuit is always up because there is no physical attachment.

Migrating the GRT to IPv6 Shortcuts

Use the following steps to migrate the Global Router Table (GRT) to use IPv6 Shortcuts over the SPBM core:

- Identify the nodes that should be enabled with IPv6 Shortcuts. Apply these steps to all of these nodes.
- Activate and validate basic IPv6 Shortcuts. For information, see SPBM IPv6 Shortcuts on page 1124.
- Configure IS-IS route preference to ensure that the IPv6 IGP protocol currently being used in the SPBM core is preferred over the IS-IS routes.
- Enable redistribution of direct and static IPv6 routes into IS-IS.
- Create route policies to permit only IPv6 IGP routes from the access side of the SPBM network.
- Configure redistribution of routes from the IPv6 route table from each of the IPv6 IGP protocols into IS-IS along with the appropriate route policy.

- Use the **show isis spbm ipv6-unicast-fib** command to check the IS-IS LSDB, IS-IS routes, and to verify that all the desired IPv6 routes are now in IS-IS.
- Configure redistribution of IS-IS routes from the IPv6 route table into each of the IPv6 IGP protocols in use. This redistribution does not require a route policy since IS-IS is only supported in the SPBM core.
- Change IS-IS route-preference to ensure that IS-IS routes are preferred over other IPv6 IGP routes.
- Disable/delete old IPv6 IGP in the SPBM core.

Important

Use only one IPv6 routing protocol in the SPBM core to prevent the possibility of routing loops.

IPv6 Shortcut Restrictions and Considerations

The following features are not supported:

- Disabling and enabling alternate routes for IPv6 routes
- Redistribution of RIP into IS-IS
- 6-in-4 tunnels are not supported when the tunnel destination IP is reachable via IPv4 Shortcuts route.

Keep the following considerations in mind when configuring IPv6 Shortcuts:

- IPv4 Shortcuts must be enabled before enabling IPv6 Shortcuts.
- IPv6 Shortcuts support Circuitless IPv6 (CLIPv6) with the following limitations:
  - Stateless address autoconfiguration (SLAAC) is not supported on IPv6 CLIP interfaces.
  - IPv6 CLIP does not support link-local address configuration.
  - To configure an IPv6 address with a prefix length from 65 to 127 on a CLIP interface, you must enable the IPv6 mode flag.
  - Neighbor discovery (ND) does not run on an IPv6 CLIP interface. Therefore, the system does not detect when you configure a duplicate IPv6 address.
  - Multiple IPv6 address configuration on an IPv6 CLIP interface is not supported.
  - You can configure a maximum of 64 IPv6 CLIP interfaces.
  - IPv6 CLIP interface is enabled by default and it cannot be disabled.
- IPv6 with vIST provides the same support as IPv4 with vIST.
- To help with debugging, CFM provides full support for both IPv4 and IPv6 addresses for the **l2ping** and **l2traceroute** commands.

ECMP with IS-IS

The Equal Cost Multipath (ECMP) feature supports and complements the IS-IS protocol.

With ECMP, the switch can determine multiple equal-cost paths to the same destination prefix.

You can use multiple paths for load sharing of traffic. These multiple paths allow faster convergence to other active paths in case of network failure. By maximizing load sharing among equal-cost paths, you can use your links between routers more efficiently when sending IP and IPv6 traffic. Equal Cost Multipath is formed using routes from the same protocol.

The number of multiple paths a switch can support differs by hardware platform. For more information about feature support, see *Fabric Engine Release Notes*.

ECMP within IS-IS routes

Equal Cost Multipath (ECMP) allows the device to determine up to eight equal cost paths to the same destination prefix. The maximum number of equal cost paths you can configure depends on the hardware platform. For more information, see *Fabric Engine Release Notes*.

If the device learns the same route from multiple sources, the information is ECMP only if the routes:

- are from the same VSN
- have the same SPBM cost
- have the same prefix cost
- have the same IP route preference

Multiple BEBs can announce the same route, either because the Layer 2 LAN connects to multiple BEBs for redundancy, or because segments of the LAN are Layer 2 bridged. In Layer 2, if the device has to tie-break between multiple sources, the tie-breaking is based on cost and hop count.

In Layer 3, hop count is not used for tie-breaking. Instead, the device uses the following precedence rules to tie-break. In the following order, the device prefers:

1. Routes that do not include nodes with the overload bit set.

   When a router node runs out of system resources (memory or CPU), it alerts the other routers in the network by setting the overload bit in its link-state packets (LSPs). When this bit is set, the node is not used for transit traffic but only for traffic packets destined to the node's directly connected networks and IP prefixes.
2. Local routes over remote routes.

   If a route is learned locally, for example, through inter-VRF route leaking, it is most preferred.
3. Routes with the lowest route preference.

   By default, IS-IS routes within the same VSN are added to the LSDB with a default preference of 7. Inter-VSN routes are added to the LSDB with a route preference of 200. You can however, change the route preference using IS-IS accept policies.
4. Metric type internal (type 1) over metric type external (type 2).
5. Routes with the lowest SPBM cost.
6. Routes with the lowest prefix cost.

   If the metric type is internal, then the tie-break is on SPB cost first, and then on the prefix cost. Otherwise the tie-break is only on the prefix cost.

   You can either change this using a route-map on the remote advertising node with the **`redistribute`** command, or using a route-map on the local node with the IS-IS accept policy.
7. Routes within a VSN with a lower Layer 3 VSN I-SID.

   The device considers the Global Routing Table (GRT) to have an I-SID equal to zero.

When you use multiple B-VLANs in the SPBM core, multiple paths exist to reach a particular SPBM node, one on each B-VLAN; therefore, any IP prefix or IPv6 prefix that the device receives from a BEB

results in multiple ECMP paths. These paths may or may not be physically diverse. SPBM supports up to two B-VLANs; a primary B-VLAN and a secondary B-VLAN.

If more ECMP paths are available than the configured number of paths, then the device adds the routes using the following order: The device selects all routes from the primary B-VLAN and orders the routes learned through that B-VLAN from lowest system ID to the highest IS-IS system ID, then the device moves on to select all routes from the secondary B-VLAN, ordering those routes from lowest IS-IS system ID to the highest IS-IS system ID until you reach the number of equal paths configured.

For example, consider an SPB core configured with two B-VLANs (primary B-VLAN 1000 and secondary B-VLAN 2000), and the device learns routes from two BEBs called BEB-A (with a lower IS-IS system ID) and BEB-B (with a higher IS-IS system ID, then the order in which the next-hop is chosen for those routes are as follows.

If a route is learned only from BEB-A with the maximum number of allowed ECMP paths configured as 8 (default), then the order in which the next-hop is chosen for that route is:

1. BEB-A B-VLAN 1000
2. BEB-A B-VLAN 2000

If routes are learned from both BEB-A and BEB-B with maximum number of allowed ECMP paths configured as 8 (default), then the order in which the next-hop is chosen for those routes are:

1. BEB-A B-VLAN 1000
2. BEB-B B-VLAN 1000
3. BEB-A B-VLAN 2000
4. BEB-B B-VLAN 2000

If ECMP is disabled, the maximum number of allowed ECMP paths is 1 and the device adds the route from the lowest system ID with the primary B-VLAN. In this example, the device adds BEB-A B-VLAN 1000.

Note

- ECMP is supported for IPv6 Shortcut routes.
- To add IS-IS equal cost paths in the routing table, you must enable IPv6 ECMP feature globally.

ECMP Impact on IS-IS Route Selection for Inter-VRF Routes with vIST

This section illustrates the impact ECMP can have on a configuration that implements user-defined VRFs in a vIST cluster and how to avoid incorrect route selection.

Understanding the Configuration

Imagine the following configuration:

- A vIST cluster exists with multiple VRF contexts.
- On both nodes, VRF A redistributes routes into IS-IS as external. VRF B uses an IS-IS accept policy to accept these routes.
- Each node learns three paths to the route:
  - The nodes learn one path using local inter-VRF redistribution.

    - The nodes learn the other two paths from the IST peer.
- The routes are treated as ECMP paths because the preference, metric-type, and metric are equal.

IS-IS sorts paths for the same route by source-BEB B-MAC and B-VLAN ID. The primary B-VLAN ID is first installed for each B-MAC, followed by the secondary B-VLAN ID for each B-MAC, as long as the ECMP max-path value is not reached. On the node with the lowest B-MAC, the first path listed is its own local inter-vrf route, while on the other node, the MIM path across the vIST is listed first.

If you disable ECMP, all but the first path is removed. Because IS-IS orders the paths by B-MAC, each node in the vIST cluster selects the same B-MAC as the nexthop. This configuration leads one of the nodes to select itself, the local inter-vrf route, while the other node selects the MIM path across the vIST to get to the inter-vrf route. This situation results in an incorrect route selection.

Avoiding Incorrect Route Selection

To avoid this situation, create a policy to prevent IS-IS from determining that the MIM path across the vIST and the local inter-VRF route are ECMP paths. Configure the local inter-VRF path as the preferred path, and the vIST path as the backup. The following list identifies way that you can accomplish this:

- Redistribute the VRF route into IS-IS using the internal metric-type. IS-IS will always select the local inter-VRF route. For more information about the metric type for IS-IS routes, see Fabric Basics and Layer 2 Services on page 840.
- If an IS-IS internal metric-type is not an option, configure an IS-IS accept policy to change the preference of inter-VRF routes learned from the IST peer. The local inter-VRF route is preferred over the inter-VRF routes learned from the IST peer.

IS-IS IP Redistribution Policies

When you connect an SPBM core using IP shortcuts to existing networks running a routing protocol such as OSPF or RIP, a redundant configuration requires two switches:

- One router redistributes IP routes from Routing Information Protocol (RIP)/Open Shortest Path First (OSPF) into IS-IS (IP).
- The second router redistributes from IS-IS (IP) into RIP or OSPF.

The following figure illustrates this configuration.

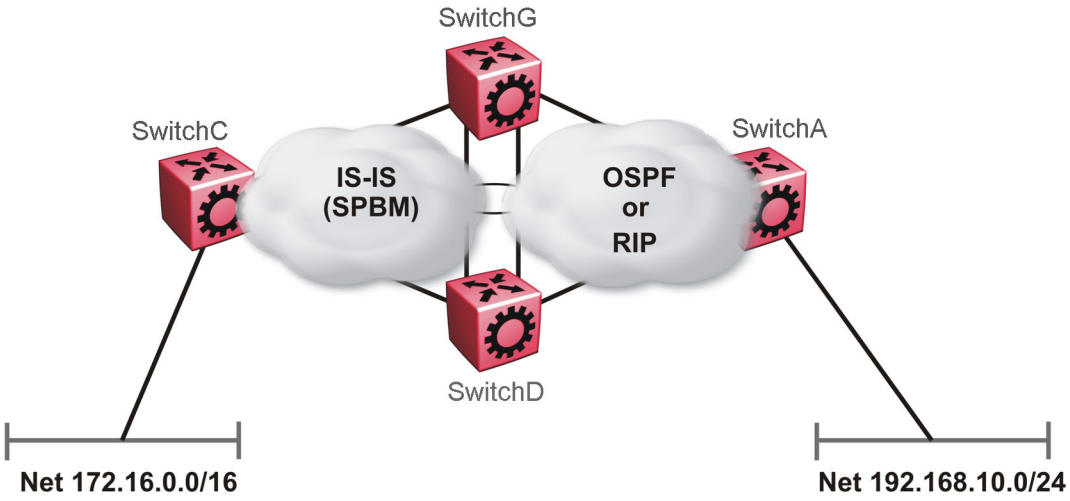

Figure 108: Redundant OSPF or RIP Network

In this scenario it is necessary to take extra care when redistributing through both switches. By default the preference value for IP routes generated by SPBM-IP (IS-IS) is 7. This is a higher preference than OSPF (20 for intra-area, 25 for inter-area, 120 for ext type1, 125 for ext type2) or RIP (100).

Important

The lower numerical value determines the higher preference.

In the preceding diagram both nodes (SwitchG and SwitchD) have an OSPF or a RIP route to 192.168.10.0/24 with the next-hop to SwitchA.

As soon as the SwitchG node redistributes that IP route into IS-IS, the SwitchD node learns the same route through IS-IS from SwitchG. (The SwitchG node already has the route through OSPF or RIP). Because IS-IS has a higher preference, SwitchD replaces its 192.168.10.0 OSPF route with an IS-IS one that points at SwitchG as the next-hop. The following figure illustrates this scenario.

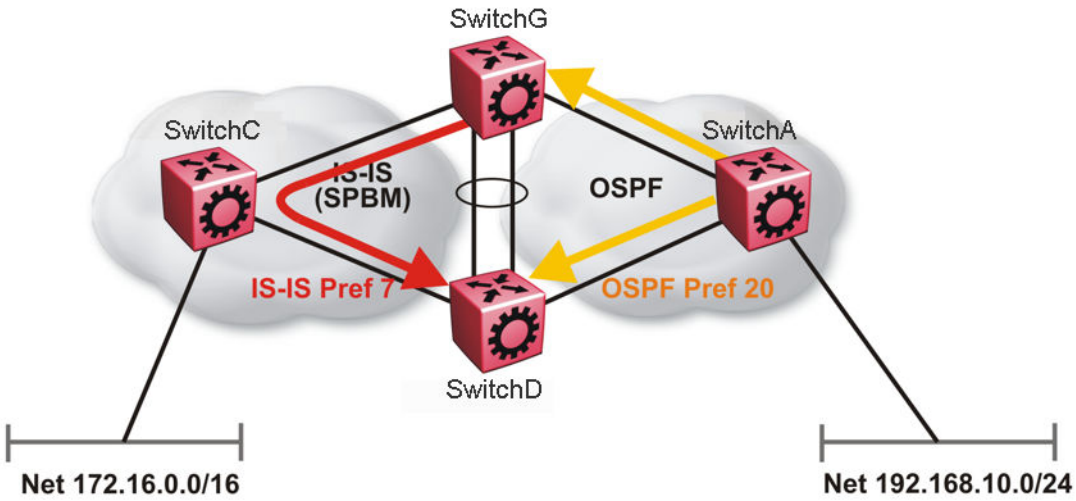

Figure 109: Redistributing Routes into IS-IS

Clearly this is undesirable and care needs to be taken to ensure that the two redistributing nodes (SwitchG and SwitchD) do not accept redistributed routes from each other. With IS-IS accept policies, you can associate an IS-IS accept policy on SwitchD to reject all redistributed IP routes received from SwitchG, and SwitchG to reject all redistribute IP routes from SwitchD.

An alternate way to solve the preceding problem with existing functionality is to reverse the problem by lowering the SPBM-IP (IS-IS) preference by configuring it to a value greater than RIP (100) or OSPF (20,25,120,125). For example, log on to Global Configuration mode and use the following command to configure a preference of 130:

```
ip route preference protocol spbm-level1 130
```

Note

For IPv6, the command is `ipv6 route preference protocol spbm-level1 130`

Now that the OSPF or RIP routes have a higher preference than SPBM-IP (IS-IS), the above problem is temporarily solved. However, the same issue resurfaces when the IS-IS IP routes are redistributed into OSPF or RIP in the reverse direction as shown in the following figure for OSPF:

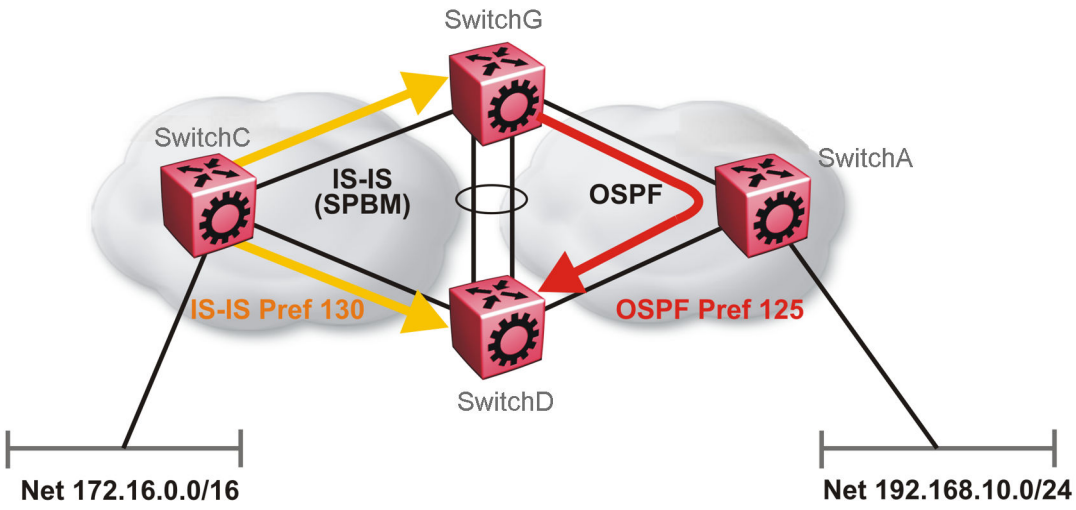

Figure 110: Redistributing Routes into OSPF

In the preceding figure, both SwitchG and SwitchD have an IS-IS IP route for 172.16.0.0/16 with the next hop as SwitchC. As soon as SwitchG redistributes the IS-IS route into OSPF, the SwitchD node learns that same route through OSPF from SwitchG. (The SwitchG node already has the route through IS-IS).

Because OSPF has a higher preference, SwitchD replaces its 172.16.0.0/16 IS-IS route with an OSPF one. (Note that the 172.16.0.0/16 route will be redistributed into OSPF as an AS external route, hence with preference 120 or 125 depending on whether type1 or type2 was used). In this case, however, you can leverage OSPF Accept policies, which can be configured to prevent SwitchD from accepting any AS External (LSA5) routes from SwitchG and prevent SwitchG from accepting any AS External (LSA5) routes from SwitchD. The following is a sample configuration:

```
enable
configure terminal
route-map

IP ROUTE MAP CONFIGURATION - GlobalRouter

route-map "reject" 1
no permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

OSPF CONFIGURATION - GlobalRouter

router ospf enable

OSPF ACCEPT CONFIGURATION - GlobalRouter

router ospf
accept adv-rtr {A.B.C.D}
```

```
accept adv-rtr {A.B.C.D} enable route-map "reject"
exit
```

Note

Disable alternative routes by issuing the command **no ip alternative-route** to avoid routing loops on the SMLT Backbone Edge Bridges (BEBs).

In the preceding figure, if SwitchA advertises 25000 OSPF routes to SwitchG and SwitchD, then both SwitchG and SwitchD install the 25000 routes as OSPF routes. Since SwitchD and SwitchG have OSPF to IS-IS redistribution enabled, they also learn these 25000 routes as IS-IS routes. IS-IS route preference is configured with a higher numerical value (130) than the OSPF route preference (125), so SwitchD and SwitchG keep IS-IS learned routes as alternative routes.

If SwitchA withdraws its 25000 OSPF routes, SwitchG and SwitchD remove the OSPF routes. While the OSPF routes are removed the routing tables of SwitchG and SwitchD activate the alternative IS-IS routes for the same prefix. Since SwitchG and SwitchD have IS-IS to OSPF redistribution enabled, SwitchA learns these routes as OSPF and this causes a routing loop. Use the **no ip alternative-route** command to disable alternative routes on SwitchG and SwitchD to avoid routing loops.

In the preceding figure, you leveraged OSPF Accept policies, which can be configured to prevent SwitchD from accepting any AS External (LSA5) routes from SwitchG and prevent SwitchG from accepting any AS External (LSA5) routes from SwitchD. In the case of a RIP access network, the preceding solution is not possible because RIP has no concept of external routes and no equivalent of accept policies. However, if you assume that a RIP network acts as an access network to an SPBM core, then it is sufficient to ensure that when IS-IS IP routes are redistributed into RIP they are aggregated into a single default route at the same time. The following figure and sample configuration example illustrates this scenario:

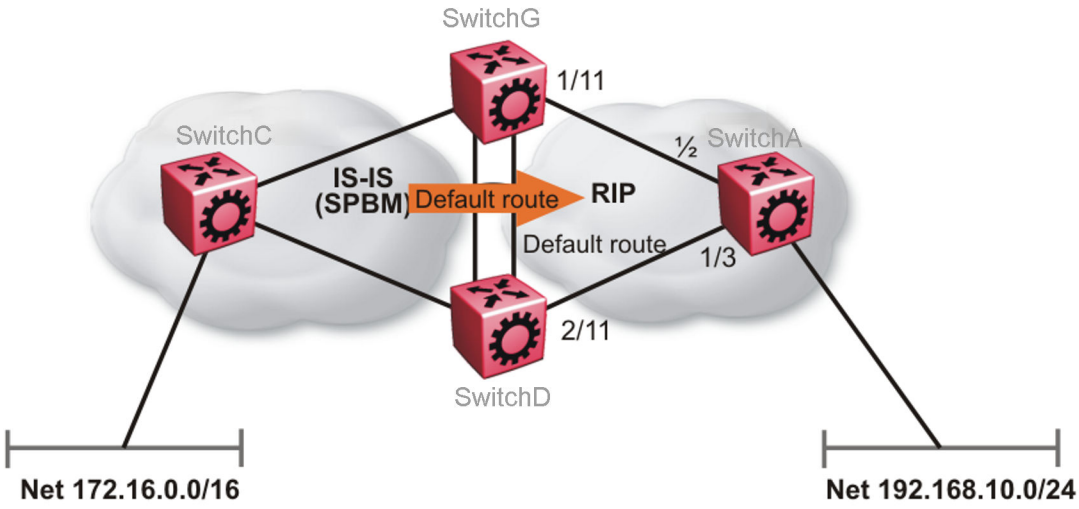

Figure 111: Redistributing Routes into RIP

SwitchG

```
IP PREFIX LIST CONFIGURATION - GlobalRouter

ip prefix-list "default" 0.0.0.0/0 ge 0 le 32

IP ROUTE MAP CONFIGURATION - GlobalRouter

route-map "inject-default" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "match-network" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "set-injectlist" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

RIP PORT CONFIGURATION

interface gigabitethernet 1/11
ip rip default-supply enable
exit

IP REDISTRIBUTION CONFIGURATION - GlobalRouter
```

```
router rip
redistribute isis
redistribute isis metric 1
redistribute isis route-map "inject-default"
redistribute isis enable
exit

IP REDISTRIBUTE APPLY CONFIGURATIONS

ip rip apply redistribute isis
```

SwitchA

```
RIP PORT CONFIGURATION

interface gigabitethernet 1/2
ip rip default-listen enable
exit
interface gigabitethernet 1/3
ip rip default-listen enable
exit
```

SwitchD

```
IP PREFIX LIST CONFIGURATION - GlobalRouter

ip prefix-list "default" 0.0.0.0/0 ge 0 le 32

IP ROUTE MAP CONFIGURATION - GlobalRouter

route-map "inject-default" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "match-network" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "set-injectlist" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

RIP PORT CONFIGURATION

interface gigabitethernet 2/11
ip rip default-supply enable
exit

IP REDISTRIBUTION CONFIGURATION - GlobalRouter

router rip
redistribute isis
redistribute isis metric 1
redistribute isis route-map "inject-default"
redistribute isis enable
exit

IP REDISTRIBUTE APPLY CONFIGURATIONS
```

```
ip rip apply redistribute isis
```

You can control the propagation of the default route on the RIP network so that both SwitchG and SwitchD supply the default route on their relevant interfaces, and not accept it on the same interfaces. Likewise, SwitchA will accept the default route on its interfaces to both SwitchG and SwitchD but it will not supply the default route back to them. This will prevent the default route advertised by SwitchG from being installed by SwitchD, and vice-versa.

The preceding example where IS-IS IP routes are aggregated into a single default route when redistributed into the RIP network also applies when redistributing IS-IS IP routes into OSPF if that OSPF network is an access network to an SPBM core. In this case use the following redistribution policy configuration as an example for injecting IS-IS IP routes into OSPF:

```
IP PREFIX LIST CONFIGURATION - GlobalRouter

ip prefix-list "default" 0.0.0.0/0 ge 0 le 32

IP ROUTE MAP CONFIGURATION - GlobalRouter

route-map "inject-default" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "match-network" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

route-map "set-injectlist" 1
permit
enable
match protocol local|static|rip|ospf|ebgp|ibgp|dvmrp|isis
exit

OSPF CONFIGURATION - GlobalRouter

router ospf enable
router ospf
as-boundary-router enable
exit

IP REDISTRIBUTION CONFIGURATION - GlobalRouter

router ospf
redistribute isis
redistribute isis route-map "inject-default"
redistribute isis enable
exit

IP REDISTRIBUTE APPLY CONFIGURATIONS

ip ospf apply redistribute isis
```

IS-IS Accept Policies

You can use Intermediate-System-to-Intermediate-System (IS-IS) accept policies (for IPv4 and IPv6) to filter incoming IS-IS routes over the SPBM cloud and apply route policies to the incoming IS-IS routes. IS-IS accept policies enable the device to determine whether to add an incoming route to the routing table.

IS-IS Accept Policies and DvR

Note

IPv6 IS-IS accept policies for DvR are not supported.

When you configure DvR in an SPB network, you can leverage IS-IS accept policies to control the DvR routes learned from the DvR backbone. The DvR backbone contains the master list of all the host routes learned from various DvR domains.

You can configure accept policies on a DvR Controller or a non-DvR BEB as a filter to determine which DvR host routes to accept into the routing table, from the DvR backbone. Accept policies apply to only those backbone (or inter-domain) host routes that are not part of the Controller's own DvR enabled subnets and do not have the same domain ID as that of the Controller.

For non-DvR BEBs, all the routes present in the backbone are learned, but you can still use the accept policies to filter specific routes.

For information on DvR, see Distributed Virtual Routing on page 621.

IS-IS Accept Policy Filters

You can filter traffic with IS-IS accept policies by:

- advertising BEB
- I-SID or I-SID list
- route-map
- backbone-route-map for IPv4 only
- a combination of route-map and backbone-route-map for IPv4 only

You can use IS-IS accept policies to apply at a global default level for all advertising Backbone Edge Bridges (BEBs) or for a specific advertising BEB.

IS-IS accept policies also allow you to use either a service instance identifier (I-SID) or an I-SID list to filter routes. The switch uses I-SIDs to define Virtual Services Networks (VSNs). I-SIDs identify and transmit virtualized traffic in an encapsulated SPBM frame. IS-IS accept policies can use I-SIDs or I-SID lists to filter the incoming virtualized traffic.

IS-IS accept policies can also apply route policies to determine what incoming traffic to accept into the routing table. With route policies the device can determine which routes to accept into the routing table based on the criteria you configure. You can match on the network or the route metric.

On DvR Controllers in a DvR domain, you can configure a backbone route policy to determine what host routes to accept from the DvR backbone, into the routing table. Also, just like on the route policy, you can configure match criteria, and set preferences on the backbone route policy.

To accept both IS-IS routes and host routes from the DvR backbone, you can configure both a route policy and a backbone route policy in the accept policy instance.

For more information on configuring route policies:

- For IPv4, see IP routing operations fundamentals on page 1594.
- For IPv6, see IPv6 Routing Basics on page 1659.

The following table describes IPv4 IS-IS accept policy filters.

Filters into	Filter	Description
Global Routing Table (GRT)	*accept route-map WORD<1-64>*	By default, the device accepts all routes into the GRT and VRF routing table. This is the default accept policy.
	accept route-map WORD<1-64> backbone-route-map WORD<1-64>	This is the default accept policy with configuration to accept specific DvR host routes from the DvR backbone.
	accept adv-rtr <x.xx.xx> route-map WORD<1-64> backbone-route-map WORD<1-64>	The device filters based on the specific advertising BEB defined by the SPBM nickname. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.
	accept i-sid <1-16777215> route-map WORD<1-64> backbone-route-map WORD<1-64>	The device filters based on the I-SID, which represents a local or remote Layer 3 VSN. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.
	accept adv-rtr <x.xx.xx> i-sid <1-16777215> route-map WORD<1-64> backbone-route-map WORD<1-64>	The device filters based on the specific advertising BEB and the I-SID, which represents a local or remote Layer 3 VSN. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.
	accept isid-list WORD<1-32> route-map WORD<1-64> backbone-route-map WORD<1-64>	The device filters based on the list of I-SIDs. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.
	accept adv-rtr <x.xx.xx> isid-list WORD<1-32> route-map WORD<1-64> backbone-route-map WORD<1-64>	The device filters based on the specific advertising BEB and the list of I-SIDs. The number 0 represents the Global Routing Table (GRT). The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.

Filters into	Filter	Description
Virtual Routing and Forwarding (VRF) routing table	*isis accept adv-rtr <x.xx.xx> route-map WORD<1-64> backbone-route-map WORD<1-64>*	The device filters based on the specific advertising BEB defined by the SPBM nickname. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.
	isis accept i-sid <0-16777215> route-map WORD<1-64> backbone-route-map WORD<1-64>	The device filters based on the I-SID, which represents a local or remote Layer 3 VSN. The number 0 represents the Global Routing Table (GRT). The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.
	isis accept adv-rtr <x.xx.xx> i-sid <0-16777215> route-map WORD<1-64> backbone-route-map WORD<1-64>	The device filters based on the specific advertising BEB and the I-SID, which represents a local or remote Layer 3 VSN. The number 0 represents the Global Routing Table (GRT). The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.
	isis accept isid-list WORD<1-32> route-map WORD<1-64> backbone-route-map WORD<1-64>	The device filters based on the list of I-SIDs to which the IS-IS accept policy applies. The number 0 represents the Global Routing Table (GRT). The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.
	isis accept adv-rtr <x.xx.xx> isid-list WORD<1-32> route-map WORD<1-64> backbone-route-map WORD<1-64>	The device filters based on the specific advertising BEB and the list of I-SIDs. The number 0 represents the Global Routing Table (GRT). The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.
	isis accept route-map WORD<1-64> route-map WORD<1-64> backbone-route-map WORD<1-64>	The device filters based on the route policy. The device, if DvR enabled, also filters the DvR host routes to accept from the DvR backbone. This is an optional filter.

The following table describes the IPv6 IS-IS accept policy filters:

Filters into	Filter	Description
Global Routing Table (GRT)	*ipv6 accept route-map WORD<1-64>*	By default, the device accepts all routes advertised. This is the default accept policy.
	ipv6 accept adv-rtr <x.xx.xx> route-map WORD<1-64>	The device filters based on the specific advertising BEB defined by the SPBM nickname.
	ipv6 accept i-sid <1-16777215> route-map WORD<1-64>	The device filters based on the I-SID, which represents a local or remote Layer 3 VSN.
	ipv6 accept adv-rtr <x.xx.xx> i-sid <1-16777215> route-map WORD<1-64>	The device filters based on the specific advertising BEB and the I-SID, which represents a local or remote Layer 3 VSN.
	ipv6 accept isid-list WORD<1-32> route-map WORD<1-64>	The device filters based on the list of I-SIDs.
	ipv6 accept adv-rtr <x.xx.xx> isid-list WORD<1-32> route-map WORD<1-64>	The device filters based on the specific advertising BEB and the list of I-SIDs. The number 0 represents the Global Routing Table (GRT).
Virtual Routing and Forwarding (VRF) routing table	*ipv6 isis accept route-map WORD<1-64> route-map WORD<1-64>*	The device filters based on the route policy.
	ipv6 isis accept adv-rtr <x.xx.xx> route-map WORD<1-64>	The device filters based on the specific advertising BEB defined by the SPBM nickname.
	ipv6 isis accept i-sid <0-16777215> route-map WORD<1-64>	The device filters based on the I-SID, which represents a local or remote Layer 3 VSN. The number 0 represents the Global Routing Table (GRT).
	ipv6 isis accept adv-rtr <x.xx.xx> i-sid <0-16777215> route-map WORD<1-64>	The device filters based on the specific advertising BEB and the I-SID, which represents a local or remote Layer 3 VSN. The number 0 represents the Global Routing Table (GRT).
	ipv6 isis accept isid-list WORD<1-32> route-map WORD<1-64>	The device filters based on the list of I-SIDs to which the IS-IS accept policy applies. The number 0 represents the Global Routing Table (GRT).
	ipv6 isis accept adv-rtr <x.xx.xx> isid-list WORD<1-32> route-map WORD<1-64>	The device filters based on the specific advertising BEB and the list of I-SIDs. The number 0 represents the Global Routing Table (GRT).

IS-IS Accept Policies for the GRT and VRFs

You can create an IS-IS accept policy for incoming routes for the Global Routing Table (GRT), which accepts routes into the routing table, or for a Virtual Routing and Forwarding (VRF) instance, which accepts incoming routes to the routing table of the VRF.

If you create an IS-IS accept policy on the switch for either the GRT or a VRF that operates at a global default level, the accept policy applies to all routes for all BEBs in the GRT or VRF.

If you create an IS-IS accept policy on the switch for a specific advertising BEB for either the GRT or a VRF, the IS-IS accept policy instance applies for that specific advertising BEB. If you use a more specific filter, the system gives preference to the specific filter over the global default level.

IS-IS Accept Policies for Inter-VRF Route Redistribution

You can also use the filter mechanism for IS-IS accept policies to redistribute routes between different VRFs, or between a VRF and the GRT. For inter-VRF route redistribution, you match the filter based on the I-SID, which represents the Layer 3 VSN context.

You can apply the filter at the global default level, where the IS-IS accept policy applies to all routes for that I-SID from all BEBs, or at a specific advertising BEB level, where the filter only applies to a specific advertising BEB. The device gives preference to a specific filter for a specific advertising BEB over the global default filter.

For inter-VRF route redistribution, an I-SID value of 0 represents the GRT. For inter-VRF route redistribution between VRFs, the I-SID is the source VRF (or remote VRF).

Note

If the primary B-VLAN is down either because you did not configure at least one network-to-network interface (NNI) or all configured NNIs are down, the switch does not redistribute inter-VRF routes through IS-IS accept policies.

IS-IS Accept Policy Considerations

Consider the following when you configure IS-IS accept policies:

- If a VRF uses a different protocol to redistribute routes from another VRF, the IS-IS accept policy feature cannot be used. You can only use the IS-IS accept policy for inter-VSN route redistribution between VRFs.
- IPv4 and IPv6 IS-IS accept policies can exist on the same VRF and GRT; The I-SID list configuration is shared across both protocol versions.

Precedence rules in the same VSN

The following precedence rules apply for IS-IS accept policies used in the same VSN:

- You can only apply one configured IS-IS accept policy for each route.
- You can apply either a default filter for all advertising BEBs or a filter for a specific advertising BEB.
- If you disable the accept filter, the system ignores the filter and the filter with the next highest precedence applies.
- The device prefers the **`accept adv-rtr`** filter, which filters based on a specific advertising BEB, over the default filter for all advertising BEBs.

- The device accepts all routes within the same VSN by default. You can apply a route policy to filter or change the characteristics of the route by metric or preference.
- The **i-sid** or **isid-list** filters are not valid for routes within the same VSN.

Precedence rules for inter-VSN route redistribution

The following precedence rules apply for IS-IS accept policies used for inter-VSN route redistribution:

- You can only apply one configured IS-IS accept policy for each route.
- You can apply filters at a global default level for all BEBs for a specific I-SID or I-SID list, or you can apply filters for a specific advertising BEB for a specific I-SID or I-SID list.
- If you disable the accept filter, the system ignores the filter and the filter with the next highest precedence applies.
- The device requires a specific filter to redistribute routes between VSNs through the use of the **i-sid** or **isid-list** filters.
- The **i-sid** filter takes precedence over the **isid-list** filter.
- The **adv-rtr** filter for a specific advertising BEB takes precedence over a filter with the same **i-sid** filter without the **adv-rtr** filter.
- The **i-sid** or **isid-list** filters only apply to routes for inter-VSN route redistribution.
- If multiple **isid-list** filters have the same I-SID within the list, the first on the list alphabetically has the higher precedence.

Route Preference

The relative value of the route preference among different protocols determines which protocol the device prefers. If multiple protocols are in the routing table, the device prefers the route with the lower value. You can change the value at the protocol level, and you can also change the preference of incoming IS-IS routes using the route-map with the IS-IS Accept policy filter for IPv4 only.

Route Metric

Use route-map to change the metric of a route when you accept a remote IS-IS route with IS-IS accept policies.

You can use route-map to change the metric of a route when you redistribute the route from another protocol to IS-IS through the route redistribution mechanism.

You can also configure the route metric with the base **redistribute** command without the use of route-map.

Note

For both IPv4 and IPv6 IS-IS accept policies, if there is a mismatch in the route-map (inbound filtering) configured, all routes are accepted by default. Unlike the redistribute route-map (outbound filtering), where if there is a mismatch, all routes are denied by default. For more information, see IP routing operations fundamentals on page 1594.

For more information on the configuration of route-map:

- For IPv4, see IP routing operations fundamentals on page 1594.
- For IPv6, see IPv6 Routing Basics on page 1659.

IP Shortcuts configuration using the CLI

This section provides procedures to configure IP Shortcuts using the CLI.

Configuring SPBM IPv4 Shortcuts

In addition to Layer 2 virtualization, the SPBM model is extended to also support Routed SPBM, otherwise called SPBM IP Shortcuts.

SPBM allows a network to make the best use of routing and forwarding techniques, where only the BEBs perform an IP route lookup and all other nodes perform standard Ethernet switching based on the existing shortest path tree. This allows for end to end IP-over-Ethernet forwarding without the need for ARP, flooding, or reverse learning.

To enable IP shortcuts on the BEBs, you can configure a circuitless IP (CLIP) address (loopback address), and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 135. In addition, to advertise routes from the BEBs into the SPBM network, you must enable route redistribution of direct and static routes into IS-IS.

Note

The loopback address on each switch or BEB must all be in different subnets to ensure connectivity between them. To do this, use a 32-bit mask with the CLIP address.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- Before redistributing routes into IS-IS, you must create the Customer VLANs, add slots/ports, and add the IP addresses and network masks.

Procedure

1. Enter Loopback Interface Configuration mode

   ```
   enable

   configure terminal

   interface Loopback <1-256>
   ```

2. Configure a CLIP interface to use as the source address for SPBM IP shortcuts:

   ```
   ip address [<1-256>] <A.B.C.D/X>
   ```

3. Exit the Loopback Interface Configuration mode to Global Configuration mode:

   ```
   exit
   ```

4. Log on to IS-IS Router Configuration mode:

   ```
   router isis
   ```

5. Specify the CLIP interface as the source address for SPBM IP shortcuts:

   ```
   ip-source-address <A.B.C.D>
   ```

6. Configure SPBM IP shortcuts:

   ```
   spbm <1-100> ip enable
   ```

7. Display the status of SPBM IP shortcuts on the switch:

   ```
   show isis spbm
   ```

8. Identify routes on the local switch to be announced into the SPBM network:
   ```
   redistribute {bgp | direct | ospf | rip | static}
   ```
9. Enable routes to be announced into the SPBM network
   ```
   redistribute {bgp | direct | ospf | rip | static} enable
   ```
10. If you want to delete the configuration, use the no option:
    ```
    no redistribute {bgp | direct | ospf | rip | static}
    ```
    ```
    no redistribute {bgp | direct | ospf | rip | static} enable
    ```
11. Exit to Global Configuration mode:
    ```
    exit
    ```
12. Apply the configured redistribution:
    ```
    isis apply redistribute {bgp | direct | ospf | rip | static | vrf
    WORD<1-16>}
    ```

Example

```
Switch:1> enable

Switch:1# configure terminal

Switch:1(config)# interface loopback 1

Switch:1(config-if)# ip address 192.0.2.2/8

Switch:1(config-if)# exit

Switch:1(config)# router isis

Switch:1(config-isis)# ip-source-address 192.0.2.2

Switch:1(config-isis)# spbm 1 ip enable

Switch:1(config-isis)# show isis spbm
```

```
show isis spbm

Variable definitions

The following table defines parameters for the **ip address** command.

Variable	Value
<1–256>	Specifies an interface ID value. This value is optional.
<A.B.C.D/X>	Specifies an IP address and subnet mask. Use the **no** option to delete the specified IP address.
<A.B.C.D>	Specifies an IP address. Use the **no** option to delete the specified IP address.

The following table defines parameters for the **ip-source-address** command.

Variable	Value
<A.B.C.D>	Specifies the CLIP interface to use as the source address for SPBM IP shortcuts.

The following table defines parameters for the **spbm** command.

Variable	Value
<1–100> ip enable	Enables or disables SPBM IP shortcut state. The default is disabled. Use the no or default options to disable SPBM IP shortcuts.

The following table defines parameters for the **redistribute** command.

Variable	Value
{bgp | direct | ospf | rip | static}	Specifies the protocol.
enable	Enables the redistribution of the specified protocol into the SPBM network. The default is disabled. Use the **no** option to disable the redistribution.
metric <0–65535>	Configures the metric (cost) to apply to redistributed routes. The default is 1.
metric-type {external|internal}	Configures the type of route to import into the protocol. The default is internal.

Variable	Value
route-map WORD<0-64>	Configures the route policy to apply to redistributed routes. Type a name between 0 to 64 characters in length.
subnets {allow| suppress}	Indicates whether the subnets are advertised individually or aggregated to their classful subnet. Choose suppress to advertise subnets aggregated to their classful subnet. Choose allow to advertise the subnets individually with the learned or configured mask of the subnet. The default is allow.

The following table defines parameters for the **isis apply redistribute** command.

Variable	Value
{bgp | direct | ospf | rip | static}	Specifies the protocol.

Configure SPBM IPv6 Shortcuts

Important

You must enable IPv4 Shortcuts before you enable IPv6 Shortcuts because IPv6 Shortcuts depend on IPv4 Shortcuts for some functions.

Configuring IPv6 Shortcuts is essentially the same as the IPv4 procedure except you use the following IPv6 commands instead of their IPv4 equivalents:

- Use **ipv6 interface address** to create a CLIPv6 interface with an IPv6 address.
- Use **ipv6 ipv6-source-address** to specify the CLIPv6 interface as the source address for IPv6 Shortcuts.
- Use **spbm ipv6 enable** to enable IPv6 Shortcuts.
- Use **ipv6 redistribute {bgp | direct | isis | rip | ospf | static} enable** to control the redistribution of GRT IPv6 routes into the SPBM IS-IS domain.
- Use **ipv6 route preference protocol spbm-level1** to change route preference values for IPv6 Shortcut routes learned through IS-IS.

To enable IPv6 Shortcuts on the BEBs, you must configure a circuitless IPv6 (CLIPv6) address (loopback address), and specify this address as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 236. In addition, to advertise routes from the BEBs into the SPBM network, you must enable route redistribution of direct and static routes into IS-IS.

Note

The loopback address on each switch or BEB must all be in different subnets to ensure connectivity between them. To do this, use a 32-bit mask with the CLIP address, and the CLIPv6 address prefix must be 128.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.

- Before redistributing routes into IS-IS, you must create the Customer VLANs, add slots/ports, and add the IPv6 addresses and network masks.

Procedure

1. Enter Loopback Interface Configuration mode

   ```
   enable

   configure terminal

   interface Loopback <1-256>
   ```

2. Configure a CLIPv6 interface to use as the source address for SPBM IPv6 Shortcuts:

   ```
   ipv6 interface address WORD<0-255>
   ```

3. Exit the Loopback Interface Configuration mode to Global Configuration mode:

   ```
   exit
   ```

4. Log on to IS-IS Router Configuration mode:

   ```
   router isis
   ```

5. Specify the CLIPv6 interface as the source address for SPBM IPv6 Shortcuts:

   ```
   ipv6-source-address WORD<0-46>
   ```

6. Enable SPBM IPv6 Shortcuts:

   ```
   spbm <1-100> ipv6 enable
   ```

7. Display the status of SPBM IPv6 Shortcuts on the switch:

   ```
   show isis spbm
   ```

8. Identify IPv6 routes on the local switch to be announced into the SPBM network.

   ```
   ipv6 redistribute {bgp | direct | ospf | rip | static}
   ```

9. Enable the IPv6 routes to be announced into the SPBM network:

   ```
   ipv6 redistribute {bgp | direct | ospf | rip | static} enable
   ```

10. Exit to Global Configuration mode:

    ```
    exit
    ```

11. (Optional) Change route preference values for IPv6 Shortcut routes learned through IS-IS:

    ```
    ipv6 route preference protocol spbm-level1 <0-255>
    ```

12. Apply the configured redistribution:

    ```
    ipv6 isis apply redistribute {bgp | direct | ospf | rip | static |}
    [vrf WORD<1-16>]
    ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface loopback 123
Switch:1(config-if)#ipv6 interface address 123::1/128
Switch:1(config-if)#exit
Switch:1(config)#router isis
Switch:1(config-isis)#ipv6 ipv6-source-address <non-link-local ipv6-address>
Switch:1(config-isis)#spbm 1 ipv6 enable
Switch:1(config-isis)#show isis spbm

 Total Num of SPBM instances: 1
----------------------------------------------------------------------------------------------------------------
```

Variable Definitions

The following table defines parameters for the IPv6 Shortcuts commands.

Variable	Value
ipv6-source-address WORD<0-46>	Specifies the source IPv6 address for locally generated IPv6 packets whose egress port is an SPBM NNI port. The *WORD<0-46>* value must be a locally configured loopback IPv6 address (CLIPv6). Use the **no** option to delete the specified IPv6 address.
spbm<1-100> ipv6 enable	Enables or disables SPBM IPv6 Shortcuts. The default is disabled. Use the **no** or **default** options to disable SPBM IPv6 Shortcuts.
ipv6 route preference protocol spbm-level1 <0-255>	Sets the route preference value for IPv6 Shortcut routes learned through IS-IS. The default preference is 7.
ipv6 redistribute {bgp | direct | static | ospf | rip} enable	Specifies the GRT IPv6 route that you want to redistribute into the SPBM IS-IS domain. The default is disabled. Use the **no** option to disable the redistribution.

Configuring inter-VRF IPv4 Accept Policies on VRFs

Configure IS-IS accept policies on a VRF to use inter-VRF accept policies in the SPB cloud. You can use IS-IS accept policies to redistribute routes between different VRFs, including the global routing table (GRT). First you apply the filter, and then you match the filter based on the I-SID, which represents the Layer 3 VSN context.

Note

- The **isis apply accept [vrf WORD<1-16>]** command can disrupt traffic and cause temporary traffic loss. After you apply **isis apply accept [vrf<1-16>]**, the command reapplies the accept policies, which deletes all of the IS-IS route,s and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply **isis apply accept [vrf WORD<1-16>]** at the end.
- If you use the **accept** command for inter-VRF routes based on the remote I-SID, the device only accepts routes coming from remote BEBs. For instance, if a local Layer 3 VSN exists with the same I-SID, the device does not add the local routes. The assumption is that the device uses existent methods, either through use of another protocol or static configuration, to obtain those routes.
- If the route policy changes, you must reapply the IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure that a route policy exists.
- Ensure that the VRFs exist.
- You must configure a route-map to apply.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal

   router vrf WORD<1-16>
   ```

2. (Optional) If you want to accept routes from a variety of I-SIDs, create an I-SID list before you create an IS-IS accept policy for the I-SID list:

   ```
   ip isid-list WORD<1-32> [<0-16777215>][list WORD<1-1024>]
   ```

   Note

   When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

   Use the command **`show ip isid-list vrf WORD<1-16>`** to view the list of truncated I-SIDs.

3. Create an IS-IS accept policy instance to apply to routes from all Backbone Edge Bridges (BEBs):

   ```
   isis accept [i-sid <0-16777215>][isid-list WORD<1-32>]
   ```

4. Create an IS-IS accept policy instance to apply to routes for a specific BEB:

   ```
   isis accept [adv-rtr <x.xx.xx>][i-sid <0-16777215>][isid-list
   WORD<1-32>]
   ```

5. (Optional) Delete an IS-IS accept policy instance:

   ```
   no isis accept [adv-rtr <x.xx.xx>][i-sid <0-16777215>][isid-list
   WORD<1-32>]
   ```

6. Specify an IS-IS route policy to apply to routes from all BEBs:

   ```
   isis accept route-map WORD<1-64>
   ```

7. Specify an IS-IS route policy to apply for a specific BEB:

   ```
   isis accept adv-rtr <x.xx.xx> route-map WORD<1-64>
   ```

8. (Optional) Delete an IS-IS route policy:

   ```
   no isis accept [adv-rtr <x.xx.xx>] [route-map]
   ```

9. Enable a configured IS-IS accept policy instance:

   ```
   isis accept [adv-rtr <x.xx.xx>][i-sid <0-16777215>][isid-list
   WORD<1-32>] [enable]
   ```

10. (Optional) Disable a configured IS-IS accept policy instance:

    ```
    no isis accept [adv-rtr <x.xx.xx>][i-sid <0-16777215>][isid-list
    WORD<1-32>] [enable]
    ```

11. Exit VRF Router Configuration mode:

    ```
    exit
    ```

    You are in Global Configuration mode.
12. Apply the IS-IS accept policy changes, which removes and re-adds all routes with updated filters:

    ```
    isis apply accept [vrf WORD<1-16>]
    ```

Example

Configure Inter-VRF accept policies on a VRF:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf green
Switch:1(router-vrf)#isis accept i-sid 100
Switch:1(router-vrf)#isis accept i-sid 100 enable
Switch:1(router-vrf)#exit
Switch:1(config)#isis apply accept vrf green
```

Variable definitions

The following table defines parameters for the **ip isid-list** command.

Variable	Value
WORD<1-32>	Creates a name for your I-SID list.
<0-16777215>	Specifies an I-SID value.
list WORD<1-1024>	Specifies a list of I-SID values. For example, in the format 1,3,5,8-10.

The following table defines parameters for the **isis accept** command.

Variable	Value
adv-rtr <x.xx.xx>	Specifies a specific advertising BEB in which to apply the IS-IS accept policy to routes for a specific advertising BEB. *x.xx.xx* specifies an SPBM nickname. The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter. The system requires an explicit filter to redistribute routes from a particular VSN. If the default global filter or the filter for a specific advertising BEB does not exist, the system does not redistribute the routes from the remote VSN.
enable	Enables the IS-IS accept policy.
i-sid <0-16777215>	Configures the I-SID to which the IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT).
isid-list WORD<1-32>	Configures a list of I-SIDs to which the IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT).
route-map WORD <1-64>	Specifies a route policy. You must configure a route policy earlier in a separate procedure.

The following table defines parameters for the **isis apply accept** command.

Variable	Value
vrf WORD<1-16>	Specifies a specific VRF instance.

Configuring Inter-VRF IPv6 Accept Policies on VRFs

Configure IPv6 IS-IS accept policies on a VRF to use inter-VRF accept policies in the SPB cloud. You can use IPv6 IS-IS accept policies to redistribute routes between different VRFs, including the global routing table (GRT). First you apply the filter, and then you match the filter based on the I-SID, which represents the Layer 3 VSN context.

Note

- The **ipv6 isis apply accept [vrf WORD<1-16>]** command can disrupt traffic and cause temporary traffic loss. After you apply **ipv6 isis apply accept [vrf<1-16>]**, the command reapplies the accept policies, which deletes all of the IS-IS routes, and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply **ipv6 isis apply accept [vrf WORD<1-16>]** at the end.
- If you use the **ipv6 accept** command for inter-VRF routes based on the remote I-SID, the device accepts routes form other local VRFs to the current VRF, therefore if the accepted I-SID is configured on the local BEB, the device accepts its own IPv6 routes advertised under the accepted I-SID.
- If the route policy changes, you must reapply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Configure IPv6 Shortcuts. For more information, see Configure SPBM IPv6 Shortcuts on page 1146.
- You must configure IPv6 IPVPN.
- Ensure that a route policy exists.
- Ensure that the VRFs exist.
- You must configure a route-map.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. (Optional) If you want to accept routes from a variety of I-SIDs, create an I-SID list before you create an IPv6 IS-IS accept policy for the I-SID list:

   ```
   ip isid-list WORD<1-32> {<0-16777215> | list WORD<1-1024>}
   ```

   Note

   When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

   Use the command **show ip isid-list vrf WORD<1-16>** to view the list of truncated I-SIDs.

3. Configure an IPv6 IS-IS accept policy instance with a route policy.

   Use one of the following options:

   a. Configure an IPv6 IS-IS accept policy based on a specific advertising BEB:

      ```
      ipv6 isis accept adv-rtr <x.xx.xx> [enable][i-sid <0-16777215>]
      [isid-list WORD<1-32>] [route-map WORD<1-64>]
      ```

   b. Configure an IPv6 IS-IS accept policy based on a particular I-SID:

      ```
      ipv6 isis accept i-sid <0-16777215> [enable] [route-map WORD<1-64>]
      ```

   c. Configure an IPv6 IS-IS accept policy based on a particular I-SID list:

      ```
      ipv6 isis accept isid-list WORD<1-32> [enable] [route-map WORD<1-
      64>]
      ```

4. Enable the configured IPv6 IS-IS accept policies:

   ```
   ipv6 isis accept [adv-rtr <x.xx.xx>] [i-sid <0-16777215>] [isid-list
   WORD<1-32>] enable
   ```

5. Exit to Global Configuration mode:

   ```
   exit
   ```

6. Apply the IPv6 IS-IS accept policy changes, which removes and re-adds all routes with updated filters:

   ```
   ipv6 isis apply accept [vrf WORD<1-16>]
   ```

Example

Configure Inter-VRF accept policies on a VRF:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf red
Switch:1(router-vrf)#ipv6 isis accept i-sid 100 enable
Switch:1(router-vrf)#exit
Switch:1(config)#ipv6 isis apply accept vrf red
```

Variable Definitions

The following table defines parameters for the **ip isid-list** command.

Note

The I-SID lists created can be associated with both IPv4 or IPv6 routes.

Variable	Value
WORD<1-32>	Creates a name for your I-SID list.
<0-16777215>	Specifies an I-SID value.
list WORD<1-1024>	Specifies a list of I-SID values. For example, in the format 1,3,5,8-10.

The following table defines parameters for the **ipv6 isis accept** command.

Variable	Value
adv-rtr <x.xx.xx>	Specifies the SPBM nickname for each advertising BEB to allow you to apply the IPv6 IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter. Note: An IPv6 IS-IS accept policy that specifies the adv-rtr without an I-SID or I-SID list will filter routes coming from the I-SID on which the policy is configured and from the specified BEB.
enable	Enables an IPv6 IS-IS accept policy.
i-sid <0-16777215>	Specifies an I-SID number to represent a local or remote Layer 3 VSN to which the IPv6 IS-IS accept policy applies. Use the parameter to apply a filter for routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system can redistribute the remote VSN to the VSN where you applied the filter. An I-SID value of 0 represents the global routing table (GRT).
isid-list WORD<1-32>	Specifies the I-SID list name that represents the local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies. Use the parameter to apply a default filter for all routes from specific I-SIDs, that represent the remote VSN. Based on the routing policy the system applies, the system redistributes the remote VSN to the VSN where you applied the filter. An I-SID value of 0 represents the global routing table (GRT).
route-map WORD <1-64>	Specifies a route policy. You must configure a route policy earlier in a separate procedure.

The following table defines parameters for the **ipv6 isis apply accept** command.

Variable	Value
vrf WORD<1-16>	Specifies a specific VRF instance.

Configuring IS-IS Accept Policies

Use the following procedure to create and enable IS-IS accept policies to apply to routes from all Backbone Edge Bridges (BEBs) or to all routes from a specific BEB.

Use IS-IS accept policies to filter incoming IS-IS routes the device receives over the SPBM cloud. Accept policies apply to incoming traffic and determine whether to add the route to the routing table.

If DvR is enabled on your switch, and the switch is either a DvR Controller or a non-DvR BEB within the domain, you can configure IS-IS accept policies to accept specific host routes from the DvR backbone. For information on DvR, see Distributed Virtual Routing on page 621.

IS-IS accept policies are disabled by default.

Note

- The **isis apply accept [vrf WORD<1-16>]** command can disrupt traffic and cause temporary traffic loss. After you apply **isis apply accept [vrf <1-16>]**, the command reapplies the accept policies, which deletes all of the IS-IS routes, and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply **isis apply accept [vrf WORD<1-16>]** at the end.
- If the route policy changes, you must reapply the IS-IS accept policy, unless the IS-IS accept policy was the last sequence in the configuration.
- The **isis apply accept [vrf WORD<1-16>]** command is not saved in the configuration file. If you use a saved configuration file for IS-IS accept policy configuration, you must apply the **isis apply accept [vrf WORD<1-16>]** command at the end.
- The number of unique Layer 3 VSN I-SIDs used on a BEB is limited to the number of VRFs supported on the switch. This includes the I-SID values used for Layer 3 VSNs and the I-SID values specified for the ISIS accept policy filters, which can be configured using the **ip isid-list [ISID#]**, **accept i-sid <value>**, or **accept adv-rtr <isis nn> i-sid <value>** commands.

  The switch supports 24 VRFs by default, so, in a default configuration, you cannot create an ip isid-list or accept policy with more than 24 unique I-SID entries. However, the configured VRFs take up an entry, so the formula to calculate the limit is: [24 VRF Limit – (currently configured VRFs)]. This gives the number of unique I-SIDs that can be used directly in the IS-IS accept policy filters, which you implement with the **ip isid-list** or **accept policy** command. The I-SIDs used for Layer 3 VSNs can be reused in IS-IS accept policy filters without affecting the limit.

  If you increase the VRF scaling, you can create more Layer 3 VSNs. For more information about how to increase the number of supported VRFs, see Configure the Maximum Number of VRFs on page 3494. The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see *Fabric Engine Release Notes*.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.

- You must configure a route-map to apply.
- Ensure that DvR is enabled on the switch before you configure an IS-IS accept policy with a backbone route policy, to accept host routes from the DvR backbone.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. (Optional) If you want to accept routes from a variety of I-SIDs, create an I-SID list before you create an IS-IS accept policy for the I-SID list:
   ```
   ip isid-list WORD<1-32> [<1-16777215>][list WORD<1-1024>]
   ```

   Note

   When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

   Use the command **show ip isid-list vrf WORD<1-16>** to view the list of truncated I-SIDs.

3. (Optional) Delete an I-SID list:
   ```
   no ip isid-list WORD<1-32> [<1-16777215>][list WORD<1-1024>]
   ```

   Note

   When deleting an I-SID list, ensure that the I-SID list is not associated with an IS-IS accept policy. Otherwise the deletion fails. An I-SID list associated with an accept policy cannot be deleted because it must contain at least one constituent I-SID.

4. Enter IS-IS Router Configuration mode:
   ```
   enable

   configure terminal

   router isis
   ```

Configure IS-IS accept policies with a route policy or a backbone route policy or a combination of both, to determine which routes the IS-IS accept policy applies to.

Configure one of the following types of IS-IS accept policies.

- **An IS-IS accept policy with only the route policy:**

  The IS-IS routes are selectively accepted based on the route policy. Since the backbone route policy is not configured, all host routes from the DvR backbone are denied.

  If you do not configure a route policy, by default, all IS-IS routes are accepted.
- **An IS-IS accept policy with only the backbone route policy:**

  The DvR host routes from the DvR backbone are selectively accepted based on the backbone route policy. Since the route policy is not configured, all IS-IS host routes are accepted.

If you do not configure a backbone route policy, all host routes from the DvR backbone are denied.

- **An IS-IS accept policy with both route policy and backbone route policy:**

  IS-IS routes are selectively accepted based on the route policy and host routes from the DvR backbone are selectively accepted based on the backbone route policy.

5. Configure an IS-IS accept policy instance with a route policy.

   Use one of the following options:

   a. Create an IS-IS accept policy instance to apply to all BEBs for a specific I-SID or I-SID list:

      `accept [i-sid <1-16777215>][isid-list WORD <1-32>]`

   b. Create an IS-IS accept policy instance to apply to a specific advertising BEB:

      `accept adv-rtr <x.xx.xx> [i-sid <1-16777215>][isid-list WORD <1-32>]`

   c. (Optional) Delete an IS-IS accept policy instance:

      `no accept [adv-rtr <x.xx.xx>][i-sid <1-16777215>][isid-list WORD <1-32>]`

   d. Specify an IS-IS route policy to apply to routes from all BEBs:

      `accept route-map WORD<1-64>`

   e. Specify an IS-IS route policy to apply to a specific advertising BEB:

      `accept adv-rtr <x.xx.xx>[route-map WORD<1-64>]`

   f. (Optional) Delete an IS-IS route policy:

      `no accept [adv-rtr <x.xx.xx>] [route-map]`

   g. Enable an IS-IS route accept instance:

      `accept [adv-rtr <x.xx.xx>][enable][i-sid <1-16777215>][i-sid-list WORD<1-32>]`

   h. (Optional) Disable an IS-IS route accept instance:

      `no accept [adv-rtr <x.xx.xx>][enable][i-sid <1-16777215>][i-sid-list WORD<1-32>]`

6. Configure an IS-IS accept policy instance with a backbone route policy to accept host routes from the DvR backbone:

   

   Note

   IS-IS accept policies typically apply to all IS-IS routes. However, to accept DvR host routes from the DvR backbone, you must explicitly configure the IS-IS accept policy with a backbone route policy.

   Use one of the following options:

   a. Create the default IS-IS accept policy instance to accept host routes from the DvR backbone:

      `accept backbone-route-map WORD <1-64>`

   b. (Optional) Delete the default IS-IS accept policy instance with backbone route policy configuration:

      `no accept backbone-route-map`

   c. Create an IS-IS accept policy instance to accept host routes from the DvR backbone, and apply to all BEBs for a specific I-SID or I-SID list:

      `accept [i-sid <1-16777215>][isid-list WORD <1-32>] backbone-route-map WORD<1-64>`

d. (Optional) Delete an IS-IS accept policy instance with backbone route policy configuration, which applies to all BEBs for a specific I-SID or I-SID list:

```
no accept [i-sid <1-16777215>][isid-list WORD <1-32>] backbone-route-map
```

e. Create an IS-IS accept policy instance to accept host routes from the DvR backbone and apply to a specific advertising BEB:

```
accept adv-rtr <x.xx.xx> backbone-route-map WORD <1-64>
```

f. (Optional) Delete an IS-IS accept policy instance with backbone route policy configuration, which applies to a specific advertising BEB

```
no accept adv-rtr <x.xx.xx> backbone-route-map
```

7. Configure an IS-IS accept policy with both route policy and backbone route policy, to selectively accept IS-IS routes as well as host routes from the DvR backbone.

a. Create the default IS-IS accept policy instance with a route policy to accept IS-IS routes and a backbone route policy to accept host routes from the DvR backbone:

```
accept route-map WORD<1-32> backbone-route-map WORD <1-64>
```

b. (Optional) Delete the default IS-IS accept policy with route policy and backbone route policy configuration:

```
no accept route-map backbone-route-map
```

c. Create an accept policy instance to selectively accept IS-IS routes and host routes from the DvR backbone, and apply to all BEBs for a specific I-SID or I-SID list:

```
accept [i-sid <1-16777215>][isid-list WORD <1-32>] route-map WORD<1-32> backbone-route-map WORD<1-64>
```

d. (Optional) Delete an accept policy instance with route policy and backbone route policy configuration, which applies to all BEBs for a specific I-SID or I-SID list:

```
no accept [i-sid <1-16777215>][isid-list WORD <1-32>] route-map backbone-route-map
```

e. Create an IS-IS accept policy instance to selectively accept IS-IS routes and host routes from the DvR backbone, and apply to a specific advertising BEB:

```
accept adv-rtr <x.xx.xx> route-map WORD<1-32> backbone-route-map WORD <1-64>
```

f. (Optional) Delete an IS-IS accept policy instance with route policy and backbone route policy configuration, which applies to a specific advertising BEB:

```
no accept adv-rtr <x.xx.xx> route-map backbone-route-map
```

8. Apply the IS-IS accept policy changes, which removes and re-adds all routes with updated filters:

```
isis apply accept [vrf WORD <1-16>]
```

9. Exit IS-IS Router Configuration mode:

```
exit
```

You are in Global Configuration mode.

Example

Configure an I-SID based IS-IS accept policy with the route policy `test`:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
```

```
Switch:1(config)#route-map test 1
Switch:1(route-map)#enable
Switch:1(route-map)#exit

Switch:1(config)#router isis
Switch:1(config-isis)#accept i-sid 101
Switch:1(config-isis)#accept i-sid 101 route-map test
Switch:1(config-isis)#accept i-sid 101 enable
Switch:1#exit
Switch:1(config)#isis apply accept
```

The following examples show the configuration of an IS-IS accept policy to accept host routes from the DvR backbone

Example 1:

To accept host routes from the DvR backbone, you must configure a backbone route policy and apply it to the IS-IS accept policy.

1. Configure a route policy for DvR:

   ```
   Switch:1>enable
   Switch:1#configure terminal
   Enter configuration commands, one per line.  End with CNTL/Z.
   Switch:1(config)#route-map dvrmap1 1
   Switch:1(route-map)#enable
   ```

2. Configure an IS-IS accept policy for I-SID `10`, and apply the route policy as a backbone route policy:

   ```
   Switch:1(route-map)#exit
   Switch:1(config)#router isis
   Switch:1(config-isis)#accept i-sid 10 backbone-route-map dvrmap1
   Switch:1(config-isis)#accept i-sid 10 enable
   Switch:1(config-isis)#exit
   ```

   OR

   Configure the default accept policy for IS-IS and DvR, and apply the route policy as a backbone route policy:

   ```
   Switch:1(config)#route-map isismap1 1
   Switch:1(route-map)#enable
   Switch:1(route-map)#exit
   Switch:1(config)#router isis
   Switch:1(config-isis)#accept route-map isismap1 backbone-route-map dvrmap1
   ```

3. Apply the IS-IS accept policy:

   ```
   Switch:1(config-isis)#exit
   Switch:1(config)#isis apply accept
   Switch:1(config)#exit
   ```

4. Verify the configuration:

   ```
   Switch:1#show ip isis accept

   ================================================================================
                              Isis Accept - GlobalRouter
   ================================================================================

   ADV_RTR  I-SID    ISID-LIST                        ENABLE POLICY       BACKBONE
                                                                          POLICY
   --------------------------------------------------------------------------------
   -        10       -                                TRUE                dvrmap1
   ```

```
-        -        -                                          isismap1     dvrmap1

2 out of 2 Total Num of Isis Accept Policies displayed
```

Example 2:

Configure an IS-IS accept policy for I–SID `10` that accepts DvR host routes in a subnet, for example, subnet `126.1.1.0/24`.

1. Configure an IP prefix list:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip prefix-list listPrefix 126.1.1.0/24
```

2. Create the route policy `dvrmap2` to match the IP prefix list:

```
Switch:1(config)#route-map dvrmap2 1
Switch:1(route-map)#match network listPrefix
Switch:1(route-map)#enable
```

3. Create an IS-IS accept policy with I-SID `10` and apply the route policy as a backbone route policy:

```
Switch:1(route-map)#exit
Switch:1(config)#router isis
Switch:1(config-isis)#accept i-sid 10 backbone-route-map dvrmap2
Switch:1(config-isis)#accept i-sid 10 enable
```

4. Apply the IS-IS accept policy:

```
Switch:1(config-isis)#exit
Switch:1(config)#isis apply accept
```

   The above command causes IS-IS to accept all routes with I-SID `10`. To deny IS-IS routes and accept only DvR host routes, you can configure an additional IS-IS route policy as follows:

```
Switch:1(config)#route-map isismap2 1
Switch:1(route-map)#no permit
Switch:1(route-map)#enable

Switch:1(route-map)#exit
Switch:1(config)#router isis
Switch:1(config-isis)#accept i-sid 10 route-map isismap2 backbone-route-map dvrmap2
Switch:1(config-isis)#accept i-sid 10 enable
Switch:1(config-isis)#exit
Switch:1(config)#isis apply accept
```

5. Verify the configuration:

```
Switch:1(config)#exit
Switch:1#show ip isis accept

================================================================================
                           Isis Accept - GlobalRouter
================================================================================

ADV_RTR  I-SID    ISID-LIST                        ENABLE POLICY       BACKBONE
                                                                       POLICY
--------------------------------------------------------------------------------
-        10       -                                TRUE   isismap2     dvrmap2

1 out of 1 Total Num of Isis Accept Policies displayed
```

The following examples show the configuration of IS-IS accept policies for a specific VRF instance.

Example 1:

Configure IS-IS accept policies to accept host routes from the DvR backbone, for a specific VRF instance.

1. In the VRF green context, configure the route policy `dvrmap3` for DvR:

```
Switch:1(config)#router vrf green
Switch:1(router-vrf)#route-map dvrmap3 1
Switch:1(router-vrf-routemap)#enable
```

2. Use one of the following options to configure an IS-IS accept policy, and apply the route policy as a backbone route policy:

   Configure an IS-IS accept policy for a specific advertising BEB with nickname `1.11.11`:

```
Switch:1(router-vrf-routemap)#isis accept adv-rtr 1.11.11 backbone-route-map dvrmap3
Switch:1(router-vrf-routemap)#exit
Switch:1(router-vrf)#isis accept adv-rtr 1.11.11 enable
Switch:1(router-vrf)#show ip isis accept vrf green

================================================================================
                            Isis Accept - VRF green
================================================================================

ADV_RTR  I-SID    ISID-LIST                       ENABLE POLICY       BACKBONE
                                                                      POLICY
--------------------------------------------------------------------------------
1.11.11  -        -                               TRUE                dvrmap3

1 out of 1 Total Num of Isis Accept Policies displayed
Switch:1(config)#show ip isis accept vrfids 2

================================================================================
                            Isis Accept - VRF green
================================================================================

ADV_RTR  I-SID    ISID-LIST                       ENABLE POLICY       BACKBONE
                                                                      POLICY
--------------------------------------------------------------------------------
1.11.11  -        -                               TRUE                dvrmap3

1 out of 1 Total Num of Isis Accept Policies displayed
```

   Configure an accept policy for I-SID `10`:

```
Switch:1(router-vrf)#isis accept i-sid 10 backbone-route-map dvrmap3
Switch:1(router-vrf)#show ip isis accept vrf green

================================================================================
                            Isis Accept - VRF green
================================================================================

ADV_RTR  I-SID    ISID-LIST                       ENABLE POLICY       BACKBONE
                                                                      POLICY
--------------------------------------------------------------------------------
-        10       -                               TRUE                dvrmap3
1 out of 1 Total Num of Isis Accept Policies displayed
```

   Configure an accept policy for the I-SID list `listisids`:

```
Switch:1(router-vrf)#isis accept isid-list listisids backbone-route-map dvrmap3
Switch:1(router-vrf)#show ip isis accept vrf green
```

```
================================================================================
                          Isis Accept - VRF green
================================================================================

ADV_RTR  I-SID    ISID-LIST                       ENABLE POLICY       BACKBONE
                                                                      POLICY
--------------------------------------------------------------------------------
-        10       listisids                       TRUE                dvrmap3
1 out of 1 Total Num of Isis Accept Policies displayed
```

Configure the default accept policy for IS-IS and DvR:

```
Switch:1(router-vrf)#route-map isismap3 1
Switch:1(router-vrf-routemap)#
Switch:1(router-vrf-routemap)#enable
Switch:1(router-vrf-routemap)#
Switch:1(router-vrf-routemap)#isis accept route-map isismap3 backbone-route-map dvrmap3
Switch:1(router-vrf)#
Switch:1(router-vrf)#show ip isis accept vrf green

================================================================================
                          Isis Accept - VRF green
================================================================================

ADV_RTR  I-SID    ISID-LIST                       ENABLE POLICY       BACKBONE
                                                                      POLICY
--------------------------------------------------------------------------------
-        -        -                               TRUE   isismap3     dvrmap3

1 out of 1 Total Num of Isis Accept Policies displayed
```

Configure the default accept policy for DvR:

```
Switch:1(router-vrf)#isis accept backbone-route-map dvrmap3
Switch:1(router-vrf)#show ip isis accept vrf green

================================================================================
                          Isis Accept - VRF green
================================================================================

ADV_RTR  I-SID    ISID-LIST                       ENABLE POLICY       BACKBONE
                                                                      POLICY
--------------------------------------------------------------------------------
-        -        -                               TRUE                dvrmap3

1 out of 1 Total Num of Isis Accept Policies displayed
```

Example 2:

Configure an accept policy for I-SID `10` that accepts DvR host routes in a subnet, for example, subnet `126.1.1.0/24`.

1. Configure an IP prefix list:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip prefix-list listPrefix 126.1.1.0/24
```

2. For a specific VRF instance, create a route policy to match the IP prefix list:

```
Switch:1(config)#router vrf green
Switch:1(router-vrf)#route-map dvrmap4 1
Switch:1(router-vrf-routemap)#match network listPrefix
```

```
Switch:1(router-vrf-routemap)#enable
Switch:1(router-vrf-routemap)#exit
Switch:1(router-vrf)#
```

3. Create an IS-IS accept policy with I-SID 10, and apply the route policy as the backbone route policy:

```
Switch:1(router-vrf)#accept i-sid 10 backbone-route-map dvrmap4
Switch:1(router-vrf)#accept i-sid 10 enable
```

4. Apply the IS-IS accept policy:

```
Switch:1(router-vrf)#exit
Switch:1(config)#isis apply accept
```

5. Verify the configuration:

```
Switch:1(config)#exit
Switch:1(router-vrf)#show ip isis accept vrf green

================================================================================
                            Isis Accept - VRF green
================================================================================

```

Variable definitions

The following table defines parameters for the **ip isid-list** command.

Variable	Value
WORD<1-32>	Creates a name for your I-SID list.
<1-16777215>	Specifies an I-SID number.
list WORD<1-1024>	Specifies a list of I-SID values. For example, in the format 1,3,5,8-10.

The following table defines parameters for the **accept** command.

Variable	Value
adv-rtr <x.xx.xx>	Specifies the SPBM nickname for each advertising BEB to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter.
backbone-route-map WORD<1-64>	Specifies the DvR backbone route map.
enable	Enables an IS-IS accept policy.
i-sid <1-16777215>	Specifies an I-SID number to represent a local or remote Layer 3 VSN to which the IS-IS accept policy applies. Use the parameter to apply a filter for routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system can redistribute the remote VSN to the VSN where you applied the filter. An I-SID value of 0 represents the global routing table (GRT).

Variable	Value
isid-list WORD<1-32>	Specifies the I-SID list name that represents the local or remote Layer 3 VSNs to which the IS-IS accept policy applies. Use the parameter to apply a default filter for all routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system redistributes the remote VSN to the VSN where you applied the filter. An I-SID value of 0 represents the global routing table (GRT).
route-map WORD<1-64>	Specifies a route policy by name. You must configure the route policy earlier in a separate procedure.

The following table defines parameters for the **isis apply accept** command.

Variable	Value
vrf WORD<1-16>	Specifies a specific VRF instance.

View IS-IS Accept Policy Information

Use the following procedure to view IS-IS accept policy information on the switch.

Procedure

1. Display IS-IS accept policy information:

   ```
   show ip isis accept [vrf WORD<1-16>][vrfids WORD<0-512>]
   ```

2. Display I-SID list information:

   ```
   show ip isid-list [vrf WORD<1-16>][vrfids WORD<0-512>][WORD<1-32>]
   ```

3. Display route information:

   ```
   show ip route [vrf WORD<1-16>]
   ```

   The NH VRF/ISID column displays the I-SID for inter-Virtual Services Network (VSN) routes redistributed with IS-IS accept policies, only if the I-SID redistributed does not have an IP VSN associated with it. If an IP VSN exists for that I-SID, the VRF name displays. If the I-SID is 0, the column represents and displays as the GlobalRouter.

   The existing IS-IS routes for Layer 3 VSNs continue to display as the VRF name of the IP VSN.

4. Display the SPBM IP unicast Forwarding Information Base (FIB):

   ```
   show isis spbm ip-unicast-fib [all] [id <1-16777215>][spbm-nh-as-mac]
   [home|remote]
   ```

Example

View IS-IS accept policy information:

```
Switch:1#show ip route vrf test
================================================================================
                    IP Route - VRF test
================================================================================

Variable Definitions

The following table defines parameters for the **show ip isis accept** command.

Variable	Value
vrf WORD<1-16>	Displays I-SID list information for a particular VRF by name.
vrfids WORD<0-512>	Displays I-SID list information for a particular VRF ID.

The following table defines parameters for the **show ip isid-list** command.

Variable	Value
vrf WORD<1-16>	Displays I-SID list information for a particular VRF by name.
vrfids WORD<0-512>	Displays I-SID list information for a particular VRF ID.
WORD<1-32>	Displays I-SID list information for a particular I-SID list name.

The following table defines parameters for the **show ip route** command.

Variable	Value
vrf WORD<1-16>	Displays I-SID list information for a particular VRF by name.

The following table defines parameters for the **show isis spbm ip-unicast-fib** command.

Variable	Value
all	Displays all IS-IS SPBM IP unicast Fowarding Information Base (FIB) information.
home	Displays the IS-IS SPBM IP unicast FIB information that the system configures in the home area.
id <1-16777215>	Displays IS-IS SPBM IP unicast FIB information by I-SID ID.
remote	Displays the IS-IS SPBM IP unicast FIB information that the system configures in the remote area.
spbm-nh-as-mac	Displays the next hop B-MAC of the IP unicast FIB entry.

Configuring IPv6 IS-IS Accept Policies

Perform the following procedure to create and enable IPv6 IS-IS accept policies based on a particular Backbone Edge Bridge (BEB), I-SID, or I-SID list. IPv6 IS-IS accept policies filter incoming IS-IS routes that the device receives over the SPBM cloud. IPv6 IS-IS accept policies apply to incoming traffic and determine whether to add the route to the routing table.

IPv6 IS-IS accept policies are disabled by default.

Note

- IPv6 IS-IS accept policies are not supported for DvR.
- The I-SID lists created can be associated with both IPv4 or IPv6 routes.
- The **ipv6 isis apply accept [vrf WORD<1-16>]** command can disrupt traffic and cause temporary traffic loss. After you apply **ipv6 isis apply accept [vrf <1-16>]**, the command reapplies the accept policies, which deletes all of the IS-IS routes, and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply **ipv6 isis apply accept [vrf WORD<1-16>]** at the end.
- If the route policy associated with an accept policy changes, you must reapply the IPv6 IS-IS accept policy, unless the IPv6 IS-IS accept policy was the last sequence in the configuration.
- The **ipv6 isis apply accept [vrf WORD<1-16>]** command is not saved in the configuration file. If you use a saved configuration file for IPv6 IS-IS accept policy configuration, you must apply the **ipv6 isis apply accept [vrf WORD<1-16>]** command at the end.

  The number of unique Layer 3 VSN I-SIDs used on a BEB is limited to the number of VRFs supported on the switch. This includes the I-SID values used for Layer 3 VSNs and the I-SID values specified for the IPv6 IS-IS accept policy filters.

  The switch supports 24 VRFs by default, so, in a default configuration, you cannot create an I-SID list or accept policy with more than 24 unique I-SID entries. However, the configured VRFs take up an entry, so the formula to calculate the limit is: [24 VRF Limit – (currently configured VRFs)]. This gives the number of unique I-SIDs that can be used directly in the IPv6 IS-IS accept policy filters, which you implement with the **ip isid-list** or **ipv6 accept** command. The I-SIDs used for Layer 3 VSNs can be reused in IPv6 IS-IS accept policy filters without affecting the limit.

  If you increase the VRF scaling, you can create more Layer 3 VSNs. For more information about how to increase the number of supported VRFs, see Configure the Maximum Number of VRFs on page 3494. The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see *Fabric Engine Release Notes*.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- Configure IPv6 Shortcuts. For more information, see Configure SPBM IPv6 Shortcuts on page 1146.
- You must configure a route-map.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. (Optional) If you want to accept routes from a variety of I-SIDs, create an I-SID list before you create an IPv6 IS-IS accept policy for the I-SID list:

   ```
   ip isid-list WORD<1-32> {<1-16777215> | list WORD<1-1024>}
   ```

   

   Note

   When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

   Use the command **show ip isid-list vrf WORD<1-16>** to view the list of truncated I-SIDs.

3. Enter VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal

   router vrf WORD<1-16>
   ```

4. Configure an IPv6 IS-IS accept policy instance with a route policy.

   Use one of the following options:

   a. Configure an IPv6 IS-IS accept policy based on a specific advertising BEB:

      ```
      ipv6 isis accept adv-rtr <x.xx.xx> [enable] [i-sid <0-16777215>]
      [isid-list WORD<1-32>] [ [route-map WORD<1-64>]
      ```

   b. Configure an IPv6 IS-IS accept policy based on a particular I-SID:

      ```
      ipv6 isis accept i-sid <0-16777215> [enable] [route-map WORD<1-64>]
      ```

   c. Configure an IPv6 IS-IS accept policy based on a particular I-SID list:

      ```
      ipv6 isis accept isid-list WORD<1-32> [enable] [route-map WORD<1-
      64>]
      ```

   d. Specify a particular route-map to use for all IS-IS routes from all BEBs unless a more specific filter exists for the advertising BEB. :

      ```
      ipv6 isis accept route-map WORD<1-64>
      ```

5. Enable the configured IPv6 IS-IS accept policies:

   ```
   ipv6 isis accept [adv-rtr <x.xx.xx>] [i-sid <0-16777215>] [isid-list
   WORD<1-32>] enable
   ```

6. Exit to Global Configuration mode:

   ```
   exit
   ```

7. Apply the IPv6 IS-IS accept policy changes, which removes and re-adds all routes with updated filters:

   ```
   ipv6 isis apply accept [vrf WORD <1-16>]
   ```

Example

Configure an IPv6 IS-IS accept policy based on a particular I-SID:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf vrftest
```

```
Switch:1(config-isis)#ipv6 isis accept i-sid 101 route-map test
Switch:1(config-isis)#ipv6 isis accept i-sid 101 enable
Switch:1#exit
Switch:1(config)#ipv6 isis apply accept
```

Variable Definitions

The following table defines parameters for the **ip isid-list** command.

Note

The I-SID lists created can be associated with both IPv4 or IPv6 routes.

Variable	Value
WORD<1-32>	Creates a name for your I-SID list.
<1-16777215>	Specifies an I-SID number.
list WORD<1-1024>	Specifies a list of I-SID values. For example, in the format 1,3,5,8-10.

The following table defines parameters for the **ipv6 isis accept** command.

Variable	Value
adv-rtr <x.xx.xx>	Specifies the SPBM nickname for each advertising BEB to allow you to apply the IPv6 IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter. Note: An IPv6 IS-IS accept policy that specifies the adv-rtr without an I-SID or I-SID list will filter routes coming from the I-SID on which the policy is configured and from the specified BEB.
enable	Enables an IPv6 IS-IS accept policy.
i-sid <0-16777215>	Specifies an I-SID number to represent a local or remote Layer 3 VSN to which the IPv6 IS-IS accept policy applies. Use the parameter to apply a filter for routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system can redistribute the remote VSN to the VSN where you applied the filter. An I-SID value of 0 represents the global routing table (GRT).
isid-list WORD<1-32>	Specifies the I-SID list name that represents the local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies. Use the parameter to apply a default filter for all routes from specific I-SIDs that represent the remote VSN. Based on the routing policy the system applies, the system redistributes the remote VSN to the VSN where you applied the filter. An I-SID value of 0 represents the global routing table (GRT).
route-map WORD<1-64>	Specifies a route policy by name. You must configure the route policy earlier in a separate procedure.

The following table defines parameters for the **ipv6 isis apply accept** command.

Variable	Value
vrf WORD<1-16>	Specifies a VRF instance.

Displaying IPv6 IS-IS Accept Policy Information

Perform the following procedure to view IPv6 IS-IS accept policy information on the switch.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Display IPv6 IS-IS accept policy information:
   ```
   show ipv6 isis accept [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

Example

Display IPv6 IS-IS accept policy information for vrfRED:

```
Switch:1>enable
Switch:1#show ipv6 isis accept vrf vrfRED
================================================================================
                              Isis Accept - VRF vrfRED
================================================================================
ADV_RTR  I-SID    ISID-LIST                       ENABLE POLICY

--------------------------------------------------------------------------------
1.11.11  1001     -                               TRUE

1 out of 1 Total Num of Isis Accept Policies displayed
```

IP Shortcuts configuration using EDM

This section provides procedures to configure IP Shortcuts using Enterprise Device Manager (EDM).

Configure SPBM IP Shortcuts

In addition to Layer 2 virtualization, the SPBM model is extended to also support Routed SPBM, otherwise called SPBM IP Shortcuts.

SPBM allows a network to make the best use of routing and forwarding techniques, where only the BEBs perform an IP route lookup and all other nodes perform standard Ethernet switching based on the existing shortest path tree. This allows for end to end IP-over-Ethernet forwarding without the need for ARP, flooding, or reverse learning.

To enable IP shortcuts on the BEBs, you can configure a circuitless IP address (loopback address) and specify this adress as the IS-IS source address. This source address is automatically advertised into IS-IS using TLV 135. In addition, to advertise routes from the BEBs into the SPBM network, you must enable route redistribution of direct and static routes into IS-IS.

After you have configured the SPBM infrastructure, you can enable SPBM IP shortcuts to advertise IP routes across the SPBM network using the following procedure.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- Before redistributing routes into IS-IS, you must create the Customer VLANs, add slots/ports, and add the IP addresses and network masks.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **IS-IS**.
3. From the **Globals** tab, in **IpSourceAddress**, specify the CLIP interface to use as the source address for SBPM IP Shortcuts.

   Note

   For IPv6 Shortcuts, select **ipv6** in **Ipv6SourceAddressType**, and then use **Ipv6SourceAddress** to specify the CLIPv6 interface to use as the source address for SBPM IPv6 Shortcuts.

4. Select **Apply**.
5. In the navigation pane, expand **Configuration** > **Fabric** > **SPBM**.
6. Select the **SPBM** tab.
7. In **IpShortcut**, select **enable**.

   Note

   For IPv6 Shortcuts, select **enable** in **Ipv6Shortcut**.

8. Select **Apply**.
9. In the navigation pane, expand **Configuration** > **IP**.
10. Select **Policy**.
11. Select the **Route Redistribution** tab.
12. Select **Insert** to identify routes on the local switch to be announced into the SPBM network.
13. Using the fields provided, specify the source protocols to redistribute into IS-IS. In **Protocol**, ensure you specify **isis** as the destination protocol.
14. Select **Insert**.

Configuring IPv4 IS-IS redistribution

Use this procedure to configure IS-IS redistribution. In the Virtual Routing and Forwarding (VRF), just like in the Global Router, the routes are not redistributed into IS-IS automatically. To advertise the VRF routes, you must explicitly redistribute one of the following protocols into IS-IS: direct, static, RIP, OSPF, or BGP, within the context of a VRF. Routing between VRFs is also possible by using redistribution policies and injecting routes from the other protocols.

The VRF specific routes are transported in TLV 184 with the I-SID assigned to the VPNs. After extracting the IP VPN IP reachability information, the routes are installed in the route tables of the appropriate VRFs based on the I-SID association.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Click **IS-IS**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Complete the fields as required.
6. Click **Insert**.

IS-IS Redistribute field descriptions

Use the data in the following table to configure the **IS-IS Redistribute** tab.

Name	Description
DstVrfId	Specifies the destination Virtual Routing and Forwarding (VRF) ID used in the redistribution.
Protocol	Specifies the protocols that receive the redistributed routes.
SrcVrfId	Specifies the source VRF ID used in the redistribution. For IS-IS, the source VRF ID must be the same as the destination VRF ID.
RouteSource	Specifies the source protocol for the route redistribution entry.
Enable	Enables or disables a redistribution entry. The default is disable.
RoutePolicy	Specifies the route policy to be used for the detailed redistribution of external routes from a specified source into the IS-IS domain.
Metric	Specifies the metric for the redistributed route. The value can be a range between 0 to 65535. The default value is 0. Use a value that is consistent with the destination protocol.
MetricType	Specifies the metric type. Specifies a type1 or a type2 metric. For metric type1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type2, the cost of the external routes is equal to the external cost alone. The default is type2.
Subnets	Indicates whether the subnets are advertised individually or aggregated to their classful subnet. Choose suppress to advertise subnets aggregated to their classful subnet. Choose allow to advertise the subnets individually with the learned or configured mask of the subnet. The default is allow.

Configure IPv6 IS-IS Redistribution

Use this procedure to configure IS-IS redistribution for IPv6. In the Virtual Routing and Forwarding (VRF), just like in the Global Router, the IPv6 routes are not redistributed into IS-IS automatically. To advertise the VRF routes, you must explicitly redistribute one of the following protocols into IS-IS:

v6direct, v6static, RIPng, OSPFv3, or BGPv6, within the context of a VRF. Routing between VRFs is also possible by using redistribution policies and injecting routes from the other protocols.

Note
RIPng is supported only on the Global Router.

The VRF specific routes are transported in TLV 184 with the I-SID assigned to the VPNs. After extracting the IPv6 VPN reachability information, the IPv6 routes are installed in the route tables of the appropriate VRFs based on the I-SID association.

Before You Begin

Change the VRF instance as required to configure IPv6 IS-IS redistribution on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **IS-IS**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Complete the fields as required.
6. Click **Insert**.
7. Click **Apply**.

Redistribute Field Descriptions

Use the data in the following table to configure the **Redistribute** tab.

Name	Description
DstVrfId	Specifies the destination Virtual Routing and Forwarding (VRF) ID used in redistribution.
Protocol	Specifies the protocols that receive the redistributed routes.
SrcVrfId	Specifies the source Virtual Routing and Forwarding (VRF) ID used in redistribution.
RouteSource	Specifies the source protocol for the route redistribution entry.
Enable	Enables or disables a redistribution entry. The default is disabled.
RoutePolicy	Specifies the route policy to be used for the detailed redistribution of external routes from a specified source into the IS-IS domain.

Name	Description
Metric	Specifies the metric for the redistributed route. The default value is 0. Use a value that is consistent with the destination protocol.
MetricType	Specifies the metric type. Specifies a type1 or a type2 metric. For metric type1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type2, the cost of the external routes is equal to the external cost alone. The default is type2.

Applying IPv4 IS-IS accept policies globally

Apply IS-IS accept policies globally. Use IS-IS accept policies to filter incoming IS-IS routes the device receives over the SPBM cloud. Accept policies apply to incoming traffic and determine whether to add the route to the routing table.

After you apply the IS-IS accept filters, the device removes and re-adds all routes with updated filters.

IS-IS accept policies are disabled by default.

Note

- After you apply IS-IS accept policies globally the application can disrupt traffic and cause temporary traffic loss. After you configure the IS-IS accept policies value to **Apply**, the device reapplies the accept policies, which deletes all of the IS-IS routes, and adds the IS-IS routes again. You should make all the relevant accept policy changes, and then apply IS-IS accept policies globally at the end.
- If the route policy changes, you must reapply the IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- Ensure the IP IS-IS filter exists.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Click **IS-IS**.
3. Click the **Accept Global** tab.
4. Select a name from the list or enter name in the **DefaultPolicyName** field, to specify the route policy name for the default filter.
5. Select **Apply** to apply the default policy.

Accept Global field descriptions

Use the data in the following table to configure the **Accept Global** tab.

Name	Description
DefaultPolicyName	Specifies the route policy name for the default filter.
DefaultBackbonePolicyName	Specifies the backbone host route policy name for the default filter.
Apply	Applies the default policy when you configure the field to apply. The device only activates the default policy if the route map (the default policy name) has a value. If you do not select apply, the device takes no action. The GRT always returns no action.

Configure an IPv4 IS-IS Accept Policy for a Specific Advertising BEB

Configure an IS-IS accept policy to apply to a specific advertising Backbone Edge Bridge (BEB). Specify the SPBM nickname and the IS-IS accept policy name to allow you to apply the IS-IS accept policy.

The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.

Note

If the route policy changes, you must re-apply the IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **IS-IS**.
3. Select the **Accept Nick Name** tab.
4. Select **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. Select enable in the **Enable** check box to enable the filter.
7. In the **PolicyName** field, specify the route-map name.
8. Select **Insert**.

Accept Nick Name field descriptions

Use the data in the following table to configure the **Accept Nick Name** tab.

Name	Description
AdvertisingRtr	Specifies the SPBM nickname to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter. The value is 2.5 bytes in the format <x.xx.xx>.
Enable	Enables or disables the SPBM nickname advertising router entry. You must enable the value to filter. The default is disabled.
PolicyName	Specifies a route policy. You must configure a policy earlier in a separate procedure.
BackbonePolicyName	Specifies the route policy for the backbone routes. You must configure a policy earlier in a separate procedure.

Configure an IS-IS Accept Policy to Apply for a Specific I-SID

Configure an IS-IS accept policy for a specific I-SID number to represent a local or remote Layer 3 VSN, which allows the system to redistribute the remote VSN to the VSN where you applied the filter. An I-SID value of 0 represents the global routing table (GRT).

Note

If the route policy changes, you must re-apply the IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Click **IS-IS**.
3. Click the **Accept Isid** tab.
4. Click **Insert**.
5. In the **Isid** field, specify the SPBM nickname.
6. Select enable in the **Enable** check box to enable the filter.
7. In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

Accept Isid field descriptions

Use the data in the following table to configure the **Accept Isid** tab.

Name	Description
Isid	Configures a specific I-SID number to represent a local or remote Layer 3 VSN to which the IS-IS accept policy applies. Based on the routing policy the system applies, the system redistributes the remote VSN to the VSN where you applied the filter. An I-SID value of 0 represents the global routing table (GRT).
Enable	Enables or disables the I-SID entry. You must enable the value to filter. The default is disabled.
PolicyName	Specifies the route map name. You must configure a policy earlier in a separate procedure.
BackbonePolicyName	Specifies the backbone route map name. You must configure a policy earlier in a separate procedure.

Configure an IPv4 IS-IS Accept Policy for a Specific Advertising BEB and I-SID

Configures a specific advertising Backbone Edge Bridge (BEB) with a specific I-SID to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB.

Note

If the route policy changes, you must re-apply the IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Click **IS-IS**.
3. Click the **Accept Nick-Name Isid** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. In the **Isid** field, specify an I-SID number.
7. Select enable in the **Enable** check box to enable the filter.
8. In the **PolicyName** field, specify the route-map name.
9. Click **Insert**.

Accept Nick-Name Isid descriptions

Use the data in the following table to configure the **Accept Nick-Name Isid** tab.

Name	Description
AdvertisingRtr	Specifies the SPBM nickname to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB. The value is 2.5 bytes in the format <x.xx.xx>.
Isid	Specifies an I-SID used to filter. The value 0 is used for the Global Router.
Enable	Enables or disables the I-SID entry. The default is disabled.
PolicyName	Specifies the route policy name. You must configure a policy earlier in a separate procedure.
BackBonePolicyName	Specifies the backbone route policy name. You must configure a policy earlier in a separate procedure.

Configuring an I-SID list for an IPv4 IS-IS accept policy

Configures a list of I-SID numbers that represent local or remote Layer 3 VSNs to which the IS-IS accept policy applies. After you create the list of I-SID numbers, you must then create, configure, and enable the IS-IS accept policy.

Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Refresh the EDM tab to view the actual list of I-SIDs in the I-SID list.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Click **IS-IS**.
3. Click the **Isid-List** tab.
4. Click **Insert**.
5. In the **Name** field, specify a name for the I-SID list.
6. Select **Isid** or **Isid-List**.
7. Specify an I-SID number or a list of I-SID numbers.
8. Click **Insert**.

Isid-List field descriptions

Use the data in the following table to configure the **Isid-List** tab.

Name	Description
Name	Specifies the name of the I-SID list.
Isid or **Isid-List**	Specifies that you either want to add a particular I-SID or a list of I-SID numbers.
Isid	Specifies a particular I-SID number or a list of I-SID numbers that represent local or remote Layer 3 VSNs to which the IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT).

Configure an IPv4 IS-IS Accept Policy for a Specific I-SID List

Configure an IS-IS accept policy for a specific I-SID list to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

Note

If the route policy changes, you must re-apply the IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Click **IS-IS**.
3. Click the **Accept Isid-List** tab.
4. Click **Insert**.
5. In the **Name** field, specify the I-SID list name.
6. Select enable in the **Enable** check box to enable the filter.
7. In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

Accept Isid–List field descriptions

Use the data in the following table to configure **Accept Isid-List** tab.

Name	Description
Name	Specifies the name of I-SID list.
Enable	Enables or disables the I-SID list entry. The value must be enabled to filter. The default is disabled.
PolicyName	Specifies the route policy name.
BackBonePolicyName	Specifies the backbone route policy name.

Configure an IPv4 IS-IS Accept Policy for a Specific Advertising BEB and I-SID-list

Configure an IS-IS accept policy to apply to a specific advertising Backbone Edge Bridge (BEB) for a specific I-SID list to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

Note

If the route policy changes, you must reapply the IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map to apply.

About This Task

The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Click **IS-IS**.
3. Click the **Accept Nick-Name Isid-List** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. In the **Name** field, specify an I-SID list name.
7. Select enable in the **Enable** check box to enable the filter.
8. In the **PolicyName** field, specify the route-map name.
9. Click **Insert**.

Accept Nick–Name Isid-List field descriptions

Use the data in the following table to configure the **Accept Nick-Name Isid-List** tab.

Name	Description
AdvertisingRtr	Specifies the SPBM nickname to allow you to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter is present the device applies the specific filter. The value is 2.5 bytes in the format <x.xx.xx>.
Name	Specifies the name of the I-SID list used to filter.
Enable	Enables or disables the SPBM nickanme advertising router entry. You must enable the value to filter. The default is disabled.
PolicyName	Specifies a route policy name.
BackBonePolicyName	Specifies a backbone route policy name.

Apply IPv6 IS-IS Accept Policies Globally

Apply IPv6 IS-IS accept policies globally. Use IPv6 IS-IS accept policies to filter incoming IS-IS routes the device receives over the SPBM cloud.

After you apply the IPv6 IS-IS accept policy filters, the device removes and re-adds all IPv6 routes with updated filters.

IPv6 IS-IS accept policies are disabled by default.

Note

- After you apply IPv6 IS-IS accept policies globally the application can disrupt traffic and cause temporary traffic loss. After you configure the IPv6 IS-IS accept policies value to **Apply**, the device reapplies the accept policies, which deletes all of the IPv6 IS-IS routes, and adds the IPv6 IS-IS routes again. You should make all the relevant accept policy changes, and then apply IPv6 IS-IS accept policies globally at the end.
- If the route policy changes, you must reapply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- Ensure the IPv6 IS-IS filter exists.
- Change the VRF instance as required to apply IPv6 IS-IS accept policies on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Select **IS-IS**.
3. Select the **Accept Global** tab.
4. (Optional) Select a name from the list or enter name in the **DefaultPolicyName** field, to specify the route policy name for the default filter.
5. Select **Apply** to apply the default policy.
6. Select **Apply**.

Accept Global Field Descriptions

Use the data in the following table to configure the **Accept Global** tab.

Name	Description
DefaultPolicyName	Specifies the route policy name for the default filter.
Apply	Applies the default policy when you select apply. The device only activates the default policy if the route map (the default policy name) has a value. If you do not select apply, the device takes no action. The GRT always returns no action.
NickNameTableSize	Shows the IPv6 IS-IS In Filter Nick Name table size.

Name	Description
IsidTableSize	Shows the IPv6 IS-IS In Filter I-SID table size.
NickNameIsidTableSize	Shows the IPv6 IS-IS In Filter Nick Name I-SID table size.
IsidListTableSize	Shows the IPv6 IS-IS In Filter I-SID List table size.
NickNameIsidListTableSize	Shows the IPv6 IS-IS In Filter Nick Name I-SID List table size.

Configuring an IPv6 IS-IS Accept Policy for a specific Advertising BEB

Configure an IPv6 IS-IS accept policy to apply to a specific advertising Backbone Edge Bridge (BEB). Specify the SPBM nickname and the IS-IS accept policy name to allow you to apply the IPv6 IS-IS accept policy.

The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.

Note

If the route policy changes, you must re-apply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular advertising BEB on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Nick Name** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. Select **Enable** to apply the filter.
7. (Optional) In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

Accept Nick Name Field Descriptions

Use the data in the following table to configure the **Accept Nick Name** tab.

Name	Description
AdvertisingRtr	Specifies the SPBM nickname to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter for a specific advertising BEB is present the device applies the specific filter.
Enable	Enables the SPBM nickname advertising router entry. The default is disabled.
PolicyName	Specifies a route policy.

Configuring an IPv6 IS-IS Accept Policy for a specific I-SID

Configure an IPv6 IS-IS accept policy for a specific I-SID to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

Note

If the route policy changes, you must re-apply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular I-SID on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Isid** tab.
4. Click **Insert**.
5. In the **Isid** field, specify the I-SID value.
6. Select **Enable** to apply the filter.
7. (Optional) In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

Accept Isid Field Descriptions

Use the data in the following table to configure the **Accept Isid** tab.

Name	Description
Isid	Specifies a particular I-SID number that represents local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT).
Enable	Enables or disables the I-SID entry. The default is disabled.
PolicyName	Specifies the route policy name.

Configuring an IPv6 IS-IS accept policy for a specific advertising BEB and I-SID

Configures a specific advertising Backbone Edge Bridge (BEB) with a specific I-SID to allow you to apply the IPv6 IS-IS accept policy to routes for a specific advertising BEB.

Note

If the route policy changes, you must re-apply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular advertising BED and I-SID on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Nick-Name Isid** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. In the **Isid** field, specify an I-SID number.
7. Select **Enable** to apply the filter.
8. (Optional) In the **PolicyName** field, specify the route-map name.
9. Click **Insert**.

Accept Nick-Name Isid Field Descriptions

Use the data in the following table to configure the **Accept Nick-Name Isid** tab.

Name	Description
AdvertisingRtr	Specifies the SPBM nickname to apply the IS-IS accept policy to routes for a specific advertising BEB.
Isid	Specifies the I-SID value. The value 0 is used for the Global Router.
Enable	Enables or disables the I-SID entry. The default is disabled.
PolicyName	Specifies the route policy name. You must configure a policy earlier in a separate procedure.

Configuring an I-SID List for an IPv6 IS-IS Accept Policy

Configures a list of I-SID numbers that represent local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies. After you create the list of I-SID numbers, you must then create, configure, and enable the IPv6 IS-IS accept policy.

Note

When creating an I-SID list, you can add I-SID entries until the maximum limit for supported Layer 3 I-SIDs is reached. The system truncates any additional I-SID entries. The maximum limit includes the I-SIDs for locally configured Layer 3 VSNs and the I-SIDs specified for IS-IS accept policy filters.

Refresh the EDM tab to view the actual list of I-SIDs in the I-SID list.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- Change the VRF instance as required to configure an I-SID list for an IPv6 IS-IS accept policy on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **IS-IS**.
3. Click the **Isid-List** tab.
4. Click **Insert**.
5. In the **Name** field, specify a name for the I-SID list.
6. Select **Isid** or **Isid-List**.
7. Specify an I-SID number or a list of I-SID numbers.
8. Click **Insert**.
9. Click **Apply**.

Isid-List Field Descriptions

Use the data in the following table to configure the **Isid-List** tab.

Name	Description
Name	Specifies the name of the I-SID list.
Isid	Specifies a particular I-SID number or a list of I-SID numbers that represent local or remote Layer 3 VSNs to which the IPv6 IS-IS accept policy applies. An I-SID value of 0 represents the global routing table (GRT).

Configuring an IPv6 IS-IS Accept Policy for a specific I-SID List

Configure an IPv6 IS-IS accept policy for a specific I-SID list to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

Note

If the route policy changes, you must re-apply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular I-SID list on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Isid-List** tab.
4. Click **Insert**.
5. In the **Name** field, specify the I-SID list name.
6. Select **Enable** to apply the filter.
7. (Optional) In the **PolicyName** field, specify the route-map name.
8. Click **Insert**.

Accept Isid-List Field Descriptions

Use the data in the following table to configure **Accept Isid-List** tab.

Name	Description
Name	Specifies the name of I-SID list.
Enable	Enables or disables the I-SID list entry. The default is disabled.
PolicyName	Specifies the route policy name.

Configuring an IPv6 IS-IS Accept Policy for a specific Advertising BEB and I-SID List

Configure an IPv6 IS-IS accept policy to apply to a specific advertising Backbone Edge Bridge (BEB) for a specific I-SID list to represent local or remote Layer 3 VSNs, which allows the system to redistribute the remote VSNs to the VSN where you applied the filter.

Note

If the route policy changes, you must reapply the IPv6 IS-IS accept policy, unless it was the last sequence in the configuration.

Before You Begin

- Enable IS-IS globally.
- Ensure the manual area exists.
- You must configure a route-map.
- Change the VRF instance as required to configure an IPv6 IS-IS accept policy for a particular advertising BEB and I-SID list on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

The system uses the default global filter unless a filter for a specific advertising BEB exists, in which case the system applies a more specific filter.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **IS-IS**.
3. Click the **Accept Nick-Name Isid-List** tab.
4. Click **Insert**.
5. In the **AdvertisingRtr** field, specify the SPBM nickname.
6. In the **Name** field, specify an I-SID list name.
7. Select **Enable** to apply the filter.
8. (Optional) In the **PolicyName** field, specify the route-map name.
9. Click **Insert**.

Accept Nick-Name Isid-List Field Descriptions

Use the data in the following table to configure the **Accept Nick-Name Isid-List** tab.

Name	Description
AdvertisingRtr	Specifies the SPBM nickname to apply the IS-IS accept policy to routes for a specific advertising BEB. The system first uses the default filter, but if a more specific filter is present the device applies the specific filter.
Name	Specifies the I-SID list name.
Enable	Enables or disables the SPBM nickanme advertising router entry. The default is disabled.
PolicyName	Specifies a route policy name.

IP Shortcuts SPBM Configuration Example

The following figure shows a sample IP Shortcuts over SPBM deployment.

Examples and network illustrations in this document may illustrate only one of the supported platforms. Unless otherwise noted, the concept illustrated applies to all supported platforms.

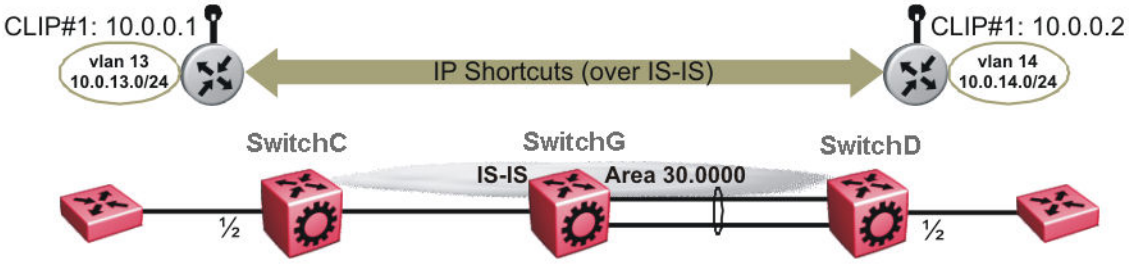

Figure 112: SPBM IP Shortcuts

The following sections show the steps required to configure the SPBM IP Shortcuts parameters in this example. You must first configure basic SPBM and IS-IS infrastructure. For more information, see SPBM and IS-IS Infrastructure Configuration on page 840.

Note the following:

- IP IS-IS redistribution needs to be configured to inject IP shortcuts routes into IS-IS. The one exception is the circuitless IP address configured as the IS-IS ip-source-address. This address is automatically advertised without the need for a redistribution rule.
- In the displayed configuration, only direct routes are injected (the same configuration is possible for static routes). To inject IPv6 routes, you must enable route redistribution of IPv6 direct, IPv6 static, and OSPFv3 routes into IS-IS.
- No IP address needs to be configured on SwitchG.

The following sections show the steps required to configure the SPBM IP Shortcuts parameters in this example.

Layer 3 VSN Configuration

Table 93: Layer 3 VSN product support

Feature	Product	Release introduced
Layer 3 VSN	5320 Series	Fabric Engine 8.6 Note: Only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration.
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Layer 3 VSN Configuration Fundamentals

This section provides fundamental concepts on Layer 3 VSN.

For information about supported service types, see Fabric Connect Service Types on page 1060.

SPBM Layer 3 VSN

The SPBM Layer 3 VSN feature is a mechanism to provide IP connectivity over SPBM for VRFs. SPBM Layer 3 VSN uses IS-IS to exchange the routing information for each VRF.

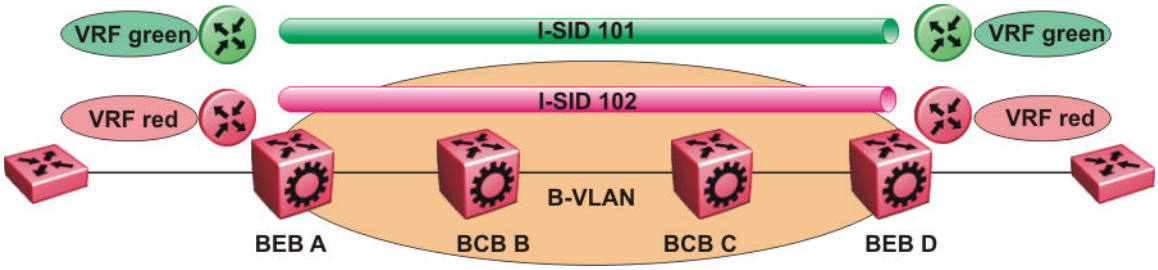

Figure 113: SPBM Layer 3 VSN

In the preceding figure, the BEBs are connected over the SPBM cloud running IS-IS. VRF red and green are configured on the BEBs. VRF red on BEB A has to send and receive routes from VRF red on BEB D. Similar operations are required for VRF green on BEB A and BEB D.

IS-IS TLV 184 is used to advertise SPBM Layer 3 VSN route information across the SPBM cloud. To associate advertised routes with the appropriate VRF, each VRF is associated with an I-SID. All VRFs in the network that share the same I-SID participate in the same VSN.

Note

IPv4 Layer 3 VSN and IPv6 Layer 3 VSN coexist and share the same I-SID. You need to configure I-SID only once. The advantage of having two separate VPNs, one for IPv4 and one for IPv6 is because it gives user an option to enable them separately.

In this example, I-SID 101 is associated with VRF green and I-SID 102 is associated with VRF red. The I-SID is used to tie the advertised routes to a particular VRF. This identifier has to be the same on all edge nodes for a particular VRF, and has to be unique across all the VRFs on the same node

When IS-IS receives an update from an edge node, it looks for the Layer 3 VSN TLV, and if one exists, it looks at the I-SID identifier. If that identifier is mapped to a local VRF, extracts the IPv4 or IPv6 routes and add them to the RTM of that VRF.

With SPBM Layer 3 VSN, the packet forwarding works in a similar fashion as the IP Shortcuts on the Global Router, with the difference that the encapsulation includes the I-SID to identify the VRF that the packet belongs to. The following figure shows the packet forwarding for VRF red.

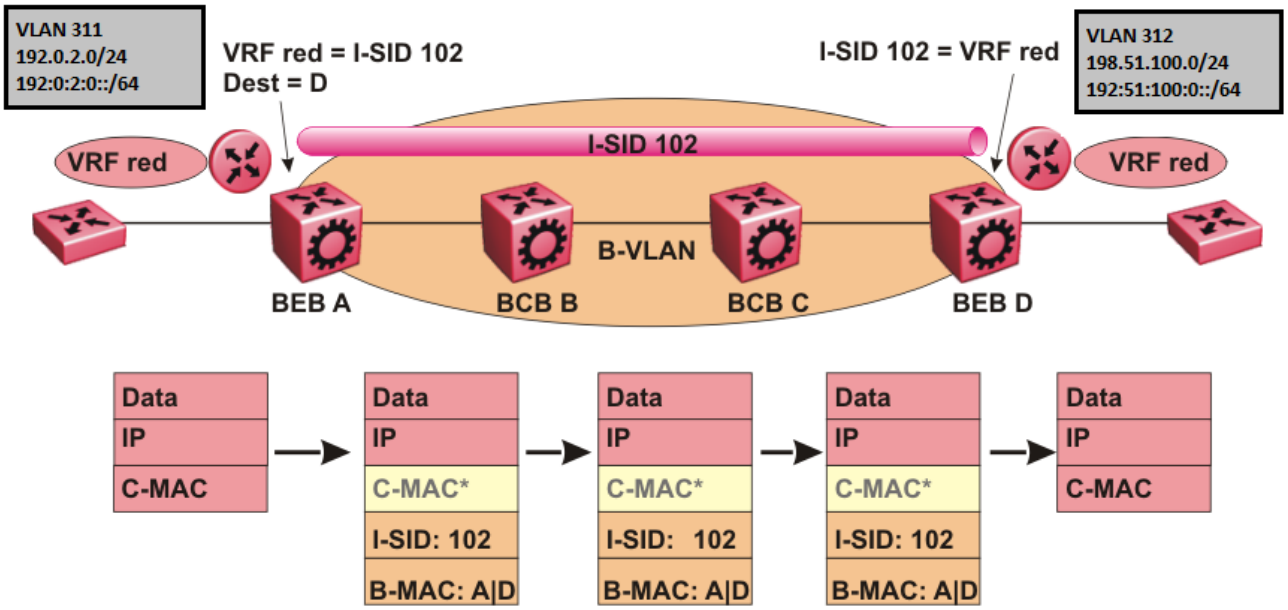

Figure 114: Packet forwarding in SPBM Layer 3 VSN

When BEB A receives traffic from VRF red that must be forwarded to the far-end location, it performs a lookup and determines that VRF red is associated with I-SID 102 and that BEB D is the destination for I-SID 102. BEB A then encapsulates the IP data into a new B-MAC header, using destination B-MAC: D.

Note

With SPBM Layer 3 VSN, the CMAC header is all null. This header does not have any significance in the backbone. It is included to maintain the same 802.1ah format for ease of implementation.

At BEB D, the node strips off the B-MAC encapsulation, and performs a lookup to determine the destination for traffic with I-SID 102. After identifying the destination as VRF red, the node forwards the packet to the destination VRF.

Note

IPv4 Layer 3 VSN and IPv6 Layer 3 VSN coexist and share the same I-SID. The advantage of having two separate VPNs, one for IPv4 and one for IPv6 is because it gives user an option to enable them separately.

IPv6 Layer 3 VSN limitations and considerations

Consider the following when you configure the IPv6 Layer 3 VSN :

- You can enable IPv6 Layer3 VSN only when **`spbm boot`** config flag is true.
- IPv4 Shortcuts and IPv6 Shortcuts must be enabled.

Enable/disable ICMP Response on VRFs/Layer 3 VSNs

This feature supports VRFs/Layer 3 VSNs to operate in stealth mode by disabling ICMP responses on specific VRFs/Layer 3 VSNs.

If the ICMP response is disabled, the switch does not respond to any ICMP requests received on the VRFs/Layer 3 VSNs.

If the ICMP response is enabled, the switch responds to ICMP requests received on the VRF/Layer 3 VSNs.

Layer 3 VSN configuration using the CLI

This section provides a procedure to configure Layer 3 VSNs using the command line interface (CLI).

Configure SPBM IPv4 Layer 3 VSN

After you have configured the SPBM infrastructure, you can enable SPBM Layer 3 VSN to advertise IPv4 routes across the SPBM network from one VRF to another using the following procedure.

SPBM Layer 3 VSN uses IS-IS to exchange the routing information for each VRF. In the VRF, just like in the Global Router (VRF 0), the routes are not redistributed into IS-IS automatically. To advertise the VRF routes, you must explicitly redistribute one of the following protocols into IS-IS: direct, static, RIP, OSPF, or BGP. Routing between VRFs is also possible by using redistribution policies and injecting routes from the other protocols.

Before You Begin

- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF on the switch. For more information, see VRF Lite configuration using the CLI on page 3486.
- You must create the Customer VLANs and add slots/ports.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal

   router vrf WORD<1-16>
   ```

2. Create an IPv4 VPN instance on the VRF:

   ```
   ipvpn
   ```

3. Configure SPBM Layer 3 VSN:

   ```
   i-sid <0-16777215>
   ```

4. Enable IPv4 VPN on the VRF:

   ```
   ipvpn enable
   ```

   By default, a new IPv4 VPN instance is disabled.

5. Display all IPv4 VPNs:

   ```
   show ip ipvpn [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

6. Identify routes on the local switch to be announced into the SPBM network:

   ```
   isis redistribute {direct | bgp | ospf | rip | static}
   ```

7. Enable routes on the local switch to be announced into the SPBM network:

   ```
   isis redistribute {direct | bgp | ospf | rip | static} enable
   ```

8. If you want to delete or disable the configuration, use the no option:

   ```
   no isis redistribute {direct | bgp | ospf | rip | static}

   no isis redistribute {direct | bgp | ospf | rip | static} enable
   ```

9. Identify other routing protocols to which to redistribute IS-IS routes:

   ```
   ip {bgp | ospf | rip} redistribute isis
   ```

10. Enable IS-IS redistribution to other routing protocols::

    ```
    ip {bgp | ospf | rip} redistribute isis enable
    ```

11. Exit Privileged EXEC mode:

    ```
    exit
    ```

12. Apply the configured redistribution:

    ```
    isis apply redistribute {direct | bgp | ospf | rip | static} vrf
    WORD<1-16>

    ip bgp apply redistribute isis vrf WORD<1-16>

    ip ospf apply redistribute isis vrf WORD<1-16>

    ip rip apply redistribute isis vrf WORD<1-16>
    ```

13. Display the redistribution configuration:

    ```
    show ip isis redistribute [vrf WORD<1-16>] [vrfids WORD<0-512>]
    ```

Example

Create the IPv4 VPN instance:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf green
Switch:1(config)#ipvpn
Switch:1(config)#i-sid 109
Switch:1(config)#ipvpn enable
Switch:1(config)#show ip ipvpn
================================================================================================
                                        IPv4 IPVPN
================================================================================================
VRF Name            VRF ID   IPv4 IPVPN   IPv6 IPVPN   I-SID        I-SID Name
------------------------------------------------------------------------------------------------
green               1        enabled      disabled     109          ExtremeServer1
------------------------------------------------------------------------------------------------
1 out of 1 Total IPv4 L3 VSN, 1 active IPv4 and 0 active IPv6 displayed.
Switch:1(config)#isis redistribute ospf
Switch:1(config)#isis redistribute ospf enable
Switch:1(config)#isis redistribute ospf enable
Switch:1(config)#end
Switch:1(config)#isis apply redistribute ospf vrf vrfred
Switch:1(config)#show ip isis redistribute vrf vrfred
================================================================================
                      ISIS Redistribute List - VRF vrfred
================================================================================

SOURCE MET MTYPE      SUBNET   ENABLE LEVEL  RPOLICY
--------------------------------------------------------------------------------
LOC    1   internal   allow    FALSE  l1
```

Variable Definitions

The following table defines parameters for the **show ip ipvpn** command.

Variable	Value
vrf WORD<1-16>	Specifies the VRF name.
vrfids WORD<0-512>	Specifies the VRF ID.

The following table defines parameters for the **i-sid** command.

Variable	Value
<0-16777215>	Assigns an I-SID to the VRF being configured. Use the **no** or **default** option to remove the I-SID to VRF allocation for this VRF.

The following table defines parameters for the **isis redistribute** command.

Variable	Value
{direct | bgp | ospf | rip | static}	Specifies the protocol.
enable	Enables the redistribution of the specified protocol into the SPBM network. The default is disabled. Use the **no** or **default** options to disable the redistribution.
metric <0–65535>	Configures the metric (cost) to apply to redistributed routes. The default is 1.
metric-type {external|internal}	Configures the type of route to import into the protocol. The default is internal.
route-map WORD<0–64>	Configures the route policy to apply to redistributed routes. Specifies a name.
subnets {allow| suppress}	Indicates whether the subnets are advertised individually or aggregated to their classful subnet. Choose suppress to advertise subnets aggregated to their classful subnet. Choose allow to advertise the subnets individually with the learned or configured mask of the subnet. The default is allow.

The following table defines parameters for the **isis apply redistribute** command.

Variable	Value
{direct | bgp | ospf | rip | static}	Specifies the protocol.
vrf WORD<1–16>	Applies IS-IS redistribute for a particular VRF. Specifies the VRF name.

Configure SPBM IPv6 Layer 3 VSN using CLI

Before You Begin

- You must enable IPv6 Shortcuts.
- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF instance on the switch. For more information, see VRF Lite configuration using the CLI on page 3486.

About This Task

After you have configured the SPBM infrastructure, you can enable SPBM Layer 3 VSN to advertise IPv6 routes across the SPBM network using the following procedure.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal

   router vrf WORD<1-16>
   ```

2. Create an IPv6 VPN instance on the VRF:

   ```
   ipv6 ipvpn
   ```

3. Configure SPBM Layer 3 VSN:

   ```
   i-sid <0-16777215>
   ```

4. Enable IPv6 VPN on the VRF:

   ```
   ipv6 ipvpn enable
   ```

5. Display all IPv6 VPNs:

   ```
   show ipv6 ipvpn [vrf WORD<1-16> | vrfids WORD<0-512>]
   ```

6. Identify routes on the local switch to be announced into the SPBM network:

   ```
   ipv6 isis redistribute {bgp | direct | ospf | static}
   ```

7. Enable routes on the local switch to be announced into the SPBM network:

   ```
   ipv6 isis redistribute {direct | bgp | ospf | rip | static} enable
   ```

8. Identify the routing protocol to which to redistribute IS-IS routes:

   ```
   ipv6 ospf redistribute isis
   ```

9. Enable IS-IS redistribution to OSPF:

   ```
   ipv6 ospf redistribute isis enable
   ```

10. Return to Privileged EXEC mode:

    ```
    end
    ```

11. Apply the configured redistribution to a specific VRF:

    ```
    ipv6 isis apply redistribute {direct | bgp | ospf | rip | static} vrf
    WORD<1-16>
    ```

12. Apply the OSPF configuration to a specific VRF:

    ```
    ipv6 ospf apply redistribute isis vrf WORD<1-16>
    ```

13. Display the redistribution configuration:

    ```
    show ipv6 isis redistribute [vrf WORD<1-16> | vrfids WORD<0-512>]
    ```

14. Verify IPv6 IS-IS routes:

    ```
    show ipv6 route vrf WORD<1-16>
    ```

Examples

Create the IPv6 VPN instance:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf vrfred
Switch:1(router-vrf)#ipv6 ipvpn
Switch:1(router-vrf)#i-sid 100
Switch:1(router-vrf)#ipv6 ipvpn enable
Switch:1(router-vrf)#show ipv6 ipvpn
================================================================================
```

```
                                        IPv6 IPVPN
================================================================================================
VRF Name            VRF ID   IPv6 IPVPN   IPv4 IPVPN   I-SID        I-SID Name
------------------------------------------------------------------------------------------------

```

Variable Definitions

The following table defines parameters for the **ipv6 ipvpn** command.

Variable	Value
enable	Enables IPv6 IPVPN. The default is disabled.

The following table defines parameters for the **show ipv6 ipvpn** command.

Variable	Value
vrf WORD<1-16>	Specifies the VRF name.
vrfids WORD<0-512>	Specifies the VRF ID.

The following table defines parameters for the **i-sid** command.

Variable	Value
<0-16777215>	Assigns an I-SID to the VRF being configured.

The following table defines parameters for the **isis redistribute** command.

Variable	Value
{bgp | direct | ospf | static}	Specifies the protocol.
enable	Enables the redistribution of the specified protocol into the SPBM network. The default is disabled.

Display SPBM IPv6 Unicast Forwarding Information Base

About This Task

Perform this procedure to display SPBM IPv6 unicast Forwarding Information Base (FIB).

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display SPBM IPv6 unicast FIB:

   ```
   show isis spbm ipv6-unicast-fib [all] [id <1-16777215>] [spbm-nh-as-mac] [home|remote]
   ```

Example

```
Switch:1>show isis spbm ipv6-unicast-fib
================================================================================================================================
                              SPBM IPv6-UNICAST FIB ENTRY INFO
================================================================================================================================
       VRF    Dest                                    OUTGOING  SPBM  PREFIX METRIC   IP ROUTE

--------------------------------------------------------------------------------------------------------------------------------
 Home: Total number of SPBM IPv6-UNICAST FIB entries 4
 Remote: Total number of SPBM IPv6-UNICAST FIB entries 0
--------------------------------------------------------------------------------------------------------------------------------
```

Variable Definitions

The following table defines parameters for the **`show isis spbm ipv6-unicast-fib`** command.

Variable	Value
all	Displays all IS-IS SPBM IPv6 unicast Fowarding Information Base (FIB) information for all VRFs.
home	Displays the IS-IS SPBM IPv6 unicast FIB information that the system configures in the home area.
id <1-16777215>	Displays IS-IS SPBM IPv6 unicast FIB information by I-SID ID.
remote	Displays the IS-IS SPBM IPv6 unicast FIB information that the system configures in the remote area.
spbm-nh-as-mac	Displays the next hop B-MAC of the IPv6 unicast FIB entry.

Display IS-IS Link State Database Information

Perform the following procedure to display the IS-IS link state database related information on the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IS-IS link state database information:

   ```
   show isis lsdb ipv6-unicast [i-sid <0-16777215>] [lspid xxxx.xxxx.xxxx.xx-xx] [sysid xxxx.xxxx.xxxx] [home|remote]
   ```

Example

```
Switch:1>show isis lsdb ipv6-unicast
================================================================================
                          ISIS IPv6-UNICAST-ROUTE SUMMARY

Layer 3 VSN configuration using EDM

Configure SPBM IPv4 Layer 3 VSN

After you have configured the SPBM infrastructure, you can enable SPBM Layer 3 Virtual Services Network (VSN) to advertise IPv4 routes across the SPBM network from one VRF to another using the following procedure.

SPBM Layer 3 VSN uses IS-IS to exchange the routing information for each VRF. In the VRF, just like in the Global Router (VRF 0), the routes are not redistributed into IS-IS automatically. To advertise the VRF routes, you must explicitly redistribute one of the following protocols into IS-IS: direct, static, RIP, OSPF, or BGP. Routing between VRFs is also possible by using redistribution policies and injecting routes from the other protocols.

Before You Begin

- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF and IP VPN instance on the switch. For more information about how to configure a VRF, see VRF Lite configuration using Enterprise Device Manager on page 3497.
- You must create the Customer VLANs and add slots/ports.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **IP-VPN**.
3. Select the **VPN** tab.
4. To create an IP VPN instance, select **Insert**.
5. Select the ellipsis button (**...**), select a VRF to associate with the IP VPN, and click **Ok**.
6. Select **Insert**.
7. In the **Enable** column, select **enable** to enable the IP VPN on the VRF.
8. In the **IsidNumber** column, specify an I-SID to associate with the VPN.
9. Select **Apply**.
10. In the navigation pane, expand **Configuration** > **IP**.
11. Select **Policy**.
12. To identify routes on the local switch to be announced into the SPBM network, select the **Route Redistribution** tab.

13. Select **Insert**.
14. In the **DstVrfId** box, select the ellipsis (**...**), and then select the destination VRF ID and select **Ok**.
15. In the **Protocol** box, select **isis** as the route destination.
16. In the **SrcVrfId** box, select (**...**) button, select the source VRF ID and click **Ok**.
17. In the **RouteSource** box, select the source protocol.
18. In the **Enable** box, select **enable**.
19. In the **RoutePolicy** box, select the ellipsis (**...**), choose the route policy to apply to the redistributed routes and select **Ok**.
20. Configure the other parameters as required.
21. Select **Insert**.
22. To apply the redistribution configuration, select the **Applying Policy** tab.
23. Select **RedistributeApply**, and then select **Apply**.

Configuring SPBM IPv6 Layer 3 VSN using EDM

About This Task

After you have configured the SPBM infrastructure, you can enable SPBM Layer 3 Virtual Services Network (VSN) to advertise IPv6 routes across the SPBM network from one VRF to another using the following procedure.

SPBM Layer 3 VSN uses IS-IS to exchange the routing information for each VRF.

Before You Begin

- You must enable IPv6 Shortcuts.
- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF and IPv6 VPN instance on the switch. For more information, see VRF Lite configuration using Enterprise Device Manager on page 3497.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **IPv6-VPN**.
3. Click the **VPN** tab.
4. Click **Insert**.
5. Click the ellipsis [**...**], and select a VRF.
6. Click **Ok**.
7. Click **Insert**.
8. In the **IsidNumber** column, double-click the **0** value, and then enter the service instance identifier (I-SID) to assign to the IPv6-VPN.
9. Click **Apply**.
10. In the **Enable** column, select **true** or **false**.
11. Click **Apply**.
12. In the navigation pane, expand **Configuration** > **VRF Context View**.
13. Click **Set VRF Context View**.
14. Click the **VRF** tab.

15. Select a context to view.
16. Click **Launch VRF Context view**.

    A new browser tab opens containing the selected VRF view
17. In the navigation pane, expand **Configuration** > **IPv6**.
18. Click **IS-IS**.
19. Click the **Redistribute** tab.
20. Click **Insert**.
21. Configure the parameters as required.
22. Click **Insert**.
23. Click **Apply**.

Layer 3 VSN configuration example

The following figure shows a sample Layer 3 VSN deployment.

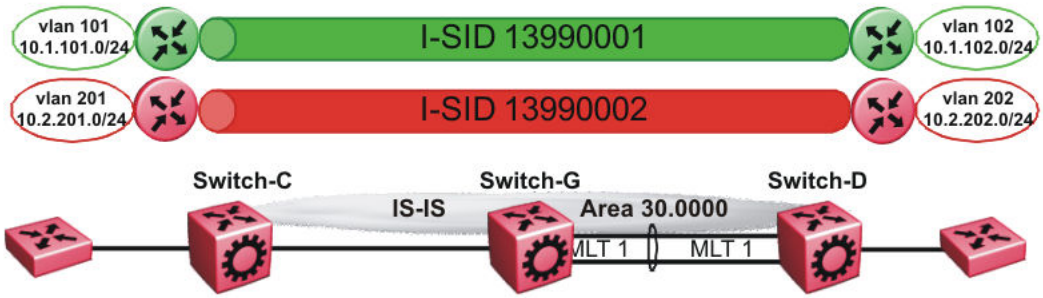

Figure 115: Layer 3 VSN

The following sections show the steps required to configure the Layer 3 VSN parameters in this example.

Note that IP IS-IS redistribution needs to be configured to inject the VRF routes into IS-IS.

You must first configure basic SPBM and IS-IS infrastructure.

VRF green configuration

The following figure shows the green VRF in this Layer 3 VSN example.

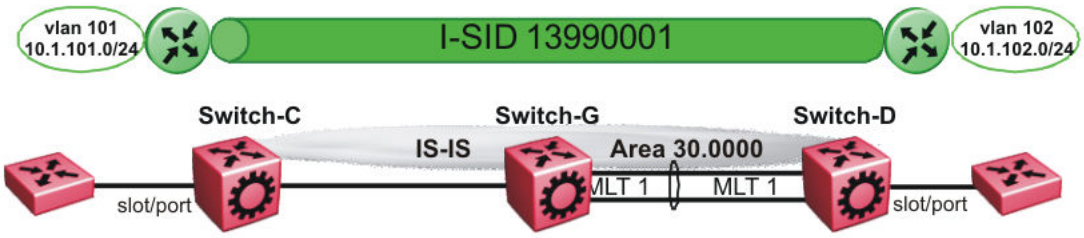

Figure 116: Layer 3 VSN — VRF green

The following sections show the steps required to configure the green VRF parameters in this example.

VRF green – Switch-C

```
VRF CONFIGURATION

Internet Key Exchange

Table 94: Internet Key Exchange product support

Feature	Product	Release introduced
Internet Key Exchange (IKE) v2	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Internet Key Exchange (IKE) protocol creates a Security Association (SA) in IPsec. The SA is the relationship between two network devices that define attributes such as authentication mechanism, encryption and hash algorithms, exchange mode, and key length for secured communications. The SA should be agreed by both devices.

The IKE protocol is based on Internet Security Association and Key Management Protocol (ISAKMP) which helps in building a secured connection between two or more hosts using the following concepts:

- authentication
- encryption
- key management
- security association (SA)
- policy

IKE uses a key exchange mechanism based on the Diffie-Hellman encryption key exchange protocol. IKE provides periodic automatic key renegotiation, pre-shared and public key infrastructures, and anti-replay defense. It is layered on top of the UDP protocol and uses UDP port 500 to exchange information between peers.

IKE Phases

A switch negotiates with a peer using IKE in two phases.

- In phase 1, the switch negotiates the IKE SA to protect the negotiations that take place in phase 2. The SAs negotiated in phase 1 are bi-directional, and are applicable to traffic originating in both directions.
- In phase 2, the peers negotiate and establish the SAs for IPsec and session keys through quick mode. A Diffie-Hellman key exchange is done to achieve perfect forward secrecy, which ensures that the compromise of a single key does not permit access to data other than that protected by that compromised key. The SAs in phase 2 are uni-directional. They are used according to the direction of the traffic. The quick mode is initiated by either of the peer endpoints irrespective of who initiated phase 1.

IKE Modes

There are two modes of exchanging messages in Phase 1:

- Main mode

  This is a secure mode of exchanging messages. It allows protection of the confidentiality of the peers during negotiation. This mode provides more flexibility in proposals compared to aggressive mode. As the main mode requires a total of 6 messages to be exchanged between peers, it is more time consuming.
- Aggressive mode

  This mode is less secure than the main mode. It does not protect the confidentiality of the peers. However, it requires only a total of 3 messages to be exchanged for phase 1, which makes this mode faster than the main mode. The number of total message exchange is reduced in this mode because some messages are embedded in other messages.

The mode of message exchange in phase 2 is called quick mode. In this mode a total of 3 messages are exchanged between the peers. This mode is used to establish IPsec SA. The negotiations in the quick mode are protected during the phase 1 negotiations in main mode.

IKE Policies

A combination of security parameters used during the IKE SA negotiation is called a policy. The policies must be configured on both the peers and at least one of the policies should match on both ends to have a successful negotiation for. If a policy is not configured on both peers or if a policy does not match on both ends, an SA cannot be setup and data cannot be exchanged.

The following are the attributes of an IKE policy:

- Encryption — This is the cryptographic algorithm that is sent in the proposal by the initiator or responder during the phase 1 negotiation. This cryptographic algorithm is used to encrypt phase 2 negotiation messages. The supported encryption algorithms are:
  - DES
  - 3DES

    - AES
- Hash function — This function is used as part of the authentication mechanism during the authentication of peers in phase 1. It is always used with the authentication algorithm. The supported values are:
    - MD5
    - SHA1
    - SHA256
- Authentication — This process authenticates the peers. Following are the supported authentication modes:
    - Digital Signatures — The digital signatures use digital certificate which is signed by the certificate authority (CA) for authentication.
    - Pre-shared keys (PSK) — The PSKs are shared out-of-band between the peers before hand. Using PSK in main mode exchange limits identifying the peer to an IP address (and not host name).
- Diffe-Hellman (DH) Group — This is an algorithm used by two peers that are unknown to each other to establish a shared secret key. This key that is decided during phase 1 is used to encrypt subsequent message exchanges during phase 2 to establish security associations (SA) and security policies (SP) for IPsec sessions. The supported DH Groups are as follows:
    - Group 1 (MODP768)
    - Group 2 (MODP1024)
    - Group 14 (MODP2048)
- Lifetime — This is a time and data limit agreed by peers to protect an SA from getting compromised. It ensures that the peers renegotiate the SAs just before the lifetime value expires, that is, when the time limit is reached.
- Dead-peer detection – This is a process in which the switch waits for a response from peer for a limited number of seconds before declaring the peer as dead. It is a keep-alive mechanism required to perform IKE peer fail-over and to reclaim lost resources by freeing up SAs that are no longer in use.

IKE Authentication

The security gateway of a peer must authenticate the security gateway of the peer it intends to communicate with. This ensures that IKE SAs are established between the peers. The switch supports the following two authentication methods:

- Digital certificates (using RSA algorithms)

  For digital certificate authentication, the initiator signs the message interchange data using the private key. The responder uses the public key of the initiator to verify the signature. The public key is exchanged by messages containing an X.509v3 certificate. This certificate provides an assurance that the identity of a peer, as represented in the certificate, is associated with a particular public key.
- Pre-shared keys

  Pre-shared key authentication, the same secret must be configured on both security gateways before the gateways can authenticate each other.

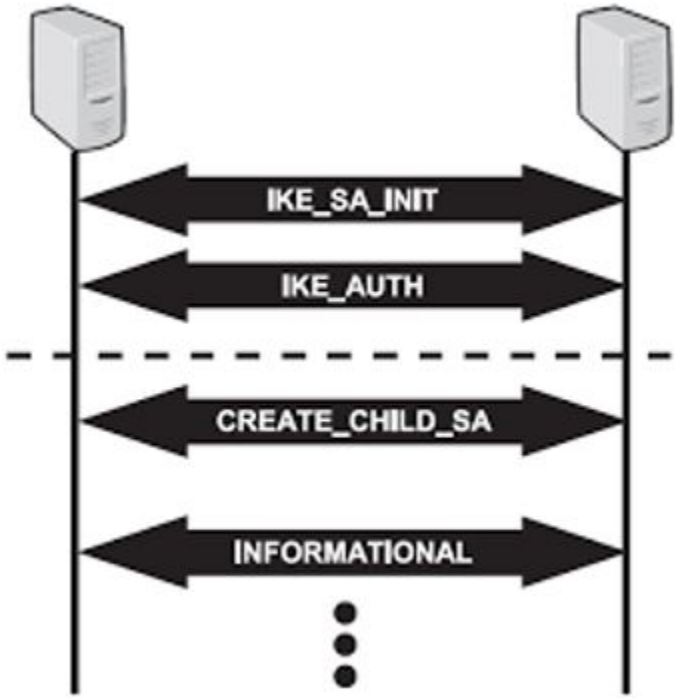
Signature Authentication

The switch receives the digital signature of its peer in a message exchange. The switch verifies the digital signature by using the public key of the peer. The certificate of the peer, received during the IKE negotiation, contains the public key. To ensure that the peer certificate is valid, the switch verifies its digital signature by using the certificate authority (CA) public key contained in the root CA certificate. The switch and its IKE peer require at least one common trusted root CA for authentication to work.

When IKE is configured to use digital certificates for authentication, the certificates are retrieved from the trusted certificate store in the switch, based on the provided distinguished name. The certificates received from the peer are verified with the public key.

IKEv2

The software supports IKEv2, which is an enhancement of the IKEv1 protocol. All IKEv2 communications consist of pairs of messages: a request and a response. The IKEv2 protocol uses a non-reliable transport protocol (UDP using ports 500). The pairs of exchanges allows ensuring of reliability to the IKEv2 protocol, as there is an expected response for each request.



IKEv2 provides a number of improvements over IKEv1, including the following:

- A simplified initial exchange of messages that reduces latency and increases connection establishment speed.
  - IKEv2 makes use of a single four-message exchange instead of the eight different initial exchanges of IKEv1.

    - It improves upon IKEv1's latency by making the initial exchange to be of two round trips of four messages, and allows the ability to add setup of a child SA on that exchange.
- Improved reliability through the use of sequence numbers, and acknowledgments.
    - IKEv2 reduces the number of possible error states by making the protocol reliable as all messages are acknowledged and sequenced.
- IKE SA integrity algorithms are supported only in IKEv2.
- Traffic Selectors are specified in IKEv2 by their own payloads type and not by overloading ID payloads. This makes the Traffic Selectors more flexible.
- No lifetime negotiations for IKEv2, but in IKEv1 SA lifetimes are negotiated.

IKEv2 OCSP Validation

Confirmation of certificate reliability is essential to achieve the security assurances public key cryptography provides. One fundamental element of such confirmation is reference to certificate revocation status. IKEv2 enables the use of Online Certificate Status Protocol (OCSP) for in-band signaling of certificate revocation status. The IKEv2 supports the authentication methods as pre shared key and digital certificate. It allows the verification of the digital certificate sent by the peer whether it is revoked or not. This is done through a method by sending the digital certificate to the OCSP server. The OCSP server in turn verifies the certificate status and sends the response back. Based on the response from OCSP server, the device validates the certificate.

Restrictions

This section describes the restrictions associated with this feature.

- XAUTH (2-factor authentication) is not supported.
- Domain of Interpretation is not supported other than for IPsec.
- Custom IKE messages and vendor ID for the messages are not supported.
- IKE fragmentation is not supported.
- IKE and IPsec are not supported on the Segmented Management Instance interfaces, or with management applications such as RADIUS and TACACS+. You can configure RADIUS security with RADsec on supported devices.

IKE Configuration using CLI

The topics in this section provide the IKE CLI configuration.

Configure an IKE Phase 1 Profile

About This Task

Use the following procedure to configure an IKE Phase 1 profile.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create an IKE phase 1 profile:

   ```
   ike profile WORD<1-32>
   ```

3. Configure the IKE phase 1 profile hash algorithm:

   ```
   ike profile WORD<1-32> hash-algo <md5|sha|sha256|any>
   ```

4. Configure the IKE phase 1 profile encryption algorithm:

   ```
   ike profile WORD<1-32> encrypt-algo <desCbc|3DesCbc|aesCbc|any>
   ```

5. Configure the IKE phase 1 profile Diffie-Hellman group:

   ```
   ike profile WORD<1-32> dh-group <modp768|modp1024|modp2048|any>
   ```

6. Configure the IKE phase 1 encryption key length:

   ```
   ike profile WORD<1-32> encrypt-key-len <128|192|256>
   ```

7. Configure the IKE phase 1 lifetime, in seconds:

   ```
   ike profile WORD<1-32> lifetime-sec <0-4294967295>
   ```

8. (Optional) Delete the IKE Phase 1 profile:

   ```
   no ike profile WORD<1-32>
   ```

Variable Definition

The following table defines parameters for the **ike profile** commands.

Variable	Value
profile WORD<1-32>	Specifies the IKE profile name.
hash-algo <md5|sha|sha256|any>	Specifies the type of hash algorithm. The default value is sha256. To set this option to the default value, use the default operator with the command: **default ike profile WORD<1-32> hash-algo**
encrypt-algo <desCbc|3DesCbc|aesCbc|any>	Specifies the type of encryption algorithm. The default value is aesCbc. To set this option to the default value, use the default operator with the command: **default ike profile WORD<1-32> encrypt-algo**
dh-group <modp768|modp1024|modp2048|any>	Specifies the Diffie-Hellman (DH) group. DH groups categorize the key used in the key exchange process, by its strength. The key from a higher group number is more secure. The default value is modp2048. To set this option to the default value, use the default operator with the command: **default ike profile WORD<1-32> dh-group**
encrypt-key-len <128|192|256>	Specifies the length of the encryption key. The default is 256. To set this option to the default value, use the default operator with the command: **default ike profile WORD<1-32> encrypt-key-len**
lifetime-sec <0-4294967295>	Specifies the lifetime value in seconds. The lifetime ensures that the peers renegotiate the SAs just before the expiry of the lifetime value, to ensure that Security Associations are not compromised. The default value is 86400 seconds. To set this option to the default value, use the default operator with the command: **default ike profile WORD<1-32> lifetime-sec**

Create an IKE Phase 1 Policy

IKE policy establishes Security Associations (SA) and message exchanges with IKE peers to successfully set up secured channels.

About This Task

Use the following procedure to create the IKE Phase 1 policy.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create an IKE Phase 1 profile:

   ```
   ike policy WORD<1-32> laddr WORD<1-256> raddr WORD<1-256>
   ```

3. (Optional) Delete the IKE Phase 1 profile:

   ```
   no ike policy WORD<1-32>
   ```

Variable Definition

The following table defines parameters for the **`ike policy <1-320> laddr`** command.

Variable	Value
`policy WORD<1-32>`	Specifies the name of the IKE Phase 1 policy.
`laddr WORD<1-256>`	Specifies the local IPv4 or IPv6 address.
`raddr WORD<1-256>`	Specifies the remote IPv4 or IPv6 address.

Configuring profile to be used for IKE Phase 1 policy

Use the following procedure to configure the IKE Phase1 profile to be used for the IKE Phase 1 policy.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the profile name to be used for IKE Phase 1 policy:

   ```
   ike policy WORD<1-32> profile WORD<1-32>
   ```

Variable Definition

The following table defines parameters for the **`ike policy WORD<1-32> profile WORD<1-32>`** command.

Variable	Value
policy WORD<1-32>	Specifies the name of the IKE Phase 1 policy.
profile WORD<1-32>	Specifies the name of the IKE Phase 1 profile to be used for the policy. To set this option to the default value, use the default operator with the command: **default ike policy WORD<1-32> profile**

Configure IKE Phase 2 Perfect Forward Secrecy

Use the following procedure to configure IKE Phase 2 perfect forward secrecy (PFS).

About This Task

A Diffie-Hellman key exchange is done to achieve perfect forward secrecy. This ensures that the compromise of even a single key does not permit access to data other than that protected by that key.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the IKE Phase 2 perfect forward secrecy:

   ```
   ike policy WORD<1-32> p2-pfs <enable|disable> [use-ike-group <enable|
   disable>][dh-group <modp768|modp1024|modp2048|any]
   ```

3. (Optional) Disable Phase 2 perfect forward secrecy:

   ```
   no ike policy <1-32> p2-pfs
   ```

Variable Definition

The following table defines parameters for the **ike policy WORD<1-32> p2-pfs** command.

Variable	Value
policy WORD<1-32>	Specifies the name of the IKE Phase 1 policy.
p2-pfs	Enables the Phase 2 perfect forward secrecy.
dh-group <modp768|modp1024|modp2048|any>	Configures the Diffie-Hellman (DH) group to be used for Phase 2 perfect forward secrecy (PFS). The default value is modp2048. To configure this option to the default value, use the default operator with the command: **default ike policy WORD<1-32> p2-pfs dh-group**. Note: For Federal Information Processing Standards (FIPS) compliance, only the default value modp2048 is supported.
use-ike-group <enable|disable>	Specifies whether to use the IKE Phase 1 DH group for Phase 2 PFS or not to use it. The default is enable. To set this option to the default value, use the default operator with the command: **default ike policy WORD<1-32> p2-pfs use-ike-group**

Configure the IKE Authentication Method

Use the following procedure to configure the IKE authentication method. The default is pre-shared key.

About This Task

As part of the IKE protocol, one security gateway must authenticate another security gateway to make sure that IKE SAs are established with the intended party. The switch supports two authentication methods:

- Digital certificates

  Configure peer identity name for IKE phase 1 and revocation check method.
- Pre-shared keys

  Configure the same secret on both security gateways before the gateways can authenticate each other.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```
2. Configure the IKE authentication method using one of the following:
   - To use a digital certificate:

     ```
     ike policy WORD<1-32> auth-method digital-certificate [peer-name
     WORD <1-64> | revocation-check-method <crl|none|ocsp>]
     ```
   - To use a pre-shared key:

     ```
     ike policy WORD<1-32> auth-method pre-shared-key

     ike policy WORD<1-32> pre-shared-key WORD<0-32>
     ```

Variable Definitions

The following table defines parameters for the **ike policy WORD<1-32> auth-method** command.

Variable	Value
pre-shared-key	Specifies the authentication method as pre-shared key.
digital-certificate peer-name WORD <1-64>	Specifies peer identity name for IKE phase 1.
digital-certificate revocation-check-method<crl|none|ocsp>	Specifies the revocation check method. To set this option to the default value, use the default operator with the command: **default ike policy WORD<1-32> revocation-check-method**

The following table defines parameters for the **ike policy WORD<1–32> pre-shared-key** command.

Variable	Value
pre-shared-key WORD<0–32>	Specifies the pre-shared key. For Federal Information Processing Standards (FIPS) compliance, the minimum length is 14 characters.

Configure Dead-Peer Detection Timeout

Use the following procedure to configure the dead-peer detection (DPD) timeout for the IKE Phase 1 policy.

About This Task

Dead Peer Detection (DPD) timeout is the interval for which the system sends messages to a peer to confirm its availability.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Configure the DPD timeout:
   ```
   ike policy WORD<1–32> dpd-timeout <1–4294967295>
   ```

Variable Definition

The following table defines parameters for the **ike policy WORD<1–32> dpd-timeout** command.

Variable	Value
policy WORD<1–32>	Specifies the name of the IKE Phase 1 policy.
dpd-timeout <1–4294967295>	Specifies the dead peer detection timeout in seconds for the IKE Phase 1 policy. The default is 300 seconds. To set this option to the default value, use the default operator with the command: **default ike policy WORD<1–32> dpd-timeout**

Enable the Admin State of IKE Phase 1 Policy

Use the following procedure to enable admin state of IKE Phase 1 policy.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Enable admin state of IKE Phase 1 policy:
   ```
   ike policy WORD<1–32> enable
   ```

3. (Optional) Disable IKE Phase 1 policy:

   ```
   no ike policy WORD<1-32> enable
   ```

Display IKE Profiles

Use the following procedure to display the configured IKE profiles:

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display all IKE profiles:

   ```
   show ike profile
   ```

3. Display a specific ike profile:

   ```
   show ike profile WORD<1-32>
   ```

Example

```
Switch:1#show ike profile
================================================================================================
                                  IKE Profile

================================================================================================
                                 Hash    Encrypt Encrypt    DH      Exchange    Lifetime
Name                             Algo     Algo   Key Len   Group    Mode        seconds
------------------------------------------------------------------------------------------------
DFLT_IKE_PROFILE                 sha256 aesCbc  256     modp2048 main        86400
ikePRO                           sha256 aesCbc  256     modp2048 main        180
test                             sha256 aesCbc  256     modp2048 main        86400
```

Variable Definition

The following table defines parameters for the **`show ike profile`** command.

Variable	Value
`profile WORD<1-32>`	Specifies the name of the profile to be displayed.

Display IKE Policies

Use the following procedure to display the configured IKE policies.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display all IKE policies:

   ```
   show ike policy
   ```

3. Display a specific IKE policy:

   ```
   show ike policy WORD<1-32>
   ```

4. Display a specific IKE policy at local address.

   ```
   show ike policy WORD<1-32> laddr WORD<1-256>
   ```

5. Display a specific IKE policy at remote address.

   ```
   show ike policy WORD<1-32> laddr WORD<1-256> raddr WORD<1-256>
   ```

Example

```
Switch:1#show ike policy
================================================================================================
                                    IKE Policy
================================================================================================

```

Variable Definition

The following table defines parameters for the **`show ike policy`** command.

Variable	Value
`policy WORD<1-32>`	Specifies the name of the policy to be displayed.
`laddr WORD<1-256>`	Specifies the local IPv4 or IPv6 address.
`raddr WORD<1-256>`	Specifies the remote IPv4 or IPv6 address.

Display IKE Security Association

Use the following procedure to display the configured IKE Phase 1 for version 1 and 2 security associations (SA).

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display all the security associations:

   ```
   show ike sa
   ```

3. Display security associations for IKE Phase 1 for version 1:

   ```
   show ike sa version v1 WORD<1-32> laddr WORD<1-256> raddr WORD<1-256>
   ```

4. Display security associations for IKE Phase 1 for version 2:

   ```
   show ike sa version v2 WORD<1-32> laddr WORD<1-256> raddr WORD<1-256>
   ```

Example

```
Switch:1(config)#show ike sa version v1

================================================================================================
                      IKE V1 Phase 1 Security Association

```

Variable Definition

The following table defines parameters for the **show ike sa** command.

Variable	Value
sa	Specifies the IKE security association identifier.
version v1 WORD<1-32> laddr WORD<1-256> raddr WORD<1-256>	Specifies the local IPv4 or IPv6 address for IKE Phase 1, version 1 SA.
version v2 WORD<1-32> laddr WORD<1-256> raddr WORD<1-256>	Specifies the local IPv4 or IPv6 address for IKE Phase 1, version 2 SA.

Configure an IKEv2 Profile

About This Task

Use the following procedure to configure an IKEv2 profile.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create an IKEv2-profile:

   ```
   ike v2-profile WORD<1-32>
   ```

3. Configure the IKEv2 profile hash algorithm:

   ```
   ike v2-profile WORD<1-32> hash-algo <md5|sha|sha256|any>
   ```

4. Configure the IKEv2 profile encryption algorithm:

   ```
   ike v2-profile WORD<1-32> encrypt-algo <desCbc|3DesCbc|aesCbc|any>
   ```

5. Configure the IKEv2 profile integrity algorithm

   ```
   ike v2-profile WORD<1-32> integrity-algo <hmac-md5|hmac-sha|hmac-
   sha256|aes-xcbc|any>
   ```

6. Configure the IKEv2 profile dh group

   ```
   ike v2-profile WORD<1-32> dh-group <modp768|modp1024|modp2048|any
   ```

7. Configure the IKEv2 profile encryption key length:

   ```
   ike v2-profile WORD<1-32> encrypt-key-len <128|192|256>
   ```

8. Configure the IKEv2 profile lifetime, in seconds:

   ```
   ike v2-profile WORD<1-32> lifetime-sec <0-4294967295>
   ```

9. (Optional) Delete the IKEv2 profile:

   ```
   no ike v2-profile WORD<1-32>
   ```

Variable Definition

The following table defines parameters for the **`ike v2-profile`** commands.

Variable	Value
profile WORD<1-32>	Specifies the IKE v2-profile name.
hash-algo <md5|sha|sha256|any>	Specifies the type of hash algorithm. The default value is sha256. To set this option to the default value, use the default operator with the command: **default ike v2-profile WORD<1-32> hash-algo**
encrypt-algo <desCbc|3DesCbc|aesCbc|any>	Specifies the type of encryption algorithm. The default value is aesCbc. To set this option to the default value, use the default operator with the command: **default ike v2-profile WORD<1-32> encrypt-algo**
integrity-algomd5|sha-1|sha-256|aes-xcbc	Specifies the type of integrity algorithm. The default is sha256. To set this option to the default value, use the default operator with the command: **default ike v2-profile WORD<1-32> integrity-algo**
dh-group <modp768|modp1024|modp2048|any>	Specifies the Diffie-Hellman (DH) group. DH groups categorize the key used in the key exchange process, by its strength. The key from a higher group number is more secure. The default value is modp2048. To set this option to the default value, use the default operator with the command: **default ike v2-profile WORD<1-32> dh-group**
encrypt-key-len <128|192|256>	Specifies the length of the encryption key. The default is 256. To set this option to the default value, use the default operator with the command: **default ike v2-profile WORD<1-32> encrypt-key-len**
lifetime-sec <0-4294967295>	Specifies the lifetime value in seconds. The lifetime ensures that the peers renegotiate the SAs just before the expiry of the lifetime value, to ensure that Security Associations are not compromised. The default value is 86400 seconds. To set this option to the default value, use the default operator with the command: **default ike v2-profile WORD<1-32> lifetime-sec**

Display IKEv2 Profiles

Use the following procedure to display the configured IKEv2 profiles.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Display all IKEv2 profiles:
   ```
   show ike v2-profile
   ```
3. Display a specific IKEv2 profile:
   ```
   show ike v2-profile WORD<1-32>
   ```

Example

```
Switch:1#show ike v2-profile test
================================================================================================
                                  IKE2 Profile

Encrypt       Exchange
Name                            Algo              Algo                      Key
Length    Mode
------------------------------------------------------------------------------------------------
```

```
test                              sha256                aesCbc
256        main

================================================================================
                                  IKE2 Profile

================================================================================
                                  DH                            Integrity
Lifetime
Name                              Group                         Algorithm
seconds
--------------------------------------------------------------------------------
test                              modp2048                      sha256
180
```

Variable Definitions

The following table defines parameters for the **show ike v-2profile** command.

Variable	Value
WORD<1-32>	Specifies the name of the policy.

Configure x509 Certificate Identity

About This Task

Use the following procedure to bind a certificate identity to the IKE certificate store.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the certificate subject name:

   ```
   ike certificate-identity cert-subject-name WORD<1-45>
   ```

Variable Definitions

The following table defines parameters for the **ike certificate-identity** command.

Variable	Value
cert-subject-name WORD<1-45>	Specifies the digital certificate subject name to be used as the identity certificate. If a subject name is not specified, the default subject name is Global.

IKE Configuration using EDM

The topics in this section provide the IKE EDM configuration.

Configure Digital Certificate Subject Name

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Control Path**.
2. Select **IKE**.
3. Select **Globals** tab.
4. In the **CertIdentitySubjectName** field, enter the digital certificate subject name use as identity certificate.

Globals *Field Definitions*

Use the data in the following table to use the **Globals** tab.

Name	Description
CertIdentitySubjectName	Specifies the digital certificate subject name use as identity certificate in IKE.

Configure IKE Phase 1 Profile

Use the following procedure to create and configure an IKE Phase 1 profile.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Control Path**.
2. Click **IKE**.
3. Click the **Profile** tab.
4. Click **Insert**.
5. In the **Name** field, type a profile name.
6. Complete the remaining optional configuration to customize the policy.
7. Click **Insert**.

IKE profile field descriptions

Use the data in the following table to use the **IKE** > **Profile** tab.

Name	Description
Name	Description
Name	Specifies the name of the profile.
HashAlgorithm	Specifies the hash algorithms that can be used during IKE Phase 1 SA negotiation. The default value is sha256.
EncryptionAlgorithm	Specifies the encryption algorithms that can be used during IKE Phase 1 SA negotiation. The default value is aesCbc.
EncryptKeyLen	Specifies the key length that should be used during IKE Phase 1 SA negotiation. The default value is 128.

Name	Description
DHGroup	Specifies the Diffie-Hellman groups that can be used during IKE Phase 1 SA negotiation. The default value is mod1024.
ExchangeMode	Specifies the IKE Phase 1 negotiation mode. The default value is main.
LifetimeSeconds	Specifies the amount of time for which an IKE Phase 1 SA can remain valid during IKE Phase 1 negotiation. A value of 0 means no the SA always remains valid. The default value is 86400 seconds.

Configure IKEv2 Profile

Use the following procedure to create and configure an IKEv2 profile.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Control Path**.
2. Click **IKE**.
3. Click the **V2 Profile** tab.
4. Click **Insert**.
5. In the **Name** field, type a profile name.
6. Complete the remaining optional configuration to customize the policy.
7. Click **Insert**.

V2 Profile *field descriptions*

Use the data in the following table to use the **IKE** > **V2 Profile** tab.

Name	Description
Name	Specifies the IKE v2 profile name.
HashAlgorithm	Specifies the type of hash algorithm that can be used during IKE version 2 SA version 2 negotiation. The default value is sha256.
EncryptionAlgorithm	Specifies the encryption algorithms that can be used during IKE version 2 SA version 2 negotiation. The default value is aesCbc.
EncryptKeyLen	Specifies the type of encryption algorithm. The default value is keylen–256.
DHGroup	Specifies the Diffie-Hellman (DH) group. DH groups categorize the key used in the key exchange process, by its strength. The key from a higher group number is more secure. The default value is modp2048.

Name	Description
ExchangeMode	Specifies the IKE v2 profile negotiation mode. The default value is main.
LifetimeSeconds	Specifies the lifetime value in seconds. The lifetime ensures that the peers renegotiate the SAs just before the expiry of the lifetime value, to ensure that Security Associations are not compromised. The default value is 86400 seconds.
IntegrityAlgorithm	Specifies the type of integrity algorithm.

Configure IKE Phase 1 Policy

Use the following procedure to create and configure an IKE Phase 1 policy.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Control Path**.
2. Click **IKE**.
3. Click the **Policy** tab.
4. Click **Insert**.
5. In the **LocalIfIndex** field, click either **Port** or **Vlan**, and then select an interface.
6. In the **LocalAddrType** field, select the type of the local address.
7. In the **LocalAddr** field, type the address of the local peer.
8. In the **RemoteAddrType** field, select the type of the remote address.
9. In the **RemoteAddr** field, type the address of the remote peer.
10. In the **Name** field, type the name for the policy.

    Name must be assigned when creating the policy. Once the policy is created, the name cannot be changed.
11. Complete the remaining optional configuration to customize the policy.
12. Click **Insert**.

Policy field descriptions

Use the data in the following table to use the **Policy** tab.

Name	Description
LocalIfIndex	Specifies the Interface Index of the local address. Only port and vlan interfaces are supported.
LocalAddrType	Specifies whether the local address is an IPv4 or IPv6 address.
LocalAddr	Specifies the address of the local peer.
RemoteAddrType	Specifies whether the remote address is an IPv4 or IPv6 address.
RemoteAddr	Specifies the address of the remote peer.

Name	Description
Name	Specifies the name given to the policy. The name should be assigned while creating the policy. You cannot change the name after the policy is created.
ProfileName	Specifies the name of the profile that should be used for this policy.
ProfileVersion	Specifies the profile version used for the policy.
PeerName	Specifies the peer name.
AuthenticationMethod	Specifies the proposed authentication method for the Phase 1 security association. The default authentication method is pre-shared key.
PSKValue	Specifies the value of the Pre-Shared Key if the authentication method is set to PSK.
DPDTimeout	Specifies the Dead Peer Detection timeout in seconds. Default value is 300 seconds.
P2PFS	Specifies whether or not the perfect forward secrecy (PFS) is used when refreshing keys. To use PFS, select enable. The default value is disable.
P2PfsUseIkeGroup	Specifies whether or not to use the same GroupId (Diffie-Hellman Group) for phase 2 as was used in phase 1. Ignore this entry if P2PFS is disabled. The default value is enable.
P2PfsDHGroup	Specifies the Diffie-Hellman group to use for phase 2 when P2PFS is enabled and P2PfsUseIkeGroup is disabled. The default value is mod1024.
AdminState	Specifies whether the policy is administratively enabled or disabled. The default value is disable.
OperStatus	Shows is the policy is operationally up or down.
RevocationCheckMethod	Specifies the revocation check method as OCSP, CRL or none.

Display IKE Phase 1 Security Association

Use the following procedure to view the IKE Phase 1 security association.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Control Path**.
2. Click **IKE**.
3. Click the **SA** tab.

IKE SA field descriptions

Use the data in the following table to use the **IKE** > **SA** tab.

Name	Description
Id	Specifies the profile ID.
LocalIfIndex	Specifies the Interface Index of the local address. Only port and vlan interfaces are supported.
LocalAddrType	Specifies whether the local address is an IPv4 or IPv6 address.
LocalAddr	Specifies the address of the local peer.
RemoteAddrType	Specifies whether the remote address is an IPv4 or IPv6 address.
RemoteAddr	Specifies the address of the remote peer.
Name	Specifies the name given to the SA.
AuthenticationMethod	Specifies the proposed authentication method for the Phase 1 security association. The default authentication method is pre-shared key.
DPDTimeout	Specifies the Dead Peer Detection timeout in seconds.
HashAlgorithm	Specifies the hash algorithm negotiated for this IKE Phase 1 SA.
EncryptionAlgorithm	Specifies the encryption algorithm negotiated for this IKE Phase 1 SA.
EncryptKeyLen	Specifies the encryption key length negotiated for this IKE Phase 1 SA.
DHGroup	Specifies the Diffie-Hellman group negotiated for this IKE Phase 1 SA.
ExchangeMode	Specifies the IKE Phase 1 SA mode.
LifetimeSeconds	Specifies the amount of time for which an IKE Phase 1 SA can remain valid during IKE Phase 1 negotiation. A value of 0 means no the SA always remains valid.
Status	Specifies whether the SA is active or inactive.
Initiator	Specifies whether specifies the whether the SA is created by an initiator or a responder.

Display IKE V2 Security Association

Use the following procedure to view the IKE version 2 security association.

Procedure

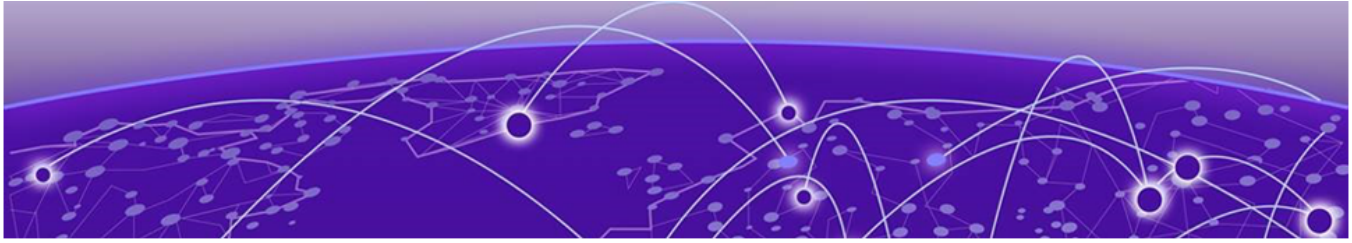
1. In the navigation pane, expand **Configuration** > **Security** > **Control Path**.
2. Click **IKE**.

3. Click the **V2 SA** tab.

V2 SA *field descriptions*

Use the data in the following table to use the **IKE** > **V2 SA** tab.

Name	Description
Id	Specifies the profile ID.
LocalIfIndex	Specifies the Interface Index of the local address. Only port and vlan interfaces are supported.
LocalAddrType	Specifies whether the local address is an IPv4 or IPv6 address.
LocalAddr	Specifies the address of the local peer.
RemoteAddrType	Specifies whether the remote address is an IPv4 or IPv6 address.
RemoteAddr	Specifies the address of the remote peer.
Name	Specifies the name given to the SA.
AuthenticationMethod	Specifies the proposed authentication method for theVersion 2 security association. The default authentication method is pre-shared key.
DPDTimeout	Specifies the Dead Peer Detection timeout in seconds.
HashAlgorithm	Specifies the hash algorithm negotiated for this IKE Version 2 SA.
EncryptionAlgorithm	Specifies the encryption algorithm negotiated for this IKE Version 2 SA.
EncryptKeyLen	Specifies the encryption key length negotiated for this IKE Version 2 SA.
DHGroup	Specifies the Diffie-Hellman group negotiated for this IKE Version 2 SA.
ExchangeMode	Specifies the IKE Version 2 SA mode.
LifetimeSeconds	Specifies the amount of time for which an IKE Version 2 SA can remain valid during IKE Version 2 negotiation. A value of 0 means no the SA always remains valid.
Status	Specifies whether the SA is active or inactive.
Initiator	Specifies whether specifies the whether the SA is created by an initiator or a responder.
IntegrityAlgorithm	Specifies the type of integrity algorithm.



IP Multicast

This section describes how to administer and configure IP Multicast Routing protocols.

The topics in this section provide conceptual background, as well as CLI and EDM configuration procedures.

IP multicast fundamentals

IP multicast extends the benefits of Layer 2 multicasting on LANs to WANs. Use multicasting techniques on LANs to help clients and servers find each other. With IP multicast, a source can send information to multiple destinations in a WAN with a single transmission. IP multicast results in efficiency at the source and saves a significant amount of bandwidth.

Enabling multicast on the switch

Shortest Path Bridging (SPB) and Protocol Independent Multicast (PIM) cannot interoperate with each other on the switch at the same time. To ensure that SPB and PIM stay mutually exclusive, use the boot flag called **spbm-config-mode**:

- The **spbm-config-mode** boot flag is enabled by default. This configuration enables you to configure SPB and IS-IS, but you cannot configure PIM either globally or on an interface.

- If you disable the boot flag, you can configure PIM and IGMP Snooping, but you cannot configure SPB or IS-IS.

Important

- Any change to the **spbm-config-mode** boot flag requires a reboot for the change to take effect.
- If you plan to disable the boot flag, remove all SPB configurations first.
- If you plan to use the default (enabled) setting, remove all PIM configurations first.

Simplified Virtual-IST

Simplified Virtual-IST (vIST) is for conventional network deployments that use SMLT and not SPB. The Simplified vIST feature provides a single CLI command to enable the virtual IST for SMLT deployments.

- Simplified vIST is available ONLY for conventional multicast deployments with PIM and IGMP when the boot flag (**spbm-config-mode**) is disabled.
- When the boot flag is enabled (default setting), Simplified vIST is not available. This means that you continue to configure SPB/IS-IS for vIST.
- Simplified VIST requires that the two vIST devices be directly connected.

Note

- PIM is supported with Simplified vIST only, not SPB vIST. However, you do not have to configure Simplified vIST to run PIM or IGMP Snooping in a non-SMLT topology.
- Do not configure LACP on SPB NNI MLT links or on the Simplified Virtual IST.
- Do not configure ECMP in PIM Simplified vIST scenarios. Running PIM in a Simplified vIST environment with ECMP enabled may lead to incorrect behavior since there are multiple options in terms of choosing the upstream node towards a host or source. For example, since the path chosen cannot be predicted (it is determined by the downstream PIM neighbor), we may end up not adding the Virtual IST MLT port in the PIM mroute's outgoing port list on the joined interface if the PIM Join Prune Message was received on an alternative path, different from the interface the local router considers to be the correct upstream to the source.

  Traffic loss can occur in such an environment. Do not enable ECMP in PIM vIST scenarios.

After you disable the **spbm-config-mode** boot flag, you can configure PIM or IGMP Snooping on any VLAN including the vIST VLAN.

To configure the boot flag and Simplified vIST, see Configuring IP multicast in SMLT topologies on page 1301 or Configuring multicast on the switch on page 1322.

vIST VLAN IP addresses

Do not configure an RP or BSR on the vIST VLAN because you cannot ping them outside of the vIST VLAN subnet. When you enter the ip pim enable command on the vIST VLAN, the following message displays:

```
WARNING: Please do not use virtual IST VLAN IP address for BSR and RP
related configurations, as unicast packets to virtual IST vlan IP
```

```
address from outside of virtual IST vlan subnet will be dropped. Use
Loopback or CLIP interface IP address for BSR and RP related
configurations.
```

Overview of IP multicast

IP multicast transmits messages to multiple recipients at the same time. This one-to-many delivery mechanism is similar to broadcasting, except that multicasting transmits to specific groups and broadcasting transmits to all receivers on a network. Because IP multicast transmits only one stream of data to the network where it replicates to many receivers, multicasting saves a considerable amount of bandwidth.

IP multicast services benefit applications such as video conferencing, dissemination of datagram information, and dissemination of mail or news to a large number of recipients.

Multicast protocols use different techniques to discover delivery paths.

A distribution tree is a set of multicast routers and subnetworks that permit the members of a group to receive traffic from a source. The source of the tree depends on the algorithm used by the multicast protocol. The following diagram is an example of a simple distribution tree where S is the multicast source and the arrows indicate the multicast broadcast procedure.

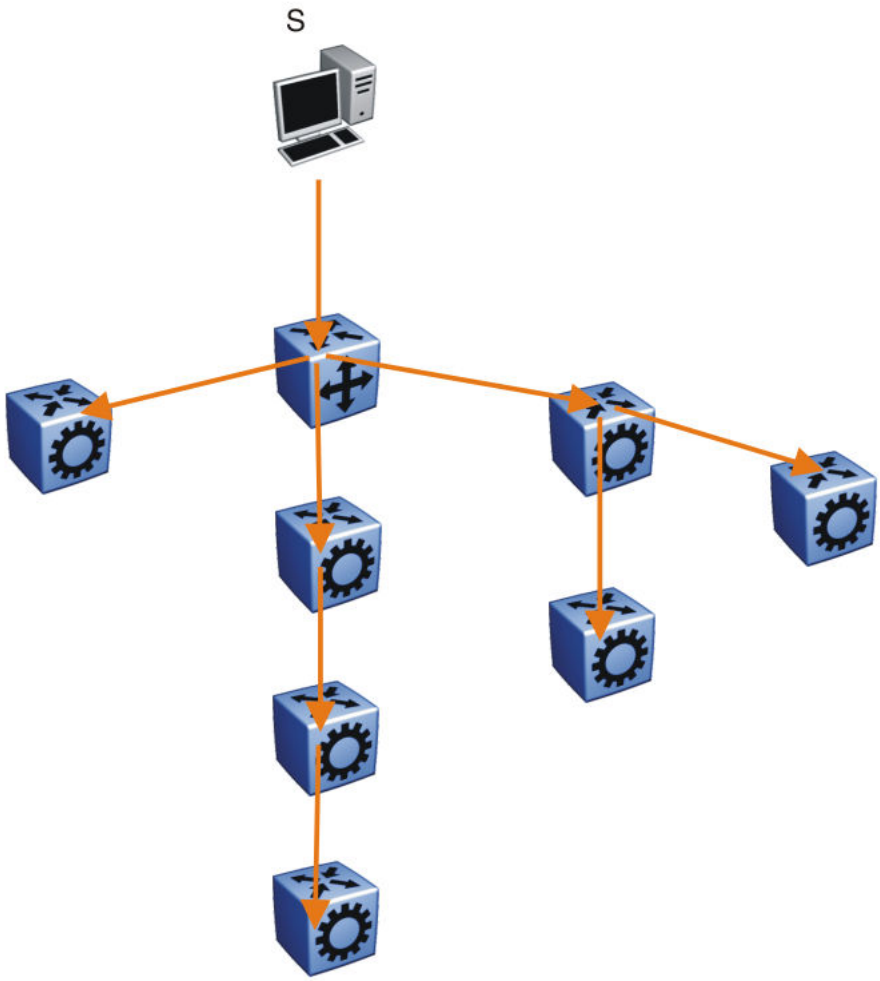


Figure 118: Multicast distribution tree and broadcasting

Broadcast and prune methods use multicast traffic to build the distribution tree. Periodically, the source sends or broadcasts data to the extremities of the internetwork to search for active group members. If no local members of the group exist, the router sends a message to the host, removing itself from the distribution tree, and thus pruning the router.

The following diagram illustrates how the host prunes routers from the distribution tree. First, the router sends a message to the source, after which the pruned routers do not receive multicast data.

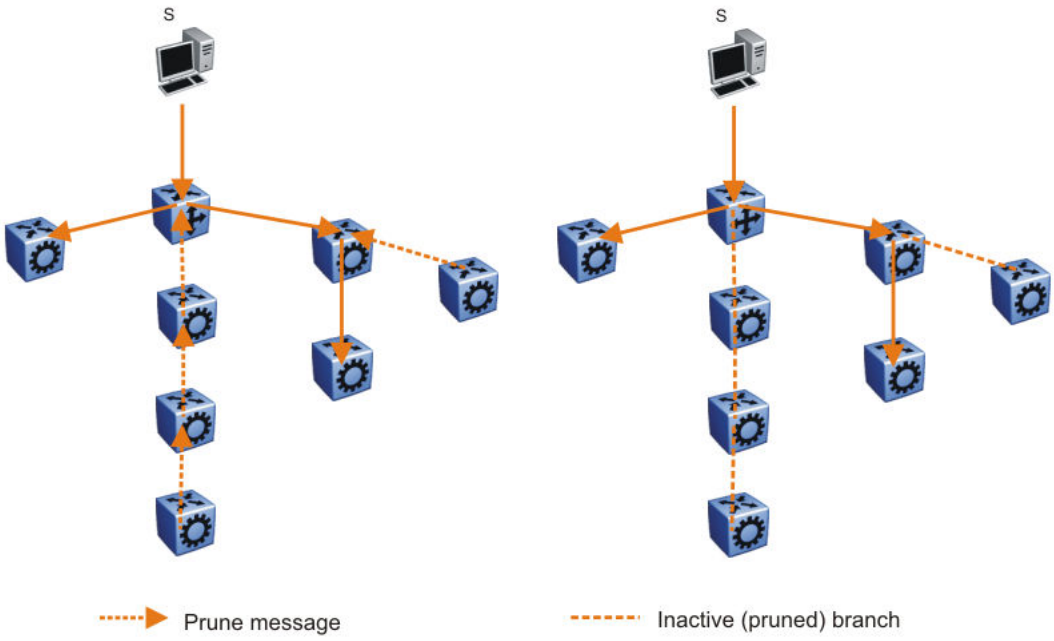

Figure 119: Pruning routers from a distribution tree

Reverse path multicast is based on the concept that a multicast distribution tree is built on the shortest path from the source to each subnetwork that contains active receivers. After a datagram arrives on an interface, the router determines the reverse path to the source of the datagram by examining the routing table of known network sources. If the datagram is not on the optimal delivery tree, the router discards it.

Multicast host groups and their group members enable the IP multicast router to transmit just to those groups interested in receiving the traffic. The switch uses the Internet Group Membership Protocol (IGMP) to learn the existence of host group members on their directly attached subnets. A router communicates with the hosts on a local network by sending IGMP queries. Hosts respond by issuing IGMP reports. For more information about host groups, see Multicast host groups and Multicast addresses on page 1235. For more information about IGMP, see Internet Group Management Protocol.

Multicast traffic forwarding transmits frames to all interfaces or subnets for which it receives IGMP reports for the multicast group indicated in the destination IP address. Multicast packets forwarded within the same virtual LAN (VLAN) remain unchanged. The switch does not forward packets to networks that do not use members of the multicast group indicated in the destination IP address.

Multicast host groups

IP multicast is a method for addressing, routing, and delivering a datagram to a collection of receivers called a host group.

Host groups are permanent or transient, with the following characteristics:

- A permanent host group uses a well-known, administratively assigned IP multicast group address. This address is permanent and defines the group. A permanent host group can consist of zero or more members.

- A transient host group exists only as long as members need its services. IP addresses in the multicast range that are not reserved for permanent groups are available for dynamic assignment to transient host groups.

A host system on an IP network sends a message to a multicast group by using the IP multicast address for the group. To receive a message addressed to a multicast group, however, the host must be a member of the group and must reside on a network where that group is registered with a local multicast router.

An IP multicast host group can consist of zero or more members and places no restrictions on its membership. Host members can reside anywhere, they can join and leave the group at any time, and they can be members of more than one group at the same time.

In general, hosts that are members of the same group reside on different networks. However, a range of multicast addresses (224.0.0.x) is reserved for locally-scoped groups. All message traffic for these hosts typically remains on the local network. Hosts that belong to a group in this address range and that reside in different networks do not receive message traffic for each other.

Important

You can apply a special set of filters (global filters) to multicast packets. You can also create, deny, or accept filters to configure the sources that can receive and send data. For more information about how to configure filters, see Traffic filtering fundamentals on page 3063.

Multicast addresses

Each host group uses a unique multicast address. To reach all members of the group, a sender uses the multicast address as the destination address of the datagram.

An IP version 4 multicast address is a Class D address (the high-order bits are 1110) from 224.0.0.0 to 239.255.255.255. These addresses are assigned statically for use by permanent groups and dynamically for use by transient groups.

The block of addresses from 224.0.0.1 to 224.0.0.255 is reserved for routing protocols and other low-level protocols. Multicast routers do not forward datagrams with addresses in this range because the time-to-live (TTL) value for the packet is usually 1.

Multicast protocols

You can use the following protocols to enable multicast routing on a switch:

- Internet Group Management Protocol (IGMP)—learns the existence of host group members on directly attached subnets.
- Multicast Router Discovery (MRDISC) protocol—discovers multicast routers in a Layer 2 bridged domain configured for IGMP snoop.
- Protocol Independent Multicast (PIM)
  - Sparse Mode (PIM-SM) protocol—suitable for implementation on networks sparsely populated by receivers.
  - Source Specific Multicast (PIM-SSM) protocol—uses a one-to-many model where members can receive traffic from one or more specific sources. This protocol is suitable for television channels and other content-distribution applications.

Static source groups

Use static source groups to configure static source-group entries in the PIM-SM, or PIM-SSM multicast routing table. PIM cannot prune these entries from the distribution tree. In other words, even if no receivers for the group exist, the multicast stream for a static source-group entry stays active. PIM never prunes static forwarding entries. If you no longer need the entries, you must manually delete them.

To configure static source groups, you must first globally enable PIM. If you disable PIM, the switch saves all of the configured static source-group entries and deactivates them. After you re-enable PIM, the switch reactivates the static source groups.

Static source groups ensure that the multicast route (mroute) records remain in the distribution tree. After receivers join the group, they do not experience a delay in receiving multicast data because they do not need to graft onto the group, or start a join process in the case of PIM. This timing is essential for applications where the multicast data must send to a receiver as soon as the receiver joins the group, for example, when a switch delivers television channels to receivers. After the receiver turns the channel, which is equivalent to joining a group, the receiver can view the channel immediately.

Static entries result in continuous traffic if the source is active, even if no receivers exist. However, the system does not forward traffic with a static entry if no receivers exist, but forwards it continuously to the switch where the entry is programmed and crosses intermediate switches on the path.

You can configure static source-group entries for a specific source or subnet. If several sources on the same subnet send traffic to the same group, traffic for all these sources flows continuously when using the subnet configuration.

After you configure static source groups, keep the following points in mind:

- If you disable PIM, the switch deactivates all of the static source groups. After you re-enable PIM, the switch activates the static source groups.
- In PIM-SM configuration, the static source-group feature works for both specific source addresses and subnet addresses by using the SrcSubnetMask field.

  When the network mask is 255.255.255.255, the full source address is used to match the (S,G) which is the specific source case. When the network mask field is a subnet mask for the source, only the source subnet is used to match (S,G)s.
- In PIM-SSM configurations, static source groups have the following limitations:

  - Subnets: SSM static source groups work only with specific IP addresses. Static source groups cannot work with source subnets, so the mask must use a full 32-bit mask, 255.255.255.255, and the source must use a host address.

IP Multicast over Fabric Connect

IP Multicast over Fabric Connect introduces extensions to the SPBM IS-IS control plane to exchange IP multicast stream advertisement and membership information. These extensions, combined with the use of IGMP snooping and querier functions at the edge of the SPBM cloud, efficiently transport IP multicast data by using sub-trees of the VSN shortest path tree per IP multicast group.

Internet Group Management Protocol

Table 95: Internet Group Management Protocol product support

Feature	Product	Release introduced
Internet Group Management Protocol (IGMP), including virtualization	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

A host uses IGMP to register group memberships with the local querier router to receive datagrams sent to this router targeted to a group with a specific IP multicast address.

A router uses IGMP to learn the existence of group members on networks to which it directly attaches. The router periodically sends a general query message to each of its local networks. A host that is a member of a multicasting group identifies itself by sending a response.

IGMP queries

When multiple IGMP routers operate on a network, one router is elected to send queries. This elected querier periodically sends host membership queries (also known as general queries) to the attached local subnets. The switch supports queries from all three versions of IGMP.

IGMP host reports

A host that receives a membership query from a local router can respond with a host membership report, one for each multicast group that joins. A host that receives a query delays its reply by a random interval and listens for a reply from other hosts in the same host group. For example, consider a network that includes two host members—host A and host B—of the same multicast group. The router sends out a host membership query on the local network. Both host A and host B receive the query and listen on the network for a host membership report. The delay timer for host B expires first, so it responds to the query with a membership report. Hearing the response, host A does not send a report of its own for the same group.

Each query from a router to a host includes a maximum response time field. IGMP inserts a value n into this field specifying the maximum time in tenths of a second within which the host must issue a reply. The host uses this value to calculate a random value between 0 and n tenths of a second for the period that it waits before sending a response. This calculation is true for IGMP versions 2 and 3. For IGMP version 1, this field is 0 but defaults to a value of 100, that is, 10 seconds.

If at least one host on the local network specifies that it is a member of a group, the router forwards to that network all datagrams that bear the multicast address for the group.

Upon initialization, the host can immediately issue a report for each of its supported multicast groups. The router accepts and processes these asynchronous reports the same as requested reports.

After hosts and routers are in a steady state, they communicate in a way that minimizes the exchange of queries and reports. The designated routers establish a path between the IP multicast stream source and the end stations and periodically query the end stations about whether to continue participation. As long as a client continues to participate, all clients, including nonparticipating end stations on the switch port, receive the IP multicast stream.

Host leave messages

If an IGMPv2 host leaves a group and it is the host that issues the most recent report, it also issues a leave group message. The multicast router on the network issues a group-specific query to determine whether other group members exist on the network. If no host responds to the query, the router assumes that no members belonging to that group exist on that interface.

Fast leave feature

The switch supports a fast leave feature that is useful for multicast-based television distribution applications. Fast leave relies on an alternative leave process where the switch stops sending traffic for the group immediately after it receives a leave message, without issuing a query to check if other group members exist on the network. Fast leave alleviates the network from additional bandwidth demand after a customer changes television channels.

The switch provides several fast leave processes for IP multicast:

- immediate leave with one user for each interface
- immediate leave with several users for each interface
- standard IGMP leave based on a Last Member Query Interval (LMQI), which you can configure in tenths of seconds

Fast leave modifies the IGMP leave processing mechanism on an IGMP interface. After the system receives an IGMP leave message on a fast leave enabled interface, the switch does not send a group-specific query and immediately stops sending traffic to the leaving member (IGMP host) port. Without fast leave, traffic continues to forward until the group times out. This situation wastes bandwidth if no receiver that requires the group traffic exists.

Fast leave mode provides two options of the fast leave mechanism—single-user mode and multiple-users mode:

- Single-user mode: In this mode, the port stops receiving traffic immediately after a group member on that port sends a leave message. Use the single-user mode if each interface port connects to only one IGMP host.
- Multiple-users mode: Use this mode if the interface port connects to multiple IGMP hosts. In this case, the port stops receiving traffic after all members leave the IGMP group. The switch removes the leaving IGMP member and, if more group members exist on that port, the switch continues sending traffic to the port.

  When operating in multiple-users mode, the switch must use the correct membership information. To support multiple-users mode, multicast receivers on the same interface cannot use IGMP report suppression. If you must use IGMP report suppression, do not use this mode. Instead, use the LMQI (configurable in units of 1/10ths of seconds) to provide a faster leave process while still sending group-specific queries after the interface receives a leave message.

Fast leave mode applies to all fast-leave enabled IGMP interfaces.

IGMP snoop

The switch provides IP multicast capability and can support all three versions of IGMP to prune group membership for each port within a VLAN. This feature is IGMP snoop.

Important

IGMP snoop can optimize only local multicast data flow. IGMP snoop does not manage the forwarding state of the multicast tree. You cannot configure a port as a static receiver in an IGMP snoop-enabled VLAN that does not contain at least one dynamic receiver port and forward multicast data.

Use the IGMP snoop feature to optimize the multicast data flow, for a group within a VLAN, to only those ports that are members of the group. The switch builds a database of group members by listening to IGMP reports from each port. The switch suppresses the reports heard by not forwarding them to ports other than the one receiving the report, thus forcing the members to continuously send their own reports. The switch relays group membership from the hosts to the multicast routers and forwards queries from multicast routers to all port members of the VLAN. Furthermore, the switch forwards multicast data only to the participating group members and to the multicast routers within the VLAN.

The multicast routing functionality can coexist with IGMP snoop on the same switch, but you can configure only one of IGMP snoop or an IP multicast routing protocol, excluding IGMP, on the same VLAN.

Multicast group trace for IGMP snoop

Use this feature to monitor the multicast group trace for an IGMP snoop-enabled switch . You can view the multicast group trace from CLI.

Multicast group trace tracks the data flow path of the multicast streams. Group trace tracks information such as the multicast group address, the source address, ingress VLAN and port, and egress VLAN and port.

IGMP proxy

If a switch receives multiple reports for the same multicast group, it does not transmit each report to the multicast upstream router. Instead, the switch consolidates the reports into a single report and forwards the one report. If you add another multicast group or the system receives a query since it last transmitted the report upstream, the system forwards the report onto the multicast router ports. This feature is IGMP proxy.

IGMP versions

The switch supports IGMPv1, IGMPv2, and IGMPv3. IGMPv1 and IGMPv2 are backward compatible and can exist together on a multicast network. The following list describes the purpose for each version:

- IGMPv1 provides the support for IP multicast routing. IGMPv1 specifies the mechanism to communicate IP multicast group membership requests from a host to its locally attached routers. For more information, see RFC1112.
- IGMPv2 extends the features in IGMPv1 by quickly reporting group membership termination to the routing protocol. This feature is important for multicast groups with highly volatile group membership. For more information, see RFC2236.
- IGMPv3 supports the PIM Source Specific Multicast (SSM) protocol, PIM-SM, and snooping. A host can selectively request or filter traffic from individual sources within a multicast group or from

specific source addresses sent to a particular multicast group. Multicast routing protocols use this information to avoid delivering multicast packets from specific sources to networks where there are no interested receivers. For more information, see RFC3376.

For the switch implementation of PIM-SSM, each group can use multiple sources.

The following list identifies group records that a report message includes:

- current-state record
- source-list-change record
- filter-mode-change record

A current-state record is sent by a system in response to a query received on an interface. It reports the current reception state of that interface, with respect to a single multicast address.

The Record Type of a current-state record has one of the following two values:

- MODE_IS_INCLUDE — Indicates that the interface has a filter mode of include for the specified multicast address. The source address fields in this group record contain the source list of the interface for the specified multicast address.
- MODE_IS_EXCLUDE — Indicates that the interface has a filter mode of exclude for the specified multicast address. The source address fields in this group record contain the source list of the interface for the specified multicast address.

Source-List Change Record — The system sends a source-list-change record after a change of source list occurs that does not coincide with a filter-mode change on the interface for a particular multicast address. The interface on which the change occurs sends a report that includes the record. The record type of a source-list-change record can be one of the following two values:

- ALLOW_NEW_SOURCES — Indicates that the source address [i] fields in this group record contain a list of the additional sources that the system wishes to hear from, for packets sent to the specified multicast address. If the change was to an include source list, these are the addresses that were added to the list. If the change was to an exclude source list, these are the addresses that were deleted from the list.
- BLOCK_OLD_SOURCES — Indicates that the source address [i] fields in this group record contain a list of the sources that the system no longer wishes to hear from, for packets sent to the specified multicast address. If the change was to an include source list, these are the addresses that were deleted from the list; if the change was to an exclude source list, these are the addresses that were added to the list.

  If a change of source list results in both allowing new sources and blocking old sources, then two group records are sent for the same multicast address, one of type ALLOW_NEW_SOURCES and one of type BLOCK_OLD_SOURCES.

Filter Mode — The switch implements the filter-mode-change record. The system sends a filter-mode-change record whenever the filter mode changes (during a change from include to exclude, or from exclude to include) for a particular multicast address. The interface on which the change occurs sends a report that includes the record. The record type of a filter-mode-change record can be one of the following two values:

- CHANGE_TO_INCLUDE_MODE — Indicates that the interface has changed to include filter mode for the specified multicast address. The source address [i] fields in this group record contain the new source list of the interface for the specified multicast address.

- CHANGE_TO_EXCLUDE_MODE — Indicates that the interface has changed to exclude filter mode for the specified multicast address. The source address [i] fields in this group record contain the new source list of the interface for the specified multicast address.

After you enable IGMPv3, the following actions occur:

- After you change the version on an interface to or from IGMPv3, the switch experiences a disruption to existing multicast traffic on that interface but traffic does recover. Do not make this change when the system passes multicast traffic.

IGMP states

Multicast routers implementing IGMPv3 keep one state for each group for every port in every attached network. This group state consists of a filter-mode, a list of sources, and various timers. For each attached network running IGMP, a multicast router records the desired reception state for that network. This state consists of a set of records of the following form:

- multicast address
- group timer
- filter mode (source records)

Each source record is of the form source address or source timer. If all sources within a given group are desired, an empty source record list is kept with filter-mode set to EXCLUDE. This means hosts on this network want all sources for this group to be forwarded. This is the IGMPv3 equivalent to a IGMPv1 or IGMPv2 group join.

Group timer

A group timer represents the time for the filter-mode to expire and switch to INCLUDE mode and is used only when a group is in EXCLUDE mode.

Group timers are updated according to the types of group records received. If a group timer is expiring when a router filter-mode for the group is EXCLUDE means, there are no listeners on the attached network in EXCLUDE mode. At this point, a router will transition to INCLUDE filter-mode.

Source timer

A source timer is maintained for every source record. Source timers are updated according to:

- the type and filter-mode of the group record received
- whenever the source is present in a received record for that group.

If a source timer expires with a router filter-mode for the group of INCLUDE, the router concludes that traffic from this particular source is no longer desired on the attached network, and deletes the associated source record.

If a source record has a running timer with a router filter-mode for the group of EXCLUDE, it means that at least one system desires the source. It should therefore be forwarded by a router on the network. If a source timer expires with a router filter-mode for the group of EXCLUDE, the router informs the routing protocol that there is no receiver on the network interested in traffic from this source. The records are deleted when the group timer expires in the EXCLUDE router filter-mode.

Processing IGMP messages for groups in SSM range

IGMP messages are processed for groups in SSM range in the following scenarios:

1. IGMPv3 interface enabled; PIM-sparse or snooping enabled
   - IGMPv3 reports that contain group records with groups within SSM range are processed with no restrictions.
   - IGMPv2 reports for groups within SSM range translate to IGMPv3 reports with one group record and type IS_EXCLUDE{NULL}. These reports are processed with no restriction as an IGMPv3 report.
   - IGMPv2 leave for groups within SSM range translate to IGMPv3 reports with one group record and type TO_INCLUDE{NULL}. These reports are processed with no restriction as an IGMPv3 report.
2. IGMPv3 interface enabled; PIM-SSM or ssm-snooping enabled
   - IGMPv3 reports that contain group records with groups within SSM range received from members in the EXCLUDE mode are discarded (eg. IS_EXCLUDE and TO_EXCLUDE messages).
   - IGMPv2 reports for groups within SSM range translate to IGMPv3 reports with one group record and type ALLOW{S1,S2,...}. The source list is obtained from the global ssm-map. If there are no sources in the global ssm-map, the message is discarded. These reports are processed with no restriction as an IGMPv3 report.
   - IGMPv2 leave for groups within SSM range translate to IGMPv3 reports with one group record and type BLOCK{S1,S2,...}. The source list is obtained from the global ssm-map. If there are no sources in the global ssm-map, the message is discarded. These reports are processed with no restriction as an IGMPv3 report.

Note

In order to accept v2 messages, you must enable the compatibility mode on the IGMPv3 interface.

IGMPv3 source-specific forwarding rules

After a multicast router receives a datagram from a source destined to a particular group, the router must decide to forward the datagram to the attached network. The multicast routing protocol uses IGMPv3 information to forward datagrams to all required sources or groups on a subnetwork.

The following table describes the forwarding suggestions that IGMPv3 makes to the routing protocol. The table also identifies the action taken after the source timer expires, based on the filter mode of the group.

Group filter-mode	Source-timer value	Action
INCLUDE	TIMER > 0	Forward the traffic from the source.
INCLUDE	TIMER = 0	Stop forwarding the traffic from the source, and remove the source record. If no more source records exist for the group, delete the group record.
INCLUDE	No source elements	Do not forward the source.
EXCLUDE	TIMER > 0	Forward the traffic from the source.

Group filter-mode	Source-timer value	Action
EXCLUDE	TIMER = 0	Do not forward the traffic from the source. If no more source records exist for the group, delete the group record.
EXCLUDE	No source elements	Forward the traffic from the source.

IGMPv3 explicit host tracking

IGMPv3 explicit host tracking enables the IGMP to track all the source and group members. To track all the source and group members, the sources that are in the include mode hold a list of members who want to receive traffic from that source.

The members that are in the exclude mode are on hold on the reporter list under the port data. By default, IGMPv3 explicit host tracking is disabled.

Important

If explicit host tracking is enabled, you cannot downgrade the IGMPv3 interface to IGMPv1 or IGMPv2.

IGMPv3 fast leave

When a BLOCK message is received for a source, you must check if the member that sent this message is the last reporter for the source. If it is the last reporter, delete the source. Else, delete the member. No group and source specific queries are sent.

When a LEAVE message is received, you must check if the member that sent this message is the last reporter for the group. If it is the last reporter, switch to INCLUDE mode if sources are available (if no sources are available the port is deleted). Else, delete the member. No group and source specific queries or group specific queries are sent.

Important

To use the IGMPv3 fast leave feature, you must first enable the explicit host tracking feature.

Synchronization of IGMPv3 over SMLT

The implementation of IGMPv3 offers support for IGMPv3 over SMLT. The Virtual-IST (vIST) peers must be in sync with the IGMPv3 reports received over SMLT links to ensure effective performance. The vIST protocol ensures the infrastructure to send such information from one vIST peer to the other.

The synchronization of IGMPv3 members and their advertised sources is different from IGMPv1 and IGMPv2. Because of IGMPv3 compatibility mode, you must consider the IGMP member version. If you have version 1 or 2 members, you must synchronize the IGMP information as IGMPv1 or IGMPv2 reports, so the peer can build an accurate database. In particular, if members with version 1 or 2 exist, the group filter mode is exclude and the exclude source list is empty. Also no v1 or v2 member will be present on any source from include list.

Each member sends IGMP reports in the same manner for all IGMP versions. The sending mechanism depends on the SMLT state.

After a vIST peer receives an IGMPv3 report over an SMLT link, it must pass the message to its peer. If the SMLT state is up, the vIST peer sends the message encapsulated in an vIST IGMPv3 message. If the SMLT state is down, the vIST peer sends the message as a plain IGMPv3 report.

In both cases the IGMPv3 message is not altered and the receiving vIST peer processes it as expected in SMLT conditions (translating the receiving port to SMLT port if applicable).

Note

If you enable compatibility mode and the member sends an IGMPv1 or IGMPv2 report, the message is either a vIST IGMPv1 or v2 encapsulated Message or a plain IGMPv1 or IGMPv2 report.

After SMLT up or down events occur, the vIST peer must synchronize its IGMPv3 database to its peer, taking into account the new state of the SMLT link.

If you enable IGMP explicit host tracking, each include source stores information for each member that advertises that particular source in an include list. This information is synchronized with the vIST peer.

If you do not enable explicit host tracking, each source from include list contains only information related to the last member that sent an IGMPv3 report. Only this information is synchronized with the vIST peer.

Backward compatibility

IGMPv3 for PIM-SSM is backward compatible with IGMPv2. You can configure the switch to operate in v3-only mode or in v2-v3 compatibility mode. If you configure the switch to use v3-only mode, it ignores all v2 and v1 messages except the query message.

If you configure the switch to operate in v2-v3 compatibility mode, the switch supports all IGMPv1, v2, and v3 messages. The switch parses the group address of the messages. If the group address is out of SSM range and it is a v3 message, the switch drops the message; if it is a v2 message, PIM-SM or IGMP snoop processes handle the message.

After the switch receives an IGMPv2 leave message and the group address in it is within SSM range, the switch sends the group-and-source specific query. If the group address is not within the SSM range, the switch sends the group specific query.

According to RFC3376, the multicast router with IGMPv3 can use one of two methods to handle older query messages:

- If an older version of IGMP is present on the router, the querier must use the lowest version of IGMP present on the network.
- If a router that is not explicitly configured to use IGMPv1 or IGMPv2 hears an IGMPv1 query or IGMPv2 general query, it logs a rate-limited warning.

You can configure if the switch dynamically downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning.

In v2-v3 compatibility mode, an IGMPv2 host can only join if you configure a static entry in SSM map and if the interface operates in PIM-SSM mode or IGMP SSM-Snoop mode.

You can use the compatibility mode with Split MultiLink Trunking (SMLT). One core switch sends an SMLT message to the other core switch after it receives an IGMPv3 message. This action synchronizes the IGMP host information.

Implementation of IGMP

You can enable and disable multicast routing on an interface basis. If you disable multicast routing on an interface, the interface does not generate IGMP queries. If the switch or interface is in IGMP router behavior mode, for example, PIM enabled, you cannot configure IGMP snoop. The switch still learns the group membership and snoops multicast receivers on the switch VLAN or ports.

IGMP Layer 2 Querier

In a Layer 2 multicast network, you can enable Layer 2 querier on one of the switches in the VLAN. IGMP Layer 2 querier provides the IGMP querier function so that the switch can provide the recurring queries that maintain IGMP groups when you do not use multicast routing for multicast traffic.

Overview

In a multicast network, if you only need to use Layer 2 switching for the multicast traffic, you do not need multicast routing. However, you must have an IGMP querier on the network for multicast traffic to flow from sources to receivers. A multicast router provides the IGMP querier function. You can also use the IGMP Layer 2 Querier feature to provide a querier on a Layer 2 network without a multicast router.

The Layer 2 querier function originates queries for multicast receivers, and processes the responses accordingly. On the connected Layer 2 VLANs, IGMP snoop continues to provide services as normal. IGMP snoop responds to queries and identifies receivers for the multicast traffic.

You must enable Layer 2 querier and configure an IP address for the querier before it can originate IGMP query messages. If a multicast router exists on the network, the switch automatically disables the Layer 2 querier.

In a Layer 2 multicast network, enable Layer 2 querier on only one of the switches in the VLAN. A Layer 2 multicast domain supports only one Layer 2 querier. No querier election exists.

IGMP Snooping

IGMP Snooping enables Layer 2 switches in the network to examine IGMP control protocol packets exchanged between downstream hosts and upstream routers.

When Layer 2 switches examine the IGMP control protocol packets, they:

- Generate the Layer 2 MAC forwarding tables used for further switching sessions
- Regulate the multicast traffic to prevent it from flooding the Layer 2 segment of the network

IGMP Layer 2 Querier and IGMP interaction

IGMP Layer 2 Querier uses IGMP to learn which groups have members on each of the attached physical networks, and it maintains a list of multicast group memberships for each attached network and a timer for each membership. In this case, multicast group memberships means the presence of at least one member of a multicast group on a given attached network, not a list of all of the members.

IGMP Layer 2 Querier can assume one of two roles for each of the attached networks:

- Querier
- Non-Querier

After you enable IGMP Layer 2 Querier, the system assumes it is a multicast router, so it sends the General Query, Group Specific/Group, and Source Specific Query when Leave/BLOCK messages are received. IGMP queries are required to maintain an IGMP group.

Note

Group Specific When Leave does not apply to IGMPv1.

IGMP Layer 2 Querier limitations

The following limitations apply to IGMP Layer 2 Querier.

- IGMP Layer 2 Querier is based on IGMP Snoop. If you disable IGMP Snoop, IGMP Layer 2 Querier does not work until you enable IGMP Snoop and IGMP Layer 2 Querier.
- After you enable IGMP Snoop and IGMP Layer 2 Querier on an interface, if the system receives no IGMP query messages, it becomes the querier.

IGMP Layer 2 Querier limitations and DvR

The following limitations apply when you configure IGMP Layer 2 Querier on DvR enabled nodes.

- You can configure IGMP Layer 2 Querier only on the DvR Controllers in a DvR domain. When you configure the following parameters on the Controllers, the configuration is automatically pushed to the DvR Leaf nodes within the domain.
  - IGMP version
  - IGMP query interval
  - IGMP query maximum response time
  - IGMP robustness value
  - IGMP last member query interval
  - IGMP compatibility mode
- You cannot configure IGMP snooping on DvR enabled Layer 2 VSNs.

For more information on DvR, see Distributed Virtual Routing Fundamentals on page 622 .

Multicast access control

Multicast access control is a set of features that operate with standard existing multicast protocols. You can configure multicast access control for an IP multicast-enabled port or VLAN with an access control policy that consists of several IP multicast groups.

You can use this feature to restrict access to certain multicast streams and to protect multicast streams from spoofing (injecting data to the existing streams). For example, in a television distribution application, instead of applying a filter to each channel (multicast group), you can apply a multicast access policy to a range of channels (groups), thereby reducing the total number of filters and providing a more efficient and scalable configuration. Also, if you want to add or remove television channels from a package, you can modify the multicast access policy; you do not need to change filters for individual

VLANs or ports. Multicast access policies contain an ID and a name (for example, PremiumChannels), the list of IP multicast addresses, and the subnet mask.

Multicast access control is not a regular filtering configuration. Multicast access control is for multicast streams and relies on handling multicast control and initial data to prevent hosts from sending or receiving specified multicast streams; it does not use filters. Also, multicast access control provides a list of multicast groups in one configuration using the same routing policy prefix list configuration. For information about prefix lists, see Configuring prefix lists on page 2608. You can configure multicast access control and change it dynamically to support changes in the configuration without restarting the protocol. You can change the access capabilities of a user or service subscriber without loss of service.

The following paragraph describes a typical application.

The local cable television company offers three packages; each one includes 35 channels (35 multicast groups). The company configures each package in an access control policy. This policy applies to a set of VLANs or ports to prevent users from viewing the channels on those VLANs. Use the same policy to prevent users from sending traffic to those groups (also known as spoofing) by specifying the deny-tx option for that port. After you define the packages, you can use them for access policy configuration. You can easily change the package by changing the group range, without changing all the port configurations.

The multicast access control functionality applies to an IP multicast application where you must control user access. You can use it in financial-type applications and other enterprise applications, such as multicast-based video conferencing.

Six types of multicast access control policies exist:

- deny-tx
- deny-rx
- deny-both
- allow-only-tx
- allow-only rx
- allow-only-both

The tx policies control the sender and ingress interface for a group; the rx policies control the receivers and egress interface for a group.

deny-tx

Use the deny-tx access policy to prevent a matching source from sending multicast traffic to the matching group on the interface where you configure the deny-tx access policy. Configure this policy on the ingress interface to the multicast source. The deny-tx access policy performs the opposite function of the allow-only-tx access policy. Therefore, the deny-tx access policy and the allow-only-tx access policy cannot exist on the same interface at the same time.

For example, in Figure 120, a VLAN 1, the ingress VLAN, uses a deny-tx access policy. This policy prevents multicast traffic sent by Sender from forwarding from VLAN 1 to a receiver, consequently preventing Receiver 1 and Receiver 2 from receiving data from the multicast group. You can create receive-only VLANs, such as VLAN 1, with the deny-tx policy.

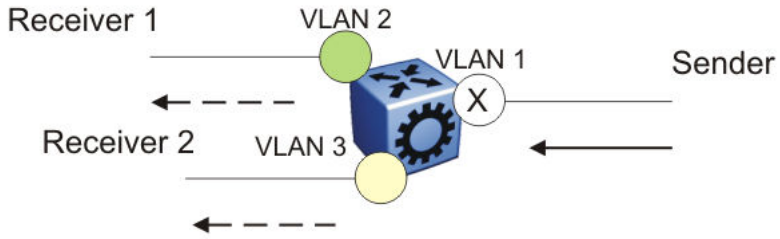

Figure 120: Data flow using deny-tx policy

deny-rx

Use the deny-rx access policy to prevent a matching group from receiving IGMP reports from the matching receiver on the interface where you configure the deny-rx access policy. The deny-rx access policy performs the opposite function of the allow-only-rx access policy. Therefore, the deny-rx access policy and the allow-only-rx access policy cannot exist on the same interface at the same time.

For example, in Figure 121, a VLAN 2 uses a deny-rx access policy, preventing IGMP reports sent by Receiver 1 from receiving on VLAN 2. You can deny a multicast group access to a specific VLAN or receiver using the deny-rx policy.

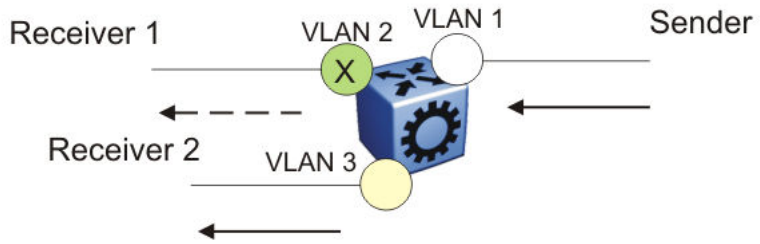

Figure 121: Data flow using deny-rx policy

deny-both

Use the deny-both access policy to prevent a matching IP address from both sending multicast traffic to, and receiving IGMP reports from, a matching receiver on an interface where you configure the deny-both policy. You can use this policy to eliminate all multicast activity for a receiver or source in a specific multicast group. The deny-both access policy performs the opposite function of the allow-only-both access policy. Therefore, the deny-both access policy and the allow-only-both access policy cannot exist on the same interface at the same time.

For example, in Figure 122, a VLAN 2 uses a deny-both access policy, preventing VLAN 2 from receiving IGMP reports sent by Receiver 2, and preventing multicast traffic sent by Sender 2 from forwarding from VLAN 2. You can prevent certain VLANs from participating in an activity involving the specified multicast groups with the deny-both policy.

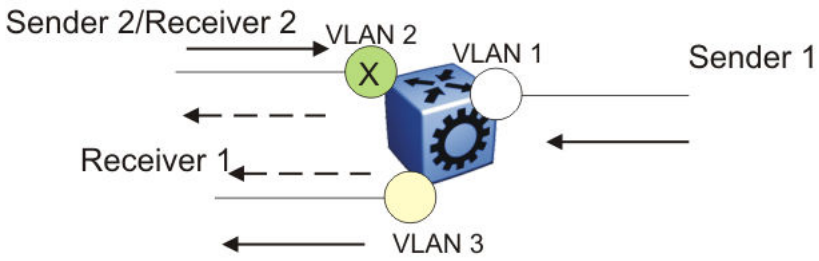

Figure 122: Data flow using deny-both policy

allow-only-tx

Use the allow-only-tx policy to allow only the matching source to send multicast traffic to the matching group on the interface where you configure the allow-only-tx policy. The interface discards all other multicast data it receives. The allow-only-tx access policy performs the opposite function of the deny-tx access policy. Therefore, the allow-only-tx access policy and the deny-tx access policy cannot exist on the same interface at the same time.

allow-only-rx

Use the allow-only-rx policy to allow only the matching group to receive IGMP reports from the matching receiver on the interface where you configure the allow-only-rx access policy. The interface discards all other multicast data it receives. The allow-only-rx access policy performs the opposite function of the deny-rx access policy. Therefore, the allow-only-rx access policy and the deny-rx access policy cannot exist on the same interface at the same time.

allow-only-both

Use the allow-only-both policy to allow only the matching IP address to both send multicast traffic to, and receive IGMP reports from, the matching receiver on the interface where you configure the allow-only-both access policy. The interface discards all other multicast data and IGMP reports. The allow-only-both access policy performs the opposite function of the deny-both access policy. Therefore, the allow-only-both access policy and the deny-both access policy cannot exist on the same interface at the same time.

Host addresses and masks

When you configure multicast access policies, you must specify the host (IP) address and host (subnet) mask of the host to filter (the host that sends multicast traffic).

You can use the host subnet mask to restrict access to a portion of the host network. For example, if you configure the host subnet mask as 255.255.255.255, you use the full host address. To restrict access to a portion of the network of a host, use a subnet mask such as 255.255.255.0. Access control applies to the specified subnet only.

Multicast stream limitation feature

You can configure the multicast stream limitation feature to limit the number of multicast groups that can join a VLAN. By limiting the number of concurrent multicast streams, a service provider can, for example, protect the bandwidth on a specific interface and control access to multicast streams.

Use multicast stream limitation in an environment where you want to limit users to a certain number of multicast streams simultaneously. For example, a television service provider can limit the number of television channels a user can watch at a time. (To a television service provider, a multicast stream is synonymous with a television channel.) If a user purchases a service contract for two single-tuner television receivers, they can use two channels flowing at the same time, but not a third. The service provider can control the bandwidth usage in addition to preventing users from watching more than the allowed number of channels at a point in time.

You can enable the multicast stream limitation feature on the switch by using one of the following methods:

- for each interface—This limitation controls the total number of streams for all clients on this brouter port.
- for each VLAN—This limitation controls the total number of streams for all clients on this VLAN. This method is equivalent to the interface stream limitation.
- for each VLAN port—This limitation controls the number of streams for all clients on this VLAN port. This method is equivalent to the interface port stream limitation.

You can configure the maximum number of streams for each limit independently. After the number of streams meets the limit, the interface drops additional join reports for new streams. The maximum number of streams for each limit is 65535 and the default is 4.

Multicast Router Discovery protocol

The Multicast Router Discovery (MRDISC) protocol can automatically discover multicast-capable routers. By listening to multicast router discovery messages, Layer 2 devices can determine where to send multicast source data and IGMP host membership reports. This feature is useful in a Layer 2 bridging domain that you configure for IGMP snoop.

IGMP multicast router discovery consists of three message types that discover multicast routers on the network:

- Multicast router advertisements: routers advertise that IP multicast forwarding is enabled on an interface.
- Multicast router solicitations: routers solicit a response of multicast router advertisements from all multicast routers on a subnet.
- Multicast router termination messages: a router terminates its multicast routing functions.

Multicast routers send multicast router advertisements periodically on all interfaces where you enable multicast forwarding. Multicast routers also send advertisements in response to multicast router solicitations.

Multicast router solicitations transmit to the IGMP-MRDISC all-routers multicast group that uses a multicast address of 224.0.0.2. Multicast router solicitations do not transmit if a router needs to discover multicast routers on a directly attached subnet.

Multicast router termination messages transmit after a router terminates its multicast routing functions. Other non-IP forwarding devices, such as Layer 2 switches, can send multicast router solicitations to solicit multicast router advertisements.

To function MRDISC on IGMP snoop interface, you must explicitly enable MRDISC. The Solicitation messages are sent only if IGMP snoop and MRDISC are enabled on the switch.

Multicast flow distribution over MLT

MultiLink Trunking (MLT) is a mechanism to distribute multicast streams over a multilink trunk and achieve an even distribution of the streams. The distribution is based on source-subnet and group addresses. In applications like television distribution, multicast traffic distribution is particularly important because the bandwidth requirements are substantial when you use a large number of television streams.

The switch enables this feature by default and you can not change the configuration.

Traffic distribution

Traffic distribution distributes the streams on the multilink trunk links if an MLT configuration change occurs. For example, you can add or delete ports.

This feature distributes active streams according to the distribution algorithm on the multilink trunk links. This distribution can cause minor traffic interruptions. To minimize the effect of distribution of multicast traffic on the multilink trunks, the implementation does not move the streams to the appropriate links at the same time. Instead, it distributes a few streams at every time tick of the system.

To that end, after a multilink trunk port becomes inactive, this feature distributes all the streams on the multilink trunk ports based on the assignment provided by the distribution algorithm.

By default, distribution is enabled and you can not change the configuration.

For more information about MLT, see MultiLink Trunking on page 2093 .

Multicast virtualization

Multicast provides simplified extension of internal video and data delivery to remote locations.

Virtualized multicast enables multiple VPN routing instances on devices and supports various unicast routing protocols so that you can provide the services of many virtual routers from one physical device.

You can configure multicast routing support with the Virtual Routing and Forwarding (VRF) Lite feature and you can use VRF Lite to emulate many virtual routers with one router.

Multicast virtualization support includes:

- IGMP snooping
- IGMP in Layer 2 virtual services networks (VSN)
- IGMP in Layer 3 VSNs

To implement multicast virtualization, you must perform the following tasks:

1. Create a VRF. For more information about how to create and configure a VRF, see Create a VRF Instance on page 3487.
2. Create a VLAN and associate it with the VRF.
3. Enable one of the following: IGMP snooping on the VLAN, Layer 2 VSN, or Layer 3 VSN.

If you use IGMP snooping on the VLAN, ensure the IGMP version on the multicast hosts or other network devices is either the same as the version on the VLAN, or enable compatibility mode.

Multicast virtualization does not support PIM. The switch supports IGMP with PIM only in the Global Router.

VRF Lite background

VRF Lite provides independent IPv4 forwarding instances and independent routing instances (contexts), which can reside on the same or different VLANs and ports.

While forwarding and routing instances are mapped to IP interfaces, incoming traffic is classified into a VLAN and IP interface and, depending on the IP interface, routed context traffic is forwarded.

Protocol Independent Multicast-Sparse Mode

Table 96: Protocol Independent Multicast - Sparse Mode product support

Feature	Product	Release introduced
Protocol Independent Multicast-Sparse Mode (PIM-SM) for IPv4	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
PIM Infinite Threshold for IPv4 and IPv6	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.5
	5520 Series	VOSS 8.5
	5720 Series	Fabric Engine 8.7

Note
PIM is supported in Global Routing Table (GRT) only.

PIM-SM, as defined in RFC2362, supports multicast groups spread out across large areas of a company or the Internet. PIM-SM sends multicast traffic only to routers that specifically join a multicast group. This technique reduces traffic flow over WAN links and overhead costs for processing unwanted multicast packets.

Dense-mode protocols use a flood-and-prune technique, which is efficient with densely-populated receivers. However, for sparsely populated networks, PIM-SM is more efficient because it sends multicast traffic only to those routers that belong to a specific multicast group and that choose to receive the traffic.

PIM-SM is independent of a specific unicast routing protocol, but it does require the presence of a unicast routing protocol, such as Routing Information Protocol (RIP) or Open Shortest Path First (OSPF). PIM-SM uses the information from the unicast routing table to create and maintain multicast trees that enable PIM-enabled routers to communicate.

Typically, a PIM-SM network consists of several multipoint data streams, each targeted to a small number of LANs in the internetwork. For example, customers whose networks consist of multiple hosts on different LANs can use PIM-SM to simultaneously access a video data stream, such as video conferencing, on a different subnet.

Important

In some cases, PIM stream initialization can take several seconds.

Hosts

A host is a source, a receiver, or both:

- A source, also known as a sender, sends multicast data to a multicast group.
- A receiver receives multicast data from one or several sources that sends data to a multicast group.

PIM-SM domain

PIM-SM operates in a domain of contiguous routers on which PIM-SM is enabled.

Each PIM-SM domain requires the following routers:

- designated router (DR)
- rendezvous point (RP) router
- bootstrap router (BSR)

Although a PIM-SM domain can use only one active RP router and one active BSR, you can configure additional routers as a candidate RP (C-RP) router and as a candidate BSR (C-BSR). Candidate routers provide backup protection in case the primary RP router or BSR fails.

As a redundancy option, you can configure several RPs for the same group in a PIM domain. As a load sharing option, you can have several RPs in a PIM-SM domain map to different groups. The switch devices use the hash function defined in the PIM-SM standard to elect the active RP.

Designated router

The designated router (DR), the router with the highest IP address on a LAN, performs the following tasks:

- sends register messages to the RP router on behalf of directly connected sources
- sends join and prune messages to the RP router on behalf of directly connected receivers
- maintains information about the status of the active RP router for local sources in each multicast group

Important

The DR is not a required configuration. Switches act automatically as the DR for directly attached sources and receivers.

Rendezvous point router

PIM-SM builds a shared multicast distribution tree within each domain, and the RP router is at the root of this shared tree. Although you can physically locate the RP anywhere on the network, it must be as close to the source as possible. Only one active RP router exists for a multicast group.

At the RP router, receivers meet new sources. Sources use the RP to identify themselves to other routers on the network; receivers use the RP to learn about new sources.

The RP performs the following tasks:

- registers a source that wants to announce itself and send data to group members
- joins a receiver that wants to receive data for the group
- forwards data to group

Candidate rendezvous point router

You can configure a set of routers as C-RP routers that serve as backup to the RP router. If an RP fails, all the routers in the domain apply the same algorithm to elect a new RP from the group of C-RP routers. To make sure that the routers use a complete list of C-RP routers, the C-RP router periodically sends unicast advertisement messages to the BSR. The most common implementation is to configure a PIM-SM router as both a C-RP router and a C-BSR.

The switch devices use the hash function defined in the PIM-SM standard to elect the active RP.

Static rendezvous point router

You can configure a static entry for an RP router with static RP. This feature avoids the process of selecting an active RP from the list of candidate RPs and dynamically learning about RPs through the BSR mechanism. Static RP-enabled switches cannot learn about RPs through the BSR because the switch loses all dynamically learned BSR information and ignores BSR messages. After you configure static RP entries, the switch adds them to the RP set as if they were learned through the BSR.

Important

In a PIM domain with both static and dynamic RP switches, the static RP switches cannot use a local interface configured as an RP.

When you configure a PIM static RP in a switch, the next hop of the unicast route toward the PIM static RP must be a PIM neighbor. The PIM protocol fails to work, due to a route change, if the next hop toward an already configured static RP becomes a non-PIM neighbor. If a PIM neighbor cannot reach the configured RP, the RP does not activate and its state remains invalid.

A static RP-enabled switch can communicate with switches from other vendors that do not use the BSR mechanism. Some vendors use either early implementations of PIM-SM v1 that do not support the BSR or proprietary mechanisms like the Cisco Auto-RP. For a network to work properly with static RP, you must map all the switches in the network (including switches from other vendors) to the same RP or RPs, if several RPs exist in the network.

To avoid a single point of failure, you can also configure redundant static RPs.

Use the static RP feature when you do not need dynamic learning mode, typically in small networks, or for security reasons, where RPs are forced to devices in the network so that they do not learn other RPs.

Static RP configuration considerations

Before you can configure a static RP, you must enable PIM-SM and enable static RP.

After you meet these prerequisites, keep in mind the following configuration considerations:

- You cannot configure a static RP-enabled switch as a BSR or as a C-RP router.
- All dynamically learned BSR information is lost. However, if you disable static RP, the switch loses the static RP information and regains the BSR functionality.
- Static RPs do not age, that is, they cannot time out.
- Switches do not advertise static RPs, so, if a new PIM neighbor joins the network, it does not know about the static RP unless you configure it with that static RP.
- Configure all the switches in the network (including switches from other vendors) to map to the same RP.
- In a PIM domain with both static and dynamic RP switches, the static RP switches cannot use a local interfaces configured as an RP.
- To avoid a single point of failure, you can configure redundant static RPs for the same group prefix. If you use a mix of vendor switches across the network, you must ensure that all switches and routers use the same active RP because other vendors can use different algorithms to elect the active RP. The switch devices use the hash function defined in the PIM-SM standard to elect the active RP; other vendors can use the lowest IP address to elect the RP.

  Important

  To reduce convergence times, create only one static RP for each group. The more static RPs you configure for redundancy, the more time PIM requires to rebuild the mroute table and associate RPs.

- Static RP configured on the switch is active as long as the switch uses a unicast route to the static RP network. If the switch loses this route, the static RP is invalidated and the hash algorithm remaps all affected groups. If the switch regains this route, the static RP is validated and the hash algorithm remaps the affected groups.

Bootstrap router

The BSR receives RP router advertisement messages from the candidate RPs. The BSR adds the RP router with its group prefix to the RP set. Only one BSR exists for each PIM-SM domain.

The BSR periodically sends bootstrap messages containing the complete RP set to all routers in the domain. The BSR ensures that all PIM-SM routers send join, prune, and register packets.

Within a PIM-SM domain, you can configure a small set of routers as C-BSRs. The C-BSR with the highest configured priority becomes the BSR for the domain. If two C-BSRs use equal priority, the candidate with the higher IP address becomes the BSR. If you add a new C-BSR with a higher priority to the domain, it automatically becomes the new BSR.

Important

Configure C-BSRs on routers that are central to all candidate RPs.

Shared trees and shortest-path trees

A PIM-SM domain uses shared trees and shortest-path trees to deliver data packets to group members. This section describes both trees.

Shared trees

Group members in a PIM-SM domain receive the first packet of data from sources across a shared tree. A shared tree consists of a set of paths that connect all members of a multicast group to the RP. PIM creates a shared tree when sources and receivers send messages toward the RP.

Shortest-path trees

After receiving a certain number of packets from the RP, the DR changes from a shared tree to an SPT. Switching to an SPT creates a direct route between the receiver and the source. The switch changes to the SPT after it receives the first packet from the RP.

Figure 123 shows a shared tree and an SPT.

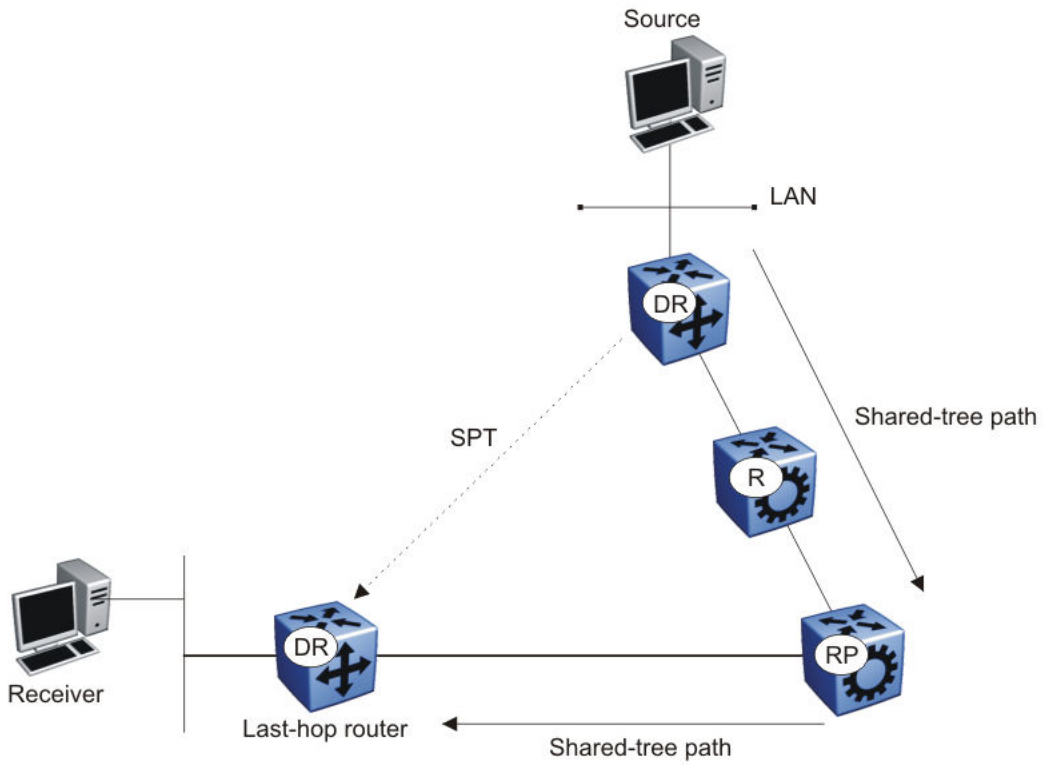

Figure 123: Shared tree and shortest-path tree

Receiver Joining a Group

The following steps describe how a receiver joins a multicast group:

1. A receiver multicasts an IGMP host membership message to the group that it wants to join.
2. After the last-hop router (the DR), normally the PIM router with the highest IP address for that VLAN, receives the IGMP message for a new group join, the router looks up the associated elected RP with responsibility for the group.
3. After it determines the RP router for the group, the last-hop router creates a (*,G) route entry in the multicast forwarding table and sends a (*,G) join message to the RP. After the last-hop router receives data packets from the RP, if the multicast packet arrival rate exceeds the DR threshold, the

last-hop router switches to the SPT by sending an (S,G) join message to the source. (S denotes the source unicast IP address, and G denotes the multicast group address.)

4. If the last-hop router switches to the SPT, the following actions occur:
   - All intermediate PIM routers along the path to the source create the (S,G) entry.
   - To trim the shared tree, the router sends an (S,G) prune message to the RP.

You can enable the PIM Infinite Threshold Policy feature to prevent the SPT switchover. Multicast traffic follows the shared tree path through a Rendezvous Point (RP) instead of switching over to SPT.

Receiver leaving a group

Before it leaves a multicast group, a receiver sends an IGMP leave message to the DR. If all directly connected members of a multicast group leave or time out, and no downstream members remain, the DR sends a prune message upstream and PIM-SM deletes the route entry after that entry times out.

When the system ages PIM mroutes, it does not clear the (S,G) entry for an inactive route immediately after the expiration period. Topology and hardware conditions can affect the polling interval and cause an inactive route to remain for up to 12-15 minutes.

Source sending packets to a group

The following steps describe how a source sends multicast packets to a group:

1. A source directly attached to a VLAN bridges the multicast data to the DR. The DR for the VLAN (the router with the highest IP address) encapsulates each packet in a register message and sends a unicast message directly to the RP router to distribute to the multicast group.
2. If a downstream group member chooses to receive multicast traffic, the RP router sends a join or prune message toward the source DR and forwards the data down the RP tree after it obtains the data natively.
3. After the receiver DR obtains the first packet, it switches to the shortest-path tree (SPT) and continues receiving data through the SPT path.
4. If no downstream members want to receive multicast traffic, the RP router sends a register-stop message (for the source) to the DR.

   The DR starts the register suppression timer after it receives the first register-stop message. During the register suppression timeout period (the default is 60 seconds), the following events occur:

   - The DR for the source sends a probe packet to the RP router before the register suppression timer expires. The probe packet prompts the RP router to determine whether new downstream receivers joined the group.
   - If no new receivers joined the group, the RP router sends another register-stop message to the DR for the source, and its register suppression timer restarts.
   - After the RP router no longer responds with a register-stop message to the source DR probe message, the register suppression timer expires and the DR sends encapsulated multicast packets to the RP router. The RP router uses this method to tell the DR that new members joined the group.

The RP sends a register-stop message to the DR immediately after it receives the first multicast data packet.

Required elements for PIM-SM operation

For PIM-SM to operate, the following elements must exist in the PIM-SM domain:

- You must enable an underlying unicast routing protocol for the switch to provide routing table information to PIM-SM.
- You must configure an active BSR to send bootstrap messages to all PIM-v2 configured switches and routers to enable them to learn group-to-RP mapping. If you configure several BSRs in a network, an active BSR is elected based on priority and IP address (if priority is equal, the BSR with the higher IP address is elected).
- You must include an RP to perform the following tasks:
  - manage one or several IP multicast groups
  - become the root for the shared tree to these groups
  - accept join messages from receiver switches for groups that it manages
  - elect an active RP based on priority and IP address (if priority is equal, the RP with the higher IP address is elected)

PIM-SM simplified example

Figure 124 shows a simplified example of a PIM-SM configuration.

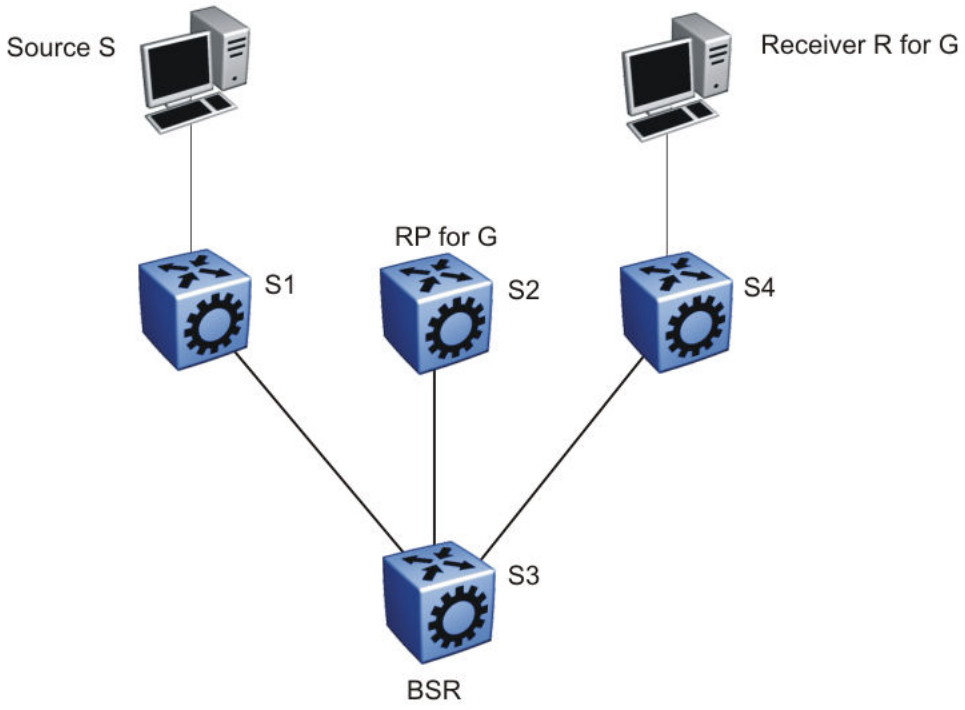

Figure 124: PIM-SM simplified example

In the sample configuration, the following events occur:

1. The BSR distributes RP information to all switches in the network.
2. R sends an IGMP membership report to S4.
3. Acting on this report, S4 sends a (*,G) join message to RP.
4. S sends data to G.

5. The DR (S1 in this example) encapsulates the data that it unicasts to RP (S2) in register messages.
6. S2 decapsulates the data, which it forwards to S4.
7. S4 forwards the data to R.
8. If the packet rate exceeds the DR threshold, S4 sends S1 an (S,G) join message.
9. S1 forwards data to S4. After S4 receives data from S1, it prunes the stream from the RP.

Important

Figure 124 on page 1258 is a simplified example and is not the best design for a network if you locate the source and receiver as shown. In general, place RPs as close as possible to sources.

PIM-SM Static Source Groups

You can configure static source groups as static source-group entries in the PIM-SM multicast routing table. PIM-SM cannot prune these entries from the distribution tree. For more information about static source groups, see Static source groups on page 1236.

Join and prune messages

The DR sends join and prune messages from a receiver toward an RP for the group to either join the shared tree or remove (prune) a branch from it. A single message contains both a join and a prune list. This list includes a set of source addresses that indicate the shortest-path trees or the shared trees that the host wants to join. The DR sends join and prune messages hop-by-hop to each PIM router on the path to the source or the RP.

Register and register-stop messages

The DR sends register messages to the RP for a directly connected source. The register message informs the RP of a new source, causing the RP to send join or prune messages back toward the DR of the source, which forwards the data down the RP tree after it obtains the data natively. After the receiver DR obtains the first packet, it switches to the shortest-path tree (SPT) and continues receiving data through the SPT path.

The DR stops sending encapsulated packets to the RP after it receives a register-stop message. This traffic stops without delay because the RP sends a register-stop message immediately after it receives the first multicast data packet, and joins the shortest-path tree.

PIM-SMLT

IP multicast routing support with Split MultiLink Trunking (SMLT) builds a virtual switch that represents the two switches of the split multilink trunk core.

When switches use PIM in the core, they need to exchange protocol-related updates as part of the interswitch trunking (IST) protocol. IST hides the fact that the edge switch attaches to two physical switches.

PIM-SMLT can work in triangular, square, and full mesh configurations with Layer 3 IP multicast. However, PIM-SSM in square or full mesh SMLT topologies is not supported.

The following rules apply:

- If a VLAN receives traffic from the IST link, it cannot forward on the split multilink trunk link or the edge for the same VLAN.
- If one side of the SMLT link toward the receiver is down, such that the traffic cannot be forwarded directly down the SMLT link from the router on which traffic is ingressing, the IST Peer MUST forward that traffic it receives over the IST link down its side of the SMLT toward the receiver. The decision of whether the IST Peer needs to forward traffic received over the IST to SMLT receivers is made in the datapath, which has full knowledge of the remote SMLT link state.
- Traffic can use the IST to route between VLANs if the forwarding decision for the multicast protocol requires that the other side of the core forwards the multicast traffic (follow the IP multicast routing and forwarding rules for routed traffic). Other VLANs that are not part of SMLT continue to behave in the same way.
- To create a temporary default route pointing to a peer IST, you must enable PIM on the IST VLAN.
- In a scaled multicast environment, if you must reconfigure the members of an MLT link, either SMLT or IST, by removing the ports from the MLT membership list, you must first shutdown the port by using the **shutdown** command at the port configuration level. Let the unicast and multicast traffic subside, and then remove the port from the MLT membership list. If you reconfigure the MLT without first shutting down the port, it can lead to excessive hardware updates to multicast forwarding records and can result in high utilization of the CPU.

Note

In a scaled PIM over Simplified vIST deployment, disabling all the PIM interfaces (**no ip routing**) causes the VLACP ports to bounce. With no user intervention, the packets start getting processed again in approximately 10 seconds. VLACP enables the ports and full functionality is restored.

SMLT provides for fast failover in all cases, but does not provide a functionality similar to Routed SMLT (RSMLT).

Important

You must enable square SMLT globally before you configure square or full-mesh configurations.

Traffic delay with PIM while restarting peer SMLT switches

If you restart peer SMLT switches, you can lose, or experience a delay in, PIM traffic. The local and remote SMLT links must be up to forward traffic. If a remote SMLT link is down, you can experience a traffic delay.

PIM uses a DR to forward data to receivers on a VLAN. If you restart the DR in an SMLT VLAN, you can lose data because of the following actions:

- If the DR is down, the non-DR switch assumes the role and starts forwarding data.
- After the DR comes back up, it takes priority (higher IP address) to forward data so the non-DR switch stops forwarding data.
- The DR is not ready to forward traffic due to protocol convergence and because it takes time to learn the RP set and create the forwarding path. This situation can result in a traffic delay of 2 to 3 minutes because the DR learns the RP set after Open Shortest Path First (OSPF) converges.

A workaround to this delay is to a configure the static RP router on the peer SMLT switches. This feature avoids the process of selecting an active RP router from the list of candidate RPs and dynamically learning about RPs through the BSR mechanism. After the DR comes back up, traffic resumes as soon as OSPF converges. This workaround reduces the traffic delay to approximately 15 to 65 seconds.

Protocol Independent Multicast-Source Specific Multicast

Table 97: Protocol Independent Multicast-Source Specific Mode product support

Feature	Product	Release introduced
PIM-Source Specific Mode (PIM-SSM) for IPv4	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Note
PIM is supported in Global Routing Table (GRT) only.

Source Specific Multicast optimizes PIM-SM by simplifying the many-to-many model. Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model that uses only a subset of the PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

SSM only builds source-based SPTs. Whereas PIM-SM always joins a shared tree first, and then switches to the source tree, SSM eliminates the need to start with a shared tree by immediately joining a source through the SPT. SSM avoids using an RP and RP-based shared trees, which can be a potential problem.

Until now only one channel for one group was allowed to exist in ssm map. From now on multiple channels for the members of the SSM group are allowed to be configured in this map.

This configuration is ideal for applications like television channel distribution and other content-distribution businesses. Banking and trade applications can also use SSM as it provides more control over the hosts receiving and sending data over their networks.

When a v2 report in SSM range is received it is translated to an igmpv3 report message with one group record with type ALLOW and the source lists copied from the igmp ssm map static entries and passed to igmpv3 module. When a v2 leave in SSM range is received it is translated to an igmpv3 report message with one group record with type BLOCK and the source lists copied from the igmp ssm map static entries and passed to igmpv3 module. This behaviour is displayed only when PIM-SSM mode is enabled.

SSM applications use IP addresses reserved by the Internet Assigned Numbers Authority (IANA) in the 232/8 range (232.0.0.0 to 232.255.255.255). SSM recognizes packets in this range and controls the behavior of multicast routing devices and hosts that use these addresses. When a source (S) transmits IP datagrams to an SSM destination address (G), a receiver can receive these datagrams by subscribing to the (S,G) channel.

A channel is a source-group (S,G) pair where S is the source that sends to the multicast group and G is an SSM group address. SSM defines channels on an individual or multiple source basis, which enforces the one-to-many concept of SSM applications. In an SSM channel, each group is associated with multiple sources.

SSM features

PIM-SM requires a unicast protocol to forward multicast traffic within the network to perform the Reverse Path Forwarding (RPF) check. PIM-SM uses the information from the unicast routing table to create and maintain the shared and shortest multicast tree that PIM-enabled routers use to communicate. The unicast routing table must contain a route to every multicast source in the network as well as routes to PIM entities like the RPs and BSR.

SSM uses only a subset of the PIM-SM features such as the SPT, DR, and some messages (hello, join, prune, and assert). However, some features are unique to SSM. These features, described in the following sections, are extensions of the IGMP and PIM protocols.

PIM-SSM architecture

The following diagram illustrates how the PIM-SSM architecture requires routers to perform the following actions:

- support IGMPv3 source-specific host membership reports and queries at the edge routers
- initiate PIM-SSM (S,G) joins directly and immediately after receiving an IGMPv3 join report from the designated router
- restrict forwarding to SPTs within the SSM address range by all PIM-SSM routers

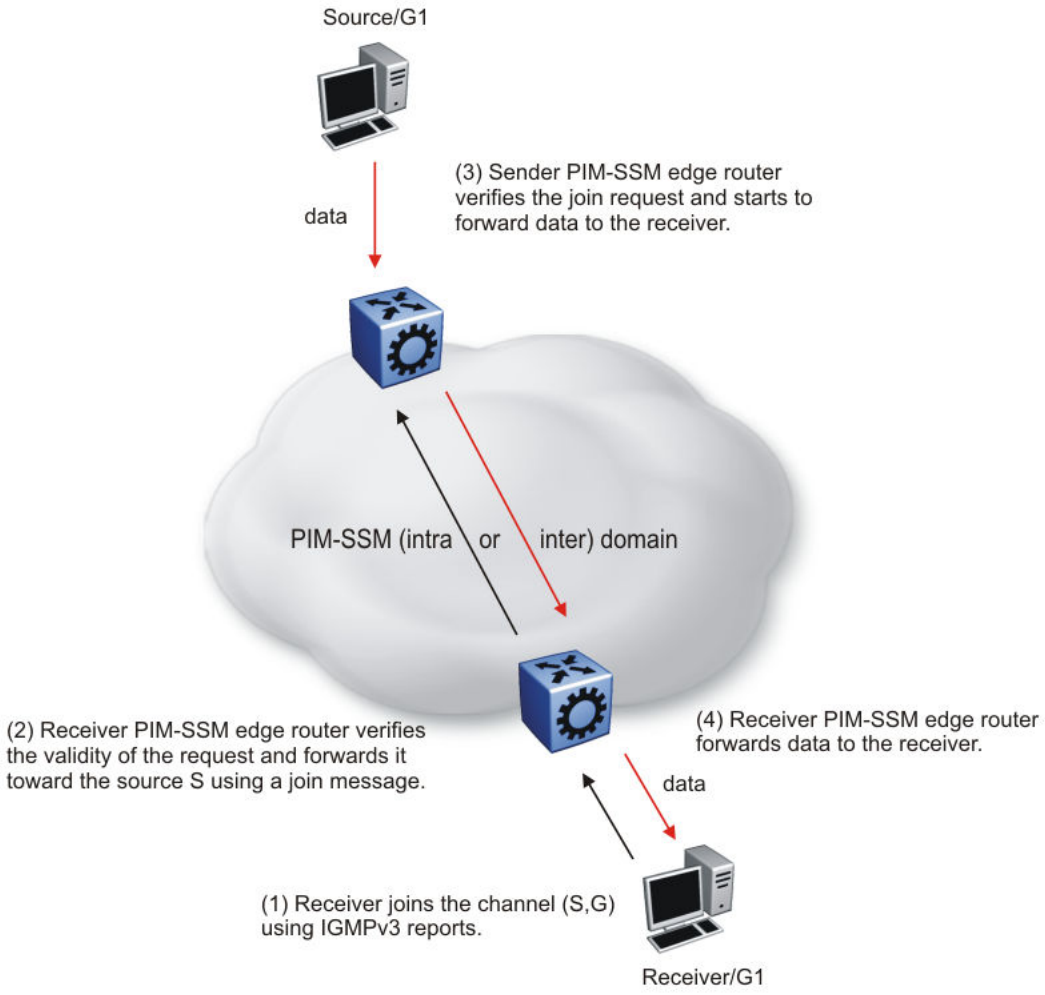

Figure 125: PIM-SSM architecture

The following rules apply to Layer 3 devices with SSM enabled:

- Receive IGMPv3 membership join reports in the SSM range and, if no entry (S,G) exists in the SSM channel table, create one.
- Receive IGMPv2 membership join reports, but only for groups that already use a static (S,G) entry in the SSM channel table.
- Send periodic join messages to maintain a steady SSM tree state.
- Use standard PIM-SM SPT procedures for unicast routing changes, but ignore rules associated with the SPT for the (S,G) route entry.
- Receive prune messages and use standard PIM-SM procedures to remove interfaces from the source tree.
- Forward data packets to interfaces from the downstream neighbors that sent an SSM join, or to interfaces with locally attached SSM group members.
- Drop data packets that do not use an exact-match lookup (S,G) in their forwarding database for S and G.

PIM-SSM Static Source Groups

You can configure static source group entries in the PIM-SSM multicast routing table with static source groups. PIM-SSM cannot prune these entries from the distribution tree. For more information about static source groups, see Static source groups on page 1236.

Implementation of SSM and IGMP

The following sections describe how the switch implements PIM-SSM and IGMP.

SSM range

The standard SSM range is 232/8, but you can extend the range to include an IP multicast address. Although you can configure the SSM range, you cannot configure it for all multicast groups (224/4 or 224.0.0.0/240.0.0.0 or 224.0.0.0/255.0.0.0).

You can extend the SSM range to configure existing applications without changing their group configurations.

SSM channel table

You can use the SSM channel to manually configure (S,G) entries that map existing groups to their sending source. These table entries apply to the whole switch, not for each interface, and both IGMPv2 and IGMPv3 hosts use the SSM channel table.

The following rule applies to an SSM channel table for an individual switch:

- You can map one source to multiple groups.
- You can allow multiple sources to the same group.

Important

Different switches can use different mappings for groups to sources, for example, different channels map differently even if they are on the same network.

SSM and IGMPv2

SSM-configured switches can accept reports from IGMPv2 hosts on IGMPv2 interfaces if the group uses an SSM channel table entry. However, the IGMPv2 host groups must exist in the SSM range defined on the switch, which is 232/8 by default.

- After the SSM switch receives an IGMPv2 report for a group that is in the SSM channel table, it joins the specified source immediately.
- After the SSM switch receives an IGMPv2 report for a group that uses an enabled static SSM channel table entry, it triggers PIM-SSM processing as if it received an equivalent IGMPv3 report.
- After the SSM switch receives an IGMPv2 report for a group out of the SSM range, it processes the report as if it is in PIM-SM mode.

Deleting or Disabling an ssm-map with IGMPv1 or IGMPv2

Before you disable or delete an ssm-map, always send IGMPv1 or IGMPv2 leave messages from hosts that operate using IGMPv1 or IGMPv2. If you do not perform this action, receiving and processing reports in SSM range on an IGMP interface enabled with IGMPv1 or IGMPv2 can lead to unexpected behavior.

Consider the following configuration scenario:

- A device is PIM-enabled, running in SSM mode, with IGMPv1 or IGMPv2 configured on the interface.
- IGMPv1 and IGMPv2 hosts send IGMPv1 or IGMPv2 reports for groups in SSM range.

The following table identifies the expected behaviors in this scenario.

Table 98: Expected behaviors for ssm-map configuration

Action	Expected behavior
You do not configure an ssm-map for the group in SSM range.	IGMPv1 and IGMPv2 reports are not processed.
You do configure an ssm-map for the group in SSM range.	IGMPv1 and IGMPv2 reports are processed and the group in SSM range is learned.

SSM and IGMPv3

The switch supports IGMPv3 for SSM. With IGMPv3, a host can selectively request or filter traffic from sources within the multicast group. IGMPv3 is an interface-level configuration.

Important

IGMPv3 works without PIM-SSM or SSM-snoop enabled on the interface.

The following rules apply to IGMPv3-enabled interfaces:

- Send only IGMPv3 (source-specific) reports for addresses in the SSM range.
- Accept IGMPv3 reports.
- Drop IGMPv2 reports.

  The IGMPv2 report mentioned in SSM and IGMPv2 on page 1264 is processed because it is an IGMPv2 report received on an IGMPv2 interface. If an IGMPv2 interface receives an IGMPv3 report, it drops the report even if PIM-SSM is enabled and the entry is in the SSM channel table. The IGMP versions must match.
- Discard IGMP packets with a group address out of the SSM range.

The switch implements IGMPv3 in one of two modes: dynamic and static.

In dynamic mode, the switch learns about new (S,G) pairs from IGMPv3 reports and adds them to the SSM channel table. If you do not enable dynamic mode and an IGMPv3-enabled interface receives a report that includes a group not listed in the SSM channel table, it ignores the report.

In static mode, you can statically configure (S,G) entries in the SSM channel table. If an IGMPv3-enabled interface receives a report that includes a group not listed in the SSM channel table, it ignores the report. The interface also ignores the report if the group is in the table, but the source or mask does not match what is in the table.

Important

After you enable IGMPv3, changes to the query interval and robustness values on the querier switch propagate to other switches on the same VLAN through IGMP query.

Both IGMPv2 and IGMPv3 hosts use the SSM channel table:

- An IGMPv2 host (with an IGMPv2 VLAN) must use an existing SSM channel entry if the group is in the SSM range.
- If you enable dynamic learning for an IGMPv3 host, the SSM channel automatically learns the group. Otherwise, the SSM channel also needs a static entry.

The following table summarizes how a switch in PIM-SSM mode works with IGMP if you disable IGMPv3 compatibility. In the following table, references to matching a static SSM channel entry assumes that the entry is enabled. If an entry is disabled, it is treated as though it is disallowed.

Table 99: PIM-SSM interaction with IGMPv2 and v3 with IGMPv3 compatibility disabled

Host	VLAN	SSM range	Action
IGMPv2 host	IGMPv3 VLAN	In or out of range	Drop report.
IGMPv3 host	IGMPv2 VLAN	In or out of range	Drop report.
IGMPv2 host	IGMPv2 VLAN	In range	If the report matches an existing static SSM channel entry, create (S,G). If the report does not match an existing static SSM channel entry, drop it.
IGMPv2 host	IGMPv2 VLAN	Out of range	Ignore the SSM channel table and process the report as if it is in PIM-SM mode.
IGMPv3 host	IGMPv3 VLAN	Out of range	Process the report.
IGMPv3 host	IGMPv3 VLAN	In range	Dynamic enabled. Create (S,G).
IGMPv3 host	IGMPv3 VLAN	In range	Dynamic disabled and matches an existing SSM channel entry. Create (S,G).
IGMPv3 host	IGMPv3 VLAN	In range	Dynamic disabled and does not match an existing SSM channel entry. Drop report.

The following table summarizes how a switch in PIM-SSM mode works with IGMP if you enable IGMPv3 compatibility.

Table 100: PIM-SSM interaction with IGMPv2 and v3 with IGMPv3 compatibility enabled

Host	VLAN	SSM range	Action
IGMPv2 Host	IGMPv3 VLAN	In range	If the report matches an existing static SSM channel entry, create (S,G). If the report does not match an existing static SSM channel entry, drop it.
IGMPv2 Host	IGMPv3 VLAN	Out of range	Process the report as in PIM-SM mode.

If an IGMPv3 group report enters the VLAN port and the port must discard one or more of the groups in that packet after the application of IGMP access controls, the port drops the entire packet and does not forward it on to other ports of the VLAN.

If an IGMPv3 interface receives an IGMPv2 or v1 query, the interface backs down to IGMPv2 or v1. As a result, the interface flushes all senders and receivers on the interface.

Configuration limitations

Run PIM-SSM on either all switches in the domain or only on the edge routers. If you use a mix of PIM-SSM and PIM-SM switches in the domain, run PIM-SSM on all the edge routers and run PIM-SM on all the core routers.

Important

A PIM domain with edge routers running PIM-SM and core routers running PIM-SSM does not operate properly. If you prefer or require a mixed PIM-SM and PIM-SSM topology, run PIM-SSM on the edge switches and PIM-SM in the core. Ensure a valid RP configuration exists for groups that exist outside of the SSM range. If a valid RP configuration exists, the SSM switches process the joins in SM mode. If no RP exists, the SSM switches drop the reports.

Static source groups cannot conflict with SSM channels. If you configure a static source group or an SSM channel, the switch performs a consistency check to make sure no conflicts exist. You can map one group (G) to different sources or multiple groups to a single source for both static source group and an SSM channel.

PIM passive interfaces

You can configure the PIM interface as active or passive. The default is active. With an active interface, you can configure transmit and receive PIM control traffic. A passive interface drops all PIM control traffic, thereby reducing the load on the system. This feature is useful when you use a high number of PIM interfaces and these interfaces connect to end users, not to other switches.

A PIM passive interface does not transmit and drops messages of the following type:

- hello
- join
- prune
- register
- register-stop
- assert
- candidate-RP-advertisement
- bootstrap

If a PIM passive interface receives these types of messages, it drops them and the switch logs a message, detailing the type of protocol message and the IP address of the sending device. These log

messages help to identify the device that performs routing on the interface, which is useful if you must disable a device that does not operate correctly.

Important

A device can send register and register-stop messages to a PIM passive interface, but these messages cannot be sent out of that interface.

The PIM passive interface maintains information about hosts, through IGMP, that are related to senders and receivers, but the interface does not maintain information about PIM neighbors. You can configure a BSR or an RP on a PIM passive interface.

You can also use the PIM passive interface feature as a security measure to prevent routing devices from becoming attached and participating in the multicast routing of the network.

Important

Before you change the state (active or passive) of a PIM interface, disable PIM on that interface. This action prevents instability in the PIM operations, especially when neighbors exists or the interface receives streams. After you disable PIM, the switch loses traffic for approximately 80 seconds.

Multicast route statistics

Table 101: Mroute statistics product support

Feature	Product	Release introduced
Multicast route (mroute) statistics for IPv4 and IPv6	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

The multicast route statistics feature provides statistics for multicast streams through the switch. Using the Command Line Interface (CLI), Simple Network Management Protocol (SNMP) or Enterprise Device Manager (EDM), you can track the number of senders sending multicast streams to a particular group address. You can also obtain a count of the packets or bytes being received for a particular multicast group address and the average size of the frames. Multicast route statistics are supported for both IPv4 and IPv6 group addresses.

Determining the route statistics is especially useful when debugging a multicast network and also when administering the network.

Multicast route statistics and DvR

When you enable or clear IP multicast route statistics on the Controller node of a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

For more information on DvR, see Distributed Virtual Routing Fundamentals on page 622.

IP multicast network design

Use multicast routing protocols to efficiently distribute a single data source among multiple users in the network. This section provides information about how to design networks that support IP multicast routing.

For more design guidelines, conceptual, and configuration information about IP Multicast over Fabric Connect, see IP Multicast over Fabric Connect on page 1236.

Multicast scalability design rules

The following section lists the design rules to increase multicast route scaling.

Important

The switch software supports the following:

- Protocol-Independent Multicast (PIM)
- Split MultiLink Trunking (SMLT) and Routed-SMLT (RSMLT)

Multicast scalability design rules

1. Whenever possible, use simple network designs that do not use VLANs that span several switches. Instead, use routed links to connect switches.
2. Whenever possible, group sources sending to the same group in the same subnet. The switch uses a single egress forwarding pointer for all sources in the same subnet sending to the same group. Be aware that these streams have separate hardware forwarding records on the ingress side.
3. Do not configure multicast routing on edge switch interfaces that do not contain multicast senders or receivers. By following this rule, you:
   - Provide secure control over multicast traffic that enters or exits the interface.
   - Reduce the load on the switch, as well as the number of routes. This improves overall performance and scalability.
4. Avoid initializing many (several hundred) multicast streams simultaneously. Initial stream setup is a resource-intensive task, and initializing a large number can increase the setup time. In some cases, this delay can result in stream loss.
5. Whenever possible, do not connect IP multicast sources and receivers by using VLANs that interconnect switches (see the following figure). In some cases, this can result in excessive hardware record use. By placing the source on the interconnected VLAN, traffic takes two paths to the destination, depending on the reverse path forwarding (RPF) checks and the shortest path to the source.

   For example, if a receiver is on VLAN 1 on switch S1 and another receiver is on VLAN 2 on switch S1, traffic can be received from two different paths to the two receivers, which results in the use of two forwarding records. If the source on switch S2 is on a different VLAN than VLAN 3, traffic takes a single path to switch S1 where the receivers are located.

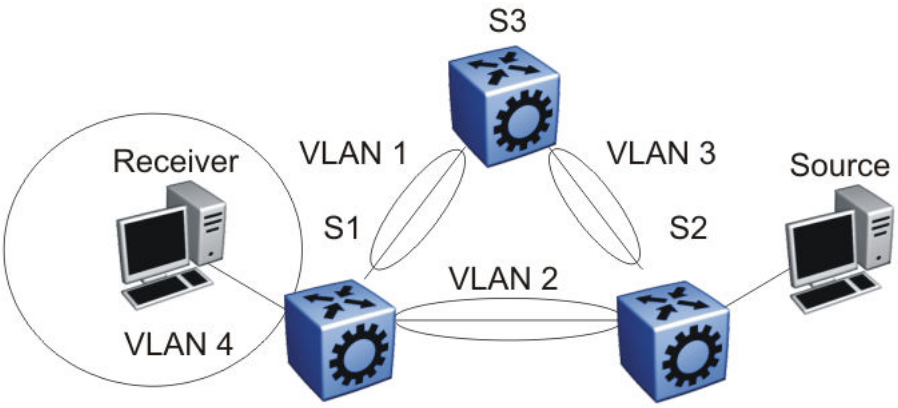

Figure 126: IP multicast sources and receivers on interconnected VLANs

IP multicast address range restrictions

IP multicast routers use D class addresses, which range from 224.0.0.0 to 239.255.255.255. Although you can use subnet masks to configure IP multicast address ranges, the concept of subnets does not exist for multicast group addresses. Consequently, the usual unicast conventions—where you reserve the all 0s subnets, all 1s subnets, all 0s host addresses, and all 1s host addresses—do not apply.

Internet Assigned Numbers Authority (IANA) reserves addresses from 224.0.0.0 through 224.0.0.255 for link-local network applications. Multicast-capable routers do not forward packets with an address in this range. For example, Open Shortest Path First (OSPF) uses 224.0.0.5 and 224.0.0.6, and Virtual Router Redundancy Protocol (VRRP) uses 224.0.0.18 to communicate across local broadcast network segments.

IANA also reserves the range of 224.0.1.0 through 224.0.1.255 for well-known applications. IANA assigns these addresses to specific network applications. For example, the Network Time Protocol (NTP) uses 224.0.1.1, and Mtrace uses 224.0.1.32. RFC1700 contains a complete list of these reserved addresses.

Multicast addresses in the 232.0.0.0/8 (232.0.0.0 to 232.255.255.255) range are reserved only for source-specific multicast (SSM) applications, such as one-to-many applications. While this range is the publicly reserved range for SSM applications, private networks can use other address ranges for SSM.

Finally, addresses in the range 239.0.0.0/8 (239.0.0.0 to 239.255.255.255) are administratively scoped addresses; they are reserved for use in private domains. Do not advertise these addresses outside the private domain. This multicast range is analogous to the 10.0.0.0/8, 172.16.0.0/20, and 192.168.0.0/16 private address ranges in the unicast IP space.

In a private network, only assign multicast addresses from 224.0.2.0 through 238.255.255.255 to applications that are publicly accessible on the Internet. Assign addresses in the 239.0.0.0/8 range to multicast applications that are not publicly accessible.

Although you can use a multicast address you choose on your own private network, it is generally not good design practice to allocate public addresses to private network entities. Do not use public addresses for unicast host or multicast group addresses on private networks.

Multicast MAC Address Mapping Considerations

Like IP, Ethernet has a range of multicast MAC addresses that natively support Layer 2 multicast capabilities. While IP has a total of 28 addressing bits available for multicast addresses, Ethernet has only 23 addressing bits assigned to IP multicast. The Ethernet multicast MAC address space is much larger than 23 bits, but only a subrange of that larger space is allocated to IP multicast. Because of this difference, 32 IP multicast addresses map to one Ethernet multicast MAC address.

IP multicast addresses map to Ethernet multicast MAC addresses by placing the low-order 23 bits of the IP address into the low-order 23 bits of the Ethernet multicast address 01:00:5E:00:00:00. Thus, more than one multicast address maps to the same Ethernet address (see the following figure). For example, all 32 addresses 224.1.1.1, 224.129.1.1, 225.1.1.1, 225.129.1.1, 239.1.1.1, 239.129.1.1 map to the same 01:00:5E:01:01:01 multicast MAC address.

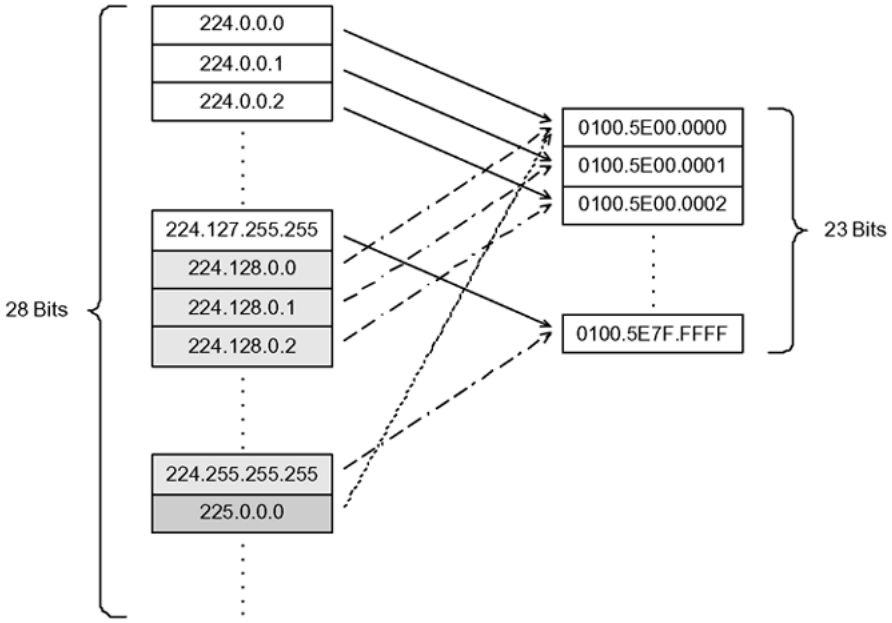

Figure 127: Multicast IP address to MAC address mapping

Most Ethernet switches handle Ethernet multicast by mapping a multicast MAC address to multiple switch ports in the MAC address table. Therefore, when you design the group addresses for multicast applications, take care to efficiently distribute streams only to hosts that are receivers.

As an example, consider two active multicast streams using addresses 239.1.1.1 and 239.129.1.1. Suppose that two Ethernet hosts, receiver A and receiver B, connect to ports on the same switch and only want the stream addressed to 239.1.1.1. Suppose also that two other Ethernet hosts, receiver C and receiver D, also connect to the ports on the same switch as receiver A and B, and want to receive the stream addressed to 239.129.1.1. If the switch uses the Ethernet multicast MAC address to make forwarding decisions, then all four receivers receive both streams—even though each host only wants one stream. This transmission increases the load on both the hosts and the switch. To avoid this extra load, ensure that you manage the IP multicast group addresses used on the network.

When an IP multicast packet is received, the lookup is based on the IP group address, regardless of whether the VLAN is bridged or routed. This problem is particularly true of pure Layer 2 switches.

In a network that includes multiple hardware platforms, the easiest way to ensure that this issue does not arise is to use only a consecutive range of IP multicast addresses that correspond to the lower-order

23 bits of that range. For example, use an address range from 239.0.0.0 through 239.127.255.255. A group address range of this size can still easily accommodate the needs of even the largest private enterprise.

Dynamic multicast configuration changes

You must not perform dynamic multicast configuration changes when multicast streams flow in a network. For example, do not change the routing protocol that runs on an interface, or the IP address, or the subnet mask for an interface until multicast traffic ceases.

For such changes, ensure that you temporarily stop all multicast traffic. If the changes are necessary and you have no control over the applications that send multicast data, you can disable the multicast routing protocols before you perform the change. For example, consider disabling multicast routing before making interface address changes. In all cases, these changes result in traffic interruptions because they affect neighbor-state machines and stream-state machines.

In addition, when removing port members of an MLT group you must first disable the ports. Changing the group set without first shutting the ports down can result in high-CPU utilization and processing in a scaled multicast environment due to the necessary hardware reprogramming on the multicast records.

IGMPv3 backward compatibility

IGMPv3 for PIM is backward compatible with IGMPv1/v2. According to RFC3376, the multicast router with IGMPv3 can use one of two methods to handle older query messages:

- If an older version of IGMP is present on the router, the querier must use the lowest version of IGMP present on the network.
- If a router that is not explicitly configured to use IGMPv1 or IGMPv2, detects an IGMPv1 query or IGMPv2 general query, it logs a rate-limited warning.

You can configure the IGMP version of an interface to version 3 regardless of the PIM or snooping mode.

You can configure whether the switch downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning.

Note

If you enable the explicit host tracking option on an IGMPv3 interface, you cannot downgrade to IGMPv1 or IGMPv2. You must disable explicit host tracking to downgrade the IGMP version.

TTL in IP multicast packets

The switch treats multicast data packets with a time-to-live (TTL) of 1 as expired packets and sends them to the CPU before dropping them. To avoid this issue, ensure that the originating application uses a hop count large enough to enable the multicast stream to traverse the network and reach all destinations without reaching a TTL of 1. Ensure that you use a TTL value of 33 or 34 to minimize the effect of looping in an unstable network.

Multicast MAC filtering

Certain network applications require multiple hosts to share a multicast MAC address. Instead of flooding all ports in the VLAN with this multicast traffic, you can use Multicast MAC filtering to forward

traffic to a configured subset of the ports in the VLAN. This multicast MAC address is not an IP multicast MAC address.

At a minimum, map the multicast MAC address to a set of ports within the VLAN. In addition, if traffic is routed on the local host, you must configure an Address Resolution Protocol (ARP) entry to map the shared unicast IP address to the shared multicast MAC address. You must configure an ARP entry because the hosts can also share a virtual IP address, and packets addressed to the virtual IP address need to reach each host.

Ensure that you limit the number of such configured multicast MAC addresses to a maximum of 100. This number is related to the maximum number of possible VLANs you can configure, because for every multicast MAC filter that you configure the maximum number of configurable VLANs reduces by one. Similarly, configuring large numbers of VLANs reduces the maximum number of configurable multicast MAC filters downward from 100.

Although you can configure addresses starting with 01.00.5E, which are reserved for IP multicast address mapping, do not enable IP multicast with streams that match the configured addresses. This configuration can result in incorrect IP multicast forwarding and incorrect multicast MAC filtering.

Guidelines for multicast access policies

Use the following guidelines when you configure multicast access policies:

- Use masks to specify a range of hosts. For example, 10.177.10.8 with a mask of 255.255.255.248 matches hosts addresses 10.177.10.8 through 10.177.10.15. The host subnet address and the host mask must be equal to the host subnet address. An easy way to determine this is to ensure that the mask has an equal or fewer number of trailing zeros than the host subnet address. For example, 3.3.0.0/255.255.0.0 and 3.3.0.0/255.255.255.0 are valid. However, 3.3.0.0/255.0.0.0 is not.
- Apply receive-access policies to all eligible receivers on a segment. Otherwise, one host joining a group makes that multicast stream available to all.
- Receive access policies are initiated after the switch receives reports with addresses that match the filter criteria.
- Transmit access policies apply after the switch receives the first packet of a multicast stream.

Multicast access policies can apply to a routed PIM interface if Internet Group Management Protocol (IGMP) reports the reception of multicast traffic.

The following rules and limitations apply to IGMP access policy parameters when you use them with IGMP instead of PIM:

- The static member parameter applies to IGMP snooping and PIM on both interconnected links and edge ports.
- The Static Not Allowed to Join parameter applies to IGMP snooping and PIM on both interconnected links and edge ports.
- For multicast access control, the denyRx parameter applies to IGMP snooping and PIM. The DenyTx and DenyBoth parameters apply only to IGMP snooping.

Split-subnet and multicast

The split-subnet issue arises when you divide a subnet into two unconnected sections in a network. This division results in the production of erroneous routing information about how to reach the hosts on that

subnet. The split-subnet problem applies to all types of traffic, but it has a larger impact on a PIM-SM network.

To avoid the split-subnet problem in PIM networks, ensure that the RP router is not in a subnet that can become a split subnet. Also, avoid having receivers on this subnet. Because the RP is an entity that must be reached by all PIM-enabled switches with receivers in a network, placing the RP on a split-subnet can impact the whole multicast traffic flow. Traffic can be affected even for receivers and senders that are not part of the split-subnet.

Protocol Independent Multicast-Sparse Mode guidelines

Protocol Independent Multicast-Sparse Mode (PIM-SM) uses an underlying unicast routing information base to perform multicast routing. PIM-SM builds unidirectional shared trees rooted at a RP router for each group and can also create shortest-path trees for each source.

PIM-SM and PIM-SSM Scalability

For more information on interface scaling, see the *Fabric Engine Release Notes*.

The software does not support virtualized PIM. PIM is supported in the Global Routing Table only.

Interfaces that run PIM must also use a unicast routing protocol (PIM uses the unicast routing table), which puts stringent requirements on the system. With a high number of interfaces, take special care to reduce the load on the system.

Use few active IP routed interfaces. You can use IP forwarding without a routing protocol enabled on the interfaces, and enable only one or two with a routing protocol. You can configure proper routing by using IP routing policies to announce and accept routes on the switch. Use PIM passive interfaces on the majority of interfaces.

Important

For information on the maximum values for total PIM interfaces and active interfaces, see the *Fabric Engine Release Notes*. If you configure the maximum number of active interfaces, all remaining interfaces must be passive.

When you use PIM-SM, the number of routes can scale up to the unicast route limit because PIM uses the unicast routing table to make forwarding decisions. For higher route scaling, use OSPF instead of Routing Information Protocol (RIP).

As a general rule, a well-designed network does not have many routes in the routing table. For PIM to work properly, ensure that all subnets configured with PIM are reachable and that PIM uses the information in the unicast routing table. For the RPF check, to correctly reach the source of any multicast traffic, PIM requires the unicast routing table.

PIM General Requirements

Design simple PIM networks where VLANs do not span several switches.

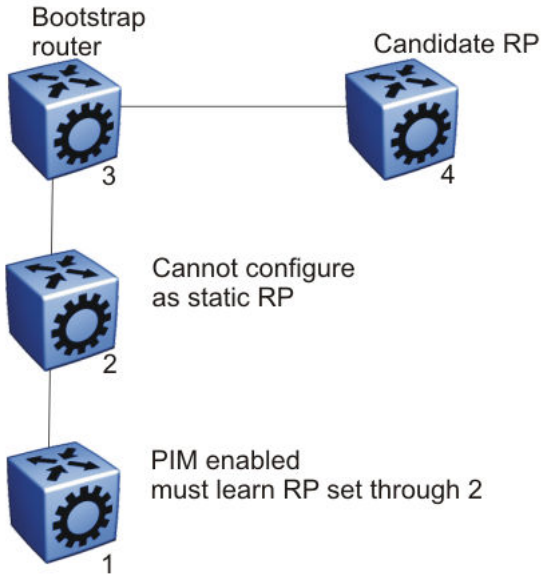
PIM relies on unicast routing protocols to perform its multicast forwarding. As a result, include in your PIM network design, a unicast design where the unicast routing table has a route to every source and receiver of multicast traffic, as well as a route to the RP router and Bootstrap router (BSR) in the network. Ensure that the path between a sender and receiver contains PIM-enabled interfaces. Receiver subnets are not always required in the routing table.

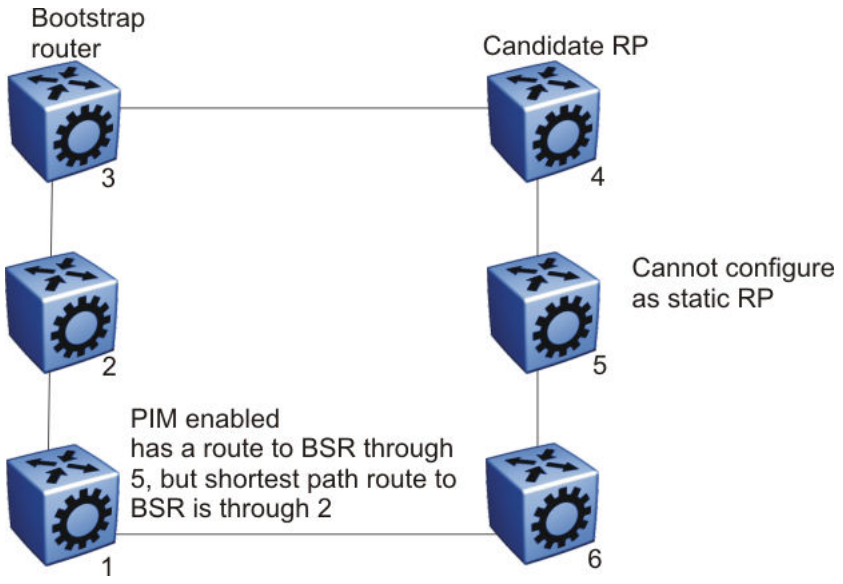
Use the following guidelines:

- Ensure that every PIM-SM domain is configured with an RP, either by static definition or via BSR.
- Ensure that every group address used in multicast applications has an RP in the network.
- As a redundancy option, you can configure several RPs for the same group in a PIM domain.
- As a load sharing option, you can have several RPs in a PIM-SM domain map to different groups.
- In order to configure an RP to cover the entire multicast range, configure an RP to use the IP address of 224.0.0.0 and the mask of 240.0.0.0.
- Configure an RP to handle a range of multicast groups by using the mask parameter. For example, an entry for group value of 224.1.1.0 with a mask of 255.255.255.192 covers groups 224.1.1.0 to 224.1.1.63.
- In a PIM domain with both static and dynamic RP switches, you cannot configure one of the (local) interfaces for the static RP switches as the RP. For example, in the following scenario:

  (static RP switch) Sw1 ------ Sw2 (BSR/Cand-RP1) -----Sw3

  You cannot configure one of the interfaces on switch Sw1 as static RP because the BSR cannot learn this information and propagate it to Sw2 and Sw3. PIM requires that you consistently configure RP on all the routers of the PIM domain, so you can only add the remote interface Candidate-RP1 (Cand-RP) to the static RP table on Sw1.
- If a switch needs to learn an RP-set, and has a unicast route to reach the BSR through this switch, you cannot enable or configure static RP on a switch in a mixed mode of candidate RP and static RP switches. For examples, see the following two figures.





PIM and Shared Tree to Shortest Path Tree Switchover

When an IGMP receiver joins a multicast group, PIM on the leaf router first joins the shared tree. After the first packet is received on the shared tree, the router uses the source address information in the packet to immediately switch over to the shortest path tree (SPT). If you enable PIM Infinite Threshold Policy for IPv4 and IPv6, multicast traffic follows the shared tree path through a Rendezvous Point (RP) instead of switching immediately over to the SPT.

PIM Traffic Delay and SMLT Peer Reboot

PIM uses a designated router (DR) to forward data to receivers on the DR VLAN. The DR is the router with the highest IP address on a LAN. If this router is down, the router with the next highest IP address becomes the DR. However, if the VLAN is an SMLT VLAN, the DR is not a factor in determining which switch forwards the data down to the receiver. Either aggregate switch can forward data to the receiver, because the switches act as one. The switch that forwards depends on where the source is located (on another SMLT/vIST link or on a non-SMLT/non-vIST link) and whether either side of the receiver SMLT link is up or down. If the forwarder switch is rebooted, traffic loss occurs until protocol convergence is completed.

Consider the following cases:

- If the source is on an SMLT link that is not the receiver SMLT, the switch that directly received the data on its side of the source SMLT link forwards it down to the receiver on the receiver SMLT regardless of which switch is the DR for the receiver VLAN. The forwarding switch sends a copy of the data over the vIST link to the peer switch, which drops the data because it knows that the remote SMLT is up and therefore the remote peer has already forwarded the data. If the forwarding switch goes down, the other switch receives the data directly over its source SMLT link and takes over forwarding to the receivers. After the original switch comes back up, the original switch again receives the data directly over its source SMLT. The original switch may not be ready to forward the data because of the protocol reconvergence, so the original switch loses traffic until reconvergence is complete.
- If the source is not learned on another SMLT link or the vIST link on each aggregate switch; they have a route to the source which is not on an SMLT or across the vIST. The switches must choose which one forwards the data down the receiver SMLT link; which one is the designated forwarder, so that

duplicate data does not occur. The highest IP address is the designated forwarder. If the designated forwarder becomes disabled, the other takes over. When it is reenabled, the other switch sees that it is no longer the highest IP address and it sees that the remote SMLT link comes up. The other switch then assumes that the vIST peer is capable of being the designated forwarder and it stops forwarding down to the receivers. If the original switch is not ready to forward the data due to reconvergence, traffic loss occurs.

In either case, configuring a static RP helps the situation. To avoid this traffic delay, a workaround is to configure a static RP on the peer SMLT switches. This configuration avoids the process of selecting an active RP router from the list of candidate RPs, and also of dynamically learning about RPs through the BSR mechanism. Then, when the DR comes back, traffic resumes as soon as OSPF converges. This workaround reduces the traffic delay.

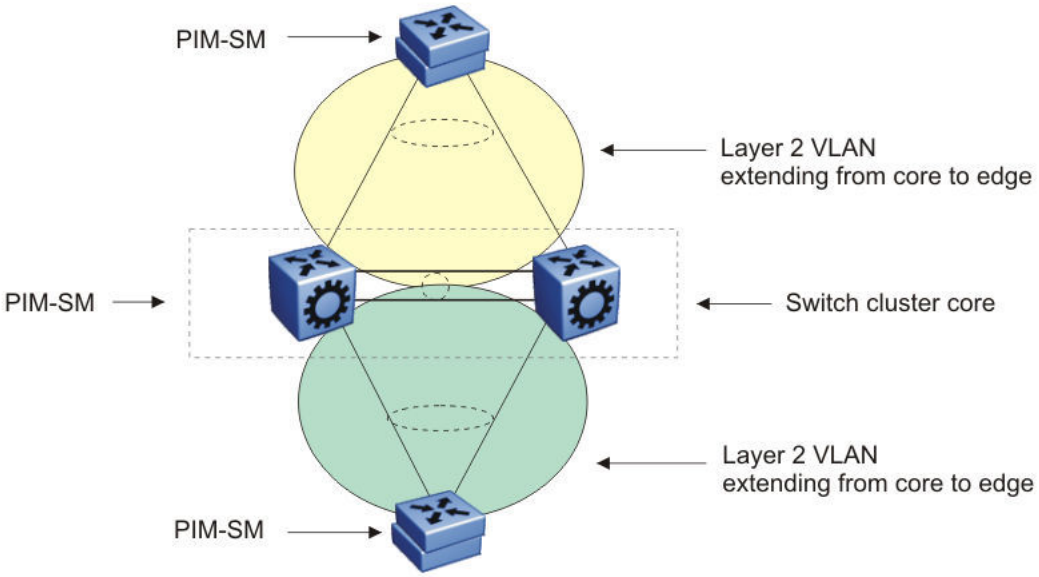
Circuitless IP for PIM-SM

Use CLIP to configure a resilient RP and BSR for a PIM network. When you configure an RP or BSR on a regular interface, if it becomes nonoperational, the RP and BSR also become nonoperational. This status results in the election of other redundant RPs and BSRs, and can disrupt IP multicast traffic flow in the network. As a best practice for multicast networks design, always configure the RP and BSR on a CLIP interface to prevent a single interface failure from causing these entities to fail.

Also, configure redundant RPs and BSRs on different switches such that these entities are on CLIP interfaces. For the successful setup of multicast streams, ensure that a unicast route exists to all CLIP interfaces from all locations in the network. A unicast route is mandatory because, for proper RP learning and stream setup on the shared RP tree, every switch in the network needs to reach the RP and BSR. You can use PIM-SM CLIP interfaces only for RP and BSR configurations, and are not intended for other purposes.

Do not configure non-SMLT IGMP leaf ports on a router to be one of the redundant RP CLIP devices. It is possible that these IGMP hosts can become isolated from the multicast data stream(s).

If you configure dual-redundant RPs (vIST peers with the same CLIP interface IP address used for the RP), the topology in the following figure does not work in link-failure scenarios. Use caution if you design a network with this topology where the vIST peers are PIM enabled, and the source and receiver edges are Layer 2.



Consider an example where one of the peers, vIST-A, is the PIM DR for the source VLAN, and the source data is hashed to vIST-A from the Layer 2 source edge. vIST-A forwards traffic to the receiver edge using the SMLT link from vIST-A to the receiver edge. If the SMLT link fails, vIST-A does not forward traffic over the vIST link to vIST-B, and the receiver edge does receive the data.

In this topology, the receiver edge sends an IGMP membership report for a group, which is recorded on both vIST peers as an IGMP LEAF on the receiver SMLT port on the receiver VLAN.

Because both of the vIST peers are the RP for the group, they do not send a (*,g) PIM JOIN message toward the other RP. The (*,g) PIM mroute does not record the vIST port as a JOIN port on either vIST device. The PIM (*,g) mroute records only a LEAF on the SMLT receiver port.

Because the source is local (Layer 2 edge), there is no PIM (s,g) JOIN message toward the source and the (s,g) PIM mroute does not record the vIST port as a JOIN port on either vIST device. The PIM (s,g) mroute records only a LEAF on the SMLT receiver port.

If the source is hashed to vIST-A, the PIM DR for the incoming VLAN, traffic is forwarded to the receiver correctly. vIST-A does not forward traffic over the vIST to vIST-B, because no JOIN exists on the vIST port. If the receiver SMLT link from the vIST-A peer is down, the traffic is not forwarded to vIST-B, and is not received by the receiver edge. Traffic resumes after the link is restored. If the source data hashes to the non-DR peer, vIST-B, no problem occurs because the non-DR always forwards traffic to the DR.

A similar situation exists in this topology when vIST-A is both the RP and the DR for the Layer 2 receiver edge. The vIST port is not in the outgoing port list because there is no JOIN message from the peer toward the source (which is not PIM enabled). Therefore, if the SMLT link from vIST-A to the receiver edge is down, the system does not forward traffic to the peer vIST-B and down to the receiver.

You can avoid the preceding problems with this topology by performing one of the following actions:

- Enable PIM on the source edge.

  The vIST peers send PIM joins toward the source and the JOIN is recorded on the vIST port for the (s,g). Data is forwarded to the peer.

- Do not configure dual redundant RPs.

  One vIST peer is the RP for a group.
- Do not configure one vIST peer as both the DR for the source VLAN and the RP for the receiver group.

  The system forwards the traffic to the RP or to the DR, depending on which peer receives the source, and, if the SMLT link to the receiver goes down there will be no data loss.

PIM-SM and Static RP

Use static RP to provide security, interoperability, and redundancy for PIM-SM multicast networks. Consider if the administrative ease derived from using dynamic RP assignment is worth the security risks involved. For example, if an unauthorized user connects a PIM-SM router that advertises itself as a candidate RP (C-RP), it can possibly take over new multicast streams that otherwise distribute through an authorized RP. If security is important, use static RP assignment.

You can use the static RP feature in a PIM environment with devices that run legacy PIM-SMv1 and Cisco Auto-RP. For faster convergence, you can also use static RP in a PIM-SMv2 environment. If you configure static RP with PIM-SMv2, the BSR is not active.

Static RP and Auto-RP

Some legacy PIM-SMv1 networks use the auto-RP protocol. Auto-RP is a Cisco proprietary protocol that provides equivalent functionality to the legacy platform supported PIM-SM RP and BSR. You can use the static RP feature to interoperate in this environment. For example, in a mixed-vendor network, you can use auto-RP among routers that support the protocol, while other routers use static RP. In such a network, ensure that the static RP configuration mimics the information that is dynamically distributed to guarantee that multicast traffic is delivered to all parts of the network.

In a mixed auto-RP and static RP network, ensure that the legacy platform does not serve as an RP because it does not support the auto-RP protocol. In this type of network, the RP must support the auto-RP protocol.

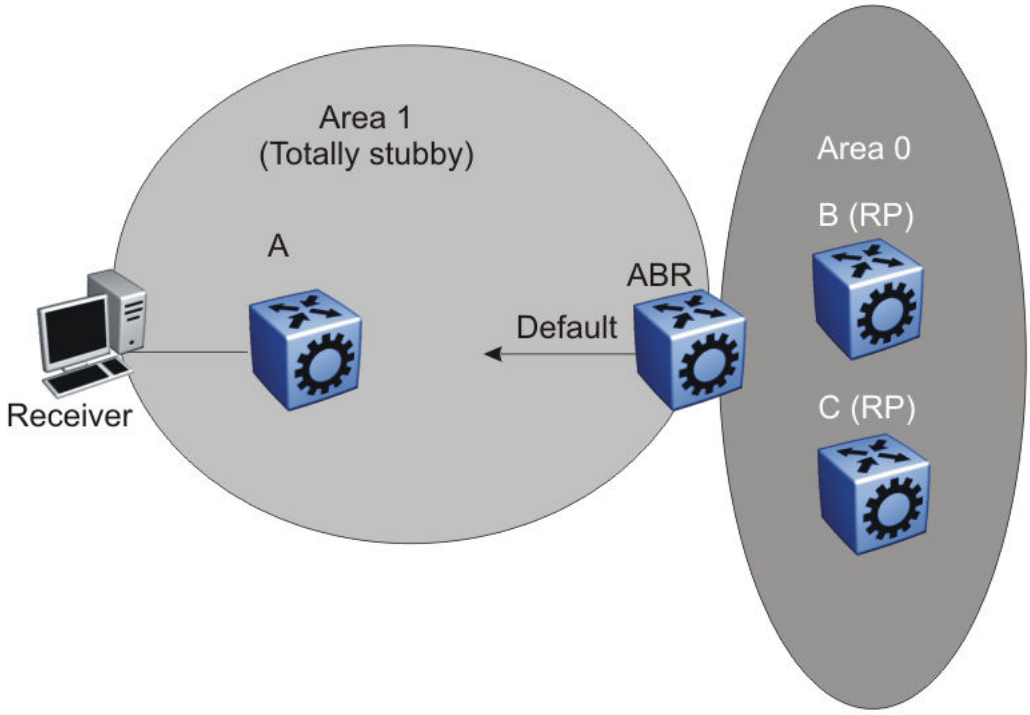
Static RP and RP Redundancy

You can provide RP redundancy through static RPs. To ensure consistency of RP selection, implement the same static RP configuration on all PIM-SM routers in the network. In a mixed vendor network, ensure that the same RP selection criteria is used among all routers. For example, to select the active RP for each group address, the switch uses a hash algorithm defined in the PIM-SMv2 standard. If a router from another vendor selects the active RP based on the lowest IP address, then the inconsistency prevents stream delivery to certain routers in the network.

If a group address-to-RP discrepancy occurs among PIM-SM routers, network outages occur. Routers that are unaware of the true RP cannot join the shared tree and cannot receive the multicast stream.

Failure detection of the active RP is determined by the unicast routing table. As long as the RP is considered reachable from a unicast routing perspective, the local router assumes that the RP is fully functional and attempts to join the shared tree of that RP.

The following figure shows a hierarchical OSPF network where a receiver is in a totally stubby area. If RP B fails, PIM-SM router A does not switch over to RP C because the injected default route in the unicast routing table indicates that RP B is still reachable.

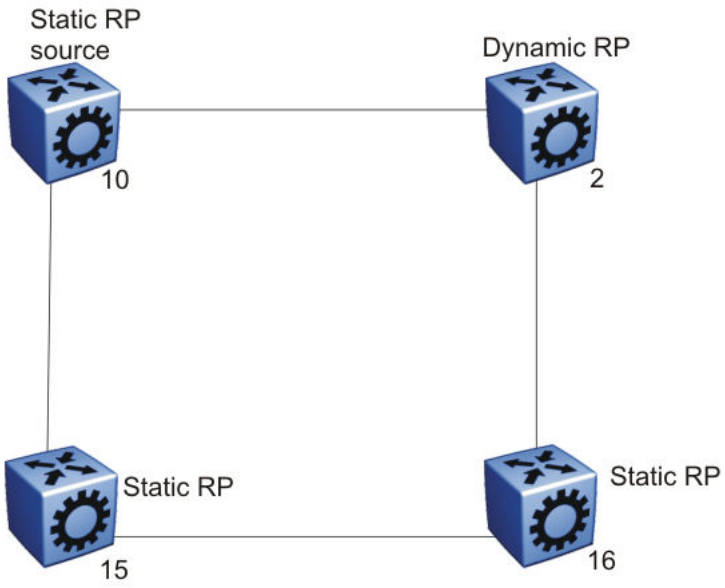


Because failover is determined by unicast routing behavior, carefully consider the unicast routing design, as well as the IP address you select for the RP. Static RP failover performance depends on the convergence time of the unicast routing protocol. For quick convergence, ensure that you use a link state protocol, such as OSPF. For example, if you use RIP as the routing protocol, an RP failure can take minutes to detect. Depending on the application, this situation can be unacceptable.

Static RP failover time does not affect routers that have already switched over to the SPT; failover time only affects newly-joining routers.

Unsupported Static RP Configurations

If you use static RP, you disable dynamic RP learning. The following figure shows an unsupported configuration for static RP. In this example because of inter-operation between static RP and dynamic RP, no RP exists at switch 2. However, (S,G) creation and deletion occurs every 210 seconds at switch 16.



Switches 10, 15, and 16 use static RP, whereas switch 2 uses dynamic RP. The source is at switch 10, and the receivers are switches 15 and 16. The RP is at switch 15 locally. The receiver on switch 16 cannot receive packets because its SPT goes through switch 2.

Switch 2 is in a dynamic RP domain, so it cannot learn about the RP on switch 15. However, (S, G) records are created and deleted on switch 16 every 210 seconds.

Rendezvous Point Router Considerations

You can place an RP on a switch when VLANs extend over several switches. However, when you use PIM-SM, ensure that you do not span VLANs on more than two switches.

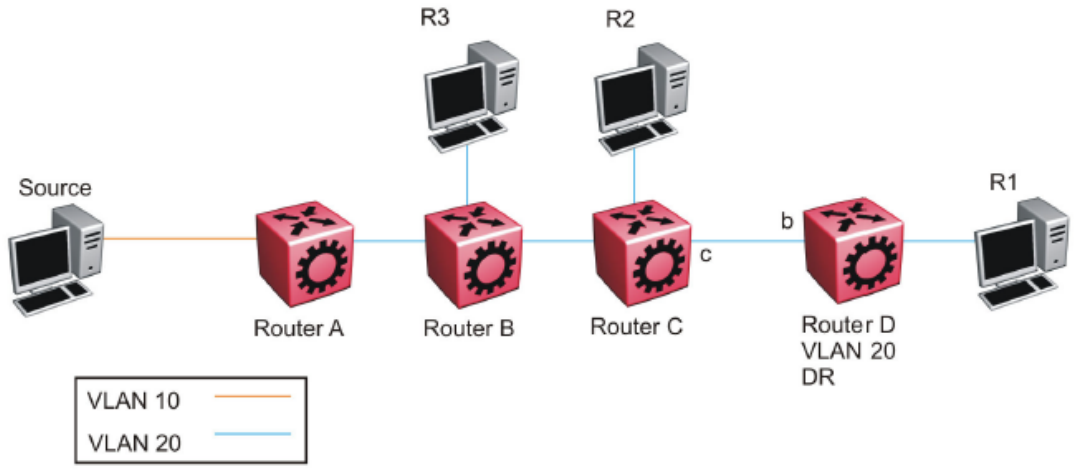
Use static group-range-to-RP mappings in an SMLT topology as opposed to RP set learning using the Bootstrap Router (BSR) mechanism. Static RP allows for faster convergence in box failure and reset, whereas there are inherent delays in the BSR mechanism as follows:

- When a router comes back up after a failover or reset, to accept and propagate (*,g) join requests from surrounding routers (either PIM join messages or local IGMP membership reports) to the RP, a PIM router must determine the address of the RP for each group for which they desire (*,g) state. The PIM router must know the unicast route to the RP address. The route to the RP address is learned by using a unicast routing protocol such as OSPF, and the RP address is either statically configured or dynamically learned using the BSR mechanism.
- When a box comes up after a reset, if the RP is not statically configured, it must wait for the BSR to select the RP from candidate RP routers, and then propagate the RP set hop-by-hop to all PIM routers. This must be done before a join message can be processed. If the PIM router receives a join message before it learns the RP set, it drops the join message, and the router waits for another join or prune message to arrive before it creates the multicast route and propagates the join message to the RP. The default Join/Prune timer is 60 seconds, and because of this and the delays inherent in BSR RP-set learning, significant multicast traffic interruptions can occur. If the RP is statically configured, the only delay is in the unicast routing table convergence and the arrival of the Join/Prune messages from surrounding boxes.

Layer 3 Multicast Extended VLANS

Avoid using a Layer 3 multicast extended VLAN topology without SMLT.

Do not connect non-SMLT PIM routers in a linear fashion on the same VLAN. This topology is called an extended VLAN. Unlike a shared VLAN topology where all routers on the same VLAN are physically one hop away from each other, a VLAN router at one end of the extended VLAN has one or more routers in between it and the router at the far end of the extended VLAN. The following figure shows an extended VLAN.

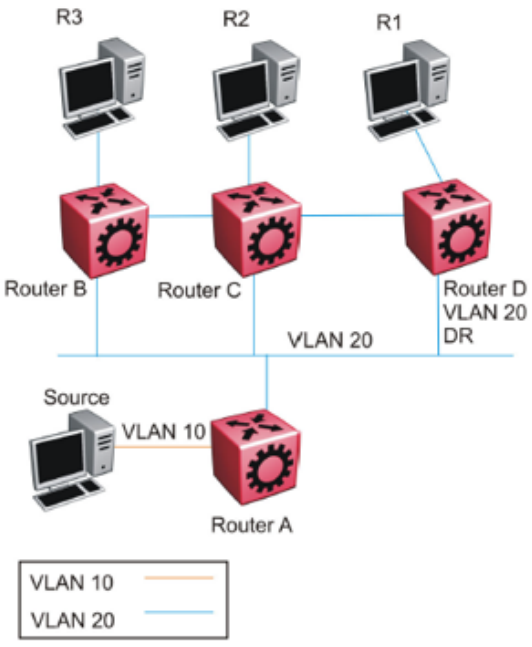


In the preceding figure, all routers use PIM-SSM. The source connects to Router A on VLAN 10. All routers and receiver hosts connect on the same extended VLAN, VLAN 20. All routers have a receiver in VLAN 20. Router D is the PIM DR for VLAN 20 and the source host is not on VLAN 20. PIM-SSM does not require a Rendezvous Point (RP).

In this topology, each router receives an IGMP membership report from its local receiver host, and then sends a PIM SG join message towards the source on VLAN 20. VLAN flooding propagates the PIM SG join message through to Router A, the PIM DR for the source VLAN 10. Each router from Router D to Router A records a PIM join on the port on which the join message was received, and then sends out its own join message toward the source. Data then flows from the source to the receiver, as long as a join exists on those ports.

Because all routers are in the same VLAN 20, they receive joins from one another due to flooding in the VLAN. For example, Router D receives join messages from Router C on its port 'b', and Router C receives join messages from Router B on its port toward Router B. In accordance with the PIM protocol rules, suppression causes Router D to stop sending a join towards the source because it receives a join for the same group and same RP on the port (port b) of the upstream neighbor (the router towards the source). Router D does not need to send a redundant join on the same VLAN. Router D stops sending a join, and the join that is recorded on port c of Router C eventually times out and is removed from the egress list of the (s,g) multicast route entry on Router C. This removal causes Router C to stop forwarding multicast traffic to Router D, and to the receiver (R1).

The purpose of join suppression is to suppress joins on a shared VLAN, such that if all routers on the shared VLAN want to receive data from the same RP and group, then only one of them needs to send the join on the VLAN. One join is enough to pull the data from the source router to the shared VLAN for all routers to receive. The other routers can suppress sending their own joins when they see such a join on the port toward the upstream router. In this way, less protocol message congestion exists in the shared VLAN. In the following figure, Router D sends the initial join message, which is seen by Router B and Router C. Router B and Router C suppress their own join messages. Router A (the PIM DR for the source VLAN 10) sends the data to VLAN 20, which is received by Routers B, C, and D due to the shared (non-extended) VLAN topology, and traffic is forwarded to all receiver hosts.



The extended VLAN topology looks exactly like the non-extended shared VLAN topology to the router, which cannot distinguish between the two.

In the current release, you cannot disable join suppression on a router. This enhancement will be added in a future release. Until this enhancement is included, you can perform the following actions:

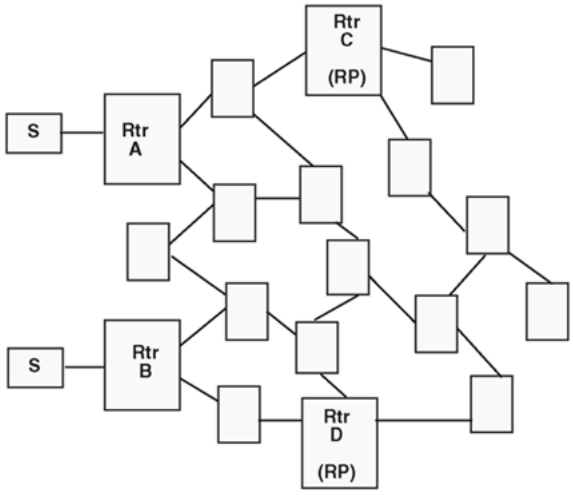
1. Avoid this type of extended VLAN topology, and instead use Layer 3 routing between the routers. Do not extend VLAN 20 throughout, but rather, create a different VLAN between each router.
2. Configure the PIM DR for VLAN 20 to be the router closer to the source (Router B) so that any join received on the VLAN 20 DR (Router B) will be recorded as an IGMP local leaf on VLAN 20 as opposed to a PIM join, which does not time out until the receiver host stops sending IGMP membership reports.

PIM-SM Design and the BSR Hash Algorithm

To optimize the flow of traffic down the shared trees in a network that uses a BSR to dynamically advertise candidate RPs, consider the hash function. The BSR uses the hash function to assign multicast group addresses to each C-RP.

The BSR distributes the hash mask used to compute the RP assignment. For example, if two RPs are candidates for the range 239.0.0.0 through 239.0.0.127, and the hash mask is 255.255.255.252, that range of addresses is divided into groups of four consecutive addresses and assigned to one or the other C-RP.

The following figure illustrates a suboptimal design where Router A sends traffic to a group address assigned to RP D. Router B sends traffic assigned to RP C. RP C and RP D serve as backups for each other for those group addresses. To distribute traffic, it is desirable that traffic from Router A use RP C and that traffic from Router B use RP D.



While still providing redundancy in the case of an RP failure, you can ensure that the optimal shared tree is used by using the following methods.

1. Use the hash algorithm to proactively plan the group-address-to-RP assignment.

   Use this information to select the multicast group address for each multicast sender on the network and to ensure optimal traffic flows. This method is helpful for modeling more complex redundancy and failure scenarios, where each group address has three or more C-RPs.

2. Allow the hash algorithm to assign the blocks of addresses on the network, and then view the results using the command **show ip pim active-rp** .

   Use the command output to assign multicast group addresses to senders that are located near the indicated RP. The limitation to this approach is that while you can easily determine the current RP for a group address, the backup RP is not shown. If more than one backup for a group address exists, the secondary RP is not obvious. In this case, use the hash algorithm to reveal which of the remaining C-RPs take over for a particular group address in the event of primary RP failure.

The hash algorithm works as follows:

1. For each C-RP router with matching group address ranges, a hash value is calculated according to the formula:

   Hash value [G, M, C(i)] = {1 103 515 245 * [(1 103 515245 * (G&M) +12 345) XOR C(i)] + 12 345} mod 2^31

   The hash value is a function of the group address (G), the hash mask (M), and the IP address of the C-RP C(i). The expression (G&M) guarantees that blocks of group addresses hash to the same value for each C-RP, and that the size of the block is determined by the hash mask.

   For example, if the hash mask is 255.255.255.248, the group addresses 239.0.0.0 through 239.0.0.7 yield the same hash value for a given C-RP. Thus, the block of eight addresses are assigned to the same RP.
2. The C-RP with the highest resulting hash value is chosen as the RP for the group. In the event of a tie, the C-RP with the highest IP address is chosen.

   This algorithm runs independently on all PIM-SM routers so that every router has a consistent view of the group-to-RP mappings.

Candidate RP Considerations

The C-RP priority parameter determines an active RP for a group. The hash values for different RPs are only compared for RPs with the highest priority. Among the RPs with the highest priority value and the same hash value, the C-RP with the highest RP IP address is chosen as the active RP.

You cannot configure the C-RP priority. Each RP has a default C-RP priority value of 0, and the algorithm uses the RP if the group address maps to the grp-prefix that you configure for that RP. If a different router in the network has a C-RP priority value greater than 0, the switch uses this part of the algorithm in the RP election process.

Currently, you cannot configure the hash mask used in the hash algorithm. Unless you configure a different PIM BSR in the network with a nondefault hash mask value, the default hash mask of 255.255.255.252 is used. Static RP configurations do not use the BSR hash mask; they use the default hash mask.

For example:

RP1 = 128.10.0.54 and RP2 = 128.10.0.56. The group prefix for both RPs is 238.0.0.0/255.0.0.0. Hash mask = 255.255.255.252.

The hash function assigns the groups to RPs in the following manner:

The group range 238.1.1.40 to 238.1.1.51 (12 consecutive groups) maps to 128.10.0.56. The group range 238.1.1.52 to 238.1.1.55 (4 consecutive groups) maps to 128.10.0.54. The group range 238.1.1.56 to 238.1.1.63 (8 consecutive groups) maps to 128.10.0.56.

PIM-SM RP Selection Algorithm Inconsistency Between Platforms

In topologies where this switch interoperates with ERS or VSP 9000 Series platforms, the selection of the RP from multiple candidate RPs can produce different results on this switch than it does on ERS or VSP 9000 Series. This switch conforms to PIM RFC 4601, while ERS and VSP 9000 Series platforms conform to RFC 2362.

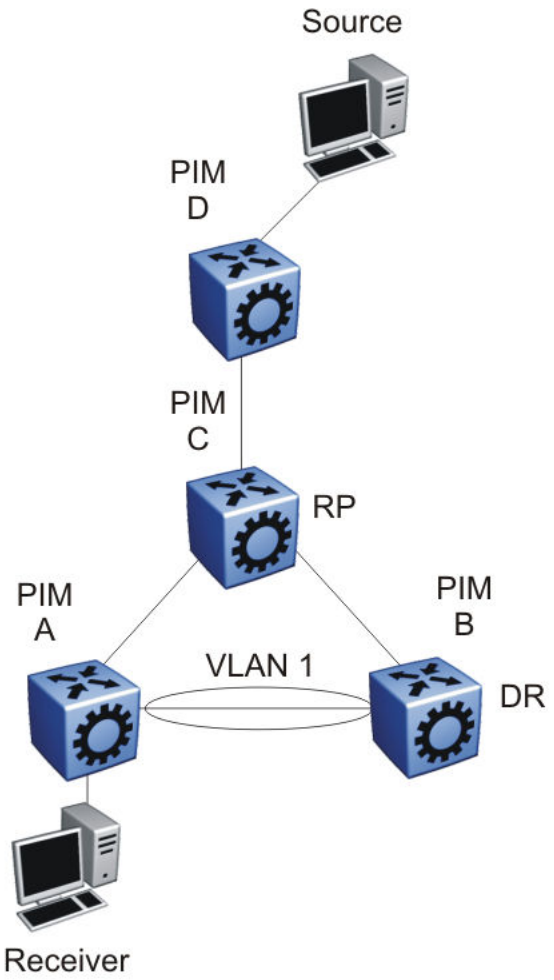
RFC 4601 is not backward compatible with RFC 2362 regarding how it defines the selection algorithm for an RP, specifically when there are several candidate RPs for the same group, but with different prefix lengths. Both RFCs have the RP selection mechanism based on a specific hash function, common to all routers in PIM domain, however there are differences in determining the pool of candidate RPs to which the hash function will be applied. In RFC 4601, only the RP of the group range with the longest prefix match for the group range will be chosen to apply the hash function and thus participate in the actual election. In RFC 2362, longest prefix match is not part of the selection criteria, and therefore ERS and VSP 9000 Series could potentially choose a different RP, because they apply the hash function on a different pool of candidate RPs. This would cause inconsistencies in the PIM-SM network.

To work around this issue, define RP group ranges with the same prefix length, such that the next RFC-defined match rule applies equally across all platforms in the network.

PIM-SM Receivers and VLANs

Some designs cause unnecessary traffic flow on links in a PIM-SM domain. In these cases, traffic is not duplicated to the receivers, but wastes bandwidth.

The following figure shows such a situation. Switch B is the DR between switches A and B. Switch C is the RP. A receiver R is on the VLAN (V1) that connects switches A and B. A source sends multicast data to the receiver.



IGMP reports that the messages that the receiver sends are forwarded to the DR, and both A and B create (*,G) records. Switch A receives duplicate data through the path from C to A, and through the second path from C to B to A. Switch A discards the data on the second path (assuming the upstream source is A to C).

To avoid this waste of resources, do not place receivers on V1. This configuration guarantees that no traffic flows between B and A for receivers attached to A. In this case, the existence of the receivers is only learned through PIM join messages to the RP [for (*,G)] and of the source through SPT joins.

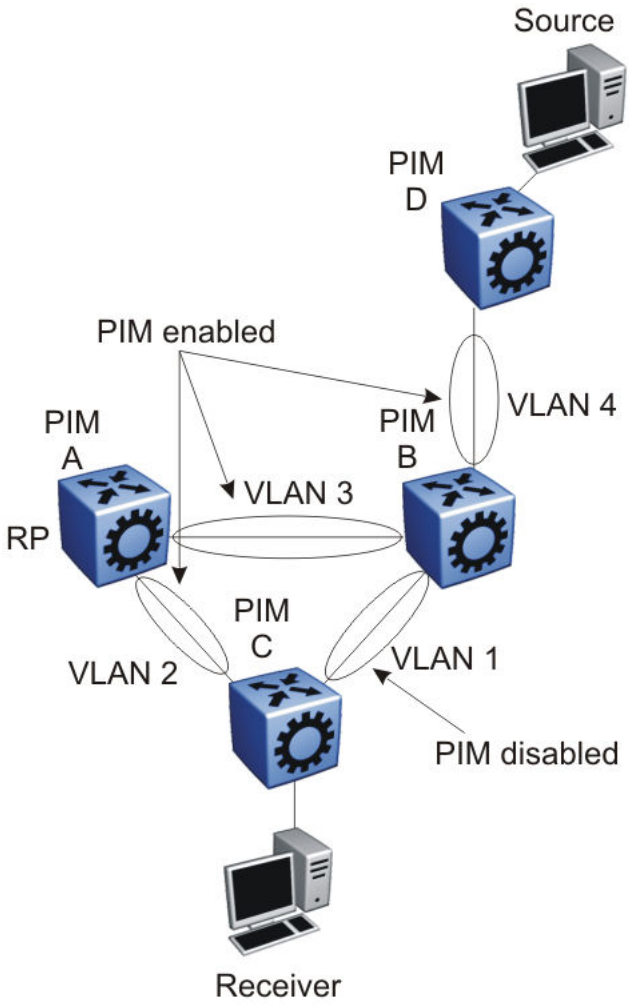
PIM Network with Non-PIM Interfaces

For proper multicast traffic flow in a PIM-SM domain, as a general rule, enable PIM-SM on all interfaces in the network (even if paths exist between all PIM interfaces). Enable PIM on all interfaces because PIM-SM relies on the unicast routing table to determine the path to the RP, BSR, and multicast sources. Ensure that all routers on these paths have PIM-SM enabled interfaces.

The following figure provides an example of this situation. If A is the RP, then initially the receiver receives data from the shared tree path (that is, through switch A).

If the shortest path from C to the source is through switch B, and the interface between C and B does not have PIM-SM enabled, then C cannot switch to the SPT. C discards data that comes through the

shared path tree (that is, through A). The simple workaround is to enable PIM on VLAN1 between C and B.



Source Filtering

The system can report interest in receiving packets from only a specific source address (INCLUDE), from all but specific source addresses (EXCLUDE), or sent to specific multicast addresses. IGMPv3 interacts with PIM-SM, PIM-SSM, and snooping to provide source filtering.

Protocol Independent Multicast-Source Specific Multicast guidelines

PIM-Source Specific Multicast (SSM) is a one-to-many model that uses a subset of the PIM-SM features. In this model, members of an SSM group can only receive multicast traffic from a specific source or sources, which is more efficient and puts less load on multicast routing devices.

IGMPv3 supports PIM-SSM by enabling a host to selectively request traffic from individual sources within a multicast group. The system can report interest in receiving packets from only specific source addresses (INCLUDE). IGMPv3 interacts with PIM-SM, PIM-SSM, and snooping to provide source filtering.

PIM-SSM design considerations

Use the following information when you design an SSM network:

- If you configure SSM, it affects SSM groups only. The switch handles other groups in sparse mode (SM) if a valid RP exists on the network.
- You can configure PIM-SSM only on switches at the edge of the network. Core switches use PIM-SM if they do not have receivers for SSM groups.
- For networks where group addresses are already in use, you can change the SSM range to match the groups.
- One switch has a single SSM range.
- You can have different SSM ranges on different switches.

  Configure the core switches that relay multicast traffic so that they cover all of these groups in their SSM range, or use PIM-SM.
- One group in the SSM range can have multiple sources for a given SSM group.

Multicast for Multimedia

The switch provides a flexible and scalable multicast implementation for multimedia applications. Several features are dedicated to multimedia applications and in particular to television distribution.

Join and leave performance

For TV applications, you can attach several TVs directly to the switch, or through an IGMP-capable Ethernet switch. Base this implementation on IGMP; the set-top boxes use IGMP reports to join a TV channel and IGMP leaves to exit the channel. After a viewer changes channels, the switch issues an IGMPv2 leave for the old channel (multicast group), and sends a membership report for the new channel. If viewers change channels continuously, the number of joins and leaves can become large, particularly if many viewers attach to the switch.

The switch supports more than a thousand joins and leaves per second, which is well adapted to TV applications.

Important

For IGMPv3, ensure a join rate of 1000 per second or less. This ensures the timely processing of join requests.

If you use the IGMP proxy functionality at the receiver edge, you reduce the number of IGMP reports received by switch. This provides better overall performance and scalability.

Fast Leave

IGMP Fast Leave supports two modes of operation: single-user mode and multiple-user mode.

In single-user mode, if more than one member of a group is on the port and one of the group members leaves the group, everyone stops receiving traffic for this group. Single-user mode does not send a group-specific query before the effective leave takes place.

Multiple-user mode allows several users on the same port or VLAN. If one user leaves the group and other receivers exist for the same stream, the stream continues. The switch tracks the number of receivers that join a given group. For multiple-user mode to operate properly, do not suppress reports. This ensures that the switch properly tracks the correct number of receivers on an interface.

The Fast Leave feature is particularly useful in IGMP-based TV distribution where only one receiver of a TV channel connects to a port. If a viewer changes channels quickly, you create considerable bandwidth savings if you use Fast Leave.

You can implement Fast Leave on a VLAN and port combination; a port that belongs to two different VLANs can have Fast Leave enabled on one VLAN (but not on the other). Thus, with the Fast Leave feature enabled, you can connect several devices on different VLANs to the same port. This strategy does not affect traffic after one device leaves a group to which another device subscribes. For example, you can use this feature when two TVs connect to a port through two set-top boxes, even if you use the single-user mode.

To use Fast Leave, you must first enable explicit host tracking. IGMP uses explicit host tracking to track all source and group members. Explicit host tracking is disabled by default. For configuration information, see Configuring Fast Leave Mode on page 1402.

Last member query interval tuning

If an IGMPv2 host leaves a group, it notifies the router by using a leave message. Because of the IGMPv2 report suppression mechanism, the router cannot access information of other hosts that require the stream. Thus, the router broadcasts a group-specific query message with a maximum response time equal to the last member query interval (LMQI).

Because this timer affects the latency between the time that the last member leaves and the time the stream actually stops, you must properly tune this parameter. This timer can especially affect TV delivery or other large-scale, high-bandwidth multimedia applications. For instance, if you assign a value that is too low, this can lead to a storm of membership reports if a large number of hosts are subscribed. Similarly, assigning a value that is too high can cause unwanted high-bandwidth stream propagation across the network if users change channels rapidly. Leave latency also depends on the robustness value, so a value of 2 equates to a leave latency of twice the LMQI.

Determine the proper LMQI value for your particular network through testing. If a very large number of users connect to a port, assigning a value of 3 can lead to a storm of report messages after a group-specific query is sent. Conversely, if streams frequently start and stop in short intervals, as in a TV delivery network, assigning a value of 10 can lead to frequent congestion in the core network.

Another performance-affecting factor that you need to be aware of is the error rate of the physical medium. For links that have high packet loss, you can find it necessary to adjust the robustness variable to a higher value to compensate for the possible loss of IGMP queries and reports.

In such cases, leave latency is adversely affected as numerous group-specific queries are unanswered before the stream is pruned. The number of unanswered queries is equal to the robustness variable (default 2). The assignment of a lower LMQI can counterbalance this effect. However, if you configure the LMQI too low, it can actually exacerbate the problem by inducing storms of reports on the network. LMQI values of 3 and 10, with a robustness value of 2, translate to leave latencies of 6/10 of a second and 2 seconds, respectively.

When you choose an LMQI, consider all of these factors to determine the best configuration for the given application and network. Test that value to ensure that it provides the best performance.

Important

In networks that have only one user connected to each port, use the Fast Leave feature instead of LMQI, because no wait is required before the stream stops. Similarly, the robustness variable does not affect the Fast Leave feature, which is an additional benefit for links with high loss.

Layer 3 switch clustering and multicast SMLT

Switch clustering is the logical aggregation of two nodes to form one logical entity known as the switch cluster. The two peer nodes in a switch cluster connect using a virtual interswitch trunk (vIST). The vIST exchanges forwarding and routing information between the two peer nodes in the cluster. This section provides guidelines for switch clusters that use multicast and Split Multilink Trunking (SMLT).

General guidelines

The following list identifies general guidelines to follow if you use multicast and switch clustering:

- Enable Protocol Independent Multicast - Sparse Mode (PIM-SM) on the vIST VLAN for fast recovery of multicast. A unicast routing protocol is not required.
- Enable Internet Group Management Protocol (IGMP) snooping and proxy on the edge switches.

The following figure shows multicast behavior in an SMLT environment. The configuration in the following figure provides fast failover if the switch or rendezvous point (RP) fails.

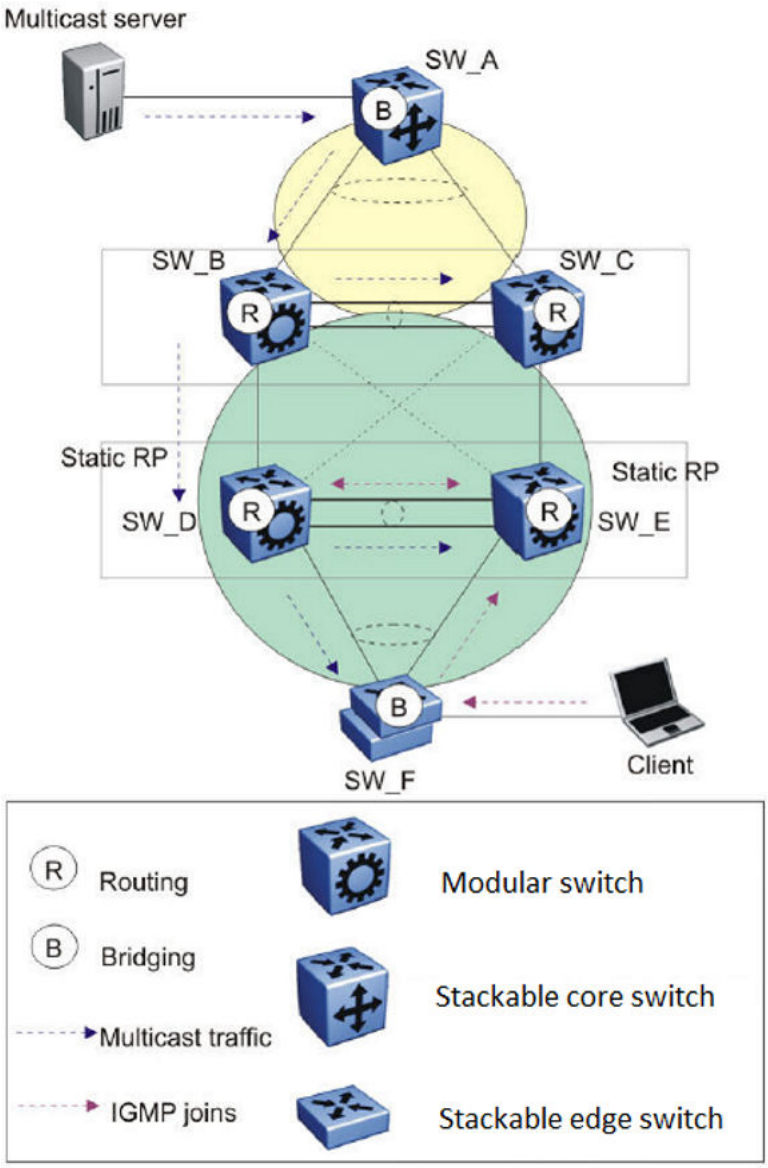


Figure 128: Multicast behavior in SMLT environment

In Multicast behavior in SMLT environment the following actions occur:

1. The multicast server sends multicast data towards the source designated router (DR).
2. The source DR sends register messages with encapsulated multicast data towards the RP.
3. After the client sends IGMP membership reports towards the multicast router, the router creates a (*,G) entry.
4. The RP sends join messages towards the source DR on the reverse path.
5. After the source DR receives the join messages, it sends native multicast traffic.
6. After SW_B or SW_D receives multicast traffic from upstream, it forwards the traffic on the vIST as well as on the SMLT link. Other aggregation switches drop multicast traffic received over the vIST at

egress. This action provides fast failover for multicast traffic. Both SW_D and SW_E (Aggregation switches) have similar (S,G) records.

7. In case of SW_D or RP failure, SW_B changes only the next-hop interface towards SW_E. Because the circuitless IP (CLIP) RP address is the same, SW_B does not flush (S,G) entries and achieves fast failover.

Multicast triangle topology

A triangle design is an SMLT configuration that connects edge switches or SMLT clients to two aggregation switches. Connect the aggregation switches together with a vIST that carries all the SMLT trunks configured on the switches.

The switch supports the following triangle configurations:

- a configuration with Layer 3 PIM-SM routing on both the edge and aggregation switches
- a configuration with Layer 2 snooping on the client switches and Layer 3 routing with PIM-SM on the aggregation switches

To avoid using an external query device to provide correct handling and routing of multicast traffic to the rest of the network, use the triangle design with IGMP Snoop at the client switches. Use multicast routing at the aggregation switches as shown in the following figure.

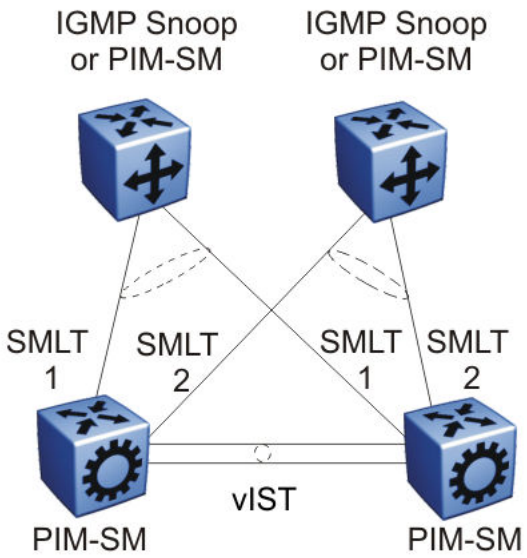

Figure 129: Multicast routing using PIM-SM

Client switches run IGMP Snoop or PIM-SM, and the aggregation switches run PIM-SM. This design is simple and, for the rest of the network, PIM-SM performs IP multicast routing. The aggregation switches are the query devices for IGMP, so an external query device is not required to activate IGMP membership. These switches also act as redundant switches for IP multicast.

Multicast data flows through the vIST link when receivers are learned on the client switch and senders are located on the aggregation switches, or when sourced data comes through the aggregation switches. This data is destined for potential receivers attached to the other side of the vIST. The data

does not reach the client switches through the two aggregation switches because only the originating switch forwards the data to the client switch receivers.

Note

Always place multicast receivers and senders on the core switches on VLANs different from those that span the vIST.

The following figure shows a switch clustering configuration with a single switch cluster core and dual-connected edge devices. This topology represents different VLANs spanning from each edge device and those VLANs routed at the switch cluster core. You can configure multiple VLANs on the edge devices, 802.1Q tagged to the switch cluster core.

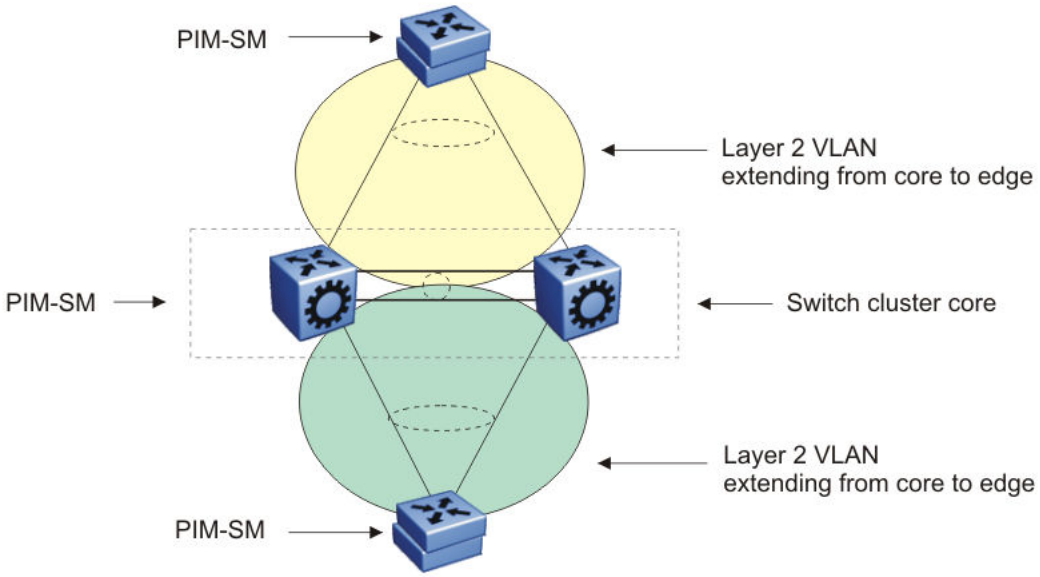

Figure 130: Multicast SMLT triangle

Use an edge device that supports a form of link aggregation. Disable spanning tree on the link aggregation group on the edge devices. Enable either Virtual Router Redundancy Protocol (VRRP) BackupMaster or Routed SMLT (RSMLT) Layer 2 Edge on the switch cluster core.

Square and full-mesh topology multicast guidelines

A square design connects a pair of aggregation switches to another pair of aggregation switches. A square design becomes a full-mesh design if the aggregation switches are connected in a full-mesh. The switch supports Layer 3 IP multicast (PIM-SM only) over a full-mesh SMLT or RSMLT configuration.

In a square design, configure all switches with PIM-SM. Place the bootstrap router (BSR) and RP in one of the four core switches; and place the RP closest to the source. If using PIM-SM over a square or full-mesh configuration, enable the **`multicast smlt-square`** flag.

The following three figures show switch clustering configurations with two-switch cluster cores and dual-connected edge devices.

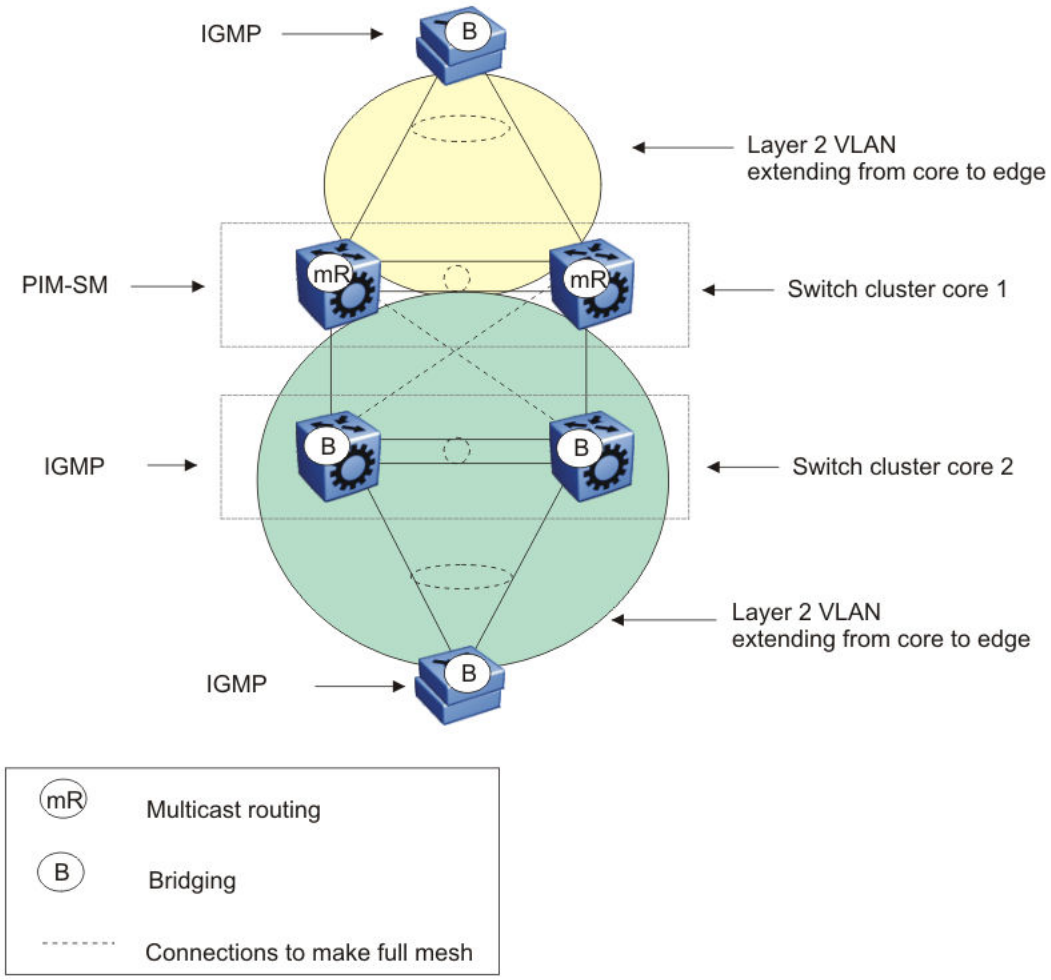

Figure 131: Multicast SMLT square 1

In the preceding figure, only one of the switch cluster cores performs Layer 3 multicast routing while the other is strictly Layer 2. Configure multiple VLANs on the edge devices, 802.1Q tagged to the switch cluster cores.

Use an edge device that supports a form of link aggregation. Disable spanning tree on the link aggregation group on the edge devices. Enable either the VRRP BackupMaster or RSMLT Layer 2 Edge on the switch cluster core.

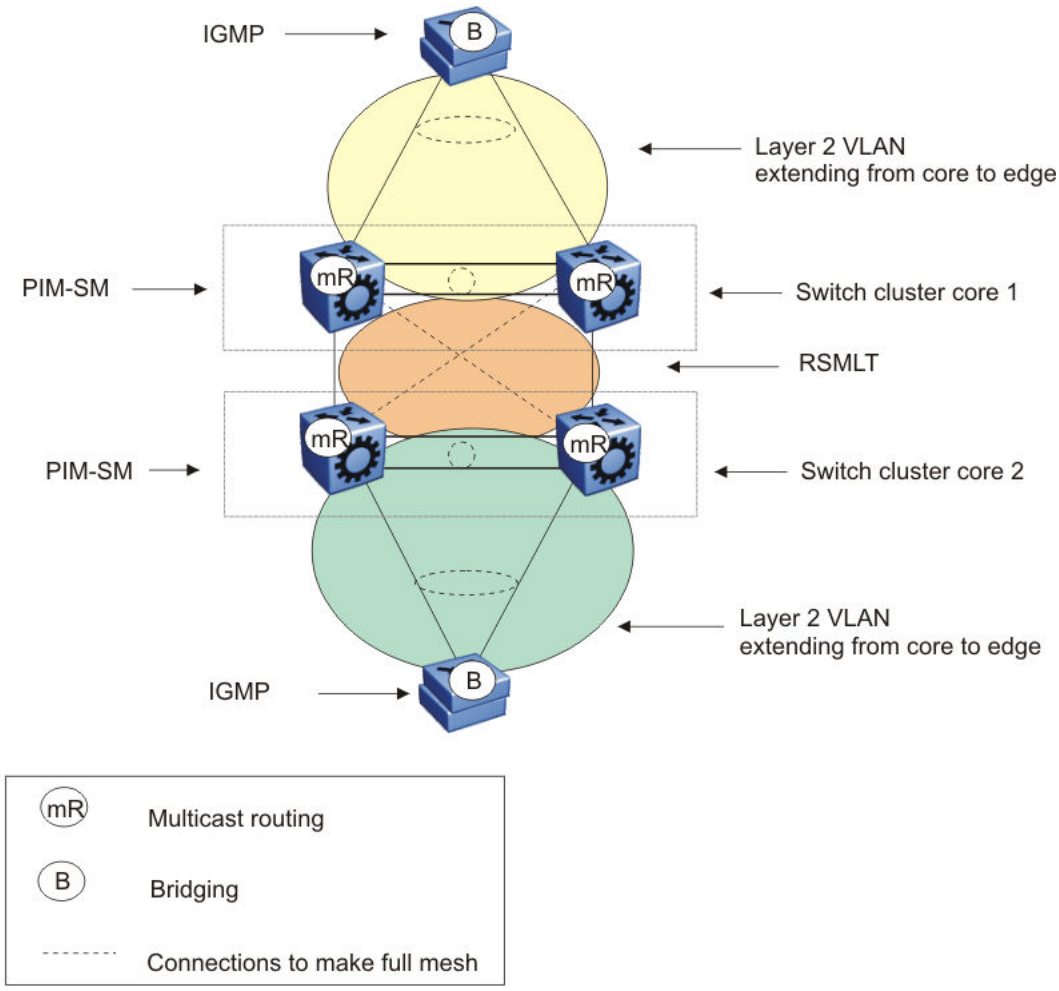

Figure 132: Multicast SMLT square 2

In the preceding figure, both of the switch cluster cores performs Layer 3 multicast routing, while the edge devices are Layer 2 IGMP.

Use an edge device that supports a form of link aggregation. Disable spanning tree on the link aggregation group on the edge devices. Enable either the VRRP BackupMaster or RSMLT Layer 2 Edge on the switch cluster cores. Do not enable VRRP on the RSMLT VLAN between switch cluster cores.

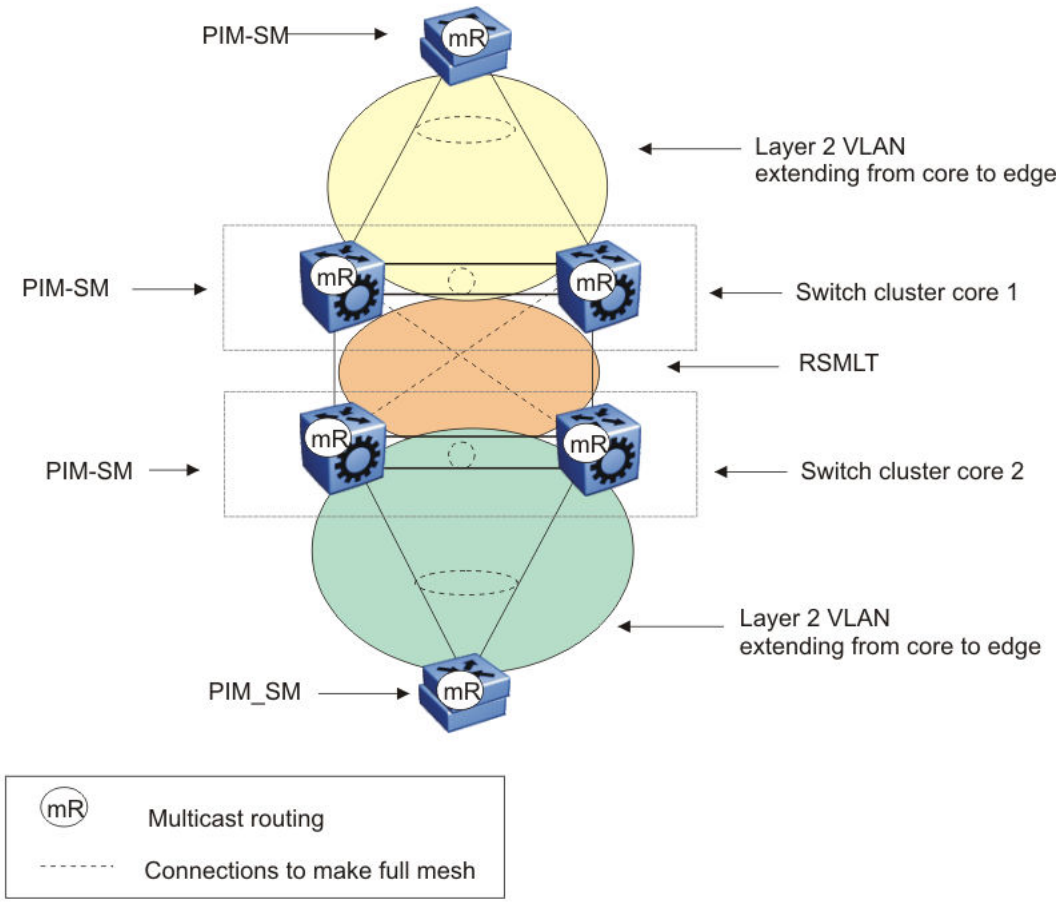

Figure 133: Multicast SMLT square 3

In the preceding figure, both of the switch cluster cores and the edge devices perform Layer 3 multicast routing.

Use an edge device that supports a form of link aggregation. Disable spanning tree on the link aggregation group on the edge devices. Enable either the VRRP BackupMaster or RSMLT Layer 2 Edge on the switch cluster cores. Do not enable VRRP on the RSMLT VLAN between switch cluster cores.

SMLT and multicast traffic issues

If PIM-SM or other multicast protocols are used in an SMLT environment, enable the protocol on the vIST. Routing protocols in general are not run over an vIST but multicast routing protocols are an exception. When using PIM-SM and a unicast routing protocol, ensure the unicast route to the BSR and RP has PIM-SM active and enabled. If multiple OSPF paths exist and PIM-SM is not active on each pair, the BSR is learned on a path that does not have PIM-SM active. The following figure demonstrates this issue.

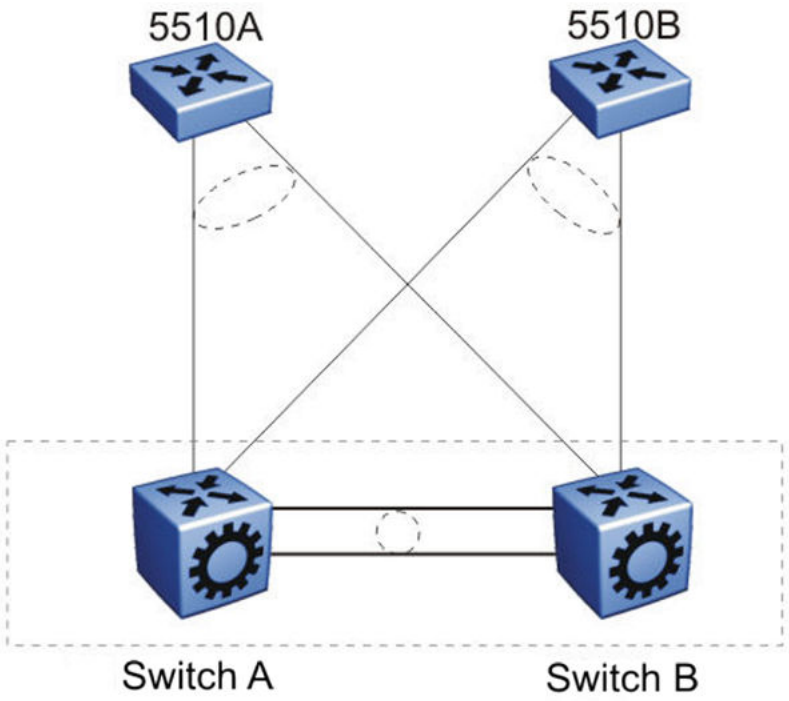

Figure 134: Unicast route example

The network configuration in the preceding figure is as follows:

- 5510A is on VLAN 101.
- 5510B is on VLAN 102.
- Switch B is the BSR.
- Switch A and Switch B have OSPF enabled.
- PIM is enabled and active on VLAN 101.
- PIM is either disabled or passive on VLAN 102.

In this example, the unicast route table on Switch A learns the BSR on Switch B through VLAN 102 using OSPF. The BSR is either not learned or does not provide the RP to Switch A.

Protocol Independent Multicast over IPv6

Table 102: PIM over IPv6 product support

Feature	Product	Release introduced
PIM over IPv6	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Note
PIM is supported in Global Routing Table (GRT) only.

Several multicast protocols are used to enable IP multicast.

Hosts use the Internet Group Management Protocol (IGMP) for IPv4 and Multicast Listener Discovery (MLD v1/v2) for IPv6 to report multicast group memberships of directly attached multicast listeners to neighboring multicast routers. MLD is the direct IPv6 replacement for the IGMP protocol used in IPv4.

Routers use Protocol Independent Multicast-Sparse Mode (PIM-SM) and PIM source Specific Mode (SSM) to exchange multicast routing information. The PIM-SM protocol is the multicast routing protocol that uses the underlying unicast routing information base to build unidirectional shared trees to group members rooted at the RP per group, and creates shortest-path trees (SPT) per source. The router forwards multicast packets along these trees. PIM-SSM does not require RP and only supports SPT.

PIM over IPv6 uses the IPv6 unicast routing table for reverse path information about source and RP.

Note
IPv4 and IPv6 multicast streams cannot interact. To configure an end-to-end PIM IPv6 network, all nodes from sender to receiver must support PIM IPv6.

PIM-SM over IPv6 features

The following are features of PIM-SM over IPv6:

- Compliant with RFC 4601
- Multicast networks built by PIM IPv4 and PIM IPv6 do not overlap
- IPv4 receiver hosts cannot receive data from IPv6 source hosts and vice versa
- IPv4 and IPv6 multicast protocols can be enabled at the same time on the same VLAN
- PIM IPv4 and PIM IPv6 can be configured on the same VLAN
- PIM IPv4 and PIM IPv6 must be configured separately
- Supports sparse and ssm modes

Operational note for PIM-SM over IPv6

The following are operational considerations when deploying PIM-SM over IPv6:

- You can only configure PIM-SM if you configure the spbm_config_mode boot flag to false.
- The following HELLO messages options are not supported:
  - GENid
  - DR priority
  - LAN-PRUNE delay
  - T-bit
- IPv6 multicast is not supported over SPBM
- IPv6 multicast routing is not virtualized, it is supported only on GRT
- IPv6 multicast configuration on SMLT VLAN is not supported. vIST peers cannot form PIM-SM over IPv6 neighbor adjacencies. Senders and receivers on the vIST peers (SMLT and non-SMLT) cannot communicate. MLT and LACP is supported.
- The switch does not support the following features:
  - Static entries
  - Bootstrap message (BSR)
  - Anycast RP
  - Virtual PIM neighbors
  - Fast join prune
  - Software forwarding
  - Passive PIM interfaces
  - IP mroute stream limit
  - Bidirectional PIM
  - Multicast Border Router (PMBR)
  - VRF support for PIM (GRT only)
  - IGMP and PIM mtrace capability

IPv6 interface multiple addresses

IPv6 interfaces can have multiple addresses associated with them. A router running PIM for IPv6 has a network unique domain-wide reachable IPv6 VLAN address used for multiple hop messages. A link local address is associated with the VLAN. The link local address is a non-routable unicast IPv6 address used as source address (primary interface address) for transmitting different types of PIM messages.

IP multicast configuration and DvR

Configuration of IPv4 multicast is supported only on the Controller nodes of a DvR domain. You cannot configure IP multicast on the DvR Leaf nodes. The following sections detail IP multicast configuration support on DvR enabled nodes (Controllers or Leaf nodes).

For more information on DvR, see Distributed Virtual Routing Fundamentals on page 622.

Multicast configuration that is pushed from DvR Controllers to DvR Leaf nodes

When you perform the following multicast configuration on the DvR enabled interface of a DvR Controller, the configuration is automatically pushed to the Leaf nodes within the domain.

- IP multicast over Fabric Connect
- IGMP Layer 2 Querier parameters, such as the IGMP Layer 2 Querier version, query interval, query maximum response time, robustness value, last member query interval and compatibility mode
- Enabling and clearing of multicast route statistics

Multicast configuration that is not supported on DvR enabled Layer 2 VSNs

- IGMP Snooping on DvR enabled Layer 2 VSNs
- SPB-PIM Gateway

  For more information on SPB-PIM Gateway, see SPB-PIM Gateway configuration on page 2862.

IP multicast basic configuration using CLI

To provide multicasting services, you need a host membership protocol and a multicast routing protocol. Hosts subscribe to multicast services using a host membership protocol. The Internet Group Management Protocol (IGMP) is an example of an IPv4 host membership protocol.

A multicast routing protocol optimizes the routing of multicast information to avoid loops and restrict multicast traffic to networks that use host membership. Examples of multicast routing protocols include Protocol Independent Multicast–Sparse Mode (PIM–SM) and Protocol Independent Multicast–Source Specific Multicast (PIM–SSM).

Configuring IP multicast in SMLT topologies

This procedure shows how to configure PIM and IGMP Snooping in an SMLT environment. The configuration steps show how to enable multicast, and then configure the usual PIM and IGMP Snooping related VLANs and global attributes. It includes steps to configure the following:

- Setting the boot config flag
- Configuring the vIST peer
- Enabling Simplified vIST

Before You Begin

SPBM must not be enabled on the vIST peers or any router that participates in the PIM network.

About This Task

The switch supports configurable VLANs in the range of 1 to 4059. VLAN 0 is invalid. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. VLAN IDs on the switch range from 2 to 4094 but, by default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Disable the boot flag:

   ```
   no boot config flags spbm-config-mode
   ```

   The system responds with these messages:

   ```
   Warning: Please save the configuration and reboot the switch for this
   to take effect.

   Warning: Please carefully save your configuration file before
   rebooting the switch. Saving configuration file when spbm-config-mode
   is changed to disable, removes SPBM configurations from the
   configuration file.
   ```

3. Save the configuration and, then reboot the switch.

   

   Important
   Any change to the **spbm-config-mode** boot flag requires a reboot for the change to take effect.

4. Create the vIST VLAN:

   ```
   vlan create <2-4059> type port-mstprstp <0-63>

   interface vlan <1-4059>

   ip address <A.B.C.D/X>
   ```

5. Configure the vIST peer address and VLAN:

   ```
   virtual-ist peer-ip <A.B.C.D> vlan <1-4059>
   ```

6. Configure the SMLT MLT:

   ```
   mlt <1-512> enable

   mlt <1-512> member {slot/port[/sub-port] [-slot/port[/sub-port]]
   [,...]}

   interface mlt <1-512>

   smlt
   ```

7. Configure the vIST MLT:

   ```
   mlt <1-512> enable

   mlt <1-512> member {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}

   mlt <1-512> encapsulation dot1q

   interface mlt <1-512>

   virtual-ist enable
   ```

   Note

   The **virtual-ist enable** command enables Simplified vIST and is only available when the **spbm-config-mode** boot flag is disabled.

8. Create a customer VLAN and assign the SMLT MLT ID:

   ```
   vlan create <2-4059>

   vlan mlt <1-4059> <1-512>

   interface vlan <1-4059>

   ip address <A.B.C.D/X>
   ```

9. Configure PIM or IGMP Snooping on the SMLT VLAN:

   ```
   interface vlan <1-4059>

   ip pim enable or ip igmp snooping
   ```

10. Configure PIM on the vIST VLAN:

    ```
    interface vlan <1-4059>

    ip pim enable
    ```

11. Enable PIM globally:

    ```
    ip pim enable
    ```

    Note

    You can also configure other global PIM attributes such as **ip pim join-prune-interval**.

Example

```
enable
configure terminal
no boot config flags spbm-config-mode
```

Save the configuration and reboot the switch.

```
virtual-ist peer-ip 198.51.100.0 vlan 50

mlt 3 enable
mlt 3 member 1/35,1/36
interface mlt 3
smlt
```

```
exit
mlt 5 enable
mlt 5 member 2/15,2/17
mlt 5 encapsulation dot1q
interface mlt 5
virtual-ist enable
exit
vlan create 50 type port-mstprstp 0
interface vlan 50
ip address 198.51.100.0 255.255.255.0 1
exit
vlan create 100
vlan mlt 100 3
interface vlan 100
ip address 192.0.2.0 255.255.255.0 2
exit
interface vlan 100
ip pim enable (or ip igmp snooping)
exit
interface vlan 50
ip pim enable
exit
ip pim enable
```

Configure PIM-SM Globally

Configure PIM-SM to enable or disable PIM-SM globally on the switch and change default global parameters.

Before You Begin

Note

Before you can enable the PIM Infinite Threshold Policy feature, you must first disable the following:

- PIM-SM
- PIM-SSM
- Simplified vIST

About This Task

PIM-SM is the default mode so you do not need to configure the PIM mode.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Enable PIM-SM:
   ```
   ip pim enable
   ```
3. Configure the time between bootstrap messages:
   ```
   ip pim bootstrap-period <5–32757>
   ```
4. Configure the timeout to discard data:
   ```
   ip pim disc-data-timeout <5–65535>
   ```

5. Enable the fast join prune interval:

   ```
   ip pim fast-joinprune
   ```

6. Configure the forward cache timeout:

   ```
   ip pim fwd-cache-timeout <10-86400>
   ```

7. Configure the interval for join and prune messages:

   ```
   ip pim join-prune-interval <1-18724>
   ```

8. Specify how long to suppress register messages:

   ```
   ip pim register-suppression-timeout <6-65535>
   ```

9. Specify how often the candidate-rendezvous point (C-RP) sends advertisements:

   ```
   ip pim rp-c-adv-timeout <5-26214>
   ```

10. Configure PIM Infinite Threshold Policy:

    a. Disable PIM-SM.

       ```
       no pim enable
       ```

    b. Enable PIM Infinite Threshold Policy:

       ```
       ip pim spt-infinite-threshold
       ```

    c. Enable PIM-SM:

       ```
       ip pim enable
       ```

11. Configure the polling interval for the routing table manager (RTM):

    ```
    ip pim unicast-route-change-timeout <2-65535>
    ```

12. Verify the configuration changes:

    ```
    show ip pim
    ```

Example

Verify the configuration changes:

```
Switch:1(config)#show ip pim
```

```
Switch:1#show ip pim
================================================================================================
                        Pim General Group - GlobalRouter
================================================================================================
PimStat               : disabled
Mode                  : sparse
StaticRP              : disabled
FastJoinPrune         : disabled
SptInfiniteThreshold  : enabled
BootstrapPeriod       : 60
CRPAdvTimeout         : 60
DiscDataTimeout       : 60
FwdCacheTimeout       : 210
RegSupprTimeout       : 60
UniRouteChangeTimeout : 5
JoinPruneInt          : 60
```

Variable Definitions

The following table describes the variables for the **ip pim** command.

Variable	Value
disc-data-timeout <5-65535>	Specifies the duration in seconds to discard data until the switch receives the join message from the rendezvous point (RP). An IP multicast discard record is created after a register packet is sent, until the timer expires or the switch receives a join message. The default value is 60.
bootstrap-period	Specifies the interval (in seconds) that the elected BSR waits between originating bootstrap messages. The range is from 5–32757 and the default is 60 seconds.
enable	Enables PIM globally on the switch. The default is disabled.
fast-joinprune	Enables or disables the PIM fast join prune feature.
fwd-cache-timeout <10-86400>	Specifies the forward cache timeout value. The default value is 120.
join-prune-interval <1-18724>	Specifies the duration in seconds before the PIM router sends out the next join or prune message to its upstream neighbors. The default value is 60.
mode <sparse> <ssm>	Configures PIM mode on the switch. The default value is sparse.
register-suppression-timeout <10-65535>	Specifies the duration in seconds the designated router (DR) suppresses sending registers to the RP. The timer starts after the DR receives a register-stop message from the RP. The default value is 60.
rp-c-adv-timeout	Specifies how often (in seconds) a router configured as a candidate rendezvous point router (C-RP) sends advertisement messages. After this timer expires, the C-RP router sends an advertisement message to the elected bootstrap router (BSR). The range is from 5–26214 and the default is 60 seconds.
spt-infinite-threshold	Enables PIM Infinite Threshold Policy for IPv4, so that multicast traffic follows the shared tree path through a Rendezvous Point (RP) instead of automatically switching over to shortest path tree (SPT). The default is disabled.
static-rp	Enables or disables the static RP feature. You can use static RP to configure a static entry for an RP. A static RP permits communication with switches from other vendors that do not use the BSR mechanism.

Variable	Value
unicast-route-change-timeout <2-65535>	Specifies the duration in seconds the switch polls the RTM for unicast routing information updates for PIM. The default value is 5.
virtual-neighbor	Specifies to enter virtual neighbor IP to an interface globally.

Enable IPv6 PIM-SM Globally

About This Task

Use this procedure to enable IPv6 PIM-SM globally. By default, IPv6 PIM-SM is disabled.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable IPv6 PIM-SM:

   ```
   ipv6 pim enable
   ```

Configure Global IPv6 PIM-SM Properties

Before You Begin

Note

Before you can enable the PIM Infinite Threshold Policy feature, you must first disable the following:

- PIM-SM
- PIM-SSM

About This Task

Use this procedure to configure the global IPv6 PIM-SM parameters on the switch.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the timeout to discard data:

   ```
   ipv6 pim disc-data-timeout <5-65535>
   ```

3. Configure the forward cache timeout:

   ```
   ipv6 pim fwd-cache-timeout <10-86400>
   ```

4. Configure the interval for join and prune messages:
   ```
   ipv6 pim join-prune-interval <1-18724>
   ```
5. Specify how long to suppress register messages:
   ```
   ipv6 pim register-suppression-timeout <10-65535>
   ```
6. Configure PIM Infinite Threshold Policy:
   ```
   ipv6 pim spt-infinite-threshold
   ```
7. Configure the polling interval for the routing table manager (RTM):
   ```
   ipv6 pim unicast-route-change-timeout <2-65535>
   ```
8. Configure the PIM mode:
   ```
   ipv6 pim mode <sparse> <ssm>
   ```
9. Verify the configuration changes:
   ```
   show ipv6 pim
   ```

Example

Verify the configuration changes:

```
Switch:1#show ipv6 pim
================================================================================================
                          Pim General Group - GlobalRouter
================================================================================================
PimStat               : enabled
Mode                  : sparse
StaticRP              : disabled
SptInfiniteThreshold  : enabled
FwdCacheTimeout       : 210
DiscDataTimeout       : 60
RegSupprTimeout       : 60
UniRouteChangeTimeout : 5
JoinPruneInt          : 60
```

Variable Definitions

The following table describes the variables for the **ipv6 pim** command.

Variable	Value
disc-data-timeout <5-65535>	Specifies the duration in seconds to discard data until the switch receives the join message from the rendezvous point (RP). An IP multicast discard record is created after a register packet is sent, until the timer expires or the switch receives a join message. The default value is 60.
enable	Enables PIM globally on the switch. The default is disabled.
fwd-cache-timeout <10-86400>	Specifies the forward cache timeout value. The default value is 120.
join-prune-interval <1-18724>	Specifies the duration in seconds before the PIM router sends out the next join or prune message to its upstream neighbors. The default value is 60.

Variable	Value
mode <sparse> <ssm>	Configures PIM mode on the switch. The default value is sparse.
register-suppression-timeout <10-65535>	Specifies the duration in seconds the designated router (DR) suppresses sending registers to the RP. The timer starts after the DR receives a register-stop message from the RP. The default value is 60.
spt-infinite-threshold	Enables PIM Infinite Threshold Policy for IPv6, so that multicast traffic follows the shared tree path through a Rendezvous Point (RP) instead of automatically switching over to shortest path tree (SPT). The default is disabled.
static-rp	Add new static-rp entries and enable static-rp.
unicast-route-change-timeout <2-65535>	Specifies the duration in seconds the switch polls the RTM for unicast routing information updates for PIM. The default value is 5.

Configure PIM on a VLAN

Configure PIM for each interface to enable the interface to perform multicasting operations.

Before You Begin

- You must enable PIM globally before you configure PIM on a VLAN.
- The interface uses a valid IP address.

Procedure

1. Enter VLAN Interface Configuration mode:

   ```
   enable

   configure terminal

   interface vlan <1-4059>
   ```

2. Create a PIM interface on a VLAN:

   ```
   ip pim enable
   ```

   This command creates an active interface, by default.

3. Configure the interval for join and prune messages:

   ```
   ip pim join-prune-interval <1-18724>
   ```

4. Configure the time between hello messages:

   ```
   ip pim hello-interval <0-18724>
   ```

5. Verify the configuration:

   ```
   show ip pim interface vlan [<1-4059>]
   ```

Example

Configure the interval for join and prune messages, the time between hello messages, and then verify the configuration.

```
Switch:1(config-if)#ip pim join-prune-interval 60
Switch:1(config-if)#ip pim hello-interval 30
Switch:1>show ip pim interface vlan 10
================================================================================
                                Vlan Ip Pim
================================================================================

VLAN-ID   PIM-ENABLE MODE    HELLOINT  JPINT   CBSRPREF      INTF TYPE
--------------------------------------------------------------------------------
10         enable    sparse  30        60      -1   (disabled) active
```

Configuring PIM on a port

Configure PIM for each interface to enable the interface to perform multicasting operations.

Before You Begin

- You must enable PIM globally before you configure it on an interface.
- The interface uses a valid IP address.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create a PIM interface on a port:

   ```
   ip pim enable
   ```

   This command creates an active interface, by default.
3. Configure the interval for join and prune messages:

   ```
   ip pim join-prune-interval <1-18724>
   ```
4. Configure the time between hello messages:

   ```
   ip pim hello-interval <0-18724>
   ```

Example

Configure the interval for join and prune messages and the time between hello messages:

```
Switch(config-if)#ip pim join-prune-interval 60
Switch(config-if)#ip pim hello-interval 30
```

Configuring IPv6 PIM on a port or VLAN

Configure PIM for each interface to enable the interface to perform multicasting operations.

Before You Begin

- Enable IPv6 interface.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create a PIM interface on a port or VLAN:

   ```
   ipv6 pim enable
   ```

   This command creates an active interface, by default.
3. Configure the interval for join and prune messages:

   ```
   ipv6 pim join-prune-interval <1-18724>
   ```
4. Configure the time between hello messages:

   ```
   ipv6 pim hello-interval <0-18724>
   ```

Example

```
Switch:1(config-if)#ipv6 pim join-prune-interval 60
Switch:1(config-if)#ipv6 pim hello-interval 30
```

Variable Definitions

The following table describes the variables for the **ipv6 pim** command.

Variable	Value
hello-interval <0-18724>	Specifies the duration in seconds before the PIM router sends out the next hello message to neighboring switches. The default value is 30 seconds.
join-prune-interval <1-18724>	Specifies the duration in seconds before the PIM router sends out the next join or prune message to its upstream neighbors. The default value is 60 seconds.

Configuring SSM globally

Configure SSM to optimize PIM-SM by simplifying the many-to-many model (servers-to-receivers).

Before You Begin

- Configure a unicast protocol, for example, Routing Information Protocol (RIP) or Open Shortest Path First (OSPF), globally and on the interfaces where you want to configure PIM. For more information about RIP, see RIP configuration using CLI on page 2507. For more information about OSPF, see OSPF configuration using CLI on page 2197.
- Enable PIM globally.

About This Task

Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model that uses only a subset of the PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

SSM is a global configuration. After you enable SSM on a switch, it is enabled on all interfaces that run PIM. On an SSM-enabled switch, SSM behavior is limited to the SSM group range.

For non-SSM groups, the protocol behavior is PIM-SM.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure PIM-SSM:

   ```
   ip pim mode ssm
   ```

Configuring IPv6 SSM globally

Configure IPv6 SSM to optimize IPv6 PIM-SM by simplifying the many-to-many model (servers-to-receivers).

Before You Begin

- Configure an IPv6 unicast protocol, for example, Routing Information Protocol Next Generation (RIPng) or Open Shortest Path First Version 3 (OSPFv3), globally and on the interfaces where you want to configure PIM.

  For more information about RIPng, see RIPng Configuration using CLI on page 2517. For more information about OSPFv3, see OSPFv3 Configuration using CLI on page 2238.
- Enable IPv6 PIM globally.

About This Task

Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model which requires only a subset of the PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

SSM is a global configuration. After you enable SSM on a switch, it is enabled on all interfaces that run PIM. On a SSM-enabled switch, SSM behavior is limited to the SSM group range.

For non-SSM groups, the protocol behavior is PIM-SM.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure IPv6 PIM-SSM:

   ```
   ipv6 pim mode ssm
   ```

Configuring IGMP on a VLAN

Configure IGMP for each interface to change default multicasting operations.

Note

When you configure the following IGMP parameters on the DvR enabled interface of a DvR Controller, the configuration is automatically pushed to the Leaf nodes within the domain.

- **ip igmp version**
- **ip igmp query-interval**
- **ip igmp query-max-response**
- **ip igmp robust-value**
- **ip igmp last-member-query-interval**
- **ip igmp compatibility-mode**

IGMP snooping is not supported on DvR enabled Layer 2 VSNs.

For more information on DvR, see .

Before You Begin

- For PIM interfaces, you must enable PIM globally and on the VLAN. For snooping interfaces, do not enable PIM.

Procedure

1. Enter VLAN Interface Configuration mode:

   ```
   enable

   configure terminal

   interface vlan <1-4059>
   ```

2. Enable IGMP v2-v3 compatibility mode:

   ```
   ip igmp compatibility-mode
   ```

3. Configure the system to downgrade the version of IGMP:

   ```
   ip igmp dynamic-downgrade-version
   ```

4. Configure message intervals and response times:

   ```
   ip igmp last-member-query-interval <0-255> [query-interval <1-65535>]
   [query-max-response <0-255>]
   ```

5. Configure expected packet loss and IGMP version:

   ```
   ip igmp robust-value <2-255> [version <1-3>]
   ```

6. Add multicast router ports:
   `ip igmp mrouter {slot/port[/sub-port][-slot/port[/sub-port]][,...]}`
7. Enable proxy-snoop:
   `ip igmp proxy`
8. Enable router alert:
   `ip igmp router-alert`
9. Enable snooping:
   `ip igmp snooping`
10. Enable SSM-snooping:
    `ip igmp ssm-snoop`

Example

Enter VLAN Interface Configuration Mode for VLAN 10:

```
Switch:1(config)# interface vlan 10
```

Configure the last member query interval to 15 tenths of a second (equal to 1.5 seconds).

```
Switch:1(config-if)# ip igmp last-member-query-interval 15
```

Configure the query interval to 100 seconds.

```
Switch:1(config-if)# ip igmp query-interval 100
```

Configure the query maximum response time to 15 tenths of a second (equal to 1.5 seconds).

```
Switch:1(config-if)# ip igmp query-max-response 15
```

Configure the robustness value to 4 seconds.

```
Switch:1(config-if)# ip igmp robust-value 4
```

Enable proxy snoop for the VLAN.

```
Switch:1(config-if)# ip igmp proxy
```

Enable snoop for the VLAN.

```
Switch:1(config-if)# ip igmp snooping
```

Enable support for SSM on the snoop interface.

```
Switch:1(config-if)# ip igmp ssm-snoop
```

Enable IGMPv3.

```
Switch:1(config-if)# ip igmp version 3
```

Variable Definitions

Use the definitions in the following table to use the **ip igmp** command.

Variable	Value
access-list WORD<1-64> {A.B.C.D/X} <eny-tx|deny-rx|deny-both|allow-only-tx|allow-only-rx|allow-only-both>	Specifies the name of the access list from 1–64 characters. Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host. Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic

compatibility-mode	Activates v2-v3 compatibility mode. The default value is disabled, which means IGMPv3 is not compatible with IGMPv2. To use the default configuration, use the default option in the command:
	`default ip igmp compatibility-mode`
	, or use the no option to disable compatibility mode:
	`no ip igmp compatibility-mode`

dynamic-downgrade-version	Configures the version of IGMP to handle older query messages if the system downgrades. If the system downgrades, the host with IGMPv3 only capability does not work. If you do not configure the system to downgrade the version of IGMP, the system logs a warning. The system downgrades to the oldest version of IGMP on the network by default. To use the default configuration, use the default option in the command:
	`default ip igmp dynamic-downgrade-version`
	or use the no option to disable downgrade:
	`no ip igmp dynamic-downgrade-version`

igmpv3-explicit-host-tracking	Enables explicit host tracking on IGMPv3. The default state is disabled.
immediate-leave	Enables fast leave on a VLAN.
immediate-leave-members {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Configures IGMP fast leave members on a VLAN to specify fast-leave-capable ports. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
last-member-query-interval <0-255>	Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1. Decreasing the value reduces the time to detect the loss of the last member of a group. The default is 10 tenths of a second. You should configure this value between 3–10 (equal to 0.3 – 1.0 seconds).

Variable	Value
mrdisc [maxadvertinterval <2-180>] [maxinitadvertinterval <2-180>] [maxinitadvertisements <2-15>] [minadvertinterval <3-180>] [neighdeadinterval <2-180>]	Configures the multicast router discovery options to enable the automatic discovery of multicast capable routers. The default parameter values are: • maxadvertinterval: 20 seconds • maxinitadvertinterval: 2 seconds • maxinitadvertisements: 3 • minadvertinterval: 15 seconds • neighdeadinterval: 60 seconds
mrouter {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Adds multicast router ports. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
proxy	Activates the proxy-snoop option globally for the VLAN.
query-interval <1-65535>	Configures the frequency (in seconds) at which the VLAN transmits host query packets. The default value is 125 seconds.
query-max-response <0-255>	Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values enable a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds). **Important:** You must configure this value lower than the query-interval.
robust-value <2-255>	Configures the expected packet loss of a network. The default value is 2 seconds. Increase the value if you expect the network to experience packet loss.
router-alert	Instructs the router to ignore IGMP packets that do not contain the router alert IP option. When disabled (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option. **Important:** To maximize network performance, configure this parameter according to the version of IGMP currently in use: • IGMPv1—Disable • IGMPv2—Enable • IGMPv3—Enable
snoop-querier	Enables the IGMP Layer 2 Querier feature on the VLAN. The default is disabled.
snoop-querier-addr {A.B.C.D}	Specifies the IGMP Layer 2 Querier source IP address.
snooping	Activates the snoop option for the VLAN.
ssm-snoop	Activates support for PIM-SSM on the snoop interface.

Variable	Value
static-group {A.B.C.D} {A.B.C.D}{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} [static|blocked]	Configures IGMP static members to add members to a snoop group. *{A.B.C.D} {A.B.C.D}* indicates the IP address range of the selected multicast group. *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}* adds ports to a static group entry. *[static|blocked]* configures the route to static or blocked.
stream-limit stream-limit-max-streams <0-65535>	Configures multicast stream limitation on a VLAN to limit the number of concurrent multicast streams on the VLAN. The default is 4.
stream-limit-group {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} enable max-streams <0-65535>	Configures multicast stream limitation members on ports of a specific VLAN to limit the number of multicast groups that can join a VLAN. The default *max-streams* value is 4.
version <1-3>	Configures the version of IGMP for this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default value is 2 (IGMPv2).

Configure IGMP Ports

Configure IGMP for each interface to change default multicasting operations.

Note

When you configure the following IGMP parameters on the DvR enabled interface of a DvR Controller, the configuration is automatically pushed to the Leaf nodes within the domain.

- **ip igmp version**
- **ip igmp query-interval**
- **ip igmp query-max-response**
- **ip igmp robust-value**
- **ip igmp last-member-query-interval**
- **ip igmp compatibility-mode**

For more information on DvR, see Distributed Virtual Routing on page 621.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable IGMP v2-v3 compatibility mode:

   ```
   ip igmp compatibility-mode
   ```

3. Configure the system to downgrade the version of IGMP:

   ```
   ip igmp dynamic-downgrade-version
   ```

4. Configure message intervals and response times:

   ```
   ip igmp last-member-query-interval <0-255> [query-interval <1-65535>]
   [query-max-response <0-255>]
   ```

5. Configure expected packet loss and IGMP version:

   ```
   ip igmp robust-value <2-255> [version <1-3>]
   ```

6. Configure IGMP for a specific port:

   ```
   ip igmp port {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```

7. Enable router alert:

   ```
   ip igmp router-alert
   ```

Example

Configure message intervals and response times:

```
Switch(config-if)#ip igmp last-member-query-interval 30 query-interval 60 query-max-
response 90
```

Configure expected packet loss and IGMP version:

```
Switch(config-if)#ip igmp robust-value 2 version 3
```

Configure IGMP for a specific port:

```
Switch(config-if)#ip igmp port 1/4
```

Enable router alert:

```
Switch(config-if)#ip igmp router-alert
```

Variable definitions

Use the definitions in the following table to use the **ip igmp** command.

Variable	Value
access-list WORD<1-64> {A.B.C.D/X} <eny-tx|deny-rx|deny-both|allow-only-tx|allow-only-rx|allow-only-both>	Specifies the name of the access list from 1–64 characters. Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host. Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic

compatibility-mode	Activates v2-v3 compatibility mode. The default value is disabled, which means IGMPv3 is not compatible with IGMPv2. To use the default configuration, use the default option in the command:
	`default ip igmp compatibility-mode`
	, or use the no option to disable compatibility mode:
	`no ip igmp compatibility-mode`

dynamic-downgrade-version	Configures if the system downgrades the version of IGMP to handle older query messages. If the system downgrades, the host with IGMPv3 only capability does not work. If you do not configure the system to downgrade the version of IGMP, the system logs a warning. The system downgrades to the oldest version of IGMP on the network by default. To use the default configuration, use the default option in the command:
	`default ip igmp dynamic-downgrade-version`
	or use the no option to disable downgrade:
	`no ip igmp dynamic-downgrade-version`

igmpv3-explicit-host-tracking	Enables explicit host tracking on IGMPv3. The default state is disabled.
immediate-leave	Enables fast leave on a port.
last-member-query-interval <0-255>	Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1. Decreasing the value reduces the time to detect the loss of the last member of a group. The default is 10 tenths of a second. You should configure this value between 3–10 (equal to 0.3 – 1.0 seconds).
port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Configures IGMP for a specific port. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Variable	Value
query-interval <1-65535>	Configures the frequency (in seconds) at which the VLAN transmits host query packets. The default value is 125 seconds.
query-max-response <0-255>	Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values enable a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds). Important: You must configure this value lower than the query-interval.
robust-value <2-255>	Configures the expected packet loss of a network. The default value is 2 seconds. Increase the value if you expect the network to experience packet loss.
router-alert	Instructs the router to ignore IGMP packets that do not contain the router alert IP option. When disabled (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option. Important: To maximize network performance, configure this parameter according to the version of IGMP currently in use: • IGMPv1—Disable • IGMPv2—Enable • IGMPv3—Enable
stream-limit stream-limit-max-streams <0-65535>	Configures multicast stream limitation on a port to limit the number of concurrent multicast streams on the port. The default is 4.
version <1-3>	Configures the version of IGMP for this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default value is 2 (IGMPv2).

Configuring IGMP on a VRF

You configure IGMP on a VRF instance the same way you configure IGMP for the Global Router, except that you must use VRF Router Configuration mode.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal

   router vrf WORD<1-16>
   ```

2. Enable SSM dynamic learning:

   ```
   ip igmp ssm dynamic-learning
   ```

3. Configure the range group:

   ```
   ip igmp ssm group-range {A.B.C.D/X}
   ```

   The system displays the following message:.

   ```
   Warning: Changing the SSM range will cause all spb-multicast and spb-
   pim-gw enabled interfaces to be internally bounced. Do you wish to
   continue? (y/n) ? (y/n)?
   ```

   Enter `y` to continue.
4. Enable the SSM map table for all static entries:

   ```
   ip igmp ssm-map all
   ```
5. Create a static entry for a specific group:

   ```
   ip igmp ssm-map {A.B.C.D} {A.B.C.D} enable
   ```
6. Enable the generation of IGMP traps:

   ```
   ip igmp generate-trap
   ```
7. Enable the generation of IGMP log messages:

   ```
   ip igmp generate-log
   ```
8. Configure the fast leave mode:

   ```
   ip igmp immediate-leave-mode {multiple-user|one-user}
   ```

Example

For the VRF Red context, configure a new IP multicast group address and create an SSM map table entry for the multicast group and the source at 192.32.99.151. Configure the administrative state to enable all the static SSM map table entries.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#router vrf red
Switch:1(router-vrf)#ip igmp ssm group-range 232.1.1.10/32

WARNING: Changing the SSM range will cause all spb-multicast and spb-pim-gw enabled
interfaces to be internally bounced. Do you wish to continue? (y/n) ? (y/n)? y
Switch:1(router-vrf)#ip igmp ssm-map 232.1.1.10 192.32.99.151
Switch:1(router-vrf)#ip igmp ssm-map all
```

Variable definitions

Use the definitions in the following table to use the **`ip igmp`** command on a VRF.

Variable	Value
generate-log	Enables the generation of IGMP log messages. The default is disabled.
generate-trap	Enables the generation of IGMP traps. The default is disabled.
immediate-leave-mode {multiple-user|one-user}	• multiple-user: Removes (from the group) the IGMP member who sent the leave message. The default is multiple-user. • one-user: Removes all group members on a fast leave enabled interface port after receiving the first leave message from a member.

Variable	Value
ssm dynamic-learning	Enables dynamic learning from IGMPv3 reports. The default is enabled.
ssm group-range {A.B.C.D/X}	Changes the SSM range group to define the SSM range. The SSM range parameter extends the default SSM range of 232/8 to include an IP multicast address. This parameter specifies an IP multicast address within the range of 224.0.0.0 and 239.255.255.255. The default is 232.0.0.0. The address mask is the IP address mask of the multicast group. The default is 255.0.0.0.
ssm-map <all | {A.B.C.D} {A.B.C.D} enable	Creates a static SSM channel table entry by specifying the group and source IP addresses. The IP address is an IP multicast address within the SSM range. The source IP address is an IP host address that sends traffic to the group. Enables the administrative state for a specific entry (group). This variable does not affect the dynamically learned entries. This state determines whether the switch uses the static entry or saves it for future use. The default is enable for each entry.

View IP Multicast Threshold Exceeded Statistics

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View statistics:

   ```
   show sys stats ipmc-threshold-exceeded-cnt
   ```

Example

```
Switch:1>show sys stats ipmc-threshold-exceeded-cnt
            SourceGroupThresholdExceeded : 7372
            EgressStreamThresholdExceeded : 7331
```

IP multicast basic configuration using EDM

To provide multicasting services, you need a host membership protocol and a multicast routing protocol. Hosts use a host membership protocol to subscribe to multicast services. The Internet Group Management Protocol (IGMP) is an example of an IPv4 host membership protocol.

A multicast routing protocol optimizes the routing of multicast information to avoid loops and restrict multicast traffic to networks that use host membership. Examples of multicast routing protocols include Protocol Independent Multicast–Sparse Mode (PIM–SM) and Protocol Independent Multicast–Source Specific Multicast (PIM–SSM).

Configuring multicast on the switch

This procedure shows how to configure PIM and IGMP Snooping in an SMLT environment. The configuration steps show how to enable multicast, and then configure the usual PIM and IGMP Snooping related VLANs and global attributes. It includes steps to configure the following:

- Setting the boot config flag
- Configuring the vIST peer
- Enabling Simplified vIST

Before You Begin

SPBM must not be enabled on the vIST peers or any router participating in the PIM network.

Procedure

1. In the navigation pane, expand the **Configuration** > **Edit** > **Chassis** folders.
2. Click the **Boot Config** tab.
3. Clear the **EnableSpbmConfigMode** to disable the boot flag.

   The system responds with these messages:

   ```
   Warning: Please save the configuration and reboot the switch for this
   to take effect.

   Warning: Please carefully save your configuration file before
   rebooting the switch. Saving configuration file when spbm-config-mode
   is changed to disable, removes SPBM configurations from the
   configuration file.
   ```
4. Click **Apply**.
5. Save the configuration, and then reboot the switch.

   

   Important

   Any change to the **EnableSpbmConfigMode** boot flag requires a reboot for the change to take effect.

6. Configure the *SMLT* MLT:
   a. Expand the following folders: **Configuration** > **VLAN** > **MLT/LACP**.
   b. Click the **MultiLink/LACP Trunks** tab.
   c. Click **Insert**.
   d. In the **Id** box, type the ID number of the MLT.
   e. In the **PortMembers** box, click the (**...**) button.
   f. In the **Port Editor: PortMembers** dialog box, select the desired ports.
   g. Click **Ok**
   h. Click **Insert**.

      The switch adds the SMLT MLT to the MultiLink/LACP Trunks tab in the MLT_LACP box.
7. Configure the *vIST* MLT:
   a. Repeat steps 6a to 6g to configure the MLT.
   b. Click **MltVistEnable** to enable Simplified vIST.

      

      Note

      The **MltVistEnable** field enables Simplified vIST and is only available when the **EnableSpbmConfigMode** boot flag is disabled.

   c. Click **Insert**.
8. Create the *vIST* VLAN:
   a. Expand the following folders: **Configuration** > **VLAN** > **VLANs**
   b. In the **Basic** tab, click **Insert**.

c. In the **Id** box, enter an unused VLAN ID, or use the ID provided.
d. In the **MstpInstance** box, click the down arrow, and then choose an MSTI instance from the list.
e. In the **Type** box, select **byPort**.
f. Click **OK**.
g. Click **Insert**.
h. Select the vIST VLAN from the list of VLANs, and then click **IP**.
i. Click **Insert**.
j. Configure the IP address for the vIST VLAN.

9. Repeat Step 8 to create an *SMLT* VLAN and assign the SMLT MLT ID to it. Do not use the vIST MLT ID.
10. Configure PIM or IGMP Snooping on the *SMLT* VLAN:
    a. To enable PIM, select the SMLT VLAN from the list of VLANs and click **IP** > **PIM**. Select **Enable** and click **Apply**.
    b. To enable IGMP Snooping, select the SMLT VLAN from the list of VLANs and click **IP** > **IGMP**. Select **SnoopEnable** and click **Apply**.
11. Configure PIM on the *SMLT* VLAN:
    a. To enable PIM, select the SMLT VLAN from the list of VLANs and click **IP** > **PIM**. Select **Enable** and click **Apply**.
12. Click **IP** > **PIM** > **Globals** to enable PIM globally.
13. Select the **Enable** check box, and then click **Apply**.

Enable IPv4 PIM-SM Globally

Enable PIM-SM to offer multicasting services. After you enable PIM-SM globally and on a particular interface, the IGMP parameters take effect.

Before You Begin

Note

Before you can enable the PIM Infinite Threshold Policy feature, you must first disable the following:

- PIM-SM
- PIM-SSM
- Simplified vIST

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Select **PIM**.
3. Select the **Globals** tab.
4. Select **sm** (sparse mode).
5. Select the **Enable** check box.
6. Select **Apply**.
7. Configure PIM Infinite Threshold Policy:
    a. To disable PIM, clear the **Enable** check box, and then click **Apply**.
    b. Select **enable**, and then click **Apply**

c. To enable PIM, select the **Enable** check box, and then click **Apply**.

Globals *field descriptions*

Use the descriptions in the following table to use the **Globals** tab.

Name	Description
Mode	Configures the mode on the routing switch: sm (Sparse Mode) or ssm (Source Specific Multicast).
Enable	Enables or disables PIM.
JoinPruneInterval	Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The range is from 1–18724 and the default is 60 seconds.
RegisterSuppTimer	Specifies how long (in seconds) the designated router suppresses sending registers to the rendezvous point (RP). The timer starts after the designated router receives a register-stop message from the RP. The range is from 6–65535 and the default is 60 seconds.
UniRouteChgTimeOut	Specifies how often (in seconds) the switch polls the routing table manager for unicast routing information updates for PIM. The range is from 2–65535 and the default is 5 seconds. Important: If you lower this value, it increases how often the switch polls the routing table manager. This value can affect the performance of the switch, especially if a high volume of traffic flows through the switch.
DiscardDataTimeOut	Specifies how long (in seconds) to discard data until the switch receives a join message from the RP. An IP multicast discard record is created after a register packet is sent, until the timer expires or the switch receives a join message. The range is from 5–65535 and the default is 60 seconds.
CRPADVTimeOut	Specifies how often (in seconds) a router configured as a candidate rendezvous point router (C-RP) sends advertisement messages. After this timer expires, the C-RP router sends an advertisement message to the elected bootstrap router (BSR). The range is from 5–26214 and the default is 60 seconds.
BootStrapPeriod	Specifies the interval (in seconds) that the elected BSR waits between originating bootstrap messages. The range is from 5–32757 and the default is 60 seconds.
StaticRP	Enables or disables the static RP feature. You can use static RP to configure a static entry for an RP. A static RP permits communication with switches from other vendors that do not use the BSR mechanism.
FwdCacheTimeOut	Specifies the PIM forward cache expiry value in seconds. This value ages PIM mroutes in seconds. The range is from 10–86400 and the default value is 210. Topology and hardware conditions can affect the polling interval and cause an inactive route to remain for up to 12-15 minutes.

Name	Description
FastJoinPrune	Enables or disables the PIM fast join prune feature.
SptInfiniteThreshold	Enables or disables PIM Infinite Threshold Policy, so that multicast traffic follows the shared tree path through a Rendezvous Point (RP) instead of automatically switching over to shortest path tree (SPT). The default value is disabled, which means that multicast traffic is automatically switched over to SPT.

Enable IPv6 PIM-SM Globally

Enable IPv6 PIM-SM to offer multicasting services. After you enable IPv6 PIM-SM globally and on a particular interface, the MLD parameters take effect.

Before You Begin

Note

Before you can enable the PIM Infinite Threshold Policy feature, you must first disable the following:

- PIM-SM
- PIM-SSM
- Simplified vIST

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Select **IPv6 PIM**.
3. Select the **Globals** tab.
4. Select the **Enable** check box.
5. Select **sm** (sparse mode).
6. Select **Apply**.
7. Configure PIM Infinite Threshold Policy:
   a. To disable PIM, clear the **Enable** check box, and then click **Apply**.
   b. Select **enable**, and then click **Apply**
   c. To enable PIM, select the **Enable** check box, and then click **Apply**.

Globals *field descriptions*

Use the descriptions in the following table to use the **Globals** tab.

Name	Description
Enable	Enables or disables PIM.
Mode	Configures the mode on the routing switch: sm (Sparse Mode) or ssm (Source Specific Multicast).

Name	Description
RegisterSuppTimer	Specifies how long (in seconds) the designated router suppresses sending registers to the rendezvous point (RP). The timer starts after the designated router receives a register-stop message from the RP. The range is from 10–65535 and the default is 60 seconds.
UniRouteChgTimeOut	Specifies how often (in seconds) the switch polls the routing table manager for unicast routing information updates for PIM. The range is from 2–65535 and the default is 5 seconds. Important: If you lower this value, it increases how often the switch polls the routing table manager. This value can affect the performance of the switch, especially if a high volume of traffic flows through the switch.
DiscardDataTimeOut	Specifies how long (in seconds) to discard data until the switch receives a join message from the RP. An IP multicast discard record is created after a register packet is sent, until the timer expires or the switch receives a join message. The range is from 5–65535 and the default is 60 seconds.
StaticRP	Enables or disables the static RP feature. You can use static RP to configure a static entry for an RP. A static RP permits communication with switches from other vendors that do not use the BSR mechanism.
FwdCacheTimeOut	Specifies the PIM forward cache expiry value in seconds. This value ages PIM mroutes in seconds. The range is from 10–86400 and the default value is 210. Topology and hardware conditions can affect the polling interval and cause an inactive route to remain for up to 12-15 minutes.
JoinPruneInterval	Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The range is from 1–18724 and the default is 60 seconds.
SptInfiniteThreshold	Enables or disables PIM Infinite Threshold Policy, so that multicast traffic follows the shared tree path through a Rendezvous Point (RP) instead of automatically switching over to shortest path tree (SPT). The default value is disabled, which means that multicast traffic is automatically switched over to SPT.

Enabling PIM on a port

Enable PIM for each interface to enable the interface to perform multicasting operations.

Before You Begin

- You must enable PIM globally before you enable it on an interface.
- The interface uses a valid IP address.

Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration** > **Edit** > **Port**.
3. Click **IP**.
4. Click the **PIM** tab.

5. Select the **Enable** check box.
6. Click **Apply**.

***PIM** field descriptions*

Use the data in the following table to use the **PIM** tab.

Name	Description
Enable	Enables (true) or disables (false) PIM for the specified port.
Mode	Displays the mode currently running on the routing switch.
IntfType	Indicates the interface type as active or passive.
HelloInterval	Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring routers. The default is 30 seconds. The range is 0-18724 seconds.
JoinPruneInterval	Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. The range is 1-18724 seconds.
CBSRPreference	Configures the preference for this local interface to become a candidate BSR (C-BSR). The C-BSR with the highest BSR priority and address is the preferred BSR. The default is –1, which indicates that the current interface is not a C-BSR. The range is -1-255.

Enabling IPv6 PIM on a port

Enable IPv6 PIM for each interface to enable the interface to perform multicasting operations.

About This Task

You can also right-click the port and use the **Edit IPv6** shortcut menu to reach this same tab.

Before You Begin

- You must enable IPv6 interface before you enable PIM on a port.

Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the **Configuration** > **Edit** > **Port** folders.
3. Click **IPv6**.
4. Click the **PIM** tab.
5. Select **Enable**.
6. Click **Apply**.

PIM *field descriptions*

Use the data in the following table to use the **PIM** tab.

Name	Description
Address	Specifies the IPv6 address of the PIM interface.
NetMask	Specifies the network mask for the IPv6 address of the PIM interface.
Enable	Enables (true) or disables (false) PIM for the specified port.
Mode	Displays the mode currently running on the routing switch.
DR	Specifies the designated router on this PIM interface.
HelloInterval	Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring routers. The default is 30 seconds. The range is 0-18724 seconds.
JoinPruneInterval	Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. The range is 1-18724 seconds.
OperState	Specifies the current operational state of this PIM interface.
Type	Specifies the type of interface.

Enable SSM Globally

Enable Source Specific Multicast (SSM) to optimize PIM-SM by simplifying the many-to-many model (servers-to-receivers). Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model that uses only a subset of the PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

Before You Begin

- Configure a unicast protocol, such as Routing Information Protocol (RIP) or Open Shortest Path First (OSPF), globally and on the interfaces where you want to configure PIM. For more information about RIP, see RIP configuration using EDM on page 2522. For more information about OSPF, see OSPF configuration using EDM on page 2263.
- Enable PIM globally.

Important

After you enable PIM in SSM mode, the IGMP parameters take effect. To take full advantage of SSM, enable IGMPv3 if hosts that attach to the switch run IGMPv3 or configure the SSM table.

About This Task

SSM is a global configuration. After you enable SSM on a switch, it is enabled on all interfaces that run PIM. On an SSM-enabled switch, SSM behavior is limited to the SSM group range. For non-SSM groups, the protocol behavior is PIM-SM.

Procedure

1. In the navigation pane, expand the **Configuration** > **IP** folders.
2. Select **PIM**.
3. Select the **Globals** tab.
4. Select **ssm** (source specific multicast).
5. Select the **Enable** check box.
6. Select **Apply**.

   The system displays the following message:

   ```
   Are you sure you want to change the PIM mode? The traffic will not be
   stopped immediately. All Static Source Group entries in the SSM range
   will be deleted. Do you wish to continue?
   ```
7. Select **Yes**.

Enable IPv6 SSM globally

Enable Source Specific Multicast (SSM) to optimize IPv6 PIM-SM by simplifying the many-to-many model (servers-to-receivers). Because most multicast applications distribute content to a group in one direction, SSM uses a one-to-many model that uses only a subset of the IPv6 PIM-SM features. This model is more efficient and reduces the load on multicast routing devices.

Before You Begin

- Configure an IPv6 unicast protocol, for example, Routing Information Protocol Next Generation (RIPng) or Open Shortest Path First Version 3 (OSPFv3), globally and on the interfaces where you want to configure PIM.

  For more information about RIPng, see RIPng Configuration using EDM on page 2532. For more information about OSPFv3, OSPFv3 Configuration using EDM on page 2299.
- Enable PIM globally.

  Important
  After you enable IPv6 PIM in SSM mode, the MLD parameters take effect. To take full advantage of SSM, enable MLDv2 if hosts that attach to the switch run MLDv2.

About This Task

SSM is a global configuration. After you enable SSM on a switch, it is enabled on all interfaces that run PIM. On a SSM-enabled switch, SSM behavior is limited to the SSM group range. For non-SSM groups, the protocol behavior is PIM-SM.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Select **IPv6 PIM**.
3. Select the **Globals** tab.
4. Select the **Enable** check box.
5. Select **ssm** (source specific multicast).

6. Select **Apply**.

   The system displays the following message:

   ```
   Warning: RP entries in the SSM range will be deleted

   Do you wish to continue? (y/n)?
   ```

7. Click **Yes**.

Enabling PIM on a VLAN interface

Configure PIM for each interface to enable the interface to perform multicasting operations.

Before You Begin

- You must enable PIM globally before you enable it on an interface.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select the VLAN ID that you want to configure with PIM.
5. Click **IP**.
6. Click the **PIM** tab.
7. Select the **Enable** check box.
8. Click **Apply**.

PIM *field descriptions*

Use the descriptions in the following table to use the **PIM** tab.

Name	Description
Enable	Enables (true) or disables (false) PIM.
Mode	Displays the mode that currently runs on the switch. The valid modes are SSM and Sparse. This variable is a read-only field.
IntfType	Specifies the type of interface: active or passive.
HelloInterval	Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring routers. The default is 30 seconds. The range is 0-18724.
JoinPruneInterval	Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. The range is 1-18724.
CBSRPreference	Configures the preference for this local interface to become a C-BSR. The C-BSR with the highest BSR priority and address is the preferred BSR. The default is –1, which indicates that the current interface is not a C-BSR. The range is -1-255.

Enabling IPv6 PIM on a VLAN interface

Configure IPv6 PIM for each interface to enable the interface to perform multicasting operations.

Before You Begin

- You must enable IPv6 PIM globally before you enable it on an interface.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select the VLAN ID that you want to configure with PIM.
5. Click **IPv6**.
6. Click the **PIM** tab.
7. Select the **Enable** check box.
8. Click **Apply**.

PIM field descriptions

Use the descriptions in the following table to use the **PIM** tab.

Name	Description
IfIndex	Specifies the interface index for PIM.
Address	Specifies the IPv6 address of the PIM interface.
Netmask	Specifies the network mask for the IPv6 address of the PIM interface.
Enable	Enables (true) or disables (false) PIM.
Mode	Displays the mode that currently runs on the switch. The valid modes are SSM and Sparse. This variable is a read-only field.
DR	Specifies the designated router on this PIM interface.
HelloInterval	Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring routers. The default is 30 seconds. The range is 0-18724.
JoinPruneInterval	Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds. The range is 1-18724.
OperState	Specifies the current operational state of this PIM interface.
Type	Specifies the type of interface.

Configuring IGMP parameters on a port

Configure IGMP for each interface to enable the interface to perform multicasting operations.

Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration** > **Edit** > **Port**.

3. Click **IP**.
4. Click the **IGMP** tab.
5. Edit the appropriate values.

Note

When you configure the following IGMP parameters on the DvR Controllers in a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

- Version
- QueryInterval
- QueryMaxResponseTime
- Robustness
- LastMembQueryIntvl
- CompatibilityModeEnable

For information on DvR, see .

Note

To use the fast leave feature on IGMP, enable explicit-host-tracking.

6. Click **Apply**.

IGMP field descriptions

Use the data in the following table to use the **IGMP** tab.

Name	Description
QueryInterval	Configures the frequency (in seconds) at which the interface transmits IGMP host query packets. The range is from 1–65535 and the default is 125.
QueryMaxResponseTime	Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values allow a router to prune groups faster. The range is from 0–255 and the default is 100 tenths of a second (equal to 10 seconds). Important: You must configure this value lower than the QueryInterval.
Robustness	Configure this parameter to tune for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect the network to lose query packets, increase the robustness value. The range is from 2–255 and the default is 2. The default value of 2 means that the switch drops one query for each query interval without the querier aging out.

Name	Description
LastMembQueryIntvl	Configures the maximum response time (in 1/10 seconds) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1. Decrease the value to reduce the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of a second. Configure this parameter to values greater than 3. If you do not require a fast leave process, Use values greater than 10. (The value 3 is equal to 0.3 seconds and 10 is equal to 1 second.)
SnoopEnable	Enables snoop on the interface. The default is disabled.
SsmSnoopEnable	Enables SSM snoop. The default is disabled.
ProxySnoopEnable	Enables proxy snoop on the interface. The default is disabled.
Version	Configures the version of IGMP (1, 2 or 3) that you want to use on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2.
FastLeaveEnable	Enables fast leave on the interface.
StreamLimitEnable	Enables or disables stream limitation on this port.
Maximum Number Of Stream	Configures the maximum number of streams this port permits. The range is from 0–65535 and the default is 4.
Current Number Of Stream	Displays the current number of streams. This variable is a read-only value.
FastLeavePortMembers	Lists ports that are enabled for fast leave.
SnoopMRouterPorts	Shows the configuration of ports as multicast router ports. Such ports attach to a multicast router, and forward multicast data and group reports to the router. Important: Configure this variable only if you use multiple multicast routers that do not attach to one another, but attach to the VLAN (technically, an invalid configuration). If multicast routers use a route between them (the valid configuration) and you configure this variable, a multicast loop forms.
RouterAlertEnable	Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option. To maximize network performance, configure this parameter according to the version of IGMP currently in use: • IGMPv1—Disable • IGMPv2—Enable • IGMPv3—Enable

Name	Description
DynamicDowngradeEnable	Configures if the switch downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning. The default value is selected (enabled), which means the switch downgrades to the oldest version of IGMP on the network.
CompatibilityModeEnable	Enables or disables v2-v3 compatibility mode. The default value is clear (disabled), which means IGMPv3 is not compatible with IGMPv2.
ExplicitHostTrackingEnable	Enables or disables IGMPv3 to track hosts per channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.

Configuring IGMP parameters on a VLAN

Configure IGMP for each interface to enable the interface to perform multicasting operations.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Select **IGMP**.
7. Configure the relevant variables.

   Note

   When you configure the following IGMP parameters on the DvR Controllers in a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

   - Version
   - QueryInterval
   - QueryMaxResponseTime
   - Robustness
   - LastMembQueryIntvl
   - CompatibilityModeEnable

   Configuration of IGMP snooping is not supported on DvR enabled Layer 2 VSNs.

8. Click **Apply**.

IGMP field descriptions

Use the data in the following table to use the **IGMP** tab.

Name	Description
QueryInterval	Configures the frequency (in seconds) at which the IGMP host query packets transmit on the interface. The range is from 1–65535 and the default is 125.
QueryMaxResponseTime	Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values allow a router to prune groups faster. The range is from 0–255 and the default is 100 tenths of a second (equal to 10 seconds.) Important: You must configure this value lower than the QueryInterval.
Robustness	Configure this parameter to tune for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect the network to lose query packets, increase the robustness value. The range is from 2–255 and the default is 2. The default value of 2 means that the switch drops one query for each query interval without the querier aging out.
LastMembQueryIntvl	Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1. Decreasing the value reduces the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of a second. Configure this parameter to values greater than 3. If you do not require a fast leave process, use values greater than 10. (The value 3 is equal to 0.3 seconds, and 10 is equal to 1 second.)
SnoopEnable	Enables snoop on the interface. The default is disabled.
SsmSnoopEnable	Enables SSM snoop. The default is disabled.
ProxySnoopEnable	Enables proxy snoop on the interface. The default is disabled.
Version	Configures the version of IGMP (1, 2, or 3) that you want to use on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2.
FastLeaveEnable	Enables or disables fast leave on the interface.
StreamLimitEnable	Enables or disables stream limitation on this VLAN.
Maximum Number Of Stream	Configures the maximum number of streams allowed on this VLAN. The range is from 0–65535 and the default is 4.
Current Number Of Stream	Displays the current number of streams. This value is a read-only value.
FastLeavePortMembers	Lists ports that are enabled for fast leave.

Name	Description
SnoopMRouterPorts	Shows the configuration of ports as multicast router ports. Such ports attach to a multicast router, and forward multicast data and group reports to the router. Important: Configure this field only if you use multiple multicast routers that do not attach to one another, but attach to the VLAN (technically, an invalid configuration). If multicast routers use a route between them (the valid configuration) and you configure this variable, a multicast loop forms.
RouterAlertEnable	Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option. To maximize network performance, configure this parameter according to the version of IGMP currently in use: • IGMPv1—Disable • IGMPv2—Enable • IGMPv3—Enable
DynamicDowngradeEnable	Configures if the switch downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning. The default value is selected (enabled), which means the switch downgrades to the oldest version of IGMP on the network.
CompatibilityModeEnable	Enables or disables v2-v3 compatibility mode. The default value is clear (disabled), which means IGMPv3 is not compatible with IGMPv2.
ExplicitHostTrackingEnable	Enables or disables IGMPv3 to track hosts per channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.
SnoopQuerierEnable	Enables snoop querier. The default is disabled. When you enable IGMP Layer 2 Querier, Layer 2 switches in your network can snoop IGMP control packets exchanged with downstream hosts and upstream routers. The Layer 2 switches then generate the Layer 2 MAC forwarding table, used for switching sessions and multicast traffic regulation, and provide the recurring queries required to maintain IGMP groups. Enable Layer 2 Querier on only one node in the VLAN.
SnoopQuerierAddr	Specifies the pseudo IP address of the IGMP snoop querier. The default IP address is 0.0.0.0.

Multicast Listener Discovery

Table 103: Multicast Listener Discovery product support

Feature	Product	Release introduced
Multicast Listener Discovery (MLD)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

MLD Fundamentals

MLD is an asymmetric protocol. It specifies separate behaviors for multicast address listeners (that is, hosts or routers that listen to multicast packets) and multicast routers. Each multicast router learns, for each directly attached link, which multicast addresses and which sources have listeners on that link. The information that MLD gathers is provided to the multicast routing protocols that the router uses. This information ensures that multicast packets arrive at all links where listeners require such packets.

A multicast router can itself be a listener of one or more multicast addresses; that is, the router performs both the multicast router role and the multicast address listener part of the protocol. The router collects the multicast listener information needed by the multicast routing protocol and informs itself and other neighboring multicast routers of the listening state.

IPv6 routers use MLD to discover:

- The presence of multicast listeners on directly attached links
- Multicast addresses required by neighboring nodes

MLD versions

The purpose of the MLD protocol in the IPv6 multicast architecture is to allow an IPv6 router to discover the presence of multicast listeners on directly-attached links and to discover which multicast addresses are of interest to neighboring nodes. MLD is the direct IPv6 replacement for the IGMP protocol used in IPv4. The MLD implementation described in this document is based on the MLDv2 standard, which is a backward-compatible update to the MLDv1 standard.

There are three versions of IGMP, and two versions of MLD. IGMPv2 is equivalent in function to MLDv1 and IGMPv3 is equivalent to MLDv2.

MLD Querier

MLD Querier is similar to IGMP querier. A multicast query router communicates with hosts on a local network by sending MLD queries. This router periodically sends a general query message to each local network of the router. This is standard multicast behavior.

Note

Queries are sent only if PIM is enabled globally and on the interface. PIM and snooping cannot be enabled at the same time.

Each VLAN using MLD multicast must have a router performing multicast queries. Networks with no stand-alone devices currently have no capability for implementing the pruning of multicast traffic. A dedicated querier must be available on the network.

There are several behavioral differences between a traditional query router and a switch or stack using the MLD Querier functionality. The following are the differences:

- There is no election process. When a switch or stack restarts, queries are sent as part of MLD startup. This process stops other devices from sending queries while they detect the new device starting up. The last active device sending queries on the network is the active one. This is not the case with Layer 3 MLD behavior.
- If the current active device stops sending queries, a timeout period must elapse before another device takes over. This can result in an ageout of groups, and subsequent flooding, before a new query is sent and the pruning process restarts. This occurs only during the transition between active query devices. Once the new device is established, queries are sent as configured in the Query Interval and Robust Values fields.
- Multiple active query devices are not supported. Enabling multiple devices establishes one active device and other devices listening to take over should the active device fail.

The querier version is determined by the received query version and establishes the interface operational version. By default, the interface operational version is MLDv1. If the interface operational version is downgraded from MLDv2 to MLDv1 (when operational version is MLDv2 and a MLDv1 query is received), then all MLDv2 listeners (registered by MLDv2 reports) are removed and all incoming MLDv2 reports are dropped.

MLD snooping

MLD snooping is an IPv6 multicast constraining mechanism running on Layer 2 devices. When MLD snooping is enabled on a VLAN, the switch examines the MLD messages between hosts and multicast routers and learns which hosts are interested in receiving traffic for a multicast group. Based on the learning, the switch forwards multicast traffic only to those interfaces in the VLAN that are connected to the interested receivers instead of flooding traffic to all the interfaces.

The following figure shows an example of this scenario. On the left side of the figure, IPv6 multicast packets are transmitted when MLD snooping is not enabled. All the hosts that are interested and not interested receive the IP Multicast traffic consuming bandwidth. Whereas, on the right side of the figure, when MLD snooping is enabled and IPv6 multicast packets are transmitted, only the interested hosts receive the IP multicast packets.

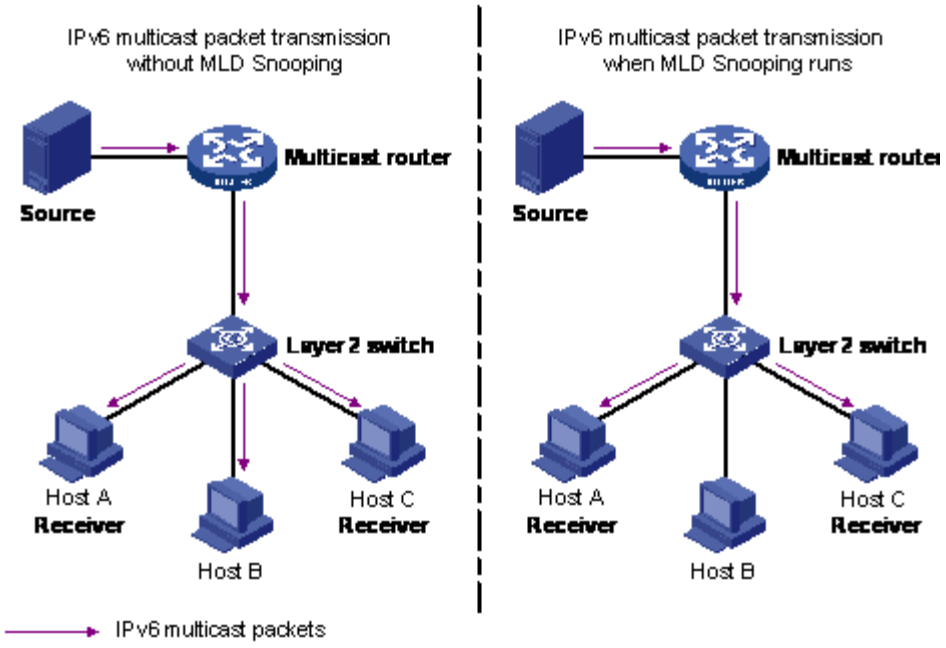

Figure 135: IPv6 multicast packet transmission when MLD snooping is enabled and not enabled

The following figure shows IPv6 multicast packets transmitted when MLD v2 snooping is enabled and not enabled.

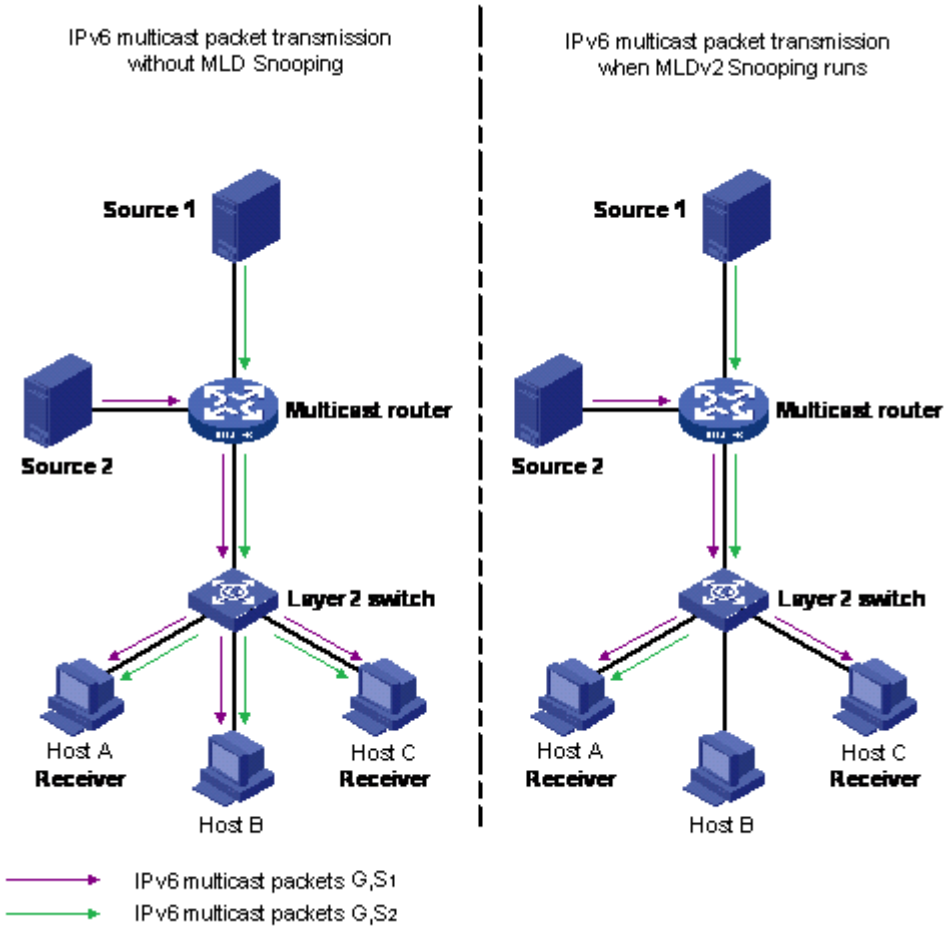

Figure 136: IPv6 multicast packet transmission when MLD v2 snooping is enabled and not enabled

MLD snooping configuration guidelines and restrictions

You can perform the following configurations to manage and control IPv6 multicast groups using the MLD snooping feature:

- Enable or disable MLD snooping on each VLAN. MLD snooping can be enabled on a maximum of 512 VLANs.
- Enable IGMP snooping and MLD snooping on the same VLAN.

Limitations

Following are the limitations for MLD snooping configuration:

- The maximum (S,G,V) entries supported in the IPv6 multicast routing table (L3_ENTRY_IPV6_MULTICAST) is 512.

  MLD snooping shares the (S,G,V) entries with IGMP snooping, where the (S,G,V) entries number = (G,V) MLD_V1 type entries number + (S,G,V) MLD_V2 type entries number + (*,G,V) MLD_V2 type entries number + number of groups without (*,G,V) registered listeners.
- IPv6 MLD proxy functionality is not supported.
- Multicast Flood Control (MFC) is not supported.

- Static mrouter ports cannot be configured.
- IPv6 MLD send query functionality is not supported.
- Configure static router ports is not supported.

MLD Configuration Using the CLI

Configuring MLD trap generation

About This Task

Use this procedure to enable MLD traps.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Enable MLD trap generation:
   ```
   ipv6 mld generate-trap
   ```
3. Disable MLD trap generation:
   ```
   no ipv6 mld generate-trap
   ```
4. Set MLD trap enable status to default:
   ```
   default ipv6 mld generate-trap
   ```

Configuring MLD log status

About This Task

Use this procedure to enable MLD traps.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Enable MLD log status:
   ```
   ipv6 mld generate-log
   ```
3. Disable MLD log status:
   ```
   no ipv6 mld generate-log
   ```
4. Set MLD log enable status to default:
   ```
   default ipv6 mld generate-log
   ```

Configuring MLD version

About This Task

Use this procedure to configure MLD version.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure MLD version:

   ```
   ipv6 mld version <1-2>
   ```

   Note

   For MLD to function correctly, the MLD version must be the same on all routers in the network.

3. Set MLD version to default:

   ```
   default ipv6 mld version
   ```

Variable Definitions

The following table describes the variables for the **ipv6 mld version** command.

Variable	Value
<1–2>	Indicates the version of MLD that runs on this interface.

Configuring the MLD last listener query interval

About This Task

Use this procedure to configure the last listener query interval in seconds for the MLD interface.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the last listener query interval:

   ```
   ipv6 mld last-listener-query-interval <0-60>
   ```

3. Set the last listener query interval to its default value:

   ```
   default ipv6 mld last-listener-query-interval
   ```

Variable Definitions

The following table describes the variables for the **`ipv6 mld last-listener-query-interval`** command.

Variable	Value
<0-60>	Indicates the last listener query interval in seconds.

Configuring the MLD query interval

About This Task

Use this procedure to configure the query interval for the MLD interface.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the query interval for the MLD interface:

   ```
   ipv6 mld query-interval <1-65535>
   ```

3. Set the query interval to its default value:

   ```
   default ipv6 mld query-interval
   ```

Variable Definitions

The following table describes the variables for the **ipv6 mld query-interval** command.

Variable	Value
<1–65535>	Indicates the frequency at which MLD host query packets transmit on this interface.

Configuring the MLD query maximum response time

About This Task

Use this procedure to configure the query maximum response time for mld interface.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable
   ```

   ```
   configure terminal
   ```

   ```
   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```
   or
   ```
   interface vlan <1–4059>
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the query maximum response time for mld interface:

   ```
   ipv6 mld query-max-response-time <0–60>
   ```

3. Set the query maximum response time to its default value:

   ```
   default ipv6 mld query-max-response-time
   ```

Variable Definitions

The following table describes the variables for the **ipv6 mld query-max-response-time** command.

Variable	Value
<0–60>	Indicates the query maximum response interval time in seconds.

Configuring the MLD robustness

About This Task

The robustness value allows the tuning for the expected packet loss on a link. If a link expects packet loss, increase the robustness variable value.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the MLD robustness:

   ```
   ipv6 mld robust-value <2-255>
   ```

3. Set the MLD robustness to its default value:

   ```
   default ipv6 mld robust-value
   ```

Variable Definitions

The following table describes the variables for the **ipv6 mld robust-value** command.

Variable	Value
<2–255>	Specifies a numerical value for MLD snooping robustness.

Enabling MLD snooping on a VLAN

About This Task

Use this procedure to enable MLD snooping on a VLAN.

Procedure

1. Enter VLAN Interface Configuration mode:

   ```
   enable

   configure terminal

   interface vlan <1-4059>
   ```

2. Enable MLD snooping:

   ```
   ipv6 mld snooping
   ```

3. Set the MLD snooping to its default value:

   ```
   default ipv6 mld snooping
   ```

Enabling MLD ssm-snooping on a VLAN

About This Task

Use this procedure to enable IPv6 MLD ssm-snooping on a VLAN.

Procedure

1. Enter VLAN Interface Configuration mode:
   ```
   enable

   configure terminal

   interface vlan <1–4059>
   ```
2. Enable MLD snooping:
   ```
   ipv6 mld ssm-snoop
   ```
3. Set the MLD snooping to its default value:
   ```
   default ipv6 mld ssm-snoop
   ```

Display MLD Snooping Configuration Status

About This Task

Use this procedure to display information about the MLD snooping configuration for the switch.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Display the switch MLD snooping configuration status:
   ```
   show ipv6 mld snooping
   ```

Example

```
Switch:1#show ipv6 mld snooping
================================================================================
                        Mld Snooping - GlobalRouter
================================================================================
IFINDEX SNOOP    SSM      ACTIVE           MROUTER
        ENABLE   SNOOP    MROUTER          EXPIRATION
                 ENABLE   PORTS            TIME
--------------------------------------------------------------------------------
V666    False    False    NONE          0
1 out of 1 entries displayed
```

Display MLD Snooping Tracing Information

About This Task

Use this procedure to display MLD snooping tracing information.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```

2. Display the MLD snooping tracing information:

   ```
   show ipv6 mld snoop-trace
   ```

Example

```
Switch:1#show ipv6 mld snoop-trace
============================================================
              Mld Snoop Trace - GlobalRouter

============================================================

```

Display MLD Interface Information

About This Task

Use this procedure to display MLD snooping interface parameters.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display MLD interface information:

   ```
   show ipv6 mld interface [gigabitethernet {slot/port[/sub-port]}] [vlan <1-4059>]
   ```

Examples

```
Switch:1#show ipv6 mld interface
================================================================================================
                        Mld Interface - GlobalRouter

Variable	Value
vlan *<1-4059>*	Displays MLD snooping information for the configured VLANs.
gigabitEthernet *{slot/port[/sub-port]}*	Displays MLD snooping information on a specific interface.

Displaying MLD system parameters

About This Task

Use this procedure to display information about the MLD traps and logs.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Display the system parameters:
   ```
   show ipv6 mld sys
   ```

Example

```
Switch:1#show ipv6 mld sys
================================================================================
                     Mld System Parameters - GlobalRouter
================================================================================
                    generate-trap : disable
                     generate-log : disable
```

Display MLD Cache Information

About This Task

Use this procedure to display the learned multicast groups in the cache.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Display the learned multicast groups in the cache:
   ```
   show ipv6 mld cache
   ```

Example

```
Switch:1#show ipv6 mld cache

Display the MLD Group Information

About This Task

Use this procedure to display the MLD group information to show the learned multicast groups and the attached ports.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display the MLD group information:

   ```
   show ipv6 mld group [count] [group] [member-subnet]
   ```

Examples

```
Switch:1#show ipv6 mld group

mgmt      ff02::1                           enabled
```

MLD Configuration Using EDM

Configuring MLD globally

About This Task

Use the following procedure to configure MLD parameters for the switch.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6** folders.
2. Click **IPv6 MLD**.
3. Click the **Globals** tab.
4. Configure the MLD global parameters as required.
5. On the toolbar, click **Apply** to save the changes.
6. On the toolbar, click **Refresh** to update the changes.

Globals field description

Use the data in the following table to use the **Globals** tab.

Field	Description
GenerateTrap	Enables MLD to generate traps.
GenerateLog	Enables MLD to generate logs.

Viewing the MLD SSM global information

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Ssm Globals** tab.

Ssm Globals field description

Use the data in the following table to use the **Ssm Globals** tab.

Field	Description
RangeGroup	Specifies the ssm range.
RangeMask	Specifies the ssm range mask.

MLD interface configuration

Configure the interfaces so that the switch forwards multicast traffic only to those interfaces in the VLAN that are connected to the interested receivers instead of flooding traffic to all the interfaces.

Configuring an MLD interface

Perform this procedure to change the configuration of existing MLD interfaces.

Procedure

1. In the navigation pane, expand the **Configuration** > **IPv6** folders.
2. Click **IPv6 MLD**.
3. Click the **Interfaces** tab.
4. On the toolbar, click **Insert**.
5. Configure the MLD interface parameters.
6. Click **Insert**.
7. On the toolbar, click **Apply** to save the changes.
8. On the toolbar, click **Refresh** to update the changes.

MLD interfaces field description

Use the data in the following table to use the **Interfaces** tab.

Field	Description
IfIndex	Specifies the internetwork layer interface value of the interface for which MLD is enabled.
QueryInterval	Specifies the frequency at which MLD host-query packets are transmitted on this interface. Values range from 1 to 65535.
Version	Indicates the MLD version.
Querier	Specifies the address of the MLD Querier on the IPv6 subnet to which this interface is attached.
QueryMaxResponseDelay	Specifies the maximum query response time advertised in MLD queries on this interface. Values range from 0 to 60.
Joins	Specifies the number of times a group membership has been added on this interface.
Groups	Specifies the current number of entries for this interface in the cache table.

Field	Description
Robustness	Specifies the robustness variable tuning for the expected packet loss on a subnet. If a subnet is expected to experience loss, the robustness variable can be increased. Values range from 2 to 255.
LastListenQueryIntvl	Specifies the maximum response delay inserted into the group-specific queries sent in response to the leave group messages. It also indicates the amount of time between group-specific query messages. Values range from 0 to 60. This value can be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group.
SnoopEnable	Indicates if snooping is enabled.
FlushAction	Specifies the MLD flush action as one of the following: • flushGrpMember • flushMrouter • flushSender
SsmEnable	Indicates if ssm is enabled.
NewQuerier	Specifies the IPv6 address of the new MLD querier.
DynamicDowngradeEnable	Enables dynamic downgrade of the MLD version when older version query message is received.
OperVersion	Specifies the operational version of the MLD running on this interface.
McastMode	Specifies the MLD interface mode as one of the following: • snoop • pim • snoopSpb • routerSpb • dvmrp • none

Configuring MLD on a port

Configure the MLD on a port.

Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the **Configuration** > **Edit** > **Port** folders.
3. Click **IPv6**.
4. Click the **MLD** tab.
5. Configure the MLD interface parameters.
6. On the toolbar, click **Apply** to save the changes.

7. On the toolbar, click **Refresh** to update the changes.

MLD field description

Use the data in the following table to use the **MLD** tab.

Field	Description
QueryInterval	Specifies the frequency at which MLD host-query packets are transmitted on this interface. Values range from 1 to 65535.
Version	Indicates the MLD version.
Querier	Specifies the address of the MLD Querier on the IPv6 subnet to which this interface is attached.
QueryMaxResponseDelay	Specifies the maximum query response time advertised in MLD queries on this interface. Values range from 0 to 60.
Joins	Specifies the number of times a group membership has been added on this interface.
Groups	Specifies the current number of entries for this interface in the cache table.
Robustness	Specifies the robustness variable tuning for the expected packet loss on a subnet. If a subnet is expected to experience loss, the robustness variable can be increased. Values range from 2 to 255.
LastListenQueryIntvl	Specifies the maximum response delay inserted into the group-specific queries sent in response to the leave group messages. It also indicates the amount of time between group-specific query messages. Values range from 0 to 60. This value can be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group.
SnoopEnable	Indicates if snooping is enabled.
FlushAction	Specifies the MLD flush action as one of the following: • flushGrpMember • flushMrouter • flushSender
SsmEnable	Indicates if ssm is enabled.
NewQuerier	Specifies the IPv6 address of the new MLD querier.
DynamicDowngradeEnable	Enables dynamic downgrade of the MLD version when older version query message is received.

Field	Description
OperVersion	Specifies the operational version of the MLD running on this interface.
McastMode	Specifies the MLD interface mode as one of the following: • snoop • pim • snoopSpb • routerSpb • dvmrp • none

Configuring MLD on a VLAN

About This Task

Configure MLD on a VLAN.

Procedure

1. In the navigation pane, expand the **Configuration** > **VLAN** folders.
2. Click **VLANs**.
3. Select a VLAN from the list.
4. Click the **IPv6** tab.
5. Click the **MLD** tab.
6. Configure the MLD interface parameters.
7. On the toolbar, click **Apply** to save the changes.
8. On the toolbar, click **Refresh** to update the changes.

MLD field description

Use the data in the following table to use the **MLD** tab.

Field	Description
QueryInterval	Specifies the frequency at which MLD host-query packets are transmitted on this interface. Values range from 1 to 65535.
Version	Indicates the MLD version.
Querier	Specifies the address of the MLD Querier on the IPv6 subnet to which this interface is attached.
QueryMaxResponseDelay	Specifies the maximum query response time advertised in MLD queries on this interface. Values range from 0 to 60.
Joins	Specifies the number of times a group membership has been added on this interface.
Groups	Specifies the current number of entries for this interface in the cache table.

Field	Description
Robustness	Specifies the robustness variable tuning for the expected packet loss on a subnet. If a subnet is expected to experience loss, the robustness variable can be increased. Values range from 2 to 255.
LastListenQueryIntvl	Specifies the maximum response delay inserted into the group-specific queries sent in response to the leave group messages. It also indicates the amount of time between group-specific query messages. Values range from 0 to 60. This value can be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group.
SnoopEnable	Indicates if snooping is enabled.
FlushAction	Specifies the MLD flush action as one of the following: • flushGrpMember • flushMrouter • flushSender
SsmEnable	Indicates if ssm is enabled.
NewQuerier	Specifies the IPv6 address of the new MLD querier.
DynamicDowngradeEnable	Enables dynamic downgrade of the MLD version when older version query message is received.
OperVersion	Specifies the operational version of the MLD running on this interface.
McastMode	Specifies the MLD interface mode as one of the following: • snoop • pim • snoopSpb • routerSpb • dvmrp • none

Configuring MLD snooping

About This Task

Use the following procedure to enable MLD snooping on the switch.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click **Snooping** tab.
4. Select a value, double-click the cell in **SnoopEnable** column, select **True** or **False**.

5. Select a value, double-click the cell in **SsmEnable** column, select **True** or **False**.
6. Click **Apply**.

Snooping field description

Use the data in the following table to use the **Snooping** tab.

Field	Description
IfIndex	Specifies the interface on which you enabled MLD snooping. It specifies the port number if the interface is a brouter port or the VLAN number if the interface is a VLAN.
SnoopEnable	Indicates the status of MLD snooping on the specified interface: • True – MLD snooping is enabled • False – MLD snooping is disabled
SsmEnable	Indicates the status of SSM on the specified interface: • True – SSM is enabled • False – SSM is disabled

Viewing the MLD snoop trace information

About This Task

Use this procedure to display information about the multicast groups traversing the snoop enabled router.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Snoop Trace** tab.

Snoop Trace field description

Use the data in the following table to use the **Snoop Trace** tab.

Field	Description
GrpAddr	Specifies the IP multicast address of the group traversing the router.
SrcAddr	Specifies the IP source address of the multicast group address.
OutVlan	Specifies the egress VLAN ID for the multicast group.
OutPort	Specifies the egress port of the multicast group.
InVlan	Specfies the ingress VLAN ID for the multicast source.

Field	Description
InPort	Specifies the ingress port for the multicast group.
Type	Specifies the port type on which the snoop entry is learnt.

Viewing the MLD cache information

About This Task

Use this procedure to display information about the learned multicast groups in the cache.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Cache** tab.

MLD cache field description

Use the data in the following table to use the **Cache** tab.

Field	Description
Address	The IPv6 multicast group address for which this entry contains information.
IfIndex	Indicates the internetwork-layer interface for which this entry contains information for an IPv6 multicast group address.
LastReporter	Indicates the source IPv6 address of the last membership report received for this IPv6 Multicast group address on this interface. If membership report is not received, the value is 0::0
ExpiryTime	Indicates the minimum amount of time remaining before the entry ages out.

Viewing the MLD V2 cache information

About This Task

Use this procedure to display information about the MLDv2 corresponding to each interface, port and multicast group paired on a router.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click the **V2 Cache** tab.

V2 Cache field description

Use the data in the following table to use the **V2 Cache** tab.

Field	Description
GroupAddress	Specifies the multicast group address that others want to join. A group address can be the same for many incoming ports.
Ifindex	Identifies a physical interface or a logical interface (VLAN), which has received group reports from various sources.
InPort	Identifies a physical interface or a logical interface (VLAN), which has received group reports from various sources.
Version1HostTimer	Specifies the time remaining until the local router assumes that there are no more MLDv1 members on the IP subnet attached to the interface. This is applicable only for MLDv1 hosts. Upon receiving an MLDv1 report, this value is reset to the group membership timer.
SourceFilterMode	Specifies the current group state applicable on MLDv2 compatible nodes.

Viewing IPv6 MLD host cache

View the learned multicast group addresses in the host cache.

Procedure

1. In the navigation tree, expand the **Configuration** > **IPv6** folders.
2. Click **IPv6 MLD**.
3. Click the **Host Cache** tab.

MLD host cache field descriptions

Use the data in the following table to use the **Host Cache** tab.

Name	Description
IfIndex	Shows the index value that uniquely identifies the interface to which this entry applies.
GrpAddress	Shows the IP address for the multicast group.
GrpLocallyRegistered	Shows the Group Locally Registered for an IPv6 MLD host-cache entry.
GrpLastReporter	Shows the Group Last Reporter address for an IPv6 MLD host-cache entry.
GrpUpTime	Shows the Group Uptime for an IPv6 MLD host-cache entry.

Name	Description
GrpExpiryTime	Shows the Group Expiry Time for an IPv6 MLD host-cache entry.
GrpFilterMode	Shows the Group Filter Mode for an IPv6 MLD host-cache entry.

Viewing the MLD source information

About This Task

Use this procedure to display information about the MLD source.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Source** tab.

Source field description

Use the data in the following table to use the **Source** tab.

Field	Description
GroupAddress	Specifies the IPv6 multicast group address for which this entry contains information.
Ifindex	Specifies the interface for which this entry contains information for an IP multicast group address.
InPort	Identifies a physical interface or logical interface (VLAN), which has received group reports for this source.
HostAddress	Specifies the host address to which this entry corresponds.
MemberAddress	Specifies the IPv6 address of a member that has sent source specific report wishing to join this source.
Expire	Specifies the state of this entry.
Mode	Specifies the current member state. This is applicable to MLDv2 compatible nodes.
MemberExpire	Specifies the time until the member for this source expires.

Viewing the MLD sender information

About This Task

Use this procedure to display information about the multicast senders.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Sender** tab.

Source field description

Use the data in the following table to use the **Sender** tab.

Field	Description
GrpAddr	Specifies the IPv6 multicast group address.
Ifindex	Specifies the interface index of the sender.
MemberAddr	Specifies the IPv6 host address.
Action	Specifies the MLD action as one of the following: • none • flushEntry • flushGrp
Port	Specifies the MLD sender port.

Viewing the MLD group information

About This Task

Use this procedure to display information about the groups configured in this device.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 MLD**.
3. Click the **Group** tab.

Group field description

Use the data in the following table to use the **Group** tab.

Field	Description
IPv6Address	Specifies the multicast group address that others want to join to. A group address can be the same for many incoming ports.
Members	Specifies the IP address of a source that has sent group report whishing to join this group.
InPort	Identifies a physical interface or a logical interface which has received group reports from various sources.

Field	Description
Expiration	Specifies the time left before group report expires on this port. This is updated upon receiving a group report.
IfIndex	Identifies a physical interface or a logical interface which has received group reports from various sources.

PIM Configuration Using the CLI

The switch supports two modes of Protocol Independent Multicast (PIM): Sparse Mode (SM) and Source Specific Multicast (SSM).

- PIM-SM supports multicast groups spread out across large areas of a company or the Internet.
- PIM-SSM optimizes PIM-SM by simplifying the many-to-many model (servers-to-receivers).

Important

The **spbm-config-mode** boot flag must be disabled before you can configure PIM or IGMP. To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

Before You Begin

For an IPv4 PIM configuration using the CLI:

- Configure an IPv4 interface.

  For more information, see IP routing configuration using the CLI on page 1605.
- Configure a unicast protocol, for example, Routing Information Protocol (RIP) or Open Shortest Path First (OSPF), globally and on the interfaces where you want to configure PIM-SM.

  For more information about RIP, see RIP configuration using CLI on page 2507. For more information about OSPF, see OSPF configuration using CLI on page 2197.
- Enable PIM-SM globally.
- Enable PIM-SM on individual interfaces.
- You must first configure and enable PIM on an IP interface, which can be circuitless, before you can utilize that interface as a candidate rendezvous point (RP). To configure PIM-SM RP for an IP interface, see Configuring a candidate rendezvous point on page 1367.
- Configure one or more bootstrap routers (BSR) to propagate RP information to all switches in the network.

For an IPv6 PIM configuration using the CLI:

- Configure an IPv6 interface.

  For more information, see Configure an IPv6 Interface on page 1683.
- Configure an IPv6 unicast protocol, for example, Routing Information Protocol Next Generation (RIPng) or Open Shortest Path First Version 3 (OSPFv3), globally and on the interfaces where you want to configure PIM.

For more information about RIPng, see RIPng Configuration using CLI on page 2517. For more information about OSPFv3, see OSPFv3 Configuration using CLI on page 2238.

- Enable IPv6 PIM-SM globally
- Enable IPv6 PIM-SM on individual interfaces.

Changing the interface status to passive

Change the PIM interface status to passive to deny PIM control traffic on the interface.

Before You Begin

- The PIM interface is disabled.

About This Task

The command you use depends on the required administrative state of the interface (enable or disable).

Procedure

1. Enter Interface Configuration mode:

   ```
   enable
   ```

   ```
   configure terminal
   ```

   ```
   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```
   or
   ```
   interface vlan <1-4059>
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create a passive interface and enable it simultaneously:

   ```
   ip pim passive
   ```

3. Create a passive interface in the disabled state:

   ```
   ip pim interface-type passive
   ```

   You must manually enable the interface.

4. Enable a disabled interface:

   ```
   ip pim enable
   ```

Variable definitions

Use the data in the following table to use the **ip pim** command.

Variable	Value
active	Configures the selected interface. You can change the state of a PIM interface after you create the interface but only if you first disable PIM on the interface. An active interface permits PIM control transmitted and received traffic. A passive interface prevents PIM control traffic from transmitting or receiving, thereby reducing the load on a system. This feature is useful if a high number of PIM interfaces exist and connect to end users, not to other switches. The default is active. To configure this option to the default value, use the **default** operator with the command.
passive	Configures the selected interface. You can change the state of a PIM interface after you create the interface but only if you first disable PIM on the interface. An active interface permits PIM control transmitted and received traffic. A passive interface prevents PIM control traffic from transmitting or receiving, thereby reducing the load on a system. This feature is useful if a high number of PIM interfaces exist and connect to end users, not to other switches. The default is active. To configure this option to the default value, use the **default** operator with the command.

Changing the interface status to active

Change the PIM interface status to active to allow PIM control traffic on the interface.

Before You Begin

- The PIM interface is disabled.

About This Task

The command you use depends on the required administrative state of the interface (enable or disable).

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]} or interface vlan <1-4059>
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create an active interface in the disabled state:

   ```
   ip pim interface-type active
   ```

   You must manually enable the interface.
3. Create an active interface and enable it simultaneously:

   ```
   ip pim active
   ```

   OR

   ```
   ip pim enable
   ```

   The second command enables an active interface only if this is the first PIM interface you create on the port or VLAN or you created an active interface in the disabled state. If you already created a passive interface in the disabled state, the second command enables that passive interface.

Variable definitions

Use the data in the following table to use the **ip pim** command.

Variable	Value
active	Configures the selected interface. You can change the state of a PIM interface after you create the interface but only if you first disable PIM on the interface. An active interface permits PIM control transmitted and received traffic. A passive interface prevents PIM control traffic from transmitting or receiving, thereby reducing the load on a system. This feature is useful if a high number of PIM interfaces exist and connect to end users, not to other switches. The default is active. To configure this option to the default value, use the **default** operator with the command.
passive	Configures the selected interface. You can change the state of a PIM interface after you create the interface but only if you first disable PIM on the interface. An active interface permits PIM control transmitted and received traffic. A passive interface prevents PIM control traffic from transmitting or receiving, thereby reducing the load on a system. This feature is useful if a high number of PIM interfaces exist and connect to end users, not to other switches. The default is active. To configure this option to the default value, use the **default** operator with the command.

Configuring the PIM virtual neighbor

Configure a PIM virtual neighbor if the next hop for a static route cannot run PIM, such as the Virtual Router Redundancy Protocol (VRRP) address on an adjacent device.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the PIM virtual neighbor:

   ```
   ip pim virtual-neighbor <A.B.C.D> <A.B.C.D>
   ```

Example

Configure the PIM virtual neighbor:

```
Switch:1(config)#ip pim virtual-neighbor 192.0.2.0 198.51.100.0
```

Variable definitions

Use the definitions in the following table to use the **ip pim virtual-neighbor** command.

Variable	Value
{A.B.C.D} {A.B.C.D}	The first IP address indicates the IP address of the selected interface. The second IP address indicates the IP address of the neighbor.

Configuring a candidate rendezvous point

Configure a candidate rendezvous point (C-RP) to serve as backup to the RP router.

About This Task

You can configure only one interface on the switch for multiple groups. You cannot configure multiple interfaces for multiple groups.

With the mask value, you can configure a C-RP router for several groups in one configuration.

For example, if you use a C-RP configuration with a group address of 224.0.0.0 and a group mask of 240.0.0.0, you can configure the C-RP router for a multicast range from 224.0.0.0 to 239.255.255.255.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Add a candidate rendezvous point:

   ```
   ip pim rp-candidate group <A.B.C.D> <A.B.C.D> rp <A.B.C.D>
   ```

3. Remove a candidate rendezvous point:

   ```
   no ip pim rp-candidate group <A.B.C.D> <A.B.C.D>
   ```

4. Display information about the candidate rendezvous points for the PIM-SM domain:

   ```
   show ip pim rp-candidate
   ```

Example

Add a candidate rendezvous point:

```
Switch:1(config)#ip pim rp-candidate group 224.1.1.0 255.255.255.0 rp 198.51.100.0
```

Variable definitions

Use the definitions in the following table to use the **ip pim rp-candidate** command.

Variable	Value
group {A.B.C.D} {A.B.C.D}	Specifies the IP address and the address mask of the multicast group. After the IP address and group mask are combined, it identifies the prefix that the local router uses to advertise itself as a C-RP router.
rp {A.B.C.D}	Specifies the IP address of the C-RP router. This address must be one of the local PIM-SM enabled interfaces.

Configuring static RP

Configure a static RP to ignore the bootstrap router (BSR) mechanism and use the statically configured RPs.

Before You Begin

- Enable PIM-SM globally.

About This Task

Static RP-enabled switches use this feature to communicate with switches from other vendors that do not use the BSR.

Important

You cannot configure a static RP-enabled switch as a BSR or as a C-RP router.

All dynamically learned BSR information is lost. However, if you disable static RP, the switch loses the static RP information and regains the BSR functionality.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable static RP:

   ```
   ip pim static-rp
   ```

   The system displays the following message:

   ```
   WARNING: RP information learnt dynamically through BSR functionality will be lost.
   Do you wish to enable Static RP? (y/n) ?
   ```

3. Enter `y`.
4. Configure a static RP entry:

   ```
   ip pim static-rp {A.B.C.D/X} {A.B.C.D}
   ```

5. Configure all the switches in the network (including switches from other vendors) to map to the same RP.

6. Display information about the candidate rendezvous points for the PIM-SM domain:

   ```
   show ip pim static-rp
   ```

Example

Configure a static RP:

```
Switch:1(config)#  ip pim static-rp 239.255.0.0/255.255.0.0 198.51.100.0
```

Variable definitions

Use the definitions in the following table to use the **ip pim static-rp** command.

Variable	Value
{A.B.C.D/X}	Specifies the IP address and address mask of the multicast group. When combined, the IP address and address mask identify the range of the multicast addresses that the RP handles.
{A.B.C.D}	Specifies the IP address of the static RP.

Configuring IPv6 PIM static RP

On IPv6 PIM BSR mechanism is not supported so static RP must be configured.

Before You Begin

Enable IPv6 PIM-SM globally.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable static RP:

   ```
   ipv6 pim static-rp
   ```

3. Configure an IPv6 static RP entry:

   ```
   ipv6 pim static-rp WORD<0-255> WORD<0-255>
   ```

4. Configure all the switches in the network (including switches from other vendors) to map to the same RP.
5. Display information about the candidate rendezvous points for the PIM-SM domain:

   ```
   show ipv6 pim static-rp
   ```

Variable Definitions

The following table describes the variables for the **ipv6 pim static-rp** command.

Variable	Value
WORD<0-255>	Specifies the IPv6 address and address mask of the multicast group. When combined, the IPv6 address and address mask identify the range of the multicast addresses that the RP handles.
WORD<0-255>	Specifies the IPv6 address of the static RP.

Configuring a candidate BSR on a port

Configure additional routers as candidate BSRs (C-BSR) to provide backup protection in the event that the primary BSR fails. PIM-SM cannot run without a BSR.

Before You Begin

- Static RP is disabled.

About This Task

The C-BSR with the highest configured preference becomes the BSR for the domain. If two C-BSRs use equal preference, the candidate with the higher IP address becomes the BSR. If you add a new C-BSR with a higher preference to the domain, it automatically becomes the new BSR.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure a candidate BSR:

   ```
   ip pim bsr-candidate preference <0–255>
   ```

Example

Configure a candidate BSR:

```
Switch:1(config-if)#ip pim bsr-candidate preference 2
```

Variable definitions

Use the definitions in the following table to use the **ip pim bsr-candidate** command.

Variable	Value
preference <0–255>	Activates the C-BSR on this interface and configures its preference value, from 0–255, to become a BSR. The C-BSR with the highest BSR preference and address is the preferred BSR. The default is –1, which indicates that the current interface is not a C-BSR. To set this option to the default value, use the **default** operator with the command.

Configuring a candidate BSR on a VLAN

Configure additional routers as candidate BSRs (C-BSR) to provide backup protection in the event that the primary BSR fails. PIM-SM cannot run without a BSR.

Before You Begin

- Static RP is disabled.

About This Task

The C-BSR with the highest configured preference becomes the BSR for the domain. If two C-BSRs use equal preference, the candidate with the higher IP address becomes the BSR. If you add a new C-BSR with a higher preference to the domain, it automatically becomes the new BSR.

Procedure

1. Enter VLAN Interface Configuration mode:

   ```
   enable

   configure terminal

   interface vlan <1–4059>
   ```

2. Configure a candidate BSR on a VLAN:

   ```
   ip pim bsr-candidate preference <0–255>
   ```

Example

Configure a candidate BSR on a VLAN:

```
Switch:1(config-if)#ip pim bsr-candidate preference 5
```

Variable definitions

Use the definitions in the following table to use the **ip pim bsr-candidate** command.

Variable	Value
preference <0–255>	Activates the C-BSR on this interface and configures its preference value, from 0–255, to become a BSR. The C-BSR with the highest BSR preference and address is the preferred BSR. The default is –1, which indicates that the current interface is not a C-BSR. To configure this option to the default value, use the **default** operator with the command.

Enabling square-SMLT globally

Use square-Split MultiLink Trunking (SMLT) to form an SMLT aggregation group. In a square configuration, enable square-SMLT globally on each of the four switches.

About This Task

Important

The following command also activates full-mesh configurations.

Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable square-SMLT:

   ```
   multicast smlt-square
   ```

PIM Configuration Using EDM

The switch supports two modes of Protocol Independent Multicast (PIM): Sparse Mode (SM) and Source Specific Multicast (SSM).

- PIM-SM supports multicast groups spread out across large areas of a company or the Internet.
- PIM-SSM optimizes PIM-SM by simplifying the many-to-many model (servers-to-receivers).

Important

The **EnableSpbmConfigMode** boot flag must be disabled before you can configure PIM or IGMP. To verify the setting, navigate to **Configuration** > **Edit** > **Chassis** and click on the **Boot Config** tab.

Before You Begin

For an IPv4 PIM configuration using EDM:

- Configure an IP interface.

  For more information, see IP routing configuration using Enterprise Device Manager on page 1632.
- Configure a unicast protocol, for example, Routing Information Protocol (RIP) or Open Shortest Path First (OSPF), globally and on the interfaces where you want to configure PIM-SM.

  For more information about RIP, see RIP configuration using EDM on page 2522. For more information about OSPF, see OSPF configuration using EDM on page 2263.
- Enable PIM-SM globally.
- Enable PIM-SM on individual interfaces.
- Configure one or more rendezvous points (RP) for the groups that multicast applications use in the network.

  Important

  If you configure the rendezvous point (RP) to be the address of a circuitless IP (CLIP) interface, then you must first configure and enable PIM on the CLIP interface before you can utilize that interface as a candidate RP. To configure a PIM-SM RP for a circuitless IP interface, see Configuring a candidate RP on page 1383.
- Configure one or more bootstrap routers (BSR) to propagate RP information to all switches in the network.

For an IPv6 PIM configuration using EDM:

- Configure an IPv6 interface. For more information, see Configure an IPv6 Interface on page 1716.
- Configure an IPv6 unicast protocol, for example, Routing Information Protocol Next Generation (RIPng) or Open Shortest Path First Version 3 (OSPFv3), globally and on the interfaces where you want to configure PIM. For more information about RIPng, see RIPng Configuration using EDM on page 2532. For more information about OSPFv3, see OSPFv3 Configuration using EDM on page 2299.
- Enable IPv6 PIM-SM globally.
- Enable IPv6 PIM-SM on individual interfaces.

Enabling static RP

Enable static RP to avoid the process of selecting an active RP from the list of candidate RPs and dynamically learning about RPs through the BSR mechanism.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **PIM**.
3. Click the **Globals** tab.
4. Select **sm** (sparse mode).
5. Select **Enable**.
6. Select **Static RP**.

7. Click **Apply**.

   The system displays the following message:

   ```
   RP information learnt dynamically through BSR functionality will be
   lost. Do you wish to enable Static RP?
   ```

8. Click **Yes**.

Enabling IPv6 static RP

Use this procedure to enable IPv6 static RP.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Globals** tab.
4. Select **sm** (sparse mode).
5. Select **Enable**.
6. Select **Static RP**.
7. Click **Apply**.
8. Click **Yes**.

Configuring a static RP

Configure a static RP to ignore the BSR mechanism and use the statically configured RPs only. A static RP-enabled switch uses this feature to communicate with switches from other vendors that do not use the BSR mechanism.

Before You Begin

- Before you can configure a static RP, you must enable the following:
  - PIM-SM
  - static RP

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **PIM**.
3. Click the **Static RP** tab.
4. Click **Insert**.
5. Type the required information in each box.
6. Click **Insert**.

***Static RP** field descriptions*

Use the descriptions in the following table to use the **Static RP** tab.

Name	Description
GroupAddress	Configures the IP address of the multicast group. When combined with the group mask, this value identifies the range of the multicast addresses that the RP handles.
GroupMask	Configures the address mask of the multicast group. When combined with the group address, this value identifies the range of the multicast addresses that the RP handles.
Address	Configures the IP address of the static RP.
Status	Shows the current status of the static RP entry. The status is valid if the switch uses a unicast route to the network for the static RP and is invalid otherwise.

Job aid

Keep in mind the following configuration considerations:

- Static RPs do not age; they cannot time out.
- Switches do not advertise static RPs, so, if a new PIM neighbor joins the network, it does not know about the static RP unless you configure it with that static RP.
- Configure all the switches in the network (including switches from other vendors) to map to the same RP for certain group range.
- To avoid a single point of failure, you can configure redundant static RPs for the same group prefix. If you use a mix of vendor switches across the network, ensure that all switches or routers use the same active RP because vendors use different algorithms to elect the active RP. This switch uses the hash function defined in the PIM-SM standard to elect the active RP; other vendors can use the lowest IP address to elect the RP.
- Static RP on the switch is active as long as the switch uses a unicast route to the network for the static RP. If the switch loses this route, the static RP is invalidated, and the hash algorithm is invoked to remap all affected groups. If the switch regains this route, the static RP is validated and the hash algorithm is invoked to remap the affected groups.

Configuring an IPv6 static RP entry

Configure an IPv6 static RP to use the statically configured RPs. A static RP-enabled switch uses this feature to elect the active RP only from the statistically configured switches, without any relation to the RP information of other switches.

Before You Begin

- Before you can configure a static RP, you must enable the following:
  - IPv6 PIM-SM
  - IPv6 static RP

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.

2. Click **IPv6 PIM**.
3. Click the **Static RP** tab.
4. Click **Insert**.
5. Type the required information in each box.
6. Click **Insert**.

Static RP *field descriptions*

Use the descriptions in the following table to use the **Static RP** tab.

Name	Description
GroupAddress	Configures the IPv6 address of the multicast group. When combined with the group mask, this value identifies the range of the multicast addresses that the RP handles.
GroupMask	Configures the address mask of the multicast group. When combined with the group address, this value identifies the range of the multicast addresses that the RP handles.
Address	Configures the global IPv6 address of the static RP.
Status	Shows the current status of the static RP entry. The status is valid if the switch uses a unicast route to the network for the static RP.

Job aid

Keep in mind the following configuration considerations:

- Static RPs do not age; they cannot time out.
- Switches do not advertise static RPs, so, if a new PIM neighbor joins the network, it does not know about the static RP unless you configure it with that static RP.
- Configure all the switches in the network (including switches from other vendors) to map to the same RP for certain group range.
- To avoid a single point of failure, you can configure redundant static RPs for the same group prefix. If you use a mix of vendor switches across the network, ensure that all switches or routers use the same active RP because vendors use different algorithms to elect the active RP. This switch uses the hash function defined in the PIM-SM standard to elect the active RP; other vendors can use the lowest IP address to elect the RP.
- Static RP on the switch is active as long as the switch uses a unicast route to the network for the static RP. If the switch loses this route, the static RP is invalidated, and the hash algorithm is invoked to remap all affected groups. If the switch regains this route, the static RP is validated and the hash algorithm is invoked to remap the affected groups.

Viewing the active RP

Perform this procedure to show information about the active RP for all the running multicast groups on the switch.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **PIM**.

3. Click the **Active RP** tab.

Active RP field descriptions

Use the data in the following table to use the **Active RP** tab.

Name	Description
GroupAddress	Shows the IP address of the multicast group.
Address	Shows the IP address of the RP router. This address must be one of the local PIM-SM enabled interfaces.
Priority	Shows the priority of the RP.

Viewing the IPv6 active RP

Perform this procedure to show information about the IPv6 active RP for all the running multicast groups on the switch.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Active RP** tab.

Active RP field descriptions

Use the data in the following table to use the **Active RP** tab.

Name	Description
GroupAddress	Shows the IPv6 address of the multicast group.
Address	Shows the IPv6 address of the RP router. This address can be one of the local PIM-SM enabled interfaces or any reachable global IPv6 address configured using the **`static-rp`** CLI command. Note: IPv6 link local address is always used as the PIM interface address.
Priority	Shows the priority of the RP.

Configuring a candidate bootstrap router

Configure routers as candidate bootstrap routers (C-BSR) to provide backup protection in case the primary BSR fails. PIM-SM cannot operate without a BSR. A PIM-SM domain can use only one active BSR.

About This Task

The C-BSR with the highest configured priority becomes the BSR for the domain. If two C-BSRs use equal priority, the candidate with the higher IP address becomes the BSR. If you add a new C-BSR with a higher priority to the domain, it automatically becomes the new BSR.

Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration** > **Edit** > **Port**.
3. Click **IP**.
4. Click the **PIM** tab.
5. Click **Enable**.
6. In the **CBSRPreference** box, type the preference.

   The C-BSR with the highest BSR-preference and address becomes the active BSR. The default is –1, which indicates that the current interface is not a C-BSR.
7. Click **Apply**.

Viewing current BSR information

View the current BSR information to review the configuration.

Before You Begin

- You must disable static RP.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **PIM**.
3. Click the **Current BSR** tab.

Current BSR *field descriptions*

Use the descriptions in the following table to use the **Current BSR** tab.

Name	Description
Address	Shows the IP address of the current BSR for the local PIM domain.
FragmentTag	Shows a randomly generated number that distinguishes fragments that belong to different bootstrap messages. Fragments that belong to the same bootstrap message carry the same fragment tag.
HashMask	Shows the mask used in the hash function to map a group to one of the C-RPs from the RP set. The hashmask allows a small number of consecutive groups to always hash to the same RP.
Priority	Shows the priority of the current BSR. The C-BSR with the highest BSR priority and address (referred to as the preferred BSR) is elected as the BSR for the domain.
BootStrapTimer	Shows the bootstrap timer. After the bootstrap timer expires, the BSR sends out bootstrap messages.

Changing VLAN interface type

Change the state (active or passive) of PIM on a VLAN interface.

Before You Begin

- Before you change the state of PIM on a VLAN interface, you must first disable PIM to prevent instability in the PIM operations, especially when neighbors exist or when the interface receives streams.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select the VLAN ID that you want to configure with PIM.
5. Click **IP**.
6. Click the **PIM** tab.
7. Clear the **Enable** check box.
8. Click **Apply**.
9. Select **active** or **passive**.
10. Reenable PIM on the VLAN interface.
11. Click **Apply**.

Editing PIM interface parameters

Edit PIM parameters for an interface to customize the PIM configuration.

Before You Begin

- Before you change the state (active or passive) of a PIM interface, first disable PIM to prevent instability in the PIM operations, especially when neighbors exist or when the interface receives streams.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **PIM**.
3. Click the **Interfaces** tab.
4. Edit the fields by double-clicking on them, and then select or type the new value.
5. Click **Apply**.

Interfaces *field descriptions*

Use the data in the following table to use the **Interfaces** tab.

Name	Description
IfIndex	Shows the interface Index. This variable is a read-only field.
Address	Shows the IP address of the PIM interface. This variable is a read-only field.

Name	Description
NetMask	Shows the network mask for the IP address of the PIM interface. This variable is a read-only field.
Mode	Shows the configured mode of this interface. The valid modes are SSM and sparse. This variable is a read-only field.
InterfaceType	Specifies if the interface is active or passive.
DR	Shows the router with the highest IP address on a LAN designated to perform these tasks.
HelloInterval	Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring switches. The default is 30 seconds.
JoinPruneInterval	Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds.
CBSRPreference	Configures the preference for this local interface to become a C-BSR. The C-BSR with the highest BSR priority and address is the preferred BSR. The default is –1, which indicates that the current interface is not a C-BSR.
OperState	Indicates the status of PIM on this interface: Up or Down.

Editing IPv6 PIM interface parameters

Edit the IPv6 PIM parameters for an interface to customize the IPv6 PIM configuration.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Interfaces** tab.
4. Edit the fields by double-clicking on them, and then select or type the new value.
5. Click **Apply**.

Interfaces *field descriptions*

Use the data in the following table to use the **Interfaces** tab.

Name	Description
IfIndex	Shows the interface Index. This variable is a read-only field.
Address	Shows the IPv6 address of the PIM interface. This variable is a read-only field.
NetMask	Shows the network mask for the IPv6 address of the PIM interface. This variable is a read-only field.
Enable	Shows the configured mode of this PIM interface. sparseDense mode is valid only for PIMv1.
Mode	Shows the configured mode of this interface. The valid modes are SSM and sparse. This variable is a read-only field.

Name	Description
DR	Shows the router with the highest IPv6 address on a LAN designated to perform these tasks.
HelloInterval	Specifies how long to wait (in seconds) before the PIM router sends out the next hello message to neighboring switches. The default is 30 seconds.
JoinPruneInterval	Specifies how long to wait (in seconds) before the PIM router sends out the next join or prune message to its upstream neighbors. The default is 60 seconds.
OperState	Indicates the status of PIM on this interface: Up or Down.
Type	Specifies the interface type.

Configuring the PIM virtual neighbor

Configure a PIM virtual neighbor if the next hop for a static route cannot run PIM, such as the Virtual Router Redundancy Protocol (VRRP) address on an adjacent device.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **PIM**.
3. Click the **Virtual Neighbors** tab.
4. Click **Insert**.
5. Specify the IP address of the virtual neighbor.
6. Specify the interface index for the PIM interface.
7. Click **Insert**.

Virtual Neighbors *field descriptions*

Use the descriptions in the following table to use the **Virtual Neighbors** tab.

Name	Description
Address	Specifies the IP address of the neighbor.
IfIndex	Specifies the IP address of the PIM interface.

Viewing PIM-SM neighbor parameters

View PIM-SM neighbor parameters to troubleshoot connection problems or review the configuration.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **PIM**.
3. Click the **Neighbors** tab.

***Neighbors** field descriptions*

Use the descriptions in the following table to use the **Neighbors** tab.

Name	Description
Address	Shows the IP address of the PIM neighbor.
IfIndex	Shows the slot and port number or VLAN ID of the interface used to reach this PIM neighbor.
UpTime	Shows the time since this neighbor became a neighbor of the local router.
ExpiryTime	Shows the time remaining before the neighbor expires.

Viewing IPv6 PIM-SM neighbor parameters

View IPv6 PIM-SM neighbor parameters to troubleshoot connection problems or review the configuration.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Neighbors** tab.

***Neighbors** field descriptions*

Use the descriptions in the following table to use the **Neighbors** tab.

Name	Description
Address	Shows the IPv6 address of the PIM neighbor.
IfIndex	Shows the slot and port number or VLAN ID of the interface used to reach this PIM neighbor.
UpTime	Shows the time since this neighbor became a neighbor of the local router.
ExpiryTime	Shows the time remaining before the neighbor expires.

Viewing IPv6 Neighbor Secondary Address

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 PIM**.
3. Click the **Neighbor Secondary Address** tab.

***Neighbor Secondary Address** field descriptions*

Use the descriptions in the following table to use the **Neighbor Secondary Address** tab.

Name	Description
IfIndex	Shows the slot and port number or VLAN ID of the interface used to reach this PIM neighbor.
Type	Shows the address type of this PIM neighbor.
Primary	The primary IPv6 address of this PIM neighbor.
SecAddress	The secondary IPv6 address of this PIM neighbor.

Viewing RP set parameters

View the RP set to see a list of rendezvous point addresses. The BSR constructs this list from C-RP advertisements, and then distributes it to all PIM routers in the PIM domain for the BSR. View the parameters for troubleshooting purposes.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **PIM**.
3. Click the **RP Set** tab.

***RP Set** field descriptions*

Use the descriptions in the following table to use the **RP Set** tab.

Name	Description
GroupAddress	Shows the IP address of the multicast group. When combined with the group mask, this value identifies the prefix that the local router uses to advertise itself as a C-RP router.
GroupMask	Shows the address mask of the multicast group. When combined with the group address, this value identifies the prefix that the local router uses to advertise itself as a C-RP router.
Address	Shows the IP address of the C-RP router.
HoldTime	Shows the time specified in a C-RP advertisement that the BSR uses to time out the RP. After the BSR receives an advertisement for the RP, it restarts the timer. If no advertisement arrives before the timer expires, the BSR removes that RP from the RP set.
ExpiryTime	Shows the time remaining before this C-RP router times out.

Configuring a candidate RP

Configure a C-RP router to add it to the RP Set.

About This Task

You can configure only one interface on a switch for multiple groups; that is, you cannot configure multiple interfaces for multiple groups.

Using the GroupMask value, you can configure a candidate RP for several groups in one configuration. For example, if you use a C-RP configuration with a GroupAddress value of 224.0.0.0 and a GroupMask of 240.0.0.0, you can configure the C-RP router for a multicast range from 224.0.0.0 to 239.255.255.255.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **PIM**.
3. Click the **Candidate RP** tab.
4. Click **Insert**.
5. Type the required information in each box.
6. Click **Insert**.

Candidate RP *field descriptions*

Use the descriptions in the following table to use the **Candidate RP** tab.

Name	Description
GroupAddress	Configures the IP address of the multicast group. When combined with the group mask, this value identifies the prefix that the local router uses to advertise itself as a C-RP router.
GroupMask	Configures the address mask of the multicast group. When combined with the group address, this value identifies the prefix that the local router uses to advertise itself as a C-RP router.
InterfaceAddress	Configures the IP address of the C-RP router. This address must be one of the local PIM-SM enabled interfaces.

Enabling square-SMLT globally

Use square-Split MultiLink Trunking (SMLT) to form an SMLT aggregation group. In a square configuration, enable square-SMLT globally on each of the four switches.

About This Task

Important
The following configuration also activates full-mesh configurations.

Note
This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**

2. Click **Multicast**.
3. Click the **Globals** tab.
4. Select **MulticastSquareSmltEnable**.

   Clear this check box if you want to disable square-SMLT globally.
5. Click **Apply**.

Viewing IPv6 RP set parameters

View the IPv6 RP set to see a list of rendezvous point addresses. View the parameters for troubleshooting purposes.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 PIM**.
3. Click the **RP Set** tab.

RP Set *field descriptions*

Use the descriptions in the following table to use the **RP Set** tab.

Name	Description
GroupAddress	Specifies the IPv6 address of the multicast group. When combined with the group mask, this value identifies a group prefix for which the address is a static RP.
GroupMask	Specifies the address mask of the multicast group. When combined with the group address, this value identifies a group prefix for which the address is a static RP.
Address	Specifies the IPv6 address of the static RP.
HoldTime	Specifies the hold time of the static RP. The value is 0.
ExpiryTime	Specifies the minimum time remaining before the static RP is down. The value is 0.

Viewing IPv6 Mroute interface information

Use the following procedure to view IPv6 Mroute information for an interface.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Interfaces** tab.

***Interfaces** field descriptions*

Use the data in the following table to use the **Interfaces** tab.

Name	Description
IfIndex	Displays the slot and port number or VLAN ID for this entry.
Ttl	Displays the datagram time-to-live (TTL) threshold for the interface. IPv6 multicast datagrams with a TTL less than this threshold are not forwarded out of the interface. The default value of 0 means that all multicast packets are forwarded out of the interface.
Protocol	Displays the protocol as one of the following: • other(1): none of the following • local(2): manually configured • netmgmt(3): configured by a network management protocol • pimSparseMode(8): PIM-SMv2 • igmpOnly(10) • pimSsmMode(11) • spb

Viewing IPv6 Mroute next hop information

Use the following procedure to view IPv6 Mroute next hop information.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Next Hop** tab.

***Next Hop** field descriptions*

Use the data in the following table to use the **Next Hop** tab.

Name	Description
Group	Displays the IPv6 multicast group for this entry that specifies a next hop on an outgoing interface.
Source	Displays the network address that, when combined with the corresponding next hop SourceMask value, identifies the source for this entry that specifies a next hop on an outgoing interface.
SourceMask	Displays the network mask that, when combined with the corresponding next hop Source value, identifies the source for this entry that specifies a next hop on an outgoing interface.
IfIndex	Displays the slot and port number or VLAN ID for this entry.
Address	Displays the address of the next hop specific to this entry. For most interfaces, it is identical to the next-hop group. Non Broadcast Multiple Access (NBMA) interfaces, however, can use multiple next hop addresses out of a single outgoing interface.

Name	Description
State	Displays whether the outgoing interface and next hop represented by this entry currently forward IPv6 datagrams. A value of forwarding indicates the information is currently used; pruned indicates it is not used.
ExpiryTime	Displays the minimum amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging.
ClosestMemberHops	Displays the minimum number of hops between this router and members of the IPv6 multicast group reached through the next hop on this outgoing interface. IPv6 multicast datagrams for the group that use a time-to-live less than this number of hops are not forwarded to the next hop.
Protocol	Displays the protocol as one of the following: • other(1): none of the following • local(2): manually configured • netmgmt(3): configured by a network management protocol • pimSparseMode(8): PIM-SMv2 • igmpOnly(10) • pimSsmMode(11) • spb

Configuring resource usage counter for IPv6 Mroute

Configure the resource usage counters to query the number of ingress and egress IPv6 multicast streams traversing the switch. After you configure the counter thresholds for ingress and egress records, if the record usage goes beyond the threshold, you receive notification through a trap on the console, a logged message, or both.

Important

If you do not configure the thresholds, EDM displays only the ingress and egress records that are currently in use.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Resource Usage** tab.
4. Configure the ingress and egress thresholds.
5. Configure the notification methods.
6. Click **Apply**.

Resource Usage *field descriptions*

Use the data in the following table to use the **Resource Usage** tab.

Name	Description
Ingress Records In-Use	Displays the number of ingress records (source or group) traversing the switch.
Egress Records In-Use	Displays the number of egress records traversing the switch.
Ingress Threshold	Configures the ingress threshold level (0–32767).
Egress Threshold	Configures the egress threshold level (0–32767).
SendTrapAndLog	Sends both trap and log notification messages after the number of streams exceeds a threshold level.
SendTrapOnly	Sends only trap notification messages after the number of streams exceeds a threshold level. You can configure only one notification type.
LogMsgOnly	Sends only log notification messages after the number of streams exceeds a threshold level.

Viewing IPv6 multicast route information

Use the following procedure to view IPv6 Mroute route information.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Route** tab.

IPv6 Multicast Route *field descriptions*

Use the data in the following table to use the **Route** tab.

Name	Description
Group	Displays the IPv6 multicast group for this entry that specifies a next hop on an outgoing interface.
Source	Displays the network address that, when combined with the corresponding next hop SourceMask value, identifies the source for this entry that specifies a next hop on an outgoing interface.
SourceMask	Displays the network mask that, when combined with the corresponding next hop Source value, identifies the source for this entry that specifies a next hop on an outgoing interface.
UpStreamNeighbor	Shows the address of the upstream neighbor from which the IPv6 datagrams from these sources are received.
IfIndex	Displays the slot and port number or VLAN ID for this entry.

Name	Description
ExpiryTime	Displays the minimum amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging.
Protocol	Displays the protocol as one of the following: • other(1): none of the following • local(2): manually configured • netmgmt(3): configured by a network management protocol • pimSparseMode(8): PIM-SMv2 • igmpOnly(10) • pimSsmMode(11) • spb

IGMP Configuration Using the CLI

Hosts use the Internet Group Management Protocol (IGMP) to report their IP multicast group memberships to neighboring multicast routers. Configure IGMP on an individual interface basis.

Important

The **spbm-config-mode** boot flag must be disabled before you can configure PIM or IGMP. To verify the setting, enter **show boot config flags** in Privileged EXEC mode.

Before You Begin

- Complete one of the following tasks:
  - Configure IGMP on a Layer 2 interface by enabling IGMP snoop.
  - Configure IGMP on a Layer 3 interface by enabling multicast routing, for example, Protocol Independent Multicast-Sparse Mode (PIM-SM) or Protocol Independent Multicast-Source Specific Multicast (PIM-SSM).

Important

To configure and use IGMP on a VRF instance you must first select and launch the VRF context.

To select and launch the VRF context, see Configuring IGMP on a VRF on page 1320.

Configuring multicast stream limitation on an Ethernet port

Configure multicast stream limitation on an Ethernet port to limit the number of concurrent multicast streams on the port. By limiting the number of concurrent multicast streams, providers can protect the bandwidth on a specific interface and control access to multicast streams.

About This Task

You can configure the maximum number of streams independently. After the number of streams reaches the limit, the port drops joins to new streams. A service provider uses this feature to control the

overall bandwidth usage in addition to restricting users from attaching more than the allowed television sets to a link.

Note

Configuration of multicast stream limitation is not supported on a node configured as the DvR Leaf within a DvR domain.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable multicast stream limitation and configure the maximum number of allowed streams:

   ```
   ip igmp stream-limit stream-limit-max-streams <0-65535>
   ```

3. If stream-limit is already enabled on the interface, change the maximum number of allowed streams:

   ```
   ip igmp stream-limit stream-limit-max-streams <0-65535>
   ```

4. Display multicast stream limitation information for the ports on a specific interface:

   ```
   show ip igmp stream-limit interface
   ```

Example

Enable multicast stream limitation on the Ethernet port and configure the maximum number of allowed streams to 8.

```
Switch:1(config-if)# ip igmp stream-limit
Switch:1(config-if)# ip igmp stream-limit stream-limit-max-streams 8
```

Variable definitions

Use the data in the following table to use the **ip igmp stream-limit-max-streams** command.

Variable	Value
<0-65535>	Configures the maximum number of allowed streams on this port. The range is from 0–65535 and the default is 4.

Configuring multicast stream limitation on a VLAN

Configure multicast stream limitation on a VLAN to limit the number of concurrent multicast streams on the VLAN. By limiting the number of concurrent multicast streams, providers can protect the bandwidth on a specific interface and control access to multicast streams.

About This Task

You can configure the maximum number of streams independently. After the number of streams reaches the limit, the VLAN drops joins to new streams. A service provider uses this feature to control the overall bandwidth usage in addition to restricting users from attaching more than the allowed television sets to a link.

Note

Configuration of multicast stream limitation is not supported on a node configured as the DvR Leaf within a DvR domain.

Procedure

1. Enter VLAN Interface Configuration mode:

   ```
   enable

   configure terminal

   interface vlan <1-4059>
   ```

2. Enable multicast stream limitation and configure the maximum number of allowed streams:

   ```
   ip igmp stream-limit stream-limit-max-streams <0-65535>
   ```

3. If stream-limit is already enabled on the VLAN, change the maximum number of allowed streams:

   ```
   ip igmp stream-limit stream-limit-max-streams <0-65535>
   ```

4. Display multicast stream limitation information for the ports on a specific interface:

   ```
   show ip igmp stream-limit port
   ```

Example

Enable multicast stream limitation and configure the maximum number of allowed streams to 8.

```
Switch:1(config-if)# ip igmp stream-limit
Switch:1(config-if)# ip igmp stream-limit stream-limit-max-streams 8
```

Variable definitions

Use the data in the following table to use the **ip igmp stream-limit** command.

Variable	Value
<0-65535>	Configures the maximum number of allowed streams on this VLAN. The range is from 0–65535 and the default is 4.

Configuring VLAN multicast stream limitation members

Configure multicast stream limitation members on ports of a specific VLAN to limit the number of multicast groups that can join a VLAN.

Procedure

1. Enter VLAN Interface Configuration mode:
   ```
   enable

   configure terminal

   interface vlan <1-4059>
   ```
2. Configure multicast stream limitation members on a VLAN:
   ```
   ip igmp stream-limit-group {slot/port[/sub-port][-slot/port[/sub-port]][,...]} enable max-streams <0-65535>
   ```

Example

Enable multicast stream limitation on ports 2/3 to 2/8 and configure the maximum allowed number of streams to 6 for this interface.

```
Switch:1(config-if)# ip igmp stream-limit-group 2/3-2/8 max-streams 6
```

Variable definitions

Use the data in the following table to use the **`ip igmp stream-limit-group`** command.

Variable	Value
<0-65535>	Configures the maximum number of allowed streams for the specified ports on this VLAN. The range is from 0–65535 and the default is 4.
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configuring multicast router discovery options

Configure the multicast router discovery options to enable the automatic discovery of multicast-capable routers.

About This Task

Important
The switch does not support the Multicast Router Discovery (MRDISC) protocol on brouter ports.

Procedure

1. Enter VLAN Interface Configuration mode:
   ```
   enable

   configure terminal

   interface vlan <1-4059>
   ```

2. Enable multicast router discovery:

   ```
   ip igmp mrdisc
   ```

3. Configure the maximum advertisement intervals between successive advertisements:

   ```
   ip igmp mrdisc maxadvertinterval <2–180> maxinitadvertinterval <2–180>
   ```

4. Configure the maximum advertisements after initialization:

   ```
   ip igmp mrdisc maxinitadvertisements <2–15>
   ```

5. Configure the minimum advertisement interval between successive advertisements:

   ```
   ip igmp mrdisc minadvertinterval <3–180>
   ```

6. Configure the time allowed before a neighbor is declared dead:

   ```
   ip igmp mrdisc neighdeadinterval <2–180>
   ```

Example

Configure the maximum advertisement intervals between successive advertisements:

```
Switch:1(config-if)#ip igmp mrdisc maxadvertinterval 30 maxinitadvertinterval 5
```

Configure the maximum advertisements after initialization:

```
Switch:1(config-if)#ip igmp mrdisc maxinitadvertisements 8
```

Configure the minimum advertisement interval between successive advertisements:

```
Switch:1(config-if)#ip igmp mrdisc minadvertinterval 30
```

Configure the time allowed before a neighbor is declared dead:

```
Switch:1(config-if)#ip igmp mrdisc neighdeadinterval 60
```

Variable definitions

Use the data in the following table to use the **ip igmp mrdisc** command.

Variable	Value
maxadvertinterval <2–180>	Configures the maximum number (in seconds) between successive advertisements. For this change to take effect, you must save the configuration, and then reset the switch. To configure this option to the default value, use the **default** operator with the command. The default is 20.
maxinitadvertinterval <2–180>	Configures the maximum number (in seconds) between successive initial advertisements. For this change to take effect, you must save the configuration, and then reset the switch. To configure this option to the default value, use the **default** operator with the command. The default is 2.

Variable	Value
maxinitadvertisements <2-15>	Configures the maximum number of initial multicast advertisements after initialization. For this change to take effect, you must save the configuration, and then reset the switch. To configure this option to the default value, use the **default** operator with the command. The default is 3.
minadvertinterval <3-180>	Configures the minimum number (in seconds) between successive advertisements. For this change to take effect, you must save the configuration, and then reset the switch. To configure this option to the default value, use the **default** operator with the command. The default is 15.
neighdeadinterval <2-180>	Configures the multicast router discovery dead interval—the number of seconds the multicast route neighbors for the switch must wait before assuming that the multicast router is down. To configure this option to the default value, use the **default** operator with the command. The default is 60.

Configure Explicit Host Tracking

Configure explicit host tracking to track all the source and group members.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure explicit host tracking:

   ```
   ip igmp igmpv3-explicit-host-tracking
   ```

3. Display all the tracked members for a specific group:

   ```
   show ip igmp group group <A.B.C.D> tracked-members [member-subnet <A.B.C.D/X>] [source-subnet <A.B.C.D/X>] [port {slot/port[/sub-port][-slot/port[/sub-port]][,...]}] [vlan <1-4059>]
   ```

4. Display the IGMPv3 specific data:

   ```
   show ip igmp group group <A.B.C.D> detail port {{slot/port[/sub-port][-slot/port[/sub-port]][,...]}} vlan <1-4059>
   ```

Examples

Configure explicit host tracking:

```
Switch:1(config-if)#ip igmp igmpv3-explicit-host-tracking
```

Display all the tracked members:

```
Switch:1#show ip igmp group

================================================================================
                            Igmp Group - GlobalRouter
================================================================================
GRPADDR         INPORT          MEMBER          EXPIRATION TYPE       L2ISID
--------------------------------------------------------------------------------
224.5.2.1       V701-1/4        62.0.1.1        214        Dynamic    40400
224.5.2.2       V702-1/4        62.0.2.1        221        Dynamic    40400
224.5.2.3       V703-1/4        62.0.3.1        217        Dynamic    40400
224.5.2.4       V704-1/4        62.0.4.1        223        Dynamic    40400

4 out of 4 group Receivers displayed

Total number of unique groups 2
```

Display all the tracked members for a specific group:

```
Switch:1(config-if)#show ip igmp group group 232.1.1.1 tracked-members
================================================================================
                          Members of Channels/Groups - GlobalRouter
================================================================================
INTERFACE       CHANNEL/GROUP         MEMBER           MEMBER_MODE EXP
--------------------------------------------------------------------------------
Vlan333-2/30    */232.1.1.1          133.133.133.200   IS_EXCLUDE  205

Note:
The "*" attached to the interface (if any) indicates that the interface has explicit host
tracking disabled.
```

Display IGMPv3 specific data:

```
Switch:1(config-if)#show ip igmp group group 232.32.32.10 detail
================================================================================
                       Igmp Group Detail - GlobalRouter
================================================================================
Interface:                      Vlan222-1/10
IGMPv3 Group:                   232.32.32.10
Interface Group Mode:           INCLUDE
Interface Compatibility Mode:  IGMP_V3
V2 Host Timer:                  Not Running
V1 Host Timer:                  Not Running
Interface Group Include Source List:
        Source Address  Expires
        133.133.133.200 114
```

Variable definitions

Use the data in the following table to use the **ip igmp igmpv3-explicit-host-tracking** command.

Variable	Value
explicit-host-tracking	Enables explicit host tracking on IGMPv3. The default state is disable.
<A.B.C.D>	Specifies the IP address of the group of the tracked member.

Configuring IGMP static members

Configure IGMP static members to add members to a snoop group. You can create a static entry to forward multicast data streams to a particular set of ports within the VLAN. After you create the entry, multicast data streams are always forwarded to the multicast router within the VLAN, in addition to the ports in this static entry.

Procedure

1. Enter VLAN Interface Configuration mode:

   ```
   enable

   configure terminal

   interface vlan <1-4059>
   ```

2. Configure interface static members:

   ```
   ip igmp static-group {A.B.C.D} {A.B.C.D} {port {slot/port[/sub-port][-slot/port[/sub-port]][,...]} [static|blocked]
   ```

Example

Configure interface static members:

```
Switch:1(config-if)#ip igmp static-group 239.1.1.1 239.1.2.1 port 2/1 static
```

Variable definitions

Use the data in the following table to use the **ip igmp static-group** command.

Variable	Value
{A.B.C.D} {A.B.C.D}	Indicates the IP address range of the selected multicast group.
port	Adds ports to a static group entry

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Creates a static group entry. Specifies the port or list of ports that is a member of the VLAN interface being configured to which you want to redirect the multicast stream for this multicast group. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<static|blocked>	Configures the route to static or blocked.

Configuring SSM dynamic learning and range group

Configure SSM dynamic learning and a range group to enable the IGMPv3 dynamic learning feature and to extend the default SSM range of 232/8 to include an IP multicast address. As new SSM channels are learned, the system displays them in the SSM channel table.

Before You Begin

- To define the range group, you must first disable PIM.

About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable SSM dynamic learning:

   ```
   ip igmp ssm dynamic-learning
   ```

3. Configure the range group:

   ```
   ip igmp ssm group-range <A.B.C.D/X>
   ```

   The system displays the following message:

   ```
   Warning: Changing the SSM range will cause all spb-multicast and spb-pim-gw enabled interfaces to be internally bounced. Do you wish to continue? (y/n) ? (y/n)?
   ```

   Enter `y` to continue.

Example

Define the SSM range group address (234.0.0.0) and mask (255.0.0.0). Enable dynamic learning from IGMPv3 reports.

```
Switch:1(config)#ip igmp ssm group-range 234.0.0.0/255.0.0.0

WARNING: Changing the SSM range will cause all spb-multicast and spb-pim-gw enabled
interfaces to be internally bounced. Do you wish to continue? (y/n) ? (y/n)? y
Switch:1(config)#ip igmp ssm dynamic-learning
```

Variable definitions

Use the data in the following table to use the **ip igmp ssm** command.

Variable	Value
{A.B.C.D/X}	Defines the SSM range. The SSM range parameter extends the default SSM range of 232/8 to include an IP multicast address. You can configure existing applications without having to change their group configurations. This parameter specifies an IP multicast address within the range of 224.0.0.0 and 239.255.255.255. The default is 232.0.0.0. The address mask is the IP address mask of the multicast group. The default is 255.0.0.0.

Changing the SSM range group

Change the SSM range group to define the SSM range. The SSM range parameter extends the default SSM range of 232/8 to include an IP multicast address.

Before You Begin

Before you disable or delete an ssm-map, always send IGMPv1 or IGMPv2 leave messages from hosts that operate in IGMPv1 or IGMPv2. If you do not perform this action, receiving and processing reports in SSM range on an IGMP interface enabled with IGMPv1 or IGMPv2 can lead to unexpected behavior.

About This Task

Important

This procedure reinitializes PIM and temporarily stops all PIM traffic. For those multicast groups out of SSM range (for example, under PIM-SM behavior), it also causes a rendezvous point (RP) relearn delay of up to 60 seconds. This delay can be longer if the bootstrap router (BSR) is local.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Disable PIM:
   `no ip pim enable`

   If you forget to disable PIM, the system displays the following error message:

   ```
   Error: PIM is enabled in SSM mode, disable PIM
   ```
3. Delete each entry in the SSM channel table:
   `no ip igmp ssm-map [all] [{A.B.C.D} enable]`

   If you forget to delete the SSM channels, the system displays the following error message:

   ```
   Error: SSM source group table not empty
   ```
4. Configure the new IP multicast group address:
   `ip igmp ssm group-range {A.B.C.D/X}`

   The system displays the following message:

   ```
   Warning: Changing the SSM range will cause all spb-multicast and spb-
   pim-gw enabled interfaces to be internally bounced. Do you wish to
   continue? (y/n) ? (y/n)?
   ```

   Enter `y` to continue.
5. Enable PIM:
   `ip pim enable`

Example

Configure the new IP multicast group address:

```
Switch:1(config)#ip igmp ssm group-range 232.0.0.0/16

WARNING: Changing the SSM range will cause all spb-multicast and spb-pim-gw enabled
interfaces to be internally bounced. Do you wish to continue? (y/n) ? (y/n)? y
```

Variable definitions

Use the data in the following table to use the **`ip igmp ssm group-range`** and **`ip igmp ssm`** commands.

Variable	Value
{A.B.C.D/X}	Defines the SSM range. The SSM range parameter extends the default SSM range of 232/8 to include an IP multicast address. You can configure existing applications without having to change their group configurations. This parameter specifies an IP multicast address within the range of 224.0.0.0 and 239.255.255.255. The default is 232.0.0.0. The address mask is the IP address mask of the multicast group. The default is 255.0.0.0.

Configuring the SSM map table

Configure the SSM map table to map groups to their sending source. SSM maps cannot conflict with static source groups. After you configure an SSM map or a static source group, the switch performs a

consistency check to make sure no conflicts exist. You can map one group (G) to different sources or multiple sources to the same group for both static source group and an SSM map.

About This Task

The consistency check applies to all SSM map entries, even if they are disabled. If you disable an entry, it becomes inactive. If you do not delete the entry, you can reenable it later.

After you disable an SSM map, the switch stops multicast traffic from the specified source to the specified group. You can use this static configuration as a security feature to block traffic from a certain source to a specific group.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Enable the SSM map table for all static entries:
   ```
   ip igmp ssm-map all
   ```
3. Create a static entry for a specific group:
   ```
   ip igmp ssm-map {A.B.C.D} {A.B.C.D} enable
   ```

Example

Create an SSM map table entry for the multicast group 234.0.1.0 and the source at 192.32.99.151. Configure the administrative state to enable all the static SSM map table entries.

```
Switch:1(config)#ip igmp ssm-map 234.0.1.0 192.32.99.151
Switch:1(config)#ip igmp ssm-map all
```

Variable definitions

Use the data in the following table to use the **`ip igmp ssm-map`** command.

Variable	Value
{A.B.C.D} {A.B.C.D}	Creates a static SSM channel table entry by specifying the group and source IP addresses. The IP address is an IP multicast address within the SSM range. The source IP address is an IP host address that sends traffic to the group.
{A.B.C.D} enable	Enables the administrative state for a specific entry (group). This variable does not affect the dynamically learned entries. This state determines whether the switch uses the static entry or saves it for future use. The default is enable for each entry.

Configuring multicast access control for an IGMP Ethernet port

Configure multicast access control for an IGMP Ethernet port to restrict access to certain multicast streams and to protect multicast streams from spoofing (injecting data to the existing streams).

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure multicast access control:

   ```
   ip igmp access-list WORD<1-64> {A.B.C.D/X} <deny-tx|deny-rx|deny-both|
   allow-only-tx|allow-only-rx|allow-only-both>
   ```

3. Change an existing access list:

   ```
   ip igmp access-list WORD<1-64>> {A.B.C.D/X} mode <deny-tx|deny-rx|
   deny-both|allow-only-tx|allow-only-rx|allow-only-both>
   ```

Variable definitions

Use the data in the following table to use the **ip igmp access-list** command

Variable	Value
{A.B.C.D/X}	Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host.
deny-tx|deny-rx|deny-both|allow-only-tx|allow-only-rx|allow-only-both	Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic
mode	Changes the access control group configuration.
WORD<1-64>	Specifies the name of the access list from 1–64 characters.

Configuring multicast access control for a VLAN

Configure multicast access control for an IGMP VLAN to restrict access to certain multicast streams and to protect multicast streams from spoofing (injecting data to the existing streams).

Procedure

1. Enter VLAN Interface Configuration mode:

   ```
   enable

   configure terminal

   interface vlan <1-4059>
   ```

2. Configure multicast access control:
   ```
   ip igmp access-list WORD<1-64> [A.B.C.D/X] <deny-tx|deny-rx|deny-both|
   allow-only-tx|allow-only-rx|allow-only-both>
   ```
3. Change an existing access list:
   ```
   ip igmp access-list WORD<1-64> [A.B.C.D/X] mode <deny-tx|deny-rx|deny-
   both|allow-only-tx|allow-only-rx|allow-only-both>
   ```

Variable definitions

Use the data in the following table to use the **ip igmp access-list** command.

Variable	Value
{A.B.C.D/X}	Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host.
deny-tx|deny-rx|deny-both|allow-only-tx|allow-only-rx|allow-only-both	Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic
mode	Changes the access control group configuration.
WORD<1-64>	Specifies the name of the access list from 1–64 characters.

Configuring Fast Leave Mode

Configure fast (immediate) leave mode to alter the leave processing on fast leave enabled IGMPv2, IGMPv3, and IGMP snoop interfaces. Normal IGMP behavior is skipped. Fast leave mode provides one command that controls all IGMP fast leave enabled interfaces.

Before You Begin

- You must enable explicit-host-tracking before configuring fast-leave mode for IGMPv3. For more information on enabling explicit-host-tracking, see Configure Explicit Host Tracking on page 1394.

About This Task

If a single user connects to an interface, you do not need to track if other users exist on the interface to perform the fast leave. In cases like this, you must change the mode to one-user.

Important

Fast leave mode applies only to fast leave enabled IGMP interfaces.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```

2. View the current fast leave mode:

   ```
   show ip igmp sys
   ```

   Note

   This command is not supported on a node configured as the DvR Leaf within a DvR domain.

3. Configure fast leave mode:

   ```
   ip igmp immediate-leave-mode <multiple-user|one-user>
   ```

Example

Change the mode to one-user.

```
Switch:1(config)#ip igmp immediate-leave-mode one-user
```

Variable definitions

Use the data in the following table to use the **`ip igmp immediate-leave-mode`** command.

Variable	Value
`multiple-user|one-user`	*`multiple-user`* removes from the group only the IGMP member who sent the leave message. Traffic does not stop if other receivers exist on the interface port. This configuration is the default. *`one-user`* removes all group members on a fast leave enabled interface port after receiving the first leave message from a member. This behavior is the same as the conventional fast leave process.

Enabling fast leave mode on a port

Enable fast (immediate) leave mode to specify if a port receives a leave message from a member of a group. If you enable fast leave mode on a port, it uses the global fast leave mode configuration.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable fast leave:

   ```
   ip igmp immediate-leave
   ```

Configuring IGMP fast leave members on a VLAN

Configure IGMP fast leave members on a VLAN to specify fast leave capable ports.

Procedure

1. Enter VLAN Interface Configuration mode:

   ```
   enable

   configure terminal

   interface vlan <1-4059>
   ```

2. Enable fast leave on the VLAN:

   ```
   ip igmp immediate-leave
   ```

3. Configure fast leave members on a VLAN:

   ```
   ip igmp immediate-leave-members {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```

Variable definitions

Use the data in the following table to use the **`ip igmp immediate-leave-members`** command.

Variable	Value
`{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}`	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Enable IGMP Layer 2 Querier

When no multicast router exists in your network, you can use IGMP Layer 2 Querier to allow the Layer 2 switch to act as a multicast router so that the system can participate in multicast environments where multicast routing is not required.

Before You Begin

- You must enable IGMP snooping.

About This Task

When you enable IGMP Layer 2 Querier, Layer 2 switches in your network can snoop IGMP control packets exchanged with downstream hosts and upstream routers. The Layer 2 switches then generate the Layer 2 MAC forwarding table, used for switching sessions and multicast traffic regulation, and provide the recurring queries required to maintain IGMP groups.

By default, IGMP Layer 2 Querier is disabled.

Enable Layer 2 Querier on only one node in the VLAN.

On Shortest Path Bridging (SPB) Customer VLANs (CVLAN), IGMP Querier is enabled automatically when you enable snooping on the VLAN.

Procedure

1. Enter VLAN Interface Configuration mode:

   ```
   enable

   configure terminal

   interface vlan <1-4059>
   ```

2. Enable IGMP Layer 2 Querier:

   ```
   ip igmp snoop-querier
   ```

What to Do Next

You must enable the IGMP Layer 2 Querier address. See EnablingIGMPLayer2QuerierAddress

Enable IGMP Layer 2 Querier Address

To use the IGMP Layer 2 Querier feature you must designate the IGMP Layer 2 Querier source IP address, the address the system uses in the query message.

Before You Begin

- Enable IGMP Layer 2 Querier.

About This Task

You must configure the IGMP Layer 2 Querier address to an IP address in the IP subnet that IGMP hosts, and to which IGMP snoopers in the VLAN belong.

The default IP address is 0.0.0.0 when the IGMP Layer 2 Querier is disabled.

Procedure

1. Enter VLAN Interface Configuration mode:

   ```
   enable

   configure terminal

   interface vlan <1-4059>
   ```

2. Enable the IGMP Layer 2 Querier address:

   ```
   ip igmp snoop-querier-addr {A.B.C.D}
   ```

3. Verify the configuration:

   ```
   show ip igmp snooping [vrf WORD<1-16>] [vrfids WORD<0-512>
   ```

Example

Enable the IGMP Layer 2 Querier feature for VLAN 4, and configure the querier address. Verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface vlan 4
```

```
Switch:1(config-if)#ip igmp snoop-querier
Switch:1(config-if)#ip igmp snoop-querier-addr 192.0.2.1
Switch:1#show ip igmp snooping

IGMP configuration using EDM

Hosts use the Internet Group Management Protocol (IGMP) to report their IP multicast group memberships to neighboring multicast routers. Configure IGMP on an individual interface basis.

Important

The **EnableSpbmConfigMode** boot flag must be disabled before you can configure PIM or IGMP. To verify the setting, navigate to **Configuration** > **Edit** > **Chassis** and click on the **Boot Config** tab.

Before You Begin

- Configure IGMP on a Layer 2 interface by enabling IGMP snoop.
- Configure IGMP on a Layer 3 interface by enabling multicast routing, for example, Protocol Independent Multicast-Sparse Mode (PIM-SM), or Protocol Independent Multicast-Source Specific Multicast (PIM-SSM).

Important

To configure and use IGMP on a VRF instance you must first select and launch the VRF context.

To select and launch the VRF context, see Select and Launch a VRF Context View on page 3504.

Enabling IGMP snoop on a VLAN

Enable IGMP snooping on a VLAN to optimize the multicast data flow for a group within a VLAN to only those that are members of the group that uses IGMP snoop.

About This Task

The switch listens to group reports from each port and builds a database of multicast group members for each port. The switch suppresses the reports heard by not forwarding them to other hosts, forcing the members to continuously send their own reports.

The switch relays group membership from the hosts to the multicast routers and forwards queries from multicast routers to all port members of the VLAN. The switch multicasts data only to the participating group members and to the multicast routers within the VLAN.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Click the **IGMP** tab.
7. Select the **SnoopEnable** check box.
8. Select the **ProxySnoopEnable** check box.
9. For SteamLimtEnable, select **enable**.
10. Click **Apply**.

Configuring IGMP interface static members

Configure IGMP interface static members to add members to a snoop group.

About This Task

You can create a static entry to forward multicast data streams to a particular set of ports within the VLAN. After you create the entry, multicast data streams always forward to the multicast router within the VLAN, in addition to the ports in this static entry.

Important

IGMP snoop can optimize only local multicast data flow. IGMP snoop does not manage the forwarding state of the multicast tree. You cannot configure a port as a static receiver in an IGMP snoop-enabled VLAN that does not contain at least one dynamic receiver port and forward multicast data.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **IGMP**.
3. Click the **Static** tab.
4. Click **Insert**.
5. Type the appropriate information.
6. Click **Insert**.

***Static** field descriptions*

Use the data in the following table to use the **Static** tab.

Name	Description
IfIndex	Shows the interface where the IGMP entry is enabled.
GrpAddr	Indicates the start of the IP multicast address range of the multicast stream. Within the indicated valid range (224.0.0.0 to 239.255.255.255), the following are invalid addresses: 244.0.0.x and the corresponding 31 multicast addresses that map to the IP MAC addresses. If you try to select them, you receive an invalid message.
ToGrpAddr	Indicates the end of the IP multicast address range of the multicast stream. If an address is not entered, the IP address in the GrpAddr field is the single address.
MemberPorts	Specifies the ports to which you want to redirect the multicast stream for this multicast group. The ports must be member ports of the VLAN.
NotAllowedToJoin	Specifies the ports that do not receive the multicast stream for this multicast group.

Configuring the SSM map table

Configure the SSM map table to map groups to their sending source. SSM maps cannot conflict with static source groups. After you configure an SSM map or a static source group, the switch performs a consistency check to make sure no conflicts exist. You can map one group (G) or multiple groups to different sources for both static source group and an SSM channel.

Before You Begin

Before you disable or delete an ssm-map, always send IGMPv1 or IGMPv2 leave messages from hosts that operate in IGMPv1 or IGMPv2. If you do not perform this action, receiving and processing reports in SSM range on an IGMP interface enabled with IGMPv1 or IGMPv2 can lead to unexpected behavior.

About This Task

The consistency check applies to all SSM channel entries, even if they are disabled. If you disable an entry, it becomes inactive. If you do not delete the entry, you can reenable it later.

After you disable an SSM map, the switch stops multicast traffic from the specified source to the specified group. You can use this static configuration as a security feature to block traffic from a certain source to a specific group.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Select **IGMP**.
3. Select the **Ssm Map** tab.
4. Select **Insert**.

5. Type the IP address for the multicast group and source.
6. Select **Insert**.

   You can change the default status of an SSM map from enable to disable in the **AdminState** field.

Ssm Map *field descriptions*

Use the data in the following table to use the **Ssm Map** tab.

Name	Description
IpMulticastGrp	Specifies an IP multicast address that is within the SSM range.
IpSource	Specifies the IP address of the source that sends traffic to the group.
LearningMode	Displays whether the entry is statically configured (Static) or dynamically-learned from IGMPv3 (Dynamic). This variable a read-only field.
Activity	Displays the current activity of the selected (S,G) entry. True indicates that traffic is flowing to the switch, otherwise, the system displays it false. This variable a read-only field.
AdminState	Configures the administrative state for the selected static entry. This state determines whether the switch uses the static entries. Configure this field to enable (default) to use the entry or disable to save for future use.

Configure SSM Range and Global Parameters

Configure the SSM range parameter to extend the default SSM range of 232/8 to include an IP multicast address. You can configure existing applications without changing their group configurations.

Before You Begin

- To change the RangeGroup configuration, you must first disable PIM.
- To change the RangeGroup configuration, you must delete all entries in the SSM channel table before you configure the new IP multicast group address.

About This Task

The other global parameters enable the IGMPv3 dynamic learning feature and configure the administrative state for all the entries in the SSM channel table.

Important

If you change the RangeGroup configuration, the switch reinitializes PIM and temporarily stops all PIM traffic. For those multicast groups out of SSM range (for example, under PIM-SM behavior), this procedure also causes a rendezvous point (RP) relearn delay of up to 60 seconds. This delay can be longer if the bootstrap router (BSR) is local.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **IGMP**.
3. Select the **Ssm Global** tab.
4. Configure the appropriate fields.
5. Select **Apply**.

Ssm Global *field descriptions*

Use the data in the following table to use the **SsmGlobal** tab.

Name	Description
DynamicLearning	Activates the dynamic learning of SSM channel (S,G) pairs from IGMPv3 reports. As new SSM channels are learned, the system displays them in the SSM channel table.
RangeGroup	Configures the IP multicast group address. The lowest group address is 224.0.0.0 and the highest is 239.255.255.255. The default is 232.0.0.0.
RangeMask	Configures the address mask of the multicast group. The default is 255.0.0.0.
SsmMapAdminAction	Configures the administrative state, which determines whether the switch uses the table entries: • enableAll—Globally activates all the static entries in the SSM channel table. This value does not affect the dynamically learned entries. • disableAll—Globally inactivates all the static entries in the SSM channel table. This value does not affect the dynamically learned entries.

Configuring multicast stream limitation on an interface

Configure multicast stream limitation to limit the number of concurrent multicast streams on the interface. By limiting the number of concurrent multicast streams, you can protect the bandwidth on a specific interface and control access to multicast streams.

About This Task

You can configure the maximum number of streams independently. After the number of streams reaches the limit, the interface drops additional join reports for new streams. You can control the overall bandwidth usage in addition to restricting users from receiving more than a specific limit of multicast streams on an interface.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **IGMP**.
3. Click the **StreamLimit** tab.
4. To change the status of an interface, double-click on the **StreamLimitEnable** field for the interface, and then select **enable** or **disable** from the menu. If the interface is enabled, you can edit the **Maximum Number of Stream** field.

5. Click **Apply**.

StreamLimit *field descriptions*

Use the data in the following tab to use the **StreamLimit** tab.

Name	Description
Interface	Displays the slot and port number or VLAN ID for this interface.
StreamLimitEnable	Enables or disables stream limitation on this interface.
Maximum Number Of Stream	Configures the maximum number of streams allowed on this interface. The range is from 0–65535, and the default is 4.
Current Number Of Stream	Displays the current number of streams received on this interface. This value is a read-only value.

Configuring multicast stream limitation on a VLAN

Configure multicast stream limitation to limit the number of concurrent multicast streams on the VLAN. By limiting the number of concurrent multicast streams, you can protect the bandwidth on a specific VLAN and control access to multicast streams.

About This Task

You can configure the maximum number of streams independently. After the number of streams reaches the limit, the VLAN drops additional join reports for new streams. You can control the overall bandwidth usage in addition to restricting users from receiving more than a specific limit of multicast streams on an interface.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Click the **IGMP** tab.
7. For StreamLimitEnable, select **enable**.
8. Configure the maximum number of streams.
9. Click **Apply**.

Configuring multicast stream limitation on a port

Configure multicast stream limitation to limit the number of concurrent multicast streams on the port. Limit the number of streams to protect the bandwidth on a specific port and control access to multicast streams.

Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration** > **Edit** > **Port**.

3. Click **IP**.
4. Click the **IGMP** tab.
5. In the StreamLimitEnable field, select the **Enable** option button.
6. Configure the maximum number of streams.
7. Click **Apply**.

Configuring multicast stream limitation members

Configure multicast stream limitation members on ports of the specified interface to configure the maximum number of streams on the interface.

About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **IGMP**.
3. Click the **StreamLimit Members** tab.
4. Click **Insert**.
5. Type the number of the VLAN to which you want to add a member or click **Vlan** to select an ID from the list.
6. Type the number of the slot and port that you want to add as a member or click **Port**, and then select one from the graphic display. If your platform supports channelization for 40 Gbps ports and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

   Important
   You must select one of the ports in the VLAN that you selected in step 4.

7. Type a maximum number of streams or accept the default of 4.
8. Click **Insert**.

StreamLimit Members *field descriptions*

Use the data in the following table to use the **StreamLimit Members** tab.

Name	Description
IfIndex	Displays the ID of the VLAN.
Port	Lists each slot and port number for this interface with stream limitation enabled. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Name	Description
MaxStreams	Configures the maximum number of allowed streams for this specific port. The number of allowed streams cannot exceed the maximum number for the interface. The range is from 0–65535 and the default is 4.
NumStreams	Displays the current number of streams received on this interface. This value is a read-only value.

Deleting multicast stream limitation member

Delete a multicast stream limitation member from an interface to remove it from the configuration.

About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **IGMP**.
3. Click the **StreamLimit Members** tab.
4. Click on the row that lists the member you want to delete.
5. Click **Delete**.

Configuring the IGMP interface

Configure the IGMP interface to change global IGMP values for the interface. Use the Interface tab to view or edit the IGMP interface table.

About This Task

If an interface does not use an IP address, the system does not display it in the IGMP table. If an interface uses an IP address, but PIM-SM is not enabled, the system displays the interface as notInService in the Status field.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**
2. Click **IGMP**.
3. Click the **Interface** tab.
4. Edit the appropriate information.
5. Click **Apply**.

Interface *Field Descriptions*

Use the data in the following table to use the **Interface** tab.

Name	Description
IfIndex	Shows the interface where IGMP is enabled.
QueryInterval	Configures the frequency (in seconds) at which the interface transmits IGMP host query packets. The default is 125.
Status	Shows the IGMP row status. If an interface uses an IP address and PIM-SM is enabled, the status is active. Otherwise, it is notInService.
Version	Configures the version of IGMP (1, 2, or 3) that you want to configure on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2.
OperVersion	Shows the version of IGMP that currently runs on this interface.
Querier	Shows the address of the IGMP querier on the IP subnet to which this interface attaches.
QueryMaxResponseTime	Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values allow a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds.) Important: You must configure this value lower than the QueryInterval.
WrongVersionQueries	Shows the number of queries received with an IGMP version that does not match the interface. You must configure all routers on a LAN to run the same version of IGMP. If the interface receives queries with the wrong version, this value indicates a version mismatch.
Joins	Shows the number of times this interface added a group membership, which is the same as the number of times an entry for this interface is added to the cache table. This number gives an indication of the amount of IGMP activity over time.
Robustness	Tunes for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect a network to lose query packets, increase the robustness value. The default value of 2 means that the switch drops one query for each query interval without the querier aging out.

Name	Description
LastMembQueryIntvl	Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1. Decrease the value to reduce the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of second. As a best practice, configure this parameter to values greater than 3. If you do not need a fast leave process, you can configure values greater than 10. (The value 3 is equal to 0.3 seconds and 10 is equal to 1 second.)
OtherQuerierPresent Timeout	Shows the length of time that must pass before a multicast router determines that no other querier exists. If the local router is the querier, the value is 0.
FlushAction	Configures the flush action to one of the following: • none • flushGrpMem • flushMrouter • flushSender
RouterAlertEnable	Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option. Important: To maximize network performance, configure this parameter according to the version of IGMP currently in use. • IGMPv1—Disable • IGMPv2—Enable • IGMPv3—Enable
SsmSnoopEnable	Enables SSM snoop.
SnoopQuerierEnable	Enables IGMP Layer 2 Querier.
SnoopQuerierAddr	Specifies the pseudo address of the IGMP snoop querier.
ExplicitHostTrackingEnable	Enables or disables IGMPv3 to track hosts for each channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.
McastMode	Indicates the protocol configured on the VLAN. • snoop — Indicates IGMP snooping is enabled on a VLAN. • snoop-spb — Indicates IGMP is enabled on a VLAN with an associated I-SID (IP multicast over Fabric Connect for a Layer 2 VSN). • pim — Indicates PIM is enabled. • routed-spb — Indicates IP multicast over Fabric Connect is enabled on the Layer 3 VSN or for IP Shortcuts.

Name	Description
ExtnUpnpFilterEnable	Enables Universal Plug and Play (uPnP) Filtering to filter multicast packets destined for a specific range. The default is disabled.
ExtnUpnpFilterAddress	Indicates the multicast destination IP address to filter on an IGMP-enabled interface. The default is 239.255.255.250/32.
ExtnUpnpFilterAddressMask	Indicates the IGMP uPnP Filtering IP subnet to which this interface is attached.
SnoopOrigin	Specifies the origin of IGMP Snooping configuration on the port. The supported values are: • config - Set by the user. • radius - Set by the Remote Authentication Dail-In User Service (RADIUS) attribute.

Configuring IGMP sender entries

Configure IGMP sender entries to identify a source that sends multicast data to a multicast group.

About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **IGMP**.
3. Click the **Sender** tab.
4. Change the appropriate options.
5. Click **Apply**.

Sender *field descriptions*

Use the data in the following table to use the **Sender** tab.

Name	Description
IfIndex	Specifies the interface where you enabled the IGMP entry.
GrpAddr	Specifies the multicast group address of the multicast stream. Within the indicated valid range (224.0.0.0 to 239.255.255.255), the following are invalid addresses: 244.0.0.x and the corresponding 31 multicast addresses that map to the IP MAC addresses. If you try to select them, you receive an invalid message.
MemberAddr	Specifies the IP address of a host.
Action	Flushes an entry or a group.
TPort	Identifies the T port.

Name	Description
State	Indicates whether a sender exists because of an IGMP access filter. The options are filtered and not filtered.
L2Isid	Specifies the Layer 2 I-SID of the C-VLAN.

Configuring Fast Leave Mode

Configure fast leave mode to control all IGMP fast leave enabled interfaces.

Before You Begin

- You must enable explicit-host-tracking before configuring fast-leave mode. To enable explicit-host-tracking, see Configuring IGMP parameters on a port on page 1332 and Configuring IGMP parameters on a VLAN on page 1335.

About This Task

Fast leave relies on an alternative leave process where the switch stops sending traffic for the group immediately after it receives a leave message, without issuing a query to check if other group members exist on the network. Use this global parameter to alter the leave processing on fast leave enabled IGMPv2, IGMPv3, and IGMP snoop interfaces.

Important

Fast leave mode applies only to fast leave enabled IGMP interfaces.

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **IGMP**.
3. Click the **Global** tab.
4. Select the mode.
5. Click **Apply**.

***Global** field descriptions*

Use the data in the following table to use the **Global** tab.

Name	Description
FastLeaveMode	Configures the mode to one of the following values: • multipleUser: Removes from the group only the IGMP member who sent the leave message. Traffic does not stop if other receivers exist on the interface port. This value is the default. • oneUser: Removes all group members on a fast leave enabled interface port after receiving the first leave message from a member. This behavior is the same as the conventional fast leave process.
GenerateTrap	Generates a trap. The default is disable.
GenerateLog	Generates a log message. The default is disable.

Configuring multicast access control for an interface

Configure multicast access control for a selected IGMP interface or VLAN to restrict access to certain multicast streams and to protect multicast streams from spoofing (injecting data to the existing streams).

About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **IGMP**.
3. Click the **Access Control** tab.
4. Click **Insert**.
5. Type the number of the slot and port or VLAN ID that you want to add as a member or click the appropriate button, and then select one from the graphic display.
6. Click the ellipsis button (**...**) next to **PrefixListId**.
7. Select a prefix list ID.
8. Click **OK**.
9. Type the host address and host mask.
10. Select the action mode that you want for the specified host.
11. Click **Insert**.

Access Control *field descriptions*

Use the data in the following table to use the **Access Control** tab.

Name	Description
IfIndex	Specifies the interface where the IGMP entry is enabled.
PrefixListId	Specifies a numeric string that identifies the prefix list.
HostAddr	Specifies the IP address of the host.
HostMask	Specifies the subnet mask that determines the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host.
PrefixListName	Specifies the name of the prefix list.
ActionMode	Specifies the action for the host identified by HostAddr. The options include the following: • denied IP multicast transmitted traffic (deny-tx). • denied IP multicast received traffic (deny-rx). • denied both IP multicast transmitted and received traffic (deny-both). • allowed IP multicast transmitted traffic (allow-only-tx). • allowed IP multicast received traffic (allow-only-rx). • allowed both IP multicast transmitted and received traffic (allow-only-both).

Viewing IGMP cache information

View IGMP cache information to view the group for which members exist on a specific interface.

About This Task

You can view IGMP information on a VRF instance the same way you view the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **IGMP**
3. Click the **Cache** tab.

Cache *field descriptions*

Use the data in the following table to use the **Cache** tab.

Name	Description
Address	Shows the IP multicast group address for this entry that contains this information.
IfIndex	Shows the interface from which the corresponding multicast group address is heard.

Name	Description
LastReporter	Shows the IP address of the source of the last membership report received for this IP multicast group address on this interface. If no membership report is received, the object uses the value 0.0.0.0.
ExpiryTime	Shows the amount of time (in seconds) that remain before this entry ages out.
Version1HostTimer	Shows the time that remains until the local router assumes that no IGMPv1 members exist on the IP subnet attached to the interface. Upon hearing IGMPv1 membership report, this value resets to the group membership timer. When the time that remains is nonzero, the local router ignores IGMPv2 leave messages for this group that it receives on this interface.
Type	Shows the type of IGMP entry.
StaticPorts	Shows the static ports associated with the entry.

Viewing IGMPv3 cache

View the IGMPv3 specific data corresponding to each interface, port, and multicast group pair on a router.

About This Task

You can view IGMP information on a VRF instance the same way you view the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **IGMP**.
3. Click the **IGMPv3 Cache** tab to view the IGMPv3 cache information.

IGMPv3 Cache *field descriptions*

Use the data in the following table to use the **IGMPv3 Cache** tab.

Name	Description
GroupAddress	Specifies the Multicast group Address (Class D) that others want to join. A group address can be the same for many incoming ports.
IfIndex	An unique value to identify a physical interface or a logical interface (VLAN), which has received Group reports from various sources.
InPort	An unique value to identify a physical interface or a logical interface (VLAN), which has received Group reports from various sources.
ModeExpiryTimer	Represents the time remaining before the interface EXCLUDE state expires and the interface state transitions to INCLUDE mode. This value is applicable only to IGMPv3-compatible nodes.

Name	Description
Version1HostTimer	Specifies the time remaining until the local router assumes that there are no longer any IGMP version 1 members on the IP subnet attached to this interface. This entry only applies to IGMPv1 hosts. Upon hearing any IGMPv1 report, this value is reset to the group membership timer. While this time remaining is non-zero, the local router ignores any IGMPv2 Leave messages for this group that it receives on this interface.
Version2HostTimer	Specifies the time remaining until the local router assumes that there are no longer any IGMP version 2 members on the IP subnet attached to this interface. Upon hearing any IGMPv2 membership report, this value is reset to the group membership timer. Assuming no IGMPv1 hosts have been detected, the local router does not ignore any IGMPv2 Leave messages for this group that it receives on this interface.
SourceFilterMode	Specifies the current group state, applicable to IGMPv3-compatible nodes. The value indicates whether the state is INCLUDE or EXCLUDE.

Viewing and editing multicast router discovery information

View multicast router discovery information to view the current configuration.

About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **IGMP**.
3. Click the **Multicast Router Discovery** tab.
4. To edit the current configuration, double-click the value, make the change, and then click **Apply**.

Multicast Router Discovery *field descriptions*

Use the data in the following table to use the **Multicast Router Discovery** tab.

Name	Description
Interface	Shows the interface where IGMP is enabled.
MrdiscEnable	Enables (true) or disables (false) the router interface to listen for multicast router discovery messages to determine where to send multicast source data and IGMPv2 reports. If you enable snoop, you automatically enable multicast router discovery.

Name	Description
DiscoveredRouterPorts	Lists ports that the Multicast Router Discovery (MRDISC) protocol discovers. Important: The switch does not support the MRDISC protocol on brouter ports.
MaxAdvertiseInterval	Shows the maximum time allowed between sending router advertisements from the interface, in seconds. The range is from 2–180 seconds. The default is 20 seconds.
MinAdvertiseInterval	Shows the minimum time allowed between sending unsolicited router advertisements from the interface, in seconds. This value must be more than 3 seconds but no greater than the value assigned to the MaxAdvertiseInterval value.
MaxInitialAdvertiseInterval	Configures the maximum number (in seconds) of multicast advertisement intervals that you can configure on the switch.
MaxInitialAdvertisements	Configures the maximum number of initial multicast advertisements that you can configure on the switch.
NeighborDeadInterval	Shows the time interval (in seconds) before the router interface drops traffic after a user leaves the multicast group.

Viewing the IGMP router source list

View the source list entries corresponding to each interface and multicast group pair on a router.

About This Task

You can view IGMP information on a VRF instance the same way you view the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **IGMP**.
3. Click the **Igmp Router Source List** tab to view the IGMPv3 cache information.

Igmp router source list *field descriptions*

Use the data in the following table to use the **Igmp Router Source List** tab.

Name	Description
GroupAddress	Specifies the IP multicast group address for which this entry contains information.
IfIndex	Specifies the interface for which this entry contains information for an IP multicast group address.
InPort	Specifies a unique value to identify a physical interface or a logical interface (VLAN), which has received Group reports for this source.

Name	Description
HostAddress	Specifies the host address to which this entry corresponds.
MemberAddress	Specifies the IP Address of a member that has sent source specific report wishing to join this source.
Expire	This value indicates the relevance of the source list entry, where a non-zero value indicates this is an INCLUDE state value, and a zero value indicates this to be an EXCLUDE state value.
Mode	Specifies the current member state, applicable to IGMPv3-compatible nodes. The value indicates whether the state is INCLUDE or EXCLUDE.
MemberExpire	This value indicates the time until the member for this source expires.

Viewing IGMP snoop information

View information about IGMP snoop to see the current configuration.

About This Task

You can configure IGMP on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **IGMP**.
3. Click the **Snoop** tab.

Snoop *field descriptions*

Use the data in the following table to use the **Snoop** tab.

Name	Description
Interface	Shows the VLAN ID for the VLAN.
SnoopEnable	Shows the status of IGMP snoop. IGMP snoop works only if a multicast router exists in the VLAN.
SsmSnoopEnable	Shows the status of SSM snoop.
ProxySnoopEnable	Indicates whether the IGMP report proxy feature is enabled. If you enable this feature, the switch forwards reports from hosts to the multicast router once for each group for each query interval, or after new group information is available. If you disable this feature, the switch forwards all reports from different hosts to multicast routers, and can forward more than one group report for the same multicast group for each query interval. The default is enabled.
FastLeaveEnable	Shows the status of fast leave for this port.
FastLeavePortMembers	Lists ports that are enabled for fast leave.

Name	Description
SnoopMRouterPorts	Shows the configuration of ports as multicast router ports. Such ports attach to a multicast router, and forward multicast data and group reports to the router. Important: Configure this variable only if you use multiple multicast routers that do not attach to one another, but attach to the VLAN (technically, an invalid configuration). If multicast routers use a route between them (the valid configuration) and you configure this variable, a multicast loop forms.
SnoopActiveMRouterPorts	Shows the active multicast router ports. Active multicast router ports are ports that directly attach to a multicast router. These ports include the querier port and all ports in the forwarding state that you configure as well as those that were dynamically learned through receiving queries.
SnoopMRouterExpiration	Indicates the time that remains before the multicast router ages out. If the switch does not receive queries before this time expires, it flushes out all group memberships known to the VLAN. The query maximum response interval (obtained from the queries received) is used as the timer resolution.

View IGMP Snoop Trace Information

View the multicast group trace to track the data flow path of multicast streams.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Click **IGMP**.
3. Click the **Snoop Trace** tab.

Snoop Trace *Field Descriptions*

Use the data in the following table to use the **Snoop Trace** tab.

Name	Description
GrpAddr	Displays the IP multicast address of the group traversing the router.
SrcAddr	Displays the IP source address of the multicast group.
OutVlan	Displays the egress VLAN ID for the multicast group.
InPort	Displays the ingress port for the multicast group.
InVlan	Displays the ingress VLAN ID for the multicast group.
OutPort	Displays the egress port of the multicast group.
Type	Displays the port type on which the snoop entry is learned.

View IGMP Group Information

View information about IGMP groups to see the current group operation on the switch.

About This Task

Note

The following procedure displays the dynamically learned IGMP groups. **IP** > **IGMP** > **Static** displays statically configured IGMP groups. This is in contrast to the CLI command **`show ip igmp group`**, which displays both dynamically learned and statically configured IGMP groups, and the CLI command **`show ip igmp static`**, which displays only the statically configured groups.

You can view IGMP information on a VRF instance the same way you view the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **IGMP**.
3. Select the **Groups** tab.

Groups *Field Descriptions*

Use the data in the following table to use the **Groups** tab.

Name	Description
IpAddress	Shows the multicast group address (Class D). A group address can be the same for many incoming ports.
Members	Shows the IP address of the host that issues the membership report to this group.
InPort	Shows the port that receives the group membership report.
IfIndex	Shows a unique value that identifies a physical interface or a logical interface (VLAN) that receives the membership report.
Expiration	Shows the time left before the group report expires on this port. This variable is updated after the port receives a group report.

Route management using the CLI

With multicast route commands, you can configure and view IP multicast routing parameters on the switch.

Configuring multicast stream limits

Limit the number of multicast streams to protect the CPU from multicast data packet bursts generated by malicious applications, such as viruses that cause the CPU to reach 100 percent utilization or that prevent the CPU from processing protocol packets or management requests. If more than a certain number of multicast streams ingress to a CPU through a port during a sampling interval, the port shuts down until you take appropriate action.

About This Task

You can enable or disable the mroute stream limit for the entire device or for individual ports when the switch is operating. If you enable the mroute stream limit for the device and for an individual port, only the periodic check is performed for that port.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable stream limitation globally:

   ```
   ip mroute stream-limit
   ```

3. Enter GigabitEthernet Interface Configuration mode.

   ```
   interface gigabitethernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

4. Enable stream limits:

   ```
   ip mroute stream-limit
   ```

5. For Gigabit Ethernet interfaces, configure the maximum number of streams and the interval at which to sample:

   ```
   ip mroute max-allowed-streams <1-32768> max-allowed-streams-timer-
   check <1-3600>
   ```

6. Show the mroute stream limit configuration:

   ```
   show ip mroute interface gigabitethernet [{slot/port[/sub-port][-slot/
   port[/sub-port]][,...]}]
   ```

Example

```
Switch:1(config)#ip mroute stream-limit
Switch:1(config)#interface gigabitethernet 3/6
Switch:1(config-if)#ip mroute stream-limit
Switch:1(config-if)#ip mroute max-allowed streams 1000 max-allowed-streams-timer-check 20
```

Variable definitions

Use the data in the following table to use the **interface** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Use the data in the following table to use the **ip mroute** command.

Variable	Value
max-allowed-streams <1-32768>	Configures the maximum number of streams on the specified port. The port is shut down if the number of streams exceeds this limit. The value is a number between 1–32768. The default value is 1984 streams. To configure this option to the default value, use the **default** operator with the command.
max-allowed-streams-timer-check <1-3600>	Configures the sampling interval, which checks if the number of ingress multicast streams to the CPU is under a configured limit or if the port needs to shut down. The range is between 1–3600. The default value is 10 seconds. To configure this option to the default value, use the **default** operator with the command.

Configuring multicast static source groups

Configure static source group entries in the Protocol Independent Multicast (PIM) multicast routing table. The PIM cannot prune these entries from the distribution tree.

Before You Begin

- Before you can configure a static source group, you must globally enable one of the following protocols:
  - PIM-Sparse Mode (SM)
  - PIM-Source Specific Multicast (SSM)

About This Task

Even if no receivers exist in the group, the multicast stream for a static source group entry remains active.

The maximum number of static source groups must not exceed 1024.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure a static source group entry:

   ```
   ip mroute static-source-group <A.B.C.D> <A.B.C.D/X>
   ```

Example

Create a static source group for two multicast groups: 224.32.2.1 and 226.50.2.2. The static source group for group 224.32.2.1 is for a source subnet 10.10.10.0/24. The static source group for group 226.50.2.2 is for the host 20.20.20.100/32.

```
Switch:1(config)#  ip mroute static-source-group 224.32.2.1 10.10.10.0/24
Switch:1(config)#  ip mroute static-source-group 226.50.2.2 20.20.20.100/32
```

Variable definitions

Use the definitions in the following table to use the **ip mroute static-source-group** command.

Variable	Value
A.B.C.D	Specifies the IP address of the multicast group. Use the **no** operator to later remove this configuration.
A.B.C.D/X	Specifies the multicast source IP address and subnet mask for the static source group entry. You cannot create duplicate groups. How you configure the source address depends on the protocol and mode you use. Use the **no** operator to later remove this configuration.

Configuring IP multicast software forwarding

When you use the IP multicast software forwarding feature you can avoid initial data loss experienced by multicast applications; this is suitable for low bandwidth conditions.

When you configure the IP multicast software forwarding feature the system forwards the initial packets of an IP multicast data stream it receives and creates a corresponding hardware record for subsequent packets.

By default, multicast software forwarding is disabled.

About This Task

Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

IP multicast software forwarding is a global system configuration feature that is only applicable to traditional PIM protocol and IGMP Snooping protocols, not SPB-PIM Gateway or Layer 3 VSN SPB

Multicast. If you enable IP multicast software forwarding, the hardware continues to forward IP multicast traffic. The software only forwards initial data traffic.

After a new data stream arrives, the first data packet is sent to the CPU, which programs the multicast route in hardware, and all packets that arrive subsequent to this programming are forwarded by hardware only.

If you enable software forwarding, all initial packets received before hardware programming is complete are sent to the CPU for forwarding and packet suppression by the hardware is disabled.

If you do not enable software forwarding, only the first data packet is sent to the CPU and subsequent packets are suppressed by the hardware so that the CPU is not overwhelmed with traffic. During this time, packets suppressed by the hardware are dropped.

Important

To avoid overloading the CPU, ensure that you do not use the IP multicast software forwarding feature for video multicast applications.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Enable software forwarding:
   ```
   multicast software-forwarding
   ```
3. Show the software forwarding configuration:
   ```
   show multicast software-forwarding
   ```

Example

```
Switch:1#show multicast software-forwarding

================================================================================
                    Mcast Software Forwarding - GlobalRouter
================================================================================
McastSoftwareForwarding        :enabled
```

Configuring the resource usage counter for multicast streams

Configure the resource usage counters to query the number of ingress and egress IP multicast streams traversing the switch.

About This Task

Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

After you configure the counter thresholds for ingress and egress records, if the record usage exceeds the threshold, you receive notification by a trap on the console, a logged message, or both.

If you do not configure the thresholds, the system displays only the ingress and egress records currently in use.

You can configure the resource usage counter on a VRF instance the same way you configure the Global Router except that you must use VRF Router Configuration mode.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the thresholds:

   ```
   ip mroute resource-usage egress-threshold <0–32767> ingress-threshold <0–32767>
   ```

3. Configure one of the following notification methods:
   - Configure a log-only notification method:

     ```
     ip mroute resource-usage log-msg
     ```

   - Configure a trap-only notification method:

     ```
     ip mroute resource-usage trap-msg
     ```

   - Configure both notification methods:

     ```
     ip mroute resource-usage log-msg trap-msg
     ```

Example

Configure the egress threshold to 200.

```
Switch:1(config)# ip mroute resource-usage egress-threshold 200
```

Configure the ingress threshold to 100.

```
Switch:1(config)# ip mroute resource-usage ingress-threshold 100
```

Enable the log message notification method.

```
Switch:1(config)# ip mroute resource-usage log-msg
```

Variable definitions

Use the data in the following table to use the **ip mroute resource-usage** command.

Variable	Value
egress-threshold <0–32767>	Configures the egress record threshold (S,G). The system sends a notification message after the number of streams exceeds a threshold level. To configure this option to the default value, use the **default** operator with the command. The default is 0.
ingress-threshold <0–32767>	Configures the ingress record threshold. The system sends a notification message after the number of streams exceeds a threshold level. To configure this option to the default value, use the **default** operator with the command. The default is 0.

Configuring prefix lists

Configure a prefix list to allow or deny specific route updates. A prefix list policy specifies route prefixes to match. After a match occurs, the system uses the route.

The prefix list contains a set of contiguous or noncontiguous routes. Reference prefix lists by name from within a routing policy.

About This Task

Important

When you configure a prefix list for a route policy, add the prefix as a.b.c.d/32. You must enter the full 32-bit mask to exact a full match of a specific IP address.

You configure prefix lists on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure a prefix list:

   ```
   ip prefix-list WORD<1-64> {A.B.C.D/X} [ge <0-32>] [le <0-32>]
   ```

3. (Optional) Rename an existing prefix list:

   ```
   ip prefix-list WORD<1-64> name WORD<1-64>
   ```

4. Display the prefix list:

   ```
   show ip prefix-list [prefix {A.B.C.D}] [vrf WORD<1-16>] [vrfids
   WORD<0-512>] [WORD <1-64>]
   ```

Example

Configure a prefix-list. Display the prefix list.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip prefix-list LIST1 47.17.121.50/255.255.255.0
Switch:1(config)#show ip prefix-list LIST1
================================================================================
                            Prefix List - GlobalRouter
================================================================================

        PREFIX           MASKLEN FROM TO
--------------------------------------------------------------------------------

List 1    LIST1:
        47.17.121.50     24      24   24
1 Total Prefix List entries configured
--------------------------------------------------------------------------------
Name Appendix for Lists Converted from Old Config:
@A=conv addr list, @N=conv net list, @NR=conv net list modified as range
```

Variable definitions

The following table defines parameters for the **ip prefix-list** command.

Variable	Value
{A.B.C.D/X}	Specifies the IP address and the mask in one of the following formats: • a.b.c.d/x • a.b.c.d/x.x.x.x • default
ge <0–32>	Specifies the minimum length to match. Lower bound and higher bound mask lengths together can define a range of networks.
le <0–32>	Specifies the maximum length to match. Lower bound and higher bound mask lengths together can define a range of networks.
name WORD<1–64>	Renames the specified prefix list. The name length is 1–64 characters.
WORD<1–64>	Specifies the name for a new prefix list.

The following table defines parameters for the **show ip prefix-list** command.

Variable	Value
{A.B.C.D}	Specifies the prefix to include in the command output.
vrf WORD<1–16>	Specifies the name of the VRF.

Variable	Value
vrfids WORD<0-512>	Specifies the ID of the VRF and is an integer in the range of 0–512.
WORD<1-64>	Specifies a prefix list, by name, to use for the command output.

The following table defines parameters for the **show ip prefix-list** command output.

Variable	Value
PREFIX	Indicates the member of a specific prefix list.
MASKLEN	Indicates the prefix mask length in bits.
FROM	Indicates the prefix mask starting point in bits.
TO	Indicates the prefix mask endpoint in bits.

Route management using EDM

View or edit interface configuration information for Layer 3 IP multicast protocols on the switch.

View Multicast Route Information

View multicast route information for troubleshooting purposes.

This tab shows multicast routing information for IP datagrams from a particular source and addressed to a particular IP multicast group address.

About This Task

Note

This procedure is supported on a DvR Controller; it is not supported on a DvR Leaf node.

You can view the multicast routes for a Layer 3 Virtual Services Network (VSN) the same way you view the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand **Configuration** > **IP** > **Multicast**.
2. Select the **Routes** tab.

***Routes** field descriptions*

Use the data in the following table to use the **Routes** tab.

Name	Description
Group	Displays the IP multicast group address for this entry that contains multicast routing information.
Source	Displays the network address that, when combined with the corresponding route SourceMask value, identifies the source that contains multicast routing information.
SourceMask	Displays the network mask that, when combined with the corresponding route Source value, identifies the multicast source.
UpstreamNeighbor	Shows the address of the upstream neighbor from which the IP datagrams from these sources are received. The address is 0.0.0.0 if the network is local.
Interface	Displays the interface, slot and portnumber, or VLAN ID where IP datagrams sent by these multicast sourcesto this multicast address are received.
ExpiryTime	Displays the amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging.
Protocol	Displays the protocol as one of the following: • other(1): none of the following • local(2): manually configured • netmgmt(3): configured by a network management protocol • pimSparseMode(8): PIM-SMv2 • igmpOnly(10) • pimSsmMode(11) • spb (12) • spbpimgw(13)

View Multicast Next-Hop Information

View all multicast next-hop information.

This tab shows information about the next hops used by outgoing interfaces to route IP multicast datagrams. Each entry is one in a list of next hops on outgoing interfaces for particular sources that send to a particular multicast group address.

About This Task

You can view the multicast routes for a Layer 3 Virtual Services Network (VSN) the same way you view the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **Multicast**.
3. Select the **Next Hops** tab.

***Next Hops** field descriptions*

Use the data in the following table to use the **Next Hops** tab.

Name	Description
Group	Displays the IP multicast group for this entry that specifies a next hop on an outgoing interface.
Source	Displays the network address that, when combined with the corresponding next hop SourceMask value, identifies the source for this entry that specifies a next hop on an outgoing interface.
SourceMask	Displays the network mask that, when combined with the corresponding next hop Source value, identifies the source for this entry that specifies a next hop on an outgoing interface.
ReceiverPort	Displays the receiver port for this next hop.
OutInterface	Displays the interface slot and portnumber or VLAN ID for the outgoing interface for this next hop.
Address	Displays the address of the next hop specific to this entry. For most interfaces, it is identical to the next-hop group. Non Broadcast Multiple Access (NBMA) interfaces, however, can use multiple next hop addresses out of a single outgoing interface.
State	Displays whether the outgoing interface and next hop represented by this entry currently forward IP datagrams. A value of forwarding indicates the information is currently used; pruned indicates it is not used.
UpTime	Displays the up time for this entry.
ExpiryTime	Displays the minimum amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging.
ClosestMemberHops	Displays the minimum number of hops between this router and members of the IP multicast group reached through the next hop on this outgoing interface. IP multicast datagrams for the group that use a time-to-live less than this number of hops are not forwarded to the next hop.
Protocol	Displays the protocol as one of the following: • other(1): none of the following • local(2): manually configured • netmgmt(3): configured by a network management protocol • pimSparseMode(8): PIM-SMv2 • igmpOnly(10) • pimSsmMode(11) • spb
Pkts	Displays the number of next hop packets.

View Multicast Interface Information

View multicast interface information to verify the multicast configuration.

This tab shows multicast routing information specific to interfaces.

About This Task

You can view multicast interface information for a Layer 3 VSN the same way you view the Global Router except that you must first launch the appropriate VRF context.

Note

This procedure is supported on a DvR Controller; it is not supported on a DvR Leaf node.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **Multicast**.
3. Select the **Interfaces** tab.

Interfaces *field descriptions*

Use the data in the following table to use the **Interfaces** tab.

Name	Description
Interface	Displays the slot and port number or VLAN ID for this entry.
Ttl	Displays the datagram time-to-live (TTL) threshold for the interface. IP multicast datagrams with a TTL less than this threshold are not forwarded out of the interface. The default value of 0 means that all multicast packets are forwarded out of the interface.
Protocol	Displays the protocol as one of the following: • other(1): none of the following • local(2): manually configured • netmgmt(3): configured by a network management protocol • pimSparseMode(8): PIM-SMv2 • igmpOnly(10) • pimSsmMode(11) • spb

Adding new static source groups

Add a new static source group to create an entry that the switch cannot prune from the distribution tree. An attempt to add a duplicate of an existing source-group entry results in an error message.

Before You Begin

- Before you can configure a static source group, you must globally enable one of the following protocols:
  - PIM-SM
  - PIM-SSM

About This Task

Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

The switch supports PIM only in the Global Router. You cannot configure static source groups for specific VRF contexts.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **Multicast**.
3. Click the **Static Source Group** tab.
4. Click **Insert**.
5. Complete the information in the dialog box.
6. Click **Insert**.

Editing static source groups

Configure static source-group entries in the PIM multicast routing table. PIM cannot prune these entries from the distribution tree. In other words, even if no receivers exist in the group, the multicast stream for a static source-group entry stays active.

Before You Begin

- Before you can configure a static source group, you must globally enable one of the following protocols:
  - PIM-Sparse Mode (SM)
  - PIM-Source Specific Multicast (SSM)

About This Task

Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

The maximum number of static source groups must not exceed 1024.

The switch supports PIM only in the Global Router. You cannot configure static source groups for specific VRF contexts.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **Multicast**.
3. Click the **Static Source Group** tab.
4. Edit the required information.
5. Click **Apply**.

Static Source Group *field descriptions*

Use the data in the following table to use the **Static Source Group** tab.

Name	Description
GroupAddress	Configures the multicast group IP address for this static source-group entry.
SourceSubnet	Configures the multicast source address for this static source-group entry. How you configure the source address depends on the protocol and mode you use.
SrcSubnetMask	Configures the subnet mask of the source for this static source-group entry.

Configuring IP multicast software forwarding

Configure IP multicast software forwarding to enable the system to initially forward IP multicast data until a hardware record is created. The system forwards the initial packets of a stream it receives and creates a corresponding hardware record for subsequent packets. The advantage of this feature is that it avoids initial data loss experienced by multicast applications and is most suited for low bandwidth.

About This Task

Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

IP multicast software forwarding is a global system configuration feature that is only applicable to traditional PIM protocol and IGMP Snooping protocols, not SPB-PIM Gateway or Layer 3 VSN SPB Multicast. If you enable IP multicast software forwarding, the hardware still forwards IP multicast traffic. The software forwards only initial data traffic.

After a new data stream arrives, the first data packet is sent to the CPU, which programs the multicast route in hardware, and all packets that arrive subsequent to this programming are forwarded by hardware only. If you enable software forwarding, all initial packets received before hardware programming is complete are sent to the CPU for forwarding. If you enable software forwarding, packet suppression by the hardware is disabled. If you do not enable software forwarding, only the first data packet is sent to the CPU and subsequent packets are suppressed by the hardware so that the CPU is not overwhelmed with traffic. During this time, packets suppressed by the hardware are dropped.

By default, the feature is disabled.

Important

To avoid overloading the CPU, do not use the IP multicast software forwarding feature for video multicast applications.

If you configure multicast software forwarding from within a VRF context, the configuration applies to the Global Router and all VRF contexts. You cannot change the multicast software forwarding configuration for individual VRF contexts.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.

2. Click **Multicast**.
3. Click the **Globals** tab.
4. Select the **SWForwardingEnable** check box.
5. Click **Apply**.

Globals *field descriptions*

Use the data in the following table to use the **Globals** tab.

Name	Description
SWForwardingEnable	Enables the system to initially forward IP multicast data until a hardware record is created. The default is disabled.
StatsEnabled	Enables or disables multicast route statistics. The default is disabled.
StatsClear	Clears multicast route statistics.

Configuring mroute stream limit

Limit the number of multicast streams to protect a CPU from multicast data packet bursts generated by malicious applications, such as viruses that cause the CPU to reach 100 percent utilization or that prevent the CPU from processing protocol packets or management requests. If more than a certain number of multicast streams ingress to a CPU through a port during a sampling interval, the port shuts down until you take appropriate action.

Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration** > **Edit** > **Port**.
3. Click **General**.
4. Select the **Mroute Stream Limit** tab.
5. Select the **StreamLimitEnable** box.
6. Edit other fields as required.
7. Click **Apply**.

Mroute Stream Limit *field descriptions*

Use the data in the following table to use the **Mroute Stream Limit** tab.

Name	Description
StreamLimitEnable	Enables or disables mroute stream limit on the port.
StreamLimit	Specifies the maximum number of multicast streams allowed to enter the CPU through this port.
StreamTimerCheck	Specifies the sampling period, in seconds, to check the number of multicast streams that enter the CPU through this port.

Configuring Mroute Stream Limit on an Extreme Integrated Application Hosting Port

Note

This procedure applies to 5720 Series only.

About This Task

Perform this procedure to limit the number of multicast streams to protect a Central Processing Unit (CPU) from multicast data packet bursts generated by malicious applications, such as viruses that cause the CPU to reach 100 percent utilization, or that prevent the CPU from processing protocol packets or management requests. If more than a certain number of multicast streams ingress to a CPU through a port during a sampling interval, the port shuts down until you take appropriate action.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit** > **Insight Port**.
2. Select the Extreme Integrated Application Hosting (IAH) port you want to configure.
3. Select the **Mroute Stream Limit** tab.
4. Select **StreamLimitEnable**.
5. Configure other fields as required.
6. Select **Apply**.

Mroute Stream Limit *Field Descriptions*

Use data in the following table to configure the **Mroute Stream Limit** tab.

Name	Description
StreamLimitEnable	Enables or disables mroute stream limit on the Extreme Integrated Application Hosting (IAH) port. The default is disabled.
StreamLimit	Specifies the maximum number of multicast streams allowed to enter the CPU through the IAH port. The default value is 1984.
StreamTimerCheck	Specifies the sampling period, in seconds, to check the number of multicast streams that enter the CPU through the IAH port. The default is 10 seconds.

Configuring resource usage counter for multicast streams

Configure the resource usage counters to query the number of ingress and egress IP multicast streams traversing the switch. After you configure the counter thresholds for ingress and egress records, if the record usage goes beyond the threshold, you receive notification through a trap on the console, a logged message, or both.

About This Task

Note

This procedure is supported only on a DvR Controller. It is not supported on a DvR Leaf node.

Important

If you do not configure the thresholds, EDM displays only the ingress and egress records that are currently in use.

You can configure the resource usage counter on a VRF instance the same way you configure the Global Router except that you must first launch the appropriate VRF context.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **Multicast**.
3. Select the **Resource Usage** tab.
4. Configure the ingress and egress thresholds.
5. Configure the notification methods.
6. Click **Apply**.

Resource Usage *field descriptions*

Use the data in the following table to use the **Resource Usage** tab.

Name	Description
Egress Records In-Use	Displays the number of egress records traversing the switch.
Ingress Records In-Use	Displays the number of ingress records (source or group) traversing the switch.
Egress Threshold	Configures the egress threshold level (0–32767).
Ingress Threshold	Configures the ingress threshold level (0–32767).
SendTrapOnly	Sends only trap notification messages after the number of streams exceeds a threshold level. Select disable if you select a different notification type. You can configure only one notification type.
SendTrapAndLog	Sends both trap and log notification messages after the number of streams exceeds a threshold level. Select disable if you select a different notification type.
LogMsgOnly	Sends only log notification messages after the number of streams exceeds a threshold level. Select disable if you select a different notification type.

Multicast route statistics configuration using the CLI

The following sections provide procedural information you can use to configure multicast route statistics using the Command Line Interface (CLI).

Enabling IP multicast route statistics

Enable the collection and display of IP multicast route statistics.

These statistics are not related to the interface (port) statistics. Rather, the statistics are displayed based on multicast group classification. By default, collection of multicast route statistics is disabled.

Note

When you enable IP multicast route statistics on the Controller node of a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable the collection of IP multicast route statistics.

   ```
   ip mroute stats enable
   ```

3. (Optional) Set the IP multicast route statistics to default.

   ```
   default ip mroute stats enable
   ```

4. (Optional) Disable the collection of IP multicast route statistics.

   ```
   no ip mroute stats enable
   ```

5. View the IP multicast route statistics.

   ```
   show ip mroute stats [WORD<3-160> {A.B.C.D[,E.F.G.H][,...]}]
   ```

Note

The maximum number of multicast group IP addresses is 10.

Example

Enable the collection of IP multicast route statistics:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ip mroute stats enable
```

View the IP multicast route statistics:

```
Switch:1#show ip mroute stats

================================================================================
                     Multicast Stats

================================================================================
--------------------------------------------------------------------------------
                           Statistics : Enabled
```

View the statistics for the multicast group IP address `225.0.0.1`:

```
Switch:1#show ip mroute stats 225.0.0.1

================================================================================
                         Multicast Stats - GlobalRouter

================================================================================
GroupAddress     SourceCounter      IngressPackets       IngressBytes  AverageSize
```

```
--------------------------------------------------------------------------------
225.0.0.1        1                  30452198             3897881344    128
```

View the statistics for multiple (up to a maximum of 10) group IP addresses.

```
Switch:1#show ip mroute stats
225.0.0.1,225.0.0.2,225.0.0.3,225.0.0.4,225.0.0.5,225.0.0.6,225.0.0.7,225.0.0.8,225.0.0.9,
225.0.0.10

================================================================================
                         Multicast Stats - GlobalRouter

================================================================================
GroupAddress     SourceCounter      IngressPackets       IngressBytes   AverageSize
--------------------------------------------------------------------------------
225.0.0.1        1                  32446194             4153112832    128
225.0.0.2        1                  32446196             4153112960    127
225.0.0.3        1                  32446197             4153113088    127
225.0.0.4        1                  32446198             4153113216    127
225.0.0.5        1                  32446199             4153113472    128
225.0.0.6        1                  32446200             4153113600    128
225.0.0.7        1                  32446201             4153113728    128
225.0.0.8        1                  32446203             4153113856    127
225.0.0.9        1                  32446203             4153113856    127
225.0.0.10       1                  32446203             4153113984    128
```

Variable definitions

Use the data in the following table to use the **`show ip mroute stats`** command.

Variable	Definition
WORD*<3–160>* *{A.B.C.D[,E.F.G.H][,...]}*	Specifies the multicast group IP address for which to display statistics. The group IP address is in one of the following formats: a single IP address or a series of IP addresses. You can specify a maximum of 10 groups.

Clearing IP multicast route statistics

Use this procedure to clear the IP multicast route statistics. This resets the IP multicast statistics counters.

Note

When you clear IP multicast route statistics on the Controller node of a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Clear the IP multicast route statistics:

   ```
   clear ip mroute stats
   ```

Example:

Clear the IP multicast route statistics:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#clear ip mroute stats
```

Monitoring IP multicast route statistics

Use this procedure to monitor the IP multicast route statistics at regular intervals.

Procedure

1. Enter Privileged EXEC mode:
   `enable`
2. Monitor the IP multicast route statistics:
   `monitor ip mroute stats WORD<7-160> {A.B.C.D[,E.F.G.H][,...]}`

Note

You can monitor a maximum of 10 group IP addresses.

Example:

Monitor the IP multicast route statistics for the group IP address `225.0.0.1`. In this example, the statistics are monitored at intervals of 5 seconds for a duration of 300 seconds.

The output from monitoring three consecutive intervals is displayed below.

```
Switch:1>en
Switch:1#monitor ip mroute stats 225.0.0.1

                         MULTICAST STATISTIC

Variable definitions

Use the data in the following table to use the **monitor ip mroute stats** command.

Variable	Definition
WORD<*7–160*> *{A.B.C.D[,E.F.G.H][,...]}*	Specifies the multicast group IP address for which to monitor statistics. The group IP address is in one of the following formats: a single IP address or a series of IP addresses, up to a maximum of 10.

Enabling IPv6 multicast route statistics

Enable the collection of IPv6 multicast route statistics.

These statistics are not related to the interface (port) statistics. Rather, the statistics are displayed based on multicast group classification. By default, collection of multicast route statistics is disabled.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable the collection of IPv6 multicast route statistics.

   ```
   ipv6 mroute stats enable
   ```

3. (Optional) Set the IPv6 multicast route statistics to default:

   ```
   default ipv6 mroute stats
   ```

4. (Optional) Disable the collection of IPv6 multicast route statistics.

   ```
   no ipv6 mroute stats
   ```

5. View the IPv6 multicast route statistics.

   ```
   show ipv6 mroute stats [WORD<7–400> {Ipv6address[,Ipv6address][,...]}]
   ```

   Note

   The maximum number of multicast group IP addresses is 10.

Example:

Enable collection of IPv6 multicast route statistics:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ipv6 mroute stats enable
```

View the IPv6 multicast route statistics:

```
Switch:1#show ipv6 mroute stats

================================================================================
                     Multicast Stats

================================================================================
--------------------------------------------------------------------------------
                     Statistics : Enabled
```

View the statistics for the multicast group IP address `FF05::1`:

```
Switch#show ipv6 mroute stats FF05::1

================================================================================================
                          Multicast Stats - GlobalRouter

================================================================================================
GroupAddress                SourceCounter      IngressPackets       IngressBytes
AverageSize
------------------------------------------------------------------------------------------------
ff05:0:0:0:0:0:0:1          1                  1962750              2355300000     1200
```

View the statistics for multiple group IP addresses (up to a maximum of 10).

```
Switch#show ipv6 mroute stats
FF05::1,FF05::2,FF05::3,FF05::4,FF05::5,FF05::6,FF05::7,FF05::8,FF05::9,FF05::a

```

Variable definitions

Use the data in the following table to use the **show ipv6 mroute stats** command

Variable	Definition
WORD<7-400> *{Ipv6address[,Ipv6address] [,...]}*	Specifies the multicast group IP address for which to display statistics. The group IP address is in one of the following formats: a single IP address or a series of IP addresses. You can specify a maximum of 10 groups.

Clearing IPv6 multicast route statistics

Use this procedure to clear the IPv6 multicast route statistics. This resets the IP multicast statistics counters.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Clear the IPv6 multicast route statistics:

   ```
   clear ipv6 mroute stats
   ```

Example:

Clear the IPv6 multicast route statistics:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#clear ipv6 mroute stats
```

Monitoring IPv6 multicast route statistics

Use this procedure to monitor IPv6 multicast route statistics at regular intervals.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Monitor IPv6 multicast route statistics:

   ```
   monitor ipv6 mroute stats WORD<7-400> {Ipv6address[,Ipv6address] [,...]}
   ```

Note

You can monitor a maximum of 10 group IP addresses.

Example:

Monitor the IPv6 multicast route statistics for the group IPv6 address `FF05::1`. In this example, the statistics are monitored at intervals of 5 seconds for a duration of 300 seconds.

The output from monitoring three consecutive intervals is displayed below.

```
Switch:1>enable
Switch:1#monitor IPv6 mroute stats FF05::1

Variable definitions

Use the data in the following table to use the **monitor ipv6 mroute stats** command:

Variable	Definition
WORD<7-400> *{Ipv6address[,Ipv6address][,...]}*	Specifies the multicast group IP address for which to monitor statistics. The group IP address is in one of the following formats: a single IP address or a series of IP addresses, up to a maximum of 10.

Multicast route statistics configuration using EDM

The following sections provide procedural information you can use to configure multicast route statistics using the Enterprise Device Manager (EDM).

Enabling IP multicast route statistics

Use this procedure to enable IP multicast route statistics.

Note

When you enable or clear IP multicast route statistics on the Controller node of a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**
2. Click **Multicast**.
3. Click the **Globals** tab.
4. In the **StatsEnabled** field, select the option to enable or disable the collection of statistics.
5. (Optional) To clear the statistics, click **StatsClear**.
6. Click **Apply**.

***Globals** Field Definitions*

Use the data in the following table to use the **Globals** tab.

Field	Description
StatsEnabled	Displays whether the multicast route statistics is enabled.
StatsClear	Clears the multicast route statistics.

Viewing IP multicast route statistics

Use this procedure to view IP multicast route statistics.

Before You Begin

- You must enable the collection of multicast statistics.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **Multicast**.
3. Click the **Stats** tab to view the statistics.

***Stats** Field Definitions*

Use the data in the following table to use the **Stats** tab.

Field	Description
GroupAddress	Specifies the multicast group IP address for which to show statistics.
SourceCounter	Specifies the number of sources associated with the multicast route record.
Pkts	Specifies the number of packets received for the associated IP address.
Bytes	Specifies the number of bytes received for the associated IP address.
AverageSizePerPkt	Specifies the average packet length for the associated group IP address. This information indicates only the ingress packet length and is calculated using the following formula: ingress packet/ingress byte.

Enabling IPv6 multicast route statistics

Enable the collection of IPv6 multicast route statistics.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Globals** tab.
4. In the **StatsEnabled** field, select the option to enable or disable the collection of statistics.
5. (Optional) To clear the statistics, click **StatsClear**.
6. Click **Apply**.

***Globals** Field Definitions*

Use the data in the following table to use the **Globals** tab.

Field	Description
StatsEnabled	Displays whether the multicast route statistics is enabled.
StatsClear	Clears the multicast route statistics.

Viewing IPv6 multicast route statistics

Use this procedure to view IPv6 multicast route statistics.

Before You Begin

- You must enable the collection of multicast statistics.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 Mroute**.
3. Click the **Stats** tab to view the statistics.

Stats *Field Definitions*

Use the data in the following table to use the **Stats** tab.

Field	Description
GroupAddress	Specifies the multicast group IP address for which to show statistics.
SourceCounter	Specifies the number of sources associated with the multicast route record.
Pkts	Specifies the number of packets received for the associated IP address.
Bytes	Specifies the number of bytes received for the associated IP address.
AverageSizePerPkt	Specifies the average packet length for the associated group IP address. This information indicates only the ingress packet length and is calculated using the following formula: ingress packet/ingress byte.

IP Multicast over Fabric Connect

IP Multicast over Fabric Connect basic configuration

Table 104: IP Multicast over Fabric Connect product support

Feature	Product	Release introduced
IP Multicast over Fabric Connect	5320 Series	Fabric Engine 8.6 Note: Only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration.
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Universal Plug and Play (uPnP) Filtering	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.3
	5720 Series	Fabric Engine 8.7

IP Multicast over Fabric Connect Fundamentals

IP Multicast over Fabric Connect

Extreme Networks is leading the industry with a new approach to transporting IP multicast using IP Multicast over Fabric Connect. IP Multicast over Fabric Connect greatly simplifies multicast deployment, with no need for any multicast routing protocols such as Protocol Independent Multicast-Sparse Mode (PIM-SM) or Protocol Independent Multicast-Source Specific Multicast (PIM-SSM). A BEB can forward a multicast stream anywhere in an SPBM network where IS-IS advertises the stream to the rest of the fabric.

The advantage of this solution over traditional approaches is the simplicity in provisioning and deploying IP multicast bridging and routing. Also, due to the fact that only one control plane protocol (IS-IS) exists, convergence times in the event of a network failure, are typically sub second.

You can compare the quick convergence times for IP Multicast over Fabric Connect to Interior Gateway Protocols like Open Shortest Path First (OSPF) combined with PIM-SM or PIM-SSM. OSPF combined with PIM-SM or PIM-SSM can have recovery times that are sub optimal with convergence times that take tens of seconds. PIM experiences longer convergence times, in part, because unicast IP routing protocols must converge before PIM can converge. PIM also maintains the network state for every multicast group and uses a mechanism based on each hop to update the network about state changes, which affects scalability.

IP Multicast over Fabric Connect is extremely scalable because you only apply the multicast bridging and routing functionality at the SPBM fabric edge, with the streams mapped to SPBM multicast trees in the fabric.

IP Multicast over Fabric Connect introduces extensions to the SPBM IS-IS control plane to exchange IP multicast stream advertisement and membership information. IP Multicast over Fabric Connect uses these extensions, along with the Internet Group Management Protocol (IGMP) Snooping and Querier functions at the edge of the SPBM cloud, to create sub-trees of the VSN SPB for each multicast group to transport IP multicast data.

With IP Multicast over Fabric Connect, the switch supports the following:

- Layer 2 Virtual Services Network with IGMP support on the access networks for optimized forwarding of IP multicast traffic in a bridged network (Layer 2 VSN with IP Multicast over Fabric Connect). Example application: Multicast in data centers.
- IP multicast routing support for IP Shortcuts using SPBM in the core and IGMP on the access (IP Shortcuts with IP Multicast over Fabric Connect). Example applications: Video surveillance, TV/Video/Ticker/Image distribution, VX-LAN.
- Layer 3 Virtual Services Network with VRF based routing support for IP Multicast over Fabric Connect in the core and IGMP on the access (Layer 3 VSN with IP Multicast over Fabric Connect). Example applications: Video surveillance, TV/Video/Ticker/Image Distribution, VX-LAN, Multi-tenant IP multicast.

IP Multicast over Fabric Connect and Universal Plug and Play Filtering

When multicast packets are received on IGMP-enabled interfaces and the multicast group matches the range of groups to be filtered, Universal Plug and Play (uPnP) Filtering drops them.

For more information, see Universal Plug and Play Filtering on page 1463.

How IP Multicast over Fabric Connect works

The BEBs act as the boundary between the multicast domain (currently only IGMP dynamic or static) and the SPBM domain. Multicast senders (sources) and receivers connect directly or indirectly (using Layer 2 switches) to the BEBs. You can enable IP Multicast over Fabric Connect services at the Layer 2 VSN level or the Layer 3 VSN level (including the GRT).

The following figure shows how multicast senders and receivers connect to the SPBM cloud using BEBs.

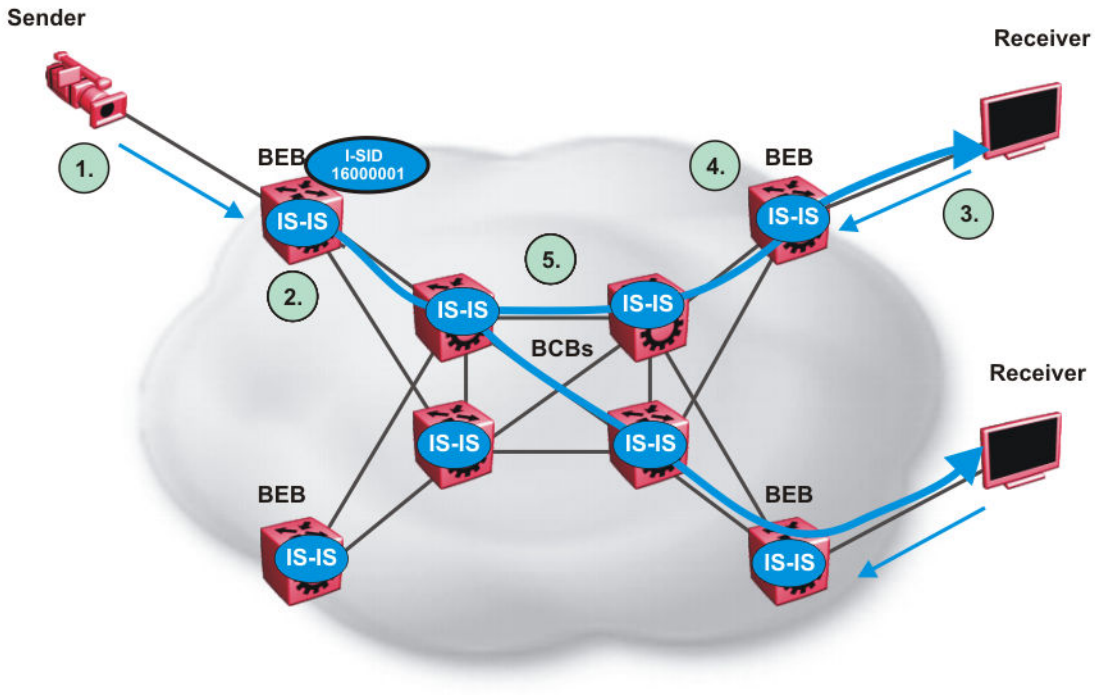

Figure 137: IP Multicast over Fabric Connect streams

The following list describes how multicast senders and receivers connect to the SPBM cloud using BEBs in the preceding diagram:

1. The sender transmits multicast traffic with group IP address 233.252.0.1.
2. After the BEB receives the IP multicast stream from the sender, the BEB allocates data I-SID 16000001 for the S,G multicast stream. The BEB sends an LSP with the TLV 185 (for Layer 2 VSN multicast and Layer 3 VSN multicast) or TLV 186 (for IP Shortcuts multicast) with the transmit bit set. The BEB also sends an IS-IS service identifier and unicast address sub-TLV (where the unicast address has the multicast bit set and the I-SID is the Data I-SID).
3. The receiver sends a join request to Group 233.252.0.1.
4. The BEB (acting as the IGMP Querier) queries the IS-IS database to find all senders for group 233.252.0.1. If the group exists, the BEB sends an LSP with the IS-IS service identifier and unicast address sub-TLV (where the unicast address has the multicast bit set and the nickname is the stream transmitter BEB and the I-SID is the data I-SID).
5. The multicast tree is calculated for the data I-SID and the data starts flowing from the sender.

Scope level

IP Multicast over Fabric Connect constrains all multicast streams within the level in which they originate, which is called the scope level. In other words, if a sender transmits a multicast stream to a BEB on a C-VLAN (a VLAN that is mapped to an I-SID, for instance, a Layer 2 VSN) with IP Multicast over Fabric Connect enabled, only receivers that are part of the same Layer 2 VSN can receive that stream. Similarly, if a sender transmits a multicast stream to a BEB on a VLAN that is part of the GRT or a Layer 3 VSN

with IP Multicast over Fabric Connect enabled, only receivers that are part of the same Layer 3 instance (GRT or L3 VSN) can receive that stream.

Note

In the context of IP Multicast over Fabric Connect, scope is either the Global Routing Table or the I-SID value of the Layer 2 or Layer 3 VSN associated with the local VLAN on which the IP multicast data was received.

Data I-SID

After the BEB receives the IP multicast stream from the sender, a BEB allocates a data Service Identifier (I-SID) in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the S,G, V tuple, which is the source IP address, the group IP address, and the local VLAN the multicast stream is received on.

The BEB propagates this information through the SPBM cloud by using IS-IS TLV updates in LSPs, which results in the creation of a multicast tree for that stream. All BEBs now know what data I-SID to use for that stream and its scope. The data I-SID is a child of the scope or VSN I-SID. If no receiver requests the IP multicast stream, the ingress BEB does not forward the multicast stream.

IGMP

After a BEB receives an IGMP join message from a receiver, a BEB queries the IS-IS database to check if a sender exists for the requested stream within the scope of the receiver. If the requested stream does not exist, the IGMP information is kept, but no further action is taken. If the requested stream exists, the BEB sends an IS-IS TLV update to its neighbors to inform them of the presence of a receiver, and this information is propagated through the SPBM cloud.

IS-IS acts dynamically using the TLV information it receives from BEBs that connect to the sender and the receivers to create a multicast tree between them. IS-IS creates very efficient multicast trees for the data I-SID allocated at the sender edge of the SPBM cloud to transport data between the sender and the receivers. The data I-SID uses Tx/Rx bits to signify whether the BEB uses the I-SID to transmit, receive, or both transmit and receive data on that I-SID. After IS-IS creates the multicast tree, the sender transports data to the receiver across the SPBM cloud using the data I-SID.

The trigger to send IS-IS updates to announce a multicast stream into the SPBM cloud is the multicast traffic arriving at the BEB. Because the BEB only interacts with IGMP and not PIM, all multicast traffic must be drawn towards the BEB for the stream to be announced, which SPBM accomplishes by making the BEB an IGMP Querier. In a VLAN, the IGMP Querier sends out periodic IGMP queries.

Note

The BEB must be the only IGMP Querier in the VLAN. If the BEB receives an IGMP query from any other device, it causes unexpected behavior, including traffic loss.

BEB as IGMP Querier

The BEB acts as the IGMP Querier and creates tables for links that need IP multicast streams. IGMP and IGMP Snooping cannot work without an IGMP Querier that sends out periodic IGMP queries.

The BEB only interacts with IGMP messages and not PIM. All multicast traffic must enter the BEB for the data stream to be announced.

The BEB must be the only IGMP Querier in the VLAN. If the BEB receives an IGMP query from any other device, unexpected behavior results, including traffic loss.

The IGMP query message is an IP packet and requires a source IP address. However, Layer 2 IGMP Snooping with SPBM by default turns on the service without the configuration of an IP address on the VLAN. By default, the BEB sends an IGMP query message with an IP source address of 0.0.0.0. If there are interoperability issues with third party vendors as a result of the 0.0.0.0 IP address, then you can configure the querier address under IGMP, without having to configure an IP address for the Layer 2 VSN VLAN.

IGMP Snooping, operating on the Layer 2 VSN, listens to conversations between hosts and routers, and maintains a table for links that need IP multicast streams.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

For more conceptual and configuration information on IGMP, see IP Multicast on page 1230.

Switch Clustering at the Edge of the SPBM Network

Typical customer deployments require redundancy all the way to the access side of the network. IP Multicast over Fabric Connect supports switch clustering, Split Multilink Trunking (SMLT) technology, at the edge of the SPBM fabric, providing redundancy to the access Layer 2 switch where you can attach multicast senders and receivers. Typical SPBM fabric deployments use two or more B-VLANs for Equal Cost Multipath (ECMP) and resiliency. For simplicity in understanding how the SPBM network works, assume that there are two B-VLANs (primary and secondary).

The following figure shows how multicast senders and receivers connect to the SPBM cloud using BEBs.

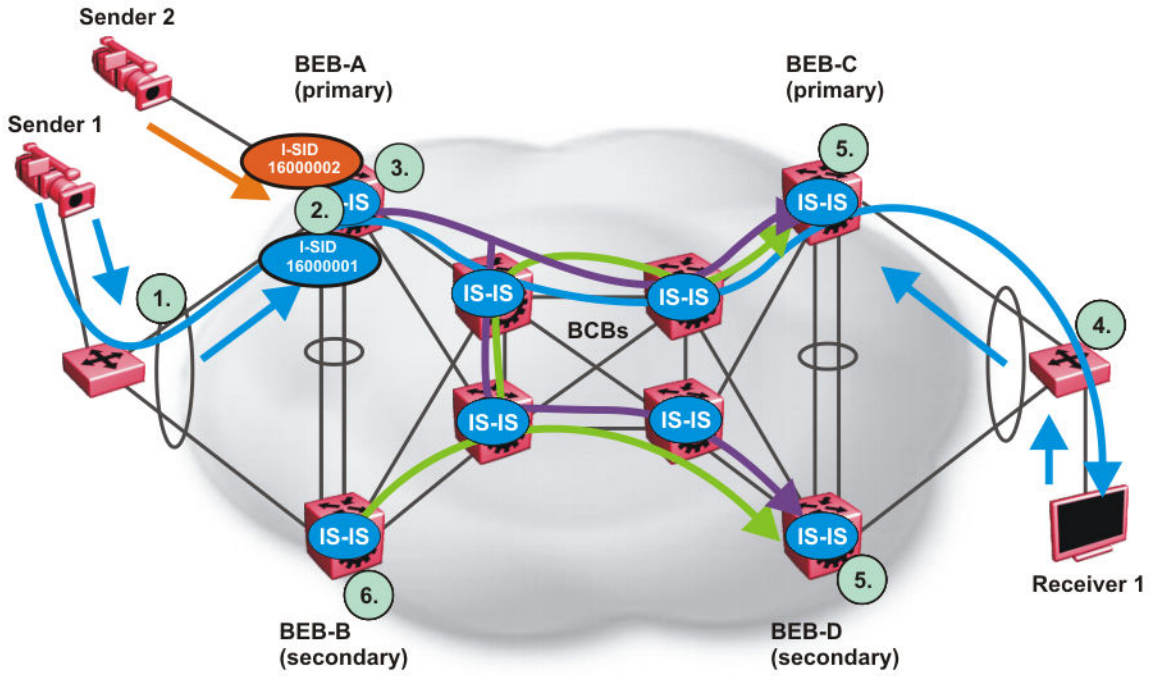

Figure 138: IP Multicast over Fabric Connect streams in an SMLT configuration

The following list describes the preceding diagram:

1. The edge switch hashes the sender multicast data to a specific MLT link.
2. A multicast stream received at the edge of the SPBM fabric is mapped to a dedicated multicast data I-SID.
3. For the non-SMLT attached sender 2, the stream is hashed to the primary or secondary B-VLAN based on whether the data I-SID is even or odd numbered. For the SMLT attached to sender 1, IS-IS advertises the stream to the rest of the fabric on the primary B-VLAN and synchronizes information to the vIST peer.
4. The edge switch hashes the receiver IGMP join to a specific MLT link.
5. Both BEBs on both B-VIDs advertise the IGMP join.
6. The multicast tree is built for (S1,G1), which is rooted in the primary sender BEB. The multicast tree is built for (S1,G1), which is rooted in the secondary sender BEB.

IGMP Snooping is widely used on Layer 2 access switches to prune multicast traffic. In IP Multicast over Fabric Connect, BEBs are the IGMP Queriers, therefore access switches forward multicast data from the senders as well as IGMP control messages from receivers to the BEBs.

When a sender transmits multicast data to the Layer 2 access switch that has an MLT to the switch cluster, it is hashed towards one or the other BEBs in the switch cluster. The receiving BEB allocates a data I-SID and sends a TLV update on either the primary B-VLAN or the secondary B-VLAN, depending on whether the BEB is the primary or secondary switch. The primary switch uses the primary B-VLAN, whereas, the secondary switch uses the secondary B-VLAN. This information is propagated through the SPBM fabric so all BEBs are aware of this stream availability.

The sender information is also synchronized over the vIST to the peer switch. Then the peer switch allocates a data I-SID for the multicast stream and sends a TLV update on the appropriate B-VLAN to

announce the availability of the stream. The data I-SIDs allocated by the primary and secondary switch cluster peers may be the same or different, as they are allocated independently by each switch.

Note

If a sender attaches to only one BEB in a switch cluster, the sender information is not synchronized over the vIST because it is not SMLT attached. The sender information is advertised, and data is sent on either the primary or secondary B-VLAN. The odd-numbered data I-SIDs use the primary B-VLAN, and the even-numbered data I-SIDs use the secondary B-VLAN. The same hashing rules apply to the forwarding of multicast data.

When a receiver sends an IGMP join message to the Layer 2 access switch that has an MLT to the switch cluster, it is hashed towards one or the other BEBs in the switch cluster. The receiving BEB queries the IS-IS Link State Database (LSDB) to check if a sender exists for the requested stream within the scope of the receiver.

If the requested stream does not exist, the BEB keeps the IGMP information but no further action is taken. If the requested stream exists, the BEB sends an IS-IS Link State Packet (LSP), with TLV update information, for both primary and secondary B-VLANs to its neighbors to inform them of the presence of a receiver. The BEB propagates this information through LSPs through the SPBM cloud. The receiver information is also synchronized over the vIST to the peer switch. The peer switch then queries its IS-IS Link State Database (LSDB) and, if the requested stream exists, it sends an IS-IS LSP, with a TLV update, for both primary and secondary B-VLANs to its neighbors to inform them of the presence of the receiver.

IS-IS uses these TLV updates in LSPs to create multicast shortest path first trees in the SPBM fabric. IS-IS creates a shortest path first tree for the primary and secondary B-VLANs, but only one of the B-VLANs transports multicast data with the other in active standby in case of failures at the SPBM edge. After IS-IS creates the trees, multicast data flows between senders and receivers.

IP Multicast over Fabric Connect and SMLT

The following section summarizes the IP Multicast over Fabric Connect actions in an SMLT environment. The BEBs on the sender side behave as follows:

- Primary SMLT peer BEB always advertises the streams it receives, and sends data for them on the primary B-VLAN.
- Secondary SMLT peer BEB always advertises the streams it receives, and sends data for them on the secondary B-VLAN.
- Non-SMLT BEBs or SMLT BEBs with single attached senders advertise streams, and send data on the primary or secondary B-VLAN based on hash criteria (odd-numbered data I-SIDs use primary B-VLAN; even-numbered data I-SIDs use secondary B-VLAN).

The BEBs on the receiver side behave as follows:

- The primary SMLT peer BEB that receives multicast data on the primary B-VLAN sends it to both SMLT and non-SMLT SPBM access (UNI) links.
- The primary SMLT peer BEB that receives multicast data on the secondary B-VLAN sends it to non-SMLT SPBM access (UNI) links only.
- The secondary SMLT peer BEB that receives multicast data on primary B-VLAN sends it to non-SMLT SPBM access (UNI) links only.

- The secondary SMLT peer BEB that receives multicast data on secondary B-VLAN sends data to both SMLT and non-SMLT SPBM access (UNI) links.
- The non-SMLT BEB that receives multicast data on primary or secondary B-VLAN sends data to all SPBM access (UNI) links.

Layer 2 Querier behavior for a switch cluster

For C-VLANs in an SMLT environment, the vIST ports are not part of the VLAN.

IGMP on a C-VLAN behaves as follows to account for the fact that vIST peers do not see the membership queries of each other:

- The vIST peer with the higher IP address sends the queries out all SMLT and non-SMLT ports on SPBM access links.
- The vIST peer with the lower IP address only sends out queries on its non-SMLT ports. This includes SMLT ports whose remote ports are down (SMLT state of 'norm').
- With the existence of an vIST peer with a higher IP address and an vIST peer with a lower IP address, it means two queriers exist within the C-VLAN. Having two queriers poses no problems in this SPB environment, as all SMLT access devices see the vIST peer with the higher IP address as the querier, and non-SMLT access devices see the directly connected vIST peer as the querier. Non-SMLT access devices that connect on either side of the vIST peers can talk to each other using the SPBM cloud.

Considerations when you connect an IP Multicast over Fabric Connect network to a PIM network

IP Multicast over Fabric Connect does not integrate PIM functionality. Apply the following considerations when you connect to a PIM network:

- You must configure static IGMP receivers on the BEB access interface that faces the PIM network when the sender is on the SPBM access network and the receiver is on the PIM network.

  Note

  The PIM router must have a configuration option to accept streams with non-local sources or the router drops the packets. The switch does not support a configuration option to accept streams with non-local sources.

  You must configure static IGMP receivers on the PIM interface that face the IP Multicast over Fabric Connect network when the sender is on the PIM network and the receiver is on the SPBM access network.

  Note

  For security reasons and to limit unnecessary multicast streams from being injected into the SPBM domain, you should configure ACLs on the BEB facing the PIM network.

IP Multicast over Fabric Connect restrictions

Review the following restrictions for the IP Multicast over Fabric Connect feature.

IGMP

The BEB must be the only IGMP querier in the network. If the BEB receives an IGMP query from any other device, it causes unpredictable behavior, including traffic loss.

SPBM supports IGMP Snooping on a C-VLAN, but it does not support PIM on a C-VLAN. If you enable IGMP Snooping on a C-VLAN, then its operating mode is Layer 2 VSN with IP Multicast over Fabric Connect.

SPBM supports Network Load Balancing (NLB) unicast and multicast modes. SPBM does not support NLB Multicast operation with IGMP.

Note

The NLB Multicast operation feature is not supported on all hardware platforms. For more information about feature support, see VLAN Feature Support on page 3412.

You must enable SSM snoop before you configure IGMP version 3, and you must enable both ssm-snoop and snooping for IGMPv3.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is either the same as the IGMP version configured on the IGMP Snooping VLAN, or that compatibility mode is enabled.

SSM

If you delete any **ssm-map** in a static range group, the switch deletes the entire static range group. For example, create an ssm-map for 232.122.122.122 to 232.122.122.122.128 and after that configure this same range in a static group. If you delete any ssm-map between 232.122.122.122. to 232.122.122.128, the switch deletes the entire static range group.

PIM

There can be no interaction with PIM and multicast routers on the access.

The BEB only interacts with IGMP messages and not PIM, so all multicast traffic must be drawn towards the BEB, which acts as the IGMP querier, for the stream to be announced.

IP Multicast over Fabric Connect does not integrate PIM functionality so the following considerations apply when connecting to a PIM network:

- You must configure static IGMP receivers on the BEB access interface facing the PIM network when the sender is on the SPBM access network and the receiver is on the PIM network. Static IGMP receivers make the PIM router accept streams and avoid a Reverse Path Forwarding (RPF) check that can change the source of the stream.
- You must configure static IGMP receivers on the PIM interface facing the IP Multicast over Fabric Connect network when the sender is on the PIM network and the receiver is on the SPBM access network.
- You must configure Access Control Lists (ACLs) on the BEB facing the PIM network for security.

Data I-SID

The BEB matches a single multicast stream to a particular data I-SID. As a result there is a one-to-one mapping between the S,G to data I-SID for each BEB.

Supported services

The switch does not support IP Multicast over Fabric Connect routing on inter-VSN routing interfaces.

The switch supports the following modes of IP Multicast over Fabric Connect:

- Layer 2 VSN multicast service — Multicast traffic remains within the same Layer 2 VSN across the SPBM cloud.
- Layer 3 VSN multicast service — Multicast traffic remains within the same Layer 3 VSN across the SPBM cloud.
- IP Shortcuts multicast service — Multicast traffic can cross VLAN boundaries but remains confined to the subset of VLANs with the Global Routing Table that have IP Multicast over Fabric Connect enabled.

SPBM Multicast FIB

Multicast FIB

SPBM runs all pair Dijkstras to produce the multicast FIB. The computing node loops through each node to run Dijkstra using that node as the root, and then prunes paths to only keep the shortest paths. The computing node then computes the intersection of the set of I-SIDs for which the root node transmits, with the set of I-SIDs for which the path endpoints receive.

The multicast addresses are built out of two pieces: the SPBM Node Nickname and the I-SID ID converted to hexadecimal format to form the multicast MAC address.

```
|----------------------------|--------------------------------|
       nickname|0x30000                  hexadecimal I-SID
```

For example, if the nickname is 0.00.10 and the I-SID is 100 (0x64), the multicast address is 03:00:10:00:00:64.

The following text shows an example of the multicast FIB.

```
Switch:1(config)#show isis spbm multicast-fib

Universal Plug and Play Filtering

The switch can filter multicast packets destined for the Universal Plug and Play (uPnP) multicast IP address with a Universal Plug and Play (uPnP) Filtering option. uPnP Filtering drops all incoming multicast packets received by a switch on an IGMP-enabled interface if the destination multicast IP address matches the configured range.

uPnP Filtering applies to both multicast receivers and multicast senders. If you want to use the uPnP Filtering address range for actual multicast streaming, you must disable uPnP Filtering on the IGMP interface.

uPnP Filtering is disabled by default. If you create a new IGMP interface, uPnP Filtering is enabled automatically on the interface for the destination multicast IP address range 239.255.255.250/32. If you enable uPnP Filtering on an existing IGMP-enabled interface with senders and receivers already present, the filter does not delete the existing senders or receivers; the filter begins to drop packets from that point forward. Existing senders and receivers eventually expire and senders are not relearned.

You can use CLI or EDM to configure a different destination multicast IP address range.

uPnP Filtering functions in the following scenarios:

- IGMP snooping is enabled on a VLAN and IP Multicast over Fabric Connect on Layer 2 VSN is configured.
- IP Multicast over Fabric Connect within the Global Routing Table (GRT) is configured.
- IP Multicast over Fabric Connect on a Layer 3 VSN is configured.

IP Multicast over Fabric Connect Configuration using the CLI

Enabling IP Multicast over Fabric Connect globally

Use this procedure to enable IP Multicast over Fabric Connect globally on the Backbone Edge Bridges (BEBs) that directly or indirectly (using Layer 2 switches) connect to IP multicast senders or receivers. By default, IP Multicast over Fabric Connect is disabled. There is no need to enable IP Multicast over Fabric Connect on the Backbone Core Bridges (BCBs).

You must configure IP Multicast over Fabric Connect at the global level, and then enable it on the service option or options you choose.

Note

IP Multicast over Fabric Connect uses I-SIDs starting at 16,000,000 and above. If Layer 2 or Layer 3 I-SIDs are in this range, the system displays an error message and the switch does not enable IP Multicast over Fabric Connect.

Note

You must enable IP multicast over Fabric Connect globally on all DvR enabled nodes (Controllers and Leaf nodes) in a DvR domain.

You must enable IP multicast over Fabric Connect globally on all DvR enabled nodes (Controllers and Leaf nodes) in a DvR domain.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.
- You must add IST slot/ports to the C-VLAN for an SMLT topology.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. Verify no I-SIDs exist in the default reserved range:
   a. For Layer 2 use the following command:
      `show vlan i-sid`
   b. For Layer 3 use the following command:
      `show ip ipvpn vrf WORD<1-16>`
3. Enter IS-IS Router Configuration mode:
   `enable`

   `configure terminal`

   `router isis`
4. Enable IP Multiast over Fabric Connect globally:
   `spbm <1-100> multicast enable`

   Note

   The switch only supports one SPBM instance.
5. (Optional) Disable IP Multicast over Fabric Connect globally:
   `no spbm <1-100> multicast enable`

   `default spbm <1-100> multicast enable`

Example

Enable IP Multicast over Fabric Connect globally:

```
Switch:1>show vlan i-sid
================================================================================
                  Vlan I-SID
================================================================================
VLAN_ID      I-SID        I-SID NAME
--------------------------------------------------------------------------------
1
10           100          Hospital-Server-10
90           1000         ISID-1000

3 out of 3 Total Num of Vlans displayed
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 multicast enable
```

Variable definitions

The following table defines parameters for the **spbm** command.

Variable	Value
<1-100>	Enables IP Multicast over Fabric Connect globally. The default is disabled. Specifies the SPBM instance. The switch only supports one instance.

Display IP Multicast over Fabric Connect information

Use this procedure to display IP Multicast over Fabric Connect summary information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the status of the global IP Multicast over Fabric Connect configuration:

   ```
   show isis spbm multicast
   ```
3. Display IP Multicast over Fabric Connect summary information for each S, G, V tuple:

   ```
   show isis spb-mcast-summary [count][host-name WORD<0-255>][lspid <xxxx.xxxx.xxxx.xx-xx>]
   ```
4. Display information about the multicast routes on the switch:

   ```
   show ip mroute route [vrf WORD<1-32>][vrfids WORD<0-255>]
   ```

Example

Display IP Multicast over Fabric Connect global configuration information:

```
Switch:1>enable
Switch:1#show isis spbm multicast

                           multicast : enable
                  fwd-cache-timeout(seconds) : 210

Switch:1#show isis spb-mcast-summary

Total 4
```

Variable Definitions

The following table defines parameters for the **`show isis spb-mcast-summary`** command.

Variable	Value
count	Displays the total number of SPB multicast entries.
host-name WORD<0-255>	Displays the IP Multicast over Fabric Connect summary information for a specific host-name.
lspid <xxx.xxx.xxx.xx-xx>	Displays the IP Multicast over Fabric Connect summary information for the specified LSP ID that you enter in xxx.xxx.xxx.xx-xx — 8 byte format.

The following table defines parameters for the **show ip mroute route** command.

Variable	Value
vrf WORD<1-32>	Specifies a VRF.
vrfids WORD<0-255>	Specifies the VRF ID

Display the Multicast FIB

About This Task

In SPBM, B-MAC addresses are carried within the IS-IS link-state database. To do this, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. Each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB).

When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

The multicast FIB is not produced until virtual services are configured and learned.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Display the SPBM multicast FIB:
   ```
   show isis spbm multicast-fib [vlan <1-4059>] [i-sid <1-16777215>]
   [nick-name <x.xx.xx>] [summary]
   ```

Example

```
Switch#show isis spbm multicast-fib

================================================================================================
                                SPBM MULTICAST FIB ENTRY INFO

Variable Definitions

The following table defines parameters for the **show isis spbm multicast-fib** command.

Variable	Value
vlan <1-4059>	Displays the FIB for the specified SPBM VLAN.
i-sid <1-16777215>	Displays the FIB for the specified I-SID.
nick-name <x.xx.xx>	Displays the FIB for the specified nickname.
summary	Displays a summary of the FIB.

Configure Universal Plug and Play (uPnP) Filtering

Before You Begin

Create a port-based VLAN.

About This Task

Use the following procedure to enable Universal Plug and Play (uPnP) Filtering on an IGMP-enabled interface. uPnP Filtering is disabled by default.

The default uPnP Filtering multicast group address range is 239.255.255.250/32. If you do not configure the multicast group range, uPnP Filtering filters multicast packets destined for the default multicast group range.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]} or interface vlan <1-4059>
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable uPnP Filtering:

   ```
   ip igmp upnp-filter [ip {A.B.C.D/X}]
   ```

Example

Enable uPnP Filtering on a VLAN using the default multicast group address range:

```
Switch:1(config-if)#ip igmp upnp-filter
```

Enable uPnP Filtering on a VLAN with configured multicast group address range:

```
Switch:1(config-if)#ip igmp upnp-filter ip 233.252.0.0/24
```

Variable Definitions

The following table defines parameters for the **ip igmp upnp-filter** command.

Variable	Value
gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
ip {A.B.C.D/X}	Configures the multicast destination IP address range to filter for an IGMP interface. The default multicast group address is 239.255.255.250/32.
vlan <1-4059>	Specifies the VLAN.

View uPnP Filtering information on an IGMP-enabled interface

Use the following command to display uPnP Filtering information on an IGMP-enabled interface.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display information about the interfaces where IGMP is enabled:

   ```
   show ip igmp interface [gigabitethernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}][vlan <1-4059>[vrf WORD<1-16>][vrfids WORD<0-512>]
   ```

Example

View the default uPnP Filtering information on an IGMP-enabled interface:

```
Switch:1#show ip igmp interface vlan 2
================================================================================================
                                    Vlan Ip Igmp
================================================================================================
VLAN QUERY QUERY ROBUST VERSION LAST  PROXY  SNOOP  SNOOP    SSM    UPnP   FAST   FAST

Variable Definitions

The following table defines parameters for the **show ip igmp interface** command.

Variable	Value
gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
vlan <1-4059>	Specifies the VLAN.
vrf WORD<1-16>	Specifies the VRF by name.
vrfids WORD<0-512>	Specifies the VRF by VRF ID.

IP Multicast over Fabric Connect configuration using the EDM

Configure IP Multicast over Fabric Connect Globally

Use this procedure to globally enable IP Multicast over Fabric Connect on the Backbone Edge Bridges (BEBs) that directly or indirectly (using Layer 2 switches) connect to IP multicast senders or receivers. By default, IP Multicast over Fabric Connect is disabled. There is no need to enable IP Multicast over Fabric Connect on the Backbone Core Bridges (BCBs).

You must configure IP Multicast over Fabric Connect at the global level, and then enable it on the service option or options you choose.IP Multicast over Fabric Connect uses I-SIDs that start at

16,000,000 and above. The device displays an error message if the Layer 2 and Layer 3 I-SIDs are within this range and the system does not enable IP Multicast over Fabric Connect.

Important

IP Multicast over Fabric Connect uses I-SIDs that start at 16,000,000 and above. The device displays an error message if the Layer 2 and Layer 3 I-SIDs are within this range and the system does not enable IP Multicast over Fabric Connect.

Note

You must enable IP multicast over Fabric Connect globally on all DvR enabled nodes (Controllers and Leaf nodes) in a DvR domain.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric** > **SPBM** to determine if any I-SIDs are within the default range reserved for multicast..
2. Select the **I-SID** tab to determine if the I-SIDs are within the default range reserved for multicast.
3. In the navigation pane, expand **Configuration** > **Fabric** > **SPBM**.
4. Select the **SPBM** tab.
5. If you want to enable multicast on an SPBM instance that already exists, in the **Mcast** column in the table, select **enable**.
6. If you want to enable multicast on an SPBM instance that does not yet exit, select **Insert**.
7. In the **Mcast** box, select **enable** to enable IP Multicast over Fabric Connect globally.
8. Select **Insert**.
9. Select **Apply**.

SPBM Field Descriptions

Use the data in the following table to use the **SPBM** tab.

Name	Description
Id	Specifies the SPBM instance ID. Only one SPBM instance is supported.
NodeNickName	Specifies a nickname for the SPBM instance globally. Valid value is 2.5 bytes in the format <x.xx.xx>.
PrimaryVlan	Specifies the primary SPBM B-VLANs to add to the SPBM instance.
Vlans	Specifies the SPBM B-VLANs to add to the SPBM instance.

Name	Description
LsdbTrap	Configures whether to enable or disable a trap when the SPBM LSDB changes. The default is disable.
IpShortcut	Enables or disables SPBM IP shortcut state. The default is disable.
SmltSplitBEB	Specifies whether the switch is the primary or secondary vIST peer. The default is primary.
SmltVirtualBmac	Specifies a virtual MAC address that can be used by both peers.
SmltPeerSysId	Specifies the system ID of the SPBM SMLT for this SPBM instance.
Mcast	Specifies if IP multicast over SPBM is enabled. The default is disabled.
McastFwdCacheTimeout	Specifies the global forward cache timeout in seconds. The default is 210 seconds.
Ipv6Shortcut	Enables or disables SPBM IPv6 shortcut state. The default is disable.
McastSpbPimGwControllerEnable	Enables or disables ISIS PLSB Multicast SPB PIM Gateway controller. Disabled by default.
McastSpbPimGwGatewayEnable	Enables or disables ISIS PLSB Multicast SPB PIM Gateway. Disabled by default.
StpMultiHoming	Enables or disables MSTP-Fabric Connect Multi Homing. The default is disabled (false).
BVlanOrigin	Shows how the B-VLAN was created. The values can be config for manual configuration using CLI or SNMP, or dynamic through Zero Touch Fabric Configuration and Auto-sense. The default is dynamic.

View IP Multicast over Fabric Connect Routes

Use this procedure to display the IP Multicast over Fabric Connect routes.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **SPBM**.
3. Select the **IpMcastRoutes** tab.

IpMcastRoutes field descriptions

Use the data in the following table to use the **IpMcastRoutes** tab.

Name	Description
VsnIsid	Specifies the VSN I-SID. Layer 2 VSN and Layer 3 VSN each require a VSN I-SID.
Group	Specifies the group IP address for the IP Multicast over Fabric Connect route.
Source	Specifies the IP address where the IP Multicast over Fabric Connect route originated.
NickName	Specifies the nick name used to filter criteria.
SourceBeb	Specifies the source BEB for the IP multicast route.
VlanID	Specifies the ID for the C-VLAN.
VrfName	Specifies the VRF name.
DataIsid	Specifies the data I-SID for the IP Multicast over Fabric Connect route. A a BEB receives IP multicast data from a sender, a BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID.
Type	Specifies the type for the IP Multicast over Fabric Connect route.
Bvlan	Specifies the B-VLAN for the IP Multicast over Fabric Connect route.
NniInterfaces	Specifies the NNI ports for the IP multicast route. SPBM runs in the core on the ports that connect to the core. These ports are NNI ports. Ports that face a customer VLAN are user-to-network interface (UNI) ports.

Displaying the UNI ports for IP multicast routes

Use this procedure to display UNI ports associated with particular IP multicast routes.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric** > **SPBM**.
2. Select the **IpMcastRoutes** tab.
3. Select the desired row and click the **UNI Ports** tab to display the UNI ports associated with a particular stream.

IpMcastRoutes Uni Ports field descriptions

Use the data in the following table to use the **IpMcastRoutes Uni Ports** tab.

Name	Description
Group	Specifies the group IP address for the IP Multicast over Fabric Connect route.
Source	Specifies the IP address where the IP Multicast over Fabric Connect route originated.
VsnIsid	Specifies the VSN I-SID. Layer 2 VSN and Layer 3 VSN each require a VSN I-SID.
DataIsid	Specifies the data I-SID for the IP multicast route. After a BEB receives the IP multicast data from a sender, a BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID.
SourceBeb	Specifies the source BEB for the IP multicast route.
VlanId	Specifies the ID for the C-VLAN.
VrfName	Specifies the VRF name.
NniPorts	Specifies the NNI ports for the IP multicast route. SPBM runs in the core on the ports that connect to the core. These ports are NNI ports. Ports facing a customer VLAN are user-to-network interface (UNI) ports.
Type	Specifies the type for the IP multicast route.
Bvlan	Specifies the B-VLANs for the IP multicast route.

Displaying the multicast FIB

Use the following procedure to display the multicast FIB.

In SPBM, B-MAC addresses are carried within the IS-IS link-state database. To do this, SPBM supports an IS-IS TLV that advertises the I-SID and B-MAC information across the network. Each node has a System ID, which also serves as Backbone MAC address (B-MAC) of the switch. These Backbone MAC addresses are populated into the SPBM VLAN Forwarding Information Base (FIB).

When the network topology is discovered and stored in the IS-IS link-state database, each node calculates shortest path trees for each source node, so that a unicast path now exists from every node to every other node. With this information, each node populates unicast information received from SPBM into the FIB for forwarding purposes.

The multicast FIB is not produced until virtual services are configured and learned.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric**.
2. Select **SPBM**.
3. Select the **Multicast FIB** tab.

Multicast FIB field descriptions

Use the data in the following table to use the **Multicast FIB** tab.

Name	Description
SysId	System ID of the node where the multicast FIB entry originated.
Vlan	VLAN of the multicast FIB entry.
McastDestMacAddr	Multicast destination MAC Address of the multicast FIB entry
Isid	I-SID of the multicast FIB entry.
Isid Name	Name assigned to the I-SID.
HostName	Host name of the node where the multicast FIB entry originated.
OutgoingInterfaces	Specifies the switched UNI port outgoing interface of multicast FIB entry.
IncomingInterface	Specifies the incoming interface (port or MLT) of the multicast FIB entry.

IP Multicast over Fabric Connect configuration examples

IP multicast over Fabric Connect global configuration

exit
```

IP Multicast over Fabric Connect Services Configuration

Layer 2 VSN Configuration Fundamentals

Layer 2 VSN IP Multicast over Fabric Connect

IP Multicast over Fabric Connect supports Layer 2 VSN functionality where multicast traffic is bridged over the SPBM core infrastructure. An application for Layer 2 VSNs using IP Multicast over Fabric Connect is multicast traffic in data centers.

For more information on Layer 2 VSN configuration, see Layer 2 VSN configuration on page 1058.

After you configure **`ip igmp snooping`** on a VLAN that has an I-SID configured (a C-VLAN), that VLAN is automatically enabled for IP Multicast over Fabric Connect services. No explicit configuration exists separate from that to enable Layer 2 VSN IP Multicast over Fabric Connect.

Multicast traffic remains in the same Layer 2 VSN across the SPBM cloud for Layer 2 VSN IP Multicast over Fabric Connect. IP Multicast over Fabric Connect constrains all multicast streams within the scope level in which they originate. If a sender transmits a multicast stream to a BEB on a Layer 2 VSN with IP Multicast over Fabric Connect enabled, only receivers that are part of the same Layer 2 VSN can receive that stream.

I-SIDs

After a BEB receives IP multicast data from a sender, the BEB allocates a data service instance identifier (I-SID) in the range of 16,000,000 to 16,512,000 for the multicast stream. The stream is identified by the S, G, V tuple, which is the source IP address, the group IP address and the local VLAN the multicast stream is received on. The data I-SID uses Tx/Rx bits to signify whether the BEB uses the I-SID to transmit, receive, or both transmit and receive data on that I-SID.

In the context of Layer 2 VSNs with IP Multicast over Fabric Connect, the scope is the I-SID value of the Layer 2 VSN associated with the local VLAN on which the IP multicast data was received.

TLVs

This information is propagated through the SPBM cloud using IS-IS Link State Packets (LSPs), which carry TLV updates, that result in the multicast tree creation for that stream. For Layer 2 VSNs, the LSPs carry I-SID information and information about where IP multicast stream senders and receivers exist using TLV 144 and TLV 185.

IS-IS acts dynamically using the TLV information received from BEBs that connect to the sender and the receivers to create a multicast tree between them.

IGMP

After a BEB receives an IGMP join message from a receiver, a BEB queries the IS-IS database to check if a sender exists for the requested stream within the scope of the receiver. If the requested stream does not exist, the IGMP information is kept, but no further action is taken. If the request stream exists, the

BEB sends an IS-IS TLV update to its neighbors to inform them of the presence of a receiver and this information is propagated through the SPBM cloud.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

Layer 2 VSN Configuration using the CLI

Configuring Layer 2 VSN IP Multicast over Fabric Connect

Use this procedure to configure IP Multicast over Fabric Connect for Layer 2 VSN functionality. With Layer 2 VSN IP Multicast over Fabric Connect, multicast traffic remains in the same Layer 2 VSN across the SPBM cloud.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the customer VLANs (C-VLANs) and add slots/ports.
- You must assign the same I-SID to the C-VLANs on all the BEBs where you configure the C-VLAN.
- You must enable IP Multicast over Fabric Connect globally.

About This Task

Traffic is only delivered to UNIs on the Layer 2 VSN where the switch receives IGMP joins and reports. Traffic does not cross the Layer 2 VSN boundary.

Configuring **`ip igmp snooping`** on a VLAN that has an I-SID configured (a C-VLAN) automatically enables that VLAN for IP Multicast over Fabric Connect services. No explicit configuration exists separate from that to enable Layer 2 VSN IP Multicast over Fabric Connect.

SPBM supports enabling IGMP Snooping on a C-VLAN, but it does not support enabling Protocol Independent Multicast (PIM) on a C-VLAN. If you enable IGMP snooping on a C-VLAN, then its operating mode is Layer 2 Virtual Services Network with IGMP support on the access networks for optimized forwarding of IP multicast traffic in a bridged network.

The switch only supports IPv4 multicast traffic.

Procedure

1. Enter VLAN Interface Configuration mode:

   ```
   enable

   configure terminal

   interface vlan <1-4059>
   ```
2. Enable proxy snoop:

   ```
   ip igmp proxy
   ```
3. Enable IGMP snooping:

   ```
   ip igmp snooping
   ```

4. (Optional) If you want to configure an address for the IGMP queries, enter the following command:

   ```
   ip igmp snoop-querier-addr <A.B.C.D>
   ```

   This step is not always required. The IGMP Querier on the BEB uses a source address 0.0.0.0 by default. When you do not configure this, a BEB sends IGMP queries on the UNI ports with 0.0.0.0 as the source IP address. Some Layer 2 edge switches do not support a 0.0.0.0 querier. You can use a fictitious IP address as the querier address, and use the same address on all BEBs in the network.
5. (Optional) Enable IGMPv3 at a VLAN level by enabling SSM-snooping and IGMPv3:

   ```
   ip igmp ssm-snoop
   ```

   ```
   ip igmp version 3
   ```

   You must enable SSM snoop before you configure IGMP version 3 and both ssm-snoop and snooping must be enabled for IGMPv3.

   For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

Example

Enable IGMPv2 at a VLAN level:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config-if)#interface vlan 501
Switch:1(config-if)#ip igmp proxy
Switch:1(config-if)#ip igmp snooping
Switch:1(config-if)#ip igmp snoop-querier-addr 192.0.2.1
```

Enable IGMPv3 at a VLAN level:

```
Switch:>enable
Switch:#configure terminal
Switch:1(config)#interface vlan 2256
Switch:1(config-if)#ip igmp proxy
Switch:1(config-if)#ip igmp snooping
Switch:1(config-if)#ip igmp snoop-querier-addr 192.0.2.1
Switch:1(config-if)#ip igmp version 3
Switch:1(config-if)#ip igmp ssm-snoop
```

View Layer 2 VSN IP Multicast over Fabric Connect information

Use the following options to display Layer 2 VSN information to confirm proper configuration.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all IP Multicast over Fabric Connect route information:

   ```
   show isis spbm ip-multicast-route [all]
   ```
3. Display detailed IP Multicast over Fabric Connect route information:

   ```
   show isis spbm ip-multicast-route [detail]
   ```
4. Display IP multicast route information by VLAN:

   ```
   show isis spbm ip-multicast-route [vlan <1-4059>]
   ```

5. Display IP Multicast over Fabric Connect route information by VSN I-SID:

   `show isis spbm ip-multicast-route [vsn-isid <1-16777215>]`

6. Display IP Multicast over Fabric Connect route information by group address:

   `show isis spbm ip-multicast-route [group {A.B.C.D}]`

7. Display IP Multicast over Fabric Connect route information by source address:

   `show isis spbm ip-multicast-route [source {A.B.C.D}]`

Important

When you use the command `show isis spbm ip-multicast-route` without parameters or use the detail or group optional parameters without specifying a VLAN ID or VSN I-SID, the command output displays Layer 3 context only. No Layer 2 context is displayed.

8. Display summary information for each S, G, V tuple with the corresponding scope, data I-SID, and the host name of the source:

   `show isis spb-mcast-summary [count][host-name WORD<0-255>][lspid <xxxx.xxxx.xxxx.xx-xx>]`

Example

```
Switch:1#show isis spbm ip-multicast-route all

Variable definitions

The following table defines parameters for the **show isis spbm ip-multicast-route** command.

Variable	Value
all	Displays all IP Multicast over Fabric Connect route information.
detail	Displays detailed IP Multicast over Fabric Connect route information.
group {A.B.C.D} *source {A.B.C.D}*	Displays information on the group IP address for the IP Multicast over Fabric Connect route. If you select source it will also display the source IP address.
vlan <0–4084>	Displays IP Multicast over Fabric Connect route information by VLAN.
vrf WORD<1–16>	Displays IP Multicast over Fabric Connect route information by VRF.
vsn-isid <1–16777215>	Displays IP Multicast over Fabric Connect route information by I-SID.

The following table defines parameters for the **show isis spb-mcast-summary** command.

Variable	Value
count	Displays the total number of SPB multicast entries.
host-name WORD<0–255>	Displays the IP Multicast over Fabric Connect summary for a given host-name.
lspid <xxxx.xxxx.xxxx.xx-xx>	Displays the IP Multicast over Fabric Connect summary for a given LSP ID.

View IGMP Information for Layer 2 VSN Multicast

Use the following commands to display IGMP information.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display information about the interfaces where IGMP is enabled:

   ```
   show ip igmp interface [gigabitethernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}][vlan <1-4059>[vrf WORD<1-16>][vrfids WORD<0-512>]
   ```

   Ensure that the output displays `snoop-spb` under MODE.

3. Display information about the IGMP cache:

   ```
   show ip igmp cache [vrf WORD<1-16>][vrfids WORD<0-512>]
   ```

4. Display information about the IGMP group:

   ```
   show ip igmp group [count][group {A.B.C.D}][member-subnet {A.B.C.D/X}] [vrf WORD<1-16>][vrfids WORD<0-512>]
   ```

5. Display information about the IGMP sender:

   ```
   show ip igmp sender [count][group {A.B.C.D}][member-subnet {A.B.C.D/X}][vrf WORD<1-16>][vrfids WORD<0-512>]
   ```

6. Display information about IGMP snoop-trace information:

   ```
   show ip igmp snoop-trace [group {A.B.C.D}][source {A.B.C.D}][vrf WORD<1-16>][vrfids WORD<0-512>]
   ```

Example

```

Variable Definitions

The following table defines parameters for the **show ip igmp interface** command.

Variable	Value
gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
vlan <1-4059>	Specifies the VLAN.
vrf WORD<1-16>	Specifies the VRF by name.
vrfids WORD<0-512>	Specifies the VRF by VRF ID.

The following table defines parameters for the **show ip igmp cache** command.

Variable	Value
vrf WORD<1–16>	Specifies the VRF by name.
vrfids WORD<0–512>	Specifies the VRF by VRF ID.

The following table defines parameters for the **show ip igmp group** command.

Variable	Value
count	Specifies the number of entries.
group {A.B.C.D}	Specifies the group address.
member-subnet {A.B.C.D/X}	Specifies the IP address and network mask.
vrf WORD<1–16>	Displays the multicast route configuration for a particular VRF by name.
vrfids WORD<0–512>	Displays the multicast route configuration for a particular VRF by VRF ID.

The following table defines parameters for the **show ip igmp sender** command.

Variable	Value
count	Specifies the number of entries.
group {A.B.C.D}	Specifies the group address.
member-subnet {A.B.C.D/X}	Specifies the IP address and network mask.
vrf WORD<1–16>	Displays the multicast route configuration for a particular VRF by name.
vrfids WORD<0–512>	Displays the multicast route configuration for a particular VRF by VRF ID.

The following table defines parameters for the **show ip igmp snoop-trace** command.

Variable	Value
group {A.B.C.D}	Specifies the group address.
source {A.B.C.D}	Specifies the source address.
vrf WORD<1–16>	Displays the multicast route configuration for a particular VRF by name.
vrfids WORD<0–512>	Displays the multicast route configuration for a particular VRF by VRF ID.

View TLV Information for Layer 2 VSN IP Multicast over Fabric Connect

Use the following commands to check TLV information.

For Layer 2 VSN with IP multicast over Fabric Connect, TLV 185 on the BEB where the source is located, displays the multicast source and group addresses and has the Tx bit set. Each multicast group has its own unique data I-SID with a value between 16,000,000 to 16,512,000. TLV 144 on the BEB bridge,

where the sender is located, has the Tx bit set. All BEB bridges, where a receiver exists, have the Rx bit set.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IS-IS Link State Database information by Type-Length-Value (TLV):
   `show isis lsdb tlv <1-236> [sub-tlv <1-3>] [detail] [home|remote]`
3. Display IS-IS Link State Database information by Link State Protocol ID:
   `show isis lsdb lspid <xxxx.xxxx.xxxx.xx-xx> tlv <1-236> [sub-tlv <1-3>] [detail] [home|remote]`

Example

```
Switch:1# show isis lsdb tlv 185 detail

Variable Definitions

The following table defines parameters for the **show isis lsdb** command.

Variable	Value
detail	Displays detailed information about the IS-IS Link State database.
home	Displays the IS-IS LSDB information that the system configures in the home area.
level {l1, l2, l12}	Displays information on the IS-IS level. The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 and combined Level 1 and 2 (l12) function is disabled.
local	Displays information on the local LSDB.
lspid<xxxx.xxxx.xxxx.xx-xx>	Specifies information about the IS-IS Link State database by LSP ID.
remote	Displays the IS-IS LSDB information that the system configures in the remote area.

Variable	Value
sub-tlv <1-3>	Specifies information about the IS-IS Link State database by sub-TLV.
sysid <xxxx.xxxx.xxxx>	Specifies information about the IS-IS Link State database by System ID.
tlv <1-236>	Specifies information about the IS-IS Link State database by TLV.

Layer 2 VSN Configuration using EDM

Viewing the IGMP interface table

Use the Interface tab to view the IGMP interface table. When an interface does not use an IP address, the system does not display it in the IGMP table.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Click **IGMP**.
3. Click the **Interface** tab.

Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
IfIndex	Shows the interface where IGMP is enabled.
QueryInterval	Configures the frequency (in seconds) at which the interface transmits IGMP host query packets. The default is 125.
Status	Shows the IGMP row status. If an interface uses an IP address and PIM-SM is enabled, the status is active. Otherwise, it is notInService.
Version	Configures the version of IGMP (1, 2, or 3) that you want to configure on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2.
OperVersion	Shows the version of IGMP that currently runs on this interface.
Querier	Shows the address of the IGMP querier on the IP subnet to which this interface attaches.
QueryMaxResponseTime	Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values allow a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds.) Important: You must configure this value lower than the QueryInterval.

Name	Description
WrongVersionQueries	Shows the number of queries received with an IGMP version that does not match the interface. You must configure all routers on a LAN to run the same version of IGMP. If the interface receives queries with the wrong version, this value indicates a version mismatch.
Joins	Shows the number of times this interface added a group membership, which is the same as the number of times an entry for this interface is added to the cache table. This number gives an indication of the amount of IGMP activity over time.
Robustness	Tunes for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect a network to lose query packets, increase the robustness value. The default value of 2 means that the switch drops one query for each query interval without the querier aging out.
LastMembQueryIntvl	Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1. Decrease the value to reduce the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of second. As a best practice, configure this parameter to values greater than 3. If you do not need a fast leave process, you can configure values greater than 10. (The value 3 is equal to 0.3 seconds and 10 is equal to 1 second.)
OtherQuerierPresent Timeout	Shows the length of time that must pass before a multicast router determines that no other querier exists. If the local router is the querier, the value is 0.
FlushAction	Configures the flush action to one of the following: • none • flushGrpMem • flushMrouter • flushSender
RouterAlertEnable	Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option. Important: To maximize network performance, configure this parameter according to the version of IGMP currently in use. • IGMPv1—Disable • IGMPv2—Enable • IGMPv3—Enable
SsmSnoopEnable	Enables SSM snoop.
SnoopQuerierEnable	Enables IGMP Layer 2 Querier.

Name	Description
SnoopQuerierAddr	Specifies the pseudo address of the IGMP snoop querier.
ExplicitHostTrackingEnable	Enables or disables IGMPv3 to track hosts for each channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.
McastMode	Indicates the protocol configured on the VLAN. • snoop — Indicates IGMP snooping is enabled on a VLAN. • snoop-spb — Indicates IGMP is enabled on a VLAN with an associated I-SID (IP multicast over Fabric Connect for a Layer 2 VSN). • pim — Indicates PIM is enabled. • routed-spb — Indicates IP multicast over Fabric Connect is enabled on the Layer 3 VSN or for IP Shortcuts.
ExtnUpnpFilterEnable	Enables Universal Plug and Play (uPnP) Filtering to filter multicast packets destined for a specific range. The default is disabled.
ExtnUpnpFilterAddress	Indicates the multicast destination IP address to filter on an IGMP-enabled interface. The default is 239.255.255.250/32.
ExtnUpnpFilterAddressMask	Indicates the IGMP uPnP Filtering IP subnet to which this interface is attached.
SnoopOrigin	Specifies the origin of IGMP Snooping configuration on the port. The supported values are: • config - Set by the user. • radius - Set by the Remote Authentication Dail-In User Service (RADIUS) attribute.

Configure IP Multicast over Fabric Connect on a Layer 2 VSN

Use this procedure to enable IP Multicast over Fabric Connect for a Layer 2 VSN. With Layer 2 VSN IP Multicast over Fabric Connect, multicast traffic remains in the same Layer 2 VSN across the SPBM cloud.

No explicit configuration exists for a Layer 2 VSN. After you configure IP IGMP snooping on a VLAN that has an I-SID configured, the device enables that VLAN for IP Multicast over Fabric Connect services.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.

About This Task

SPBM supports enabling IGMP snooping on a C-VLAN, but it does not support enabling PIM on a C-VLAN. If you enable IGMP snooping on a C-VLAN, then its operating mode is Layer 2 VSN with IGMP support on the access networks for optimized forwarding of IP multicast traffic in a bridged network.

This switch only supports IPv4 multicast traffic.

Procedure

1. In the navigation pane, expand **Configuration** > **VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select a VLAN.
5. Select **IP**.
6. Select the **IGMP** tab.
7. Select the **SnoopEnable** check box.
8. (Optional) Select the **SsmSnoopEnable** check box, if you use IGMP version 3.
9. (Optional) Select the **ProxySnoopEnable** check box.
10. (Optional) If you want to enable IGMP version 3, select version3 in the **Version** check box.

    You must enable SSM snoop before you configure IGMP version 3 and both ssm-snoop and snooping must be enabled for IGMPv3.
11. If you want to enable IGMP version 2, select version2 in the **Version** check box.

    For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.
12. (Optional) If you want to enable snoop querier, select **SnoopQuerierEnable**.
13. (Optional) If you want to configure an address for IGMP queries, enter the IP address in **SnoopQuerierAddr**.

    Note

    This step is not always required. The IGMP Querier on the BEB uses a source address 0.0.0.0 by default. When you do not configure this, a BEB sends IGMP queries on the UNI ports with 0.0.0.0 as the source IP address. Some Layer 2 edge switches do not support a 0.0.0.0 querier. You can use a fictitious IP address as the querier address, and use the same address on all BEBs in the network.

14. Select **Apply**.

Layer 2 VSN with IP Multicast over Fabric Connect configuration example

The example below shows the configuration steps to enable IP Multicast over Fabric Connect support on C-VLAN 1001 that is part of a Layer 2 VSN, including the querier address.

```
enable
configure terminal

ISIS SPBM CONFIGURATION

router isis
spbm 1 multicast enable

VLAN CONFIGURATION

interface vlan 9
ip igmp snooping
ip igmp snoop-querier-addr 192.0.2.201
exit
```

When using IGMPv3, the configuration is:

```
enable
configure terminal

ISIS SPBM CONFIGURATION

router isis
spbm 1 multicast enable

VLAN CONFIGURATION

interface vlan 19
ip igmp snooping
ip igmp version 3
ip igmp ssm-snoop
ip igmp snoop-querier-addr 192.0.2.201
exit
```

Note

You must enable SSM snoop before you configure IGMP version to version 3, and you must enable both **ssm-snoop** and **snooping** for IGMPv3.

Note

You must configure basic SPBM and IS-IS infrastructure.

IP Shortcuts Configuration

This section provides fundamentals concepts for IP Shortcuts configuration. For more information on IP Shortcuts basic configuration, see IP Shortcuts Configuration on page 1121.

IP Multicast over Fabric Connect within the GRT

IP Multicast over Fabric Connect within the GRT enables you to exchange IP multicast traffic with all or a subset of VLANs that are in the Global Routing Table (GRT). This restriction is called the *scope level*, which IP Multicast over Fabric Connect uses to constrain the multicast streams within the level in which they originate. For example, if a sender transmits a multicast stream to a BEB on a VLAN that is part of the GRT with IP Multicast over Fabric Connect enabled, only receivers that are part of the same GRT can receive that stream.

Applications that can use IP Multicast over Fabric Connect within the GRT include: Video surveillance, TV/Video/Ticker/Image distribution, VX-LAN.

Both IP Shortcuts and IP Multicast over Fabric Connect within the GRT use the GRT for the scope level to constrain multicast streams. However, they are separate features that work independently from each other.

Important

You do not have to enable IP Shortcuts to support IP Multicast over Fabric Connect within the GRT.

With IP Multicast over Fabric Connect within the GRT, routing of IP multicast traffic is allowed within the subset of VLANs in the GRT that have IP Multicast over Fabric Connect enabled. When you enable IP

Multicast over Fabric Connect on a VLAN, the VLAN automatically becomes a multicast routing interface.

You must enable **ip spb-multicast** on each of the VLANs within the GRT that need to support IP multicast traffic. Enable IP Multicast over Fabric Connect on all VLANs to which IP multicast senders and receivers attach. IP Multicast over Fabric Connect is typically configured only on BEBs.

Note

If no IP interface exists on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).

I-SIDs

Unlike IP Shortcuts with unicast, a data I-SID (for mac-in-mac encapsulation of the multicast traffic) is required for IP Multicast over Fabric Connect within the GRT. When the multicast stream reaches the BEB, the BEB assigns a data I-SID to the stream. The data I-SID uses Tx/Rx bits to signify whether the BEB uses the I-SID to transmit, receive, or both transmit and receive data on that I-SID.

Unlike Layer 2 VSNs and Layer 3 VSNs, IP Multicast over Fabric Connect within the GRT does not have a scope I-SID to determine the scope of the multicast traffic. Instead the scope is the Global Routing Table.

TLVs

The scope and data I-SID information is propagated through the SPBM cloud using IS-IS Link State Packets (LSPs), which carry TLV updates, and result in the multicast tree creation for that stream. For IP Multicast over Fabric Connect within the GRT, the LSPs carry I-SID information and information about where IP multicast stream senders and receivers exist using TLV 144 and TLV 186.

IGMP

After you configure **ip spb-multicast enable**, you cannot enable IGMP, IGMP Snooping, or IGMP proxy on the interface. If you try to enable IGMP Snooping or proxy on any interface where IP Multicast over Fabric Connect is enabled, the system displays an error message.

After you configure **ip spb-multicast enable** on each of the VLANs within the GRT that need to support IP multicast traffic, any IGMP functions required for IP Multicast over Fabric Connect within the GRT are automatically enabled. You do not need to configure anything IGMP related.

DvR

When you enable **ip spb-multicast** on the Controller nodes, the configuration is automatically pushed to all the Leaf nodes within the domain.

For more information on DvR, see Distributed Virtual Routing on page 621.

IP Shortcuts Configuration using the CLI

Configure IP Multicast over Fabric Connect within the GRT

Use this procedure to configure IP Multicast over Fabric Connect within the GRT. The default is disabled.

- Note
  - You do not have to enable IP Shortcuts to support IP multicast routing in the GRT using SPBM.
  - You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.
- If no IP interface exists on the VLAN, then you create one. (The IP interface must be the same subnet as the IGMP hosts that connect to the VLAN).

About This Task

With IP Multicast over Fabric Connect within the GRT, routing of IP multicast traffic is allowed within the subset of VLANs in the GRT that have IP Multicast over Fabric Connect enabled. When you enable IP Multicast over Fabric Connect on a VLAN, the VLAN automatically becomes a multicast routing interface.

You must configure **`ip spb-multicast enable`** on each of the VLANs within the GRT that need to support IP multicast traffic. The default is disabled. After you enable IP Multicast over Fabric Connect on each of the VLANs within the GRT that need to support IP multicast traffic, any IGMP functions required for IP Multicast over Fabric Connect within the GRT are automatically enabled. You do not need to configure anything IGMP related.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing, which allows for you to more easily migrate from a PIM environment to IP Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first and then migrate unicast separately or not at all.

The switch only supports IPv4 addresses with IP Multicast over Fabric Connect.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable
   ```

   ```
   configure terminal
   ```

   ```
   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create an IP interface on the VLAN:

   ```
   ip address <A.B.C.D/X>
   ```

3. Enable IP Multicast over Fabric Connect:

   ```
   ip spb-multicast enable
   ```

   Note

   After you configure **ip spb-multicast enable**, you cannot enable IGMP, IGMP Snooping, or IGMP proxy on the interface. If you try to enable IGMP Snooping or proxy on any interface where IP Multicast over Fabric Connect is enabled, an error message displays.

   Note

   When you configure **ip spb-multicast enable** on the Controller node of a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

4. (Optional) Disable IP Multicast over Fabric Connect:

   ```
   no ip spb-multicast enable
   ```

   ```
   default ip spb-multicast enable
   ```

5. Ensure IP Multicast over Fabric Connect within the GRT is configured properly:

   ```
   show ip igmp interface
   ```

   If `routed-spb` displays under mode, IP Multicast over Fabric Connect within the GRT is properly enabled on the VLAN.

Example

Enable IP Multicast over Fabric Connect within the GRT:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 500
Switch:1(config-if)#ip address 192.0.2.1 255.255.255.0
Switch:1(config-if)#ip spb-multicast enable
Switch:1#show ip igmp interface

================================================================================
```

```
                        Igmp Interface - GlobalRouter

```

Variable Definitions

The following table defines parameters for the **interface vlan** command.

Variable	Value
<1-4059>	Specifies the VLAN ID.

The following table defines parameters for the **interface GigabitEthernet** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

The following table defines parameters for the **ip address** command.

Variable	Value
<A.B.C.D/X>	Specifies the address and mask.

Configuring the VRF timeout value

Use this procedure to configure the VRF timeout value. The timeout value ages out the sender when there is no multicast stream on the VRF. The default is 210 seconds.

Note

You can use this procedure for Layer 3 VSN with IP Multicast over Fabric Connect services and IP Multicast over Fabric Connect for IP Shortcuts.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal

   router vrf WORD<1-16>
   ```

2. Configure the timeout value on the VRF:

   ```
   mvpn fwd-cache-timeout(seconds) <10-86400>
   ```

3. (Optional) Configure the timeout value to the default value of 210 seconds:

   ```
   no mvpn fwd-cache-timeout

   default mvpn fwd-cache-timeout(seconds)
   ```

Example

Configure the timeout value on the VRF to 500 seconds:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf green
Switch:1(router-vrf)#mvpn fwd-cache-timeout(seconds) 500
```

Variable definitions

The following table defines parameters for the **router vrf** command.

Variable	Value
WORD<1-16>	Specifies the VRF name.

The following table defines parameters for the **mvpn fwd-cache-timeout(seconds)** command.

Variable	Value
<10-86400>	Specifies the timeout value. The default is 210 seconds.

Configuring the Global Routing Table timeout value

Use this procedure to configure the timeout value in the GRT. The timeout value ages out the sender when there are no multicast streams coming from the sender for a specified period of time in seconds. The default timeout value is 210 seconds.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.

Procedure

1. Enter IS-IS Router Configuration mode:

   ```
   enable

   configure terminal

   router isis
   ```

2. Configure the IP Multicast over Fabric Connect forward-cache timeout:

   ```
   spbm <1–100> multicast fwd-cache-timeout(seconds) <10–86400>
   ```

3. (Optional) Configure the IP Multicast over Fabric Connect forward-cache timeout to the default value of 210 seconds:

   ```
   default spbm <1–100> multicast fwd-cache-timeout(seconds)

   no spbm <1–100> multicast fwd-cache-timeout(seconds)
   ```

Example

Configure the IP Multicast over Fabric Connect forward-cache timeout to 300:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 multicast 1 fwd-cache-timeout 300
```

Variable definitions

The following table defines parameters for the **spbm** command.

Variable	Value
<1–100>	Specifies the SPBM instance. The switch only supports one instance.
<10–86400>	Specifies the IP Multicast over Fabric Connect forward-cache timeout in seconds. The default is 210 seconds.

Viewing IP Multicast over Fabric Connect within the GRT information

Use the following options to display IP Multicast over Fabric Connect within the GRT information to confirm proper configuration.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all IP Multicast over Fabric Connect route information:

   ```
   show isis spbm ip-multicast-route [all]
   ```

3. Display detailed IP Multicast over Fabric Connect route information:

   ```
   show isis spbm ip-multicast-route [detail]
   ```

4. Display the IP Multicast over Fabric Connect multicast group and source address information:

   ```
   show isis spbm ip-multicast-route [group {A.B.C.D}] [source {A.B.C.D}]
   [source-beb WORD<0–255>]
   ```

5. Display summary information for each S, G, V tuple with the corresponding scope, data I-SID, and the host name of the source:

   `show isis spb-mcast-summary [count][host-name WORD<0-255>][lspid <xxxx.xxxx.xxxx.xx-xx>]`

Example

Display IP Multicast over Fabric Connect within the GRT information:

```
Switch:1#show isis spbm ip-multicast-route all
================================================================================
                              SPBM IP-multicast ROUTE INFO ALL

Variable definitions

The following table defines parameters for the **show isis spbm ip-multicast-route** command.

Variable	Value
all	Displays all IP Multicast over Fabric Connect route information.
detail	Displays detailed IP Multicast over Fabric Connect route information.
group {A.B.C.D} source {A.B.C.D} [source-beb *WORD<0-255>*]	Displays information on the group IP address for the IP Multicast over Fabric Connect route. If you select source it will also display the source IP address. Specifies the source BEB name.
vlan	Displays IP Multicast over Fabric Connect route information by VLAN.
vrf	Displays IP Multicast over Fabric Connect route information by VRF.
vsn-isid	Displays IP Multicast over Fabric Connect route information by I-SID.

The following table defines parameters for the **show isis spb-mcast-summary** command.

Variable	Value
count	Displays the total number of SPB multicast entries.
host-name	Displays the IP Multicast over Fabric Connect summary for a given host-name.
lspid <xxxx.xxxx.xxxx.xx-xx>	Displays the IP Multicast over Fabric Connect summary for a given LSP ID.

View IGMP Information for IP Multicast over Fabric Connect within the GRT

Use the following commands to display IGMP information.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display information about the interfaces where IGMP is enabled:

   ```
   show ip igmp interface [gigabitethernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}][vlan <1-4059>][vrf WORD<1-16>][vrfids WORD<0-512>]
   ```

   Ensure that the ouput displays `routed-spb` under MODE.

3. Display information about the IGMP cache:

   `show ip igmp cache [vrf WORD<1-16>][vrfids WORD<0-512>]`

4. Display information about the IGMP group:

   `show ip igmp group [count][group {A.B.C.D}][member-subnet default|{A.B.C.D/X}][vrf WORD<1-16>][vrfids WORD<0-512>]`

5. Display information about the IGMP sender:

   `show ip igmp sender [count][group {A.B.C.D}][member-subnet default|{A.B.C.D/X}][vrf WORD<1-16>][vrfids WORD<0-512>]`

Example

Display IGMP information for IP multicast over Fabric Connect within the GRT:

```
Switch:1#show ip igmp interface

Variable definitions

The following table defines parameters for the **show ip igmp interface** command.

Variable	Value
gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
vlan <1-4059>	Specifies the VLAN.
vrf WORD<1-16>	Specifies the VRF by name.
vrfids WORD<0-512>	Specifies the VRF by VRF ID.

The following table defines parameters for the **show ip igmp cache** command.

Variable	Value
vrf WORD<1-16>	Specifies the VRF by name.
vrfids WORD<0-512>	Specifies the VRF by VRF ID.

The following table defines parameters for the **show ip igmp group** command.

Variable	Value
count	Specifies the number of entries.
group {A.B.C.D}	Specifies the group address.
member-subnet {A.B.C.D/X}	Specifies the IP address and network mask.
vrf WORD<1-16>	Displays the multicast route configuration for a particular VRF by name.
vrfids WORD<0-512>	Displays the multicast route configuration for a particular VRF by VRF ID.

The following table defines parameters for the **show ip igmp sender** command.

Variable	Value
count	Specifies the number of entries.
group {A.B.C.D}	Specifies the group address.
member-subnet {A.B.C.D/X}	Specifies the IP address and network mask.
vrf WORD<1-16>	Displays the multicast route configuration for a particular VRF by name.
vrfids WORD<0-512>	Displays the multicast route configuration for a particular VRF by VRF ID.

View TLV Information for IP Multicast over Fabric Connect within the GRT

Use the following commands to check TLV information.

For IP Multicast over Fabric Connect within the GRT, TLV 186 on the BEB where the source is located displays the multicast source and group addresses and have the Tx bit set. Each multicast group has its own unique data I-SID with a value between 16,000,000 to 16,512,000. TLV 144 on the BEB bridge, where the sender is located, has the Tx bit set while on all BEB bridges, where a receiver exists, has the Rx bit set.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IS-IS Link State Database information by TLV:
   `show isis lsdb tlv <1-236> [sub-tlv <1-3>][detail] [home|remote]`
3. Display IS-IS Link State Database information by Link State Protocol ID:
   `show isis lsdb lspid <xxxx.xxxx.xxxx.xx-xx> tlv <1-236> [sub-tlv <1-3>] [detail] [home|remote]`

Example

Display TLV information:

```
Switch:1# show isis lsdb tlv 186 detail
================================================================================

Variable Definitions

The following table defines parameters for the **show isis lsdb** command.

Variable	Value
detail	Displays detailed information about the IS-IS Link State database.
home	Displays the IS-IS LSDB information that the system configures in the home area.
level {l1, l2, l12}	Displays information on the IS-IS level. The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 function is disabled.
local	Displays information on the local LSDB.

Variable	Value
lspid <xxxx.xxxx.xxxx.xx-xx>	Specifies information about the IS-IS Link State database by LSP ID.
remote	Displays the IS-IS LSDB information that the system configures in the remote area.
sub-tlv <1-3>	Specifies information about the IS-IS Link State database by sub-TLV.
sysid <xxxx.xxxx.xxxx>	Specifies information about the IS-IS Link State database by System ID.
tlv <1-236>	Specifies information about the IS-IS Link State database by TLV.

IP Shortcuts configuration using the EDM

This section provides procedures to configure IP Shortcuts using the EDM.

Configuring IP Multicast over Fabric Connect on a VLAN within the GRT

Use this procedure to enable IP Multicast over Fabric Connect on each of the VLANs within the GRT that need to support IP multicast traffic. The default is disabled.

To configure a VRF with IP Multicast over Fabric Connect, see Configuring IP Multicast over Fabric Connect on a VLAN for Layer 3 on page 1523.

Note

- You do not have to enable IP Shortcuts to support IP multicast routing in the GRT using SPBM.
- You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.
- If there is no IP interface on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).

About This Task

With IP Multicast over Fabric Connect within the GRT, routing of IP multicast traffic is allowed within the subset of VLANs in the GRT that have IP Multicast over Fabric Connect enabled. When you enable IP Multicast over Fabric Connect on a VLAN, the VLAN automatically becomes a multicast routing interface.

You must enable IP Multicast over Fabric Connect on each of the VLANs within the GRT that need to support IP multicast traffic. After you enable IP Multicast over Fabric Connect on the VLANs, any IGMP functions required for IP Multicast over Fabric Connect within the GRT are automatically enabled. You do not need to configure anything IGMP related.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing within the GRT does not depend on unicast routing. This allows for you to more easily migrate from a PIM environment to IP Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first and then migrate unicast separately or not at all.

The switch only supports IPv4 addresses with IP Multicast over Fabric Connect.

Procedure

1. In the navigation pane, expand **Configuration** > **VLAN**.
2. Click **VLANs**.
3. Choose a VLAN, and then click the **IP** button.
4. Click the **SPB Multicast** tab.

Note

After you enable IP Multicast over Fabric Connect, you cannot enable IGMP, IGMP Snooping, or IGMP proxy on the interface. If you try to enable IGMP Snooping or proxy on any interface where SPBM multicast is enabled, the system displays an error message.

Note

When you enable IP Multicast over Fabric Connect on a Controller switch in a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

5. Click **Enable**.
6. Click **Apply**.

Configuring IP Multicast over Fabric Connect on a brouter port within the GRT

Use this procedure to enable IP Multicast over Fabric Connect on a brouter port IP interface. The default is enabled.

To configure a brouter port for a VRF with IP Multicast over Fabric Connect, see Configuring IP Multicast over Fabric Connect on a brouter port for a Layer 3 VSN on page 1524.

Note

- You do not have to enable IP Shortcuts to support IP multicast routing in the GRT using SPBM.
- You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.
- If there is no IP interface on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).

About This Task

With IP Multicast over Fabric Connect within the GRT, routing of IP multicast traffic is allowed within the subset of VLANs in the GRT that have IP Multicast over Fabric Connect enabled. When you enable IP Multicast over Fabric Connect on a VLAN, the VLAN automatically becomes a multicast routing interface.

You must enable IP Multicast over Fabric Connect on each of the VLANs within the GRT that need to support IP multicast traffic. After you enable IP Multicast over Fabric Connect on the VLANs, any IGMP functions required for IP Multicast over Fabric Connect within the GRT are automatically enabled.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing, which allows for you to more easily migrate from a PIM environment to Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first, and then migrate unicast separately or not at all.

The switch only supports IPv4 addresses with IP Multicast over Fabric Connect.

Procedure

1. Select an enabled port on the Physical Device View.
2. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
3. Click **IP**.
4. Click the **SPB Multicast** tab.
5. Click **Enable**.

   Note

   When you enable IP Multicast over Fabric Connect on a DvR Controller switch in a DvR domain, the configuration is automatically pushed to the Leaf nodes within the domain.

6. Click **Apply**.

SPB Multicast field description

Use the data in the following table to use the SPB Multicast tab.

Name	Description
Enable	Enables or disables SPB Multicast. The default is disable.

Configuring the Global Routing Table timeout value

Use this procedure to configure the timeout value in the GRT. The timeout value ages out the sender when there are no multicast streams coming from the sender for a specified period of time. The default timeout value is 210 seconds.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.

- You must enable IP Multicast over Fabric Connect globally.

Procedure

1. In the navigation pane, expand **Configuration** > **Fabric** > **SPBM**.
2. Select the **SPBM** tab.
3. Modify the **McastFwdCacheTimeout** value.
4. Select **Apply**.

IP multicast over SPBM within the GRT configuration example

The following example shows the configuration steps to enable IP multicast over SPBM support on VLANs 10 and 11 that are part of the GRT:

```
ISIS SPBM CONFIGURATION

router isis
spbm 1 multicast enable

VLAN CONFIGURATION - PHASE I

interface vlan 500
ip address 192.0.2.1 255.255.255.0
ip spb-multicast enable
exit

interface vlan 501
ip address 192.0.2.2 255.255.255.0
ip spb-multicast enable
exit
```

Layer 3 VSN Fundamentals

This section provides fundamentals concepts for Layer 3 VSN configuration. For more information on Layer 3 VSN basic configuration, see Layer 3 VSN Configuration on page 1190.

Layer 3 VSN with IP Multicast over Fabric Connect

IP Multicast over Fabric Connect supports Layer 3 VSN functionality where multicast traffic is bridged over the SPBM core infrastructure. Layer 3 VSN using IP Multicast over Fabric Connect is helpful when you need complete security and total isolation of data. No one outside of the Layer 3 VSN can join or even see the Layer 3 VSN. Applications that can use Layer 3 VSN with IP Multicast over Fabric Connect include: Video surveillance, TV/Video/Ticker/Image Distribution, VX-LAN, Multi-tenant IP multicast.

Configure the Layer 3 VSN (VRF) as a multicast VPN, and then enable IP Multicast over Fabric Connect on VRF VLANs to which IP multicast senders and receivers attach. This configuration automatically enables IGMP snooping and proxy on those VLANs. IGMPv2 at the VLAN level is the default setting, with no other configuration required. If you want to use IGMPv3, you must configure IGMPv3.

IP Multicast over Fabric Connect is only configured on BEBs.

Note

- You do not need to enable IP Shortcuts to support multicast routing in the Layer 3 VSN using SPBM. IPVPN creation and I-SID assignment for the IPVPN is required, but you do not need to enable IPVPN.
- If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing for Layer 3 VSNs using VRFs, which allows you to more easily migrate from a PIM environment to IP Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first and then migrate unicast separately or not at all.
- If no IP interface exists on the VLAN, then you create one. (The IP interface must be the same subnet as the IGMP hosts that connect to the VLAN).

With Layer 3 VSN with IP Multicast over Fabric Connect, multicast traffic remains in the same Layer 3 VSN across the SPBM cloud. For a Layer 3 VSN, traffic can cross VLAN boundaries but remains confined to the subset of VLANs within the VRF that has IP Multicast over Fabric Connect enabled. If a sender transmits a multicast stream to a BEB on a Layer 3 VSN with IP Multicast over Fabric Connect enabled, only receivers that are part of the same Layer 3 VSN can receive that stream.

I-SIDs

After a BEB receives IP multicast data from a sender, the BEB allocates a data service instance identifier (I-SID) in the range of 16,000,000 to 16,512,000 for the multicast stream. The stream is identified by the S, G, V tuple, which is the source IP address, the group IP address and the local VLAN the multicast stream is received on. The data I-SID uses Tx/Rx bits to signify whether the BEB uses the I-SID to transmit, receive, or both transmit and receive data on that I-SID.

In the context of Layer 3 VSNs with IP Multicast over Fabric Connect, the scope is the I-SID value of the Layer 3 VSN associated with the local VLAN that the IP multicast data was received on.

TLVs

This information is propagated through the SPBM cloud using IS-IS Link State Packets (LSPs), which carry TLV updates, that result in the multicast tree creation for that stream. For Layer 3 VSNs, the LSPs carry I-SID information and information about where IP multicast stream senders and receivers exist using TLV 144 and TLV 185.

IS-IS acts dynamically using the TLV information received from BEBs that connect to the sender and the receivers to create a multicast tree between them.

IGMP

After a BEB receives an IGMP join message from a receiver, the BEB queries the IS-IS database to check if a sender exists for the requested stream within the scope of the receiver. If the requested stream does not exist, the IGMP information is kept, but no further action is taken. If the requested stream exists, the BEB sends an IS-IS TLV update to its neighbors to inform them of the presence of a receiver and this information is propagated through the SPBM cloud.

DvR

On DvR Controllers in a DvR domain, you must manually configure IP multicast over Fabric Connect on Layer 3 VSNs (VRFs). This configuration is then automatically pushed to the Leaf nodes in the DvR domain.

For more information on DvR, see Distributed Virtual Routing on page 621.

Layer 3 VSN Configuration using the CLI

Configure Layer 3 VSN with IP Multicast over Fabric Connect

Use this procedure to configure IP Multicast over Fabric Connect for a Layer 3 VSN.

Configure the Layer 3 VSN (VRF) as a multicast VPN, and then enable IP Multicast over Fabric Connect on VRF VLANs to which IP multicast senders and receivers attach. After you enable IP Multicast over Fabric Connect on VRF VLANs, snooping and proxy on those VLANs is enabled. IGMPv2 at the VLAN level is the default setting. No configuration is required.

Note

On DvR Controllers in a DvR domain, you must manually configure IP multicast over Fabric Connect on Layer 3 VSNs (VRFs). This configuration is then automatically pushed to the Leaf nodes in the DvR domain.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect globally.
- You must assign an I-SID for the IPVPN.

About This Task

With Layer 3 VSN IP Multicast over Fabric Connect, multicast traffic remains in the same Layer 3 VSN across the SPBM cloud.

For a Layer 3 VSN, traffic can cross VLAN boundaries but remains confined to the subset of VLANs within the VRF that have **`ip spbm-multicast`** enabled. The default is disabled.

All or a subset of VLANs within a Layer 3 VSN can exchange multicast traffic. The BEB only sends out traffic for a multicast stream on which IGMP joins and reports are received.

The switch only supports IPv4 multicast traffic.

Note

You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN. The IP VPN does not need to be enabled for Layer 3 VSN multicast to function.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal

   router vrf WORD<1-16>
   ```

2. Enable Layer 3 VSN IP Multicast over Fabric Connect for a particular VRF:

   ```
   mvpn enable
   ```

   The default is disabled.

3. Exit to Global Configuration mode:

   ```
   exit
   ```

4. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]} or interface vlan <1-4059>
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

5. Enable Layer 3 VSN IP Multicast over Fabric Connect for a particular VRF:

   ```
   ip spb-multicast enable
   ```

6. (Optional) Enable IGMP version 3:

   ```
   ip igmp snooping

   ip igmp ssm-snoop

   ip igmp compatibility-mode

   ip igmp version 3
   ```

   Note

   IGMPv2 at the VLAN level is the default setting, with no other configuration required. You only need to use these commands if you use IGMPv3. You must enable SSM snoop before you configure IGMP version 3, and you must enable both ssm-snoop and snooping for IGMPv3.

   For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

7. (Optional) Enable the IGMP Layer 2 Querier address:

   ```
   ip igmp snoop-querier-addr {A.B.C.D}
   ```

   Note

   If the SPBM bridge connects to an edge switch, it can be necessary to add an IGMP query address. If you omit adding a query address, the SPB bridge sends IGMP queries with a source address of 0.0.0.0. Some edge switch models do not accept a query with a source address of 0.0.0.0.

Example

Configure IP Multicast over Fabric Connect for a Layer 3 VSN:

```
Switch:>enable
Switch:#configure terminal
Switch:(config)# router vrf green
Switch:(config-vrf)#mvpn enable
Switch:(config)#exit
Switch:(config)#interface vlan 500
Switch:(config-if)#ip spb-multicast enable
```

Variable Definitions

The following table defines parameters for the **`router vrf`** command.

Variable	Value
WORD<1-16>	Specifies the name of the VRF.

The following table defines parameters for the **`interface vlan`** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

The following table defines parameters for the **`GigabitEthernet`** command.

Variable	Value
GigabitEthernet{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

The following table defines parameters for the **ip igmp** command.

Variable	Value
access-list WORD<1-64> {A.B.C.D/X} <eny-tx|deny-rx| deny-both|allow-only-tx| allow-only-rx|allow-only-both>	Specifies the name of the access list from 1–64 characters. Creates an access control group entry for a specific IGMP interface. Specify the IP address of the host and the subnet mask used to determine the host or hosts covered by this configuration. You can use the host subnet mask to restrict access to a portion of the network for the host. Indicates the action for the specified IGMP interface. For example, if you specify deny-both, the interface denies both transmitted and received traffic.

compatibility-mode	Activates v2-v3 compatibility mode. The default value is disabled, which means IGMPv3 is not compatible with IGMPv2. To use the default configuration, use the default option in the command:
	`default ip igmp compatibility-mode`
	, or use the no option to disable compatibility mode:
	`no ip igmp compatibility-mode`

dynamic-downgrade-version	Configures if the system downgrades the version of IGMP to handle older query messages. If the system downgrades, the host with IGMPv3 only capability does not work. If you do not configure the system to downgrade the version of IGMP, the system logs a warning. The system downgrades to the oldest version of IGMP on the network by default. To use the default configuration, use the default option in the command:
	`default ip igmp dynamic-downgrade-version`
	or use the no option to disable downgrade:
	`no ip igmp dynamic-downgrade-version`

igmpv3-explicit-host-tracking	Enables explicit host tracking on IGMPv3. The default state is disabled.
immediate-leave	Enables fast leave on a VLAN.
immediate-leave-members {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Configures IGMP fast leave members on a VLAN to specify fast-leave-capable ports.
last-member-query-interval <0-255>	Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1. Decreasing the value reduces the time to detect the loss of the last member of a group. The default is 10 tenths of a second. Configure this value between 3–10 (equal to 0.3 – 1.0 seconds).

Variable	Value
mrdisc [maxadvertinterval <2-180>] [maxinitadvertinterval <2-180>] [maxinitadvertisements <2-15>] [minadvertinterval <3-180>] [neighdeadinterval <2-180>]	Configure the multicast router discovery options to enable the automatic discovery of multicast capable routers. The default parameter values are: • maxadvertinterval: 20 seconds • maxinitadvertinterval: 2 seconds • maxinitadvertisements: 3 • minadvertinterval: 15 seconds • neighdeadinterval: 60 seconds
mrouter {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Adds multicast router ports.
proxy	Activates the proxy-snoop option globally for the VLAN.
query-interval <1-65535>	Configures the frequency (in seconds) at which the VLAN transmits host query packets. The default value is 125 seconds.
query-max-response <0-255>	Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values enable a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds). Important: You must configure this value lower than the query-interval.
robust-value <2-255>	Configures the expected packet loss of a network. The default value is 2 seconds. Increase the value if you expect the network to experience packet loss.
router-alert	Instructs the router to ignore IGMP packets that do not contain the router alert IP option. When disabled (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option. Important: To maximize network performance, configure this parameter according to the version of IGMP currently in use: • IGMPv1—Disable • IGMPv2—Enable • IGMPv3—Enable
snoop-querier	Enables the IGMP Layer 2 Querier feature on the VLAN. The default is disabled.
snoop-querier-addr {A.B.C.D}	Specifies the IGMP Layer 2 Querier source IP address.
snooping	Activates the snoop option for the VLAN.
ssm-snoop	Activates support for SSM on the snoop interface.

Variable	Value
static-group {A.B.C.D} {A.B.C.D} [port] {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} [static|blocked]	Configures IGMP static members to add members to a snoop group. *{A.B.C.D} {A.B.C.D}* indicates the IP address range of the selected multicast group. *[port] {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}* adds ports to a static group entry. *[static|blocked]* configures the route to static or blocked.
stream-limit stream-limit-max-streams <0-65535>	Configures multicast stream limitation on a VLAN to limit the number of concurrent multicast streams on the VLAN. The default is 4.
stream-limit-group {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} enable max-streams <0-65535>	Configures multicast stream limitation members on ports of a specific VLAN to limit the number of multicast groups that can join a VLAN. The default *max-streams* value is 4.
version <1-3>	Configures the version of IGMP that you want to configure on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default value is 2 (IGMPv2).

View Layer 3 VSN with IP Multicast over Fabric Connect Information

Use the following options to display Layer 3 VSN with IP Multicast over Fabric Connect information to confirm proper configuration.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all the VRFs that have MVPN enabled and their corresponding forward cache timeout values:

   ```
   show ip vrf mvpn
   ```
3. Display IP Multicast over Fabric Connect route information:

   ```
   show isis spbm ip-multicast-route [all][detail]
   ```
4. Display IP Multicast over Fabric Connect by group and source address:

   ```
   show isis spbm ip-multicast-route [group {A.B.C.D}][detail][source {A.B.C.D}]
   ```
5. Display IP Multicast over Fabric Connect route information by VRF:

   ```
   show isis spbm ip-multicast-route [vrf WORD<1-16>] [group {A.B.C.D}]
   ```
6. Display IP Multicast over Fabric Connect route information by VLAN:

   ```
   show isis spbm ip-multicast-route [vlan <1-4059>][detail][group {A.B.C.D}]
   ```
7. Display IP Multicast over Fabric Connect information by VSN I-SID:

   ```
   show isis spbm ip-multicast-route [vsn-isid <1-16777215>][detail] [group {A.B.C.D}]
   ```
8. Display summary information for each S, G, V tuple with the corresponding scope, Data I-SID, and the host name of the source:

   ```
   show isis spb-mcast-summary [count][host-name WORD<0-255>][lspid <xxxx.xxxx.xxxx.xx-xx>]
   ```

Example

Display Layer 3 VSN with IP Multicast over Fabric Connect information:

```
Switch:1>enable
Switch:1#show ip vrf mvpn

                            Vrf name : green
                                mvpn : enable
                    fwd-cache-timeout(seconds) : 210

                            Vrf name : 4
                                mvpn : enable
                    fwd-cache-timeout(seconds) : 210

                            Vrf name : blue
                                mvpn : enable
                    fwd-cache-timeout(seconds) : 210

```

Variable Definitions

The following table defines parameters for the **show isis spbm ip-multicast-route** command.

Variable	Value
all	Displays all IP Multicast over Fabric Connect route information.
detail	Displays detailed IP Multicast over Fabric Connect route information.
group{A.B.C.D}	Displays information on the group IP address for the IP Multicast over Fabric Connect route.
vlan<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
vrfWORD<1-16>	Displays IP Multicast over Fabric Connect route information by VRF.
vsn-isid<1-16777215>	Displays IP Multicast over Fabric Connect route information by I-SID.

The following table defines parameters for the **show isis spb-mcast-summary** command.

Variable	Value
count	Displays the total number of SPB multicast entries.
host-nameWORD<0-255>	Displays the IP Multicast over Fabric Connect summary information by host-name.
lspid<xxxx.xxxx.xxxx.xx-xx>	Displays the IP Multicast over Fabric Connect summary information by LSP ID.

View IGMP Information for Layer 3 VSN Multicast

Use the following commands to check IGMP information.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display information about the interfaces where IGMP is enabled:

   ```
   show ip igmp interface [gigabitethernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}][vlan <1-4059>[vrf WORD<1-16>][vrfids WORD<0-512>]
   ```

   Ensure that the output displays `routed-spb` under MODE.

3. Display information about the IGMP cache:

   ```
   show ip igmp cache [vrf WORD<1-16>][vrfids WORD<0-512>]
   ```

4. Display information about the IGMP group:

   ```
   show ip igmp group [count][member-subnet default|{A.B.C.D/X}][vrf WORD<1-16>][vrfids WORD<0-512>]
   ```

5. Display information about the IGMP sender:

   `show ip igmp sender [count][member-subnet` *`default|{A.B.C.D/X}`*`][vrf` *`WORD<1-16>`*`][vrfids` *`WORD<0-512>`*`]`

Example

Display IGMP information for Layer 3 VSN with IP multicast over Fabric Connect:

```
Switch:#enable
Switch:1#show ip igmp interface vrf green

Total number of unique groups 10
```

Variable Definitions

The following table defines parameters for the **show ip igmp interface** command.

Variable	Value
gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
vlan <1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
vrf WORD<1-16>	Specifies the VRF by name.
vrfids WORD<0-512>	Specifies the VRF by VRF ID.

The following table defines parameters for the **show ip igmp cache** command.

Variable	Value
vrf WORD<1-16>	Specifies the VRF by name.
vrfids WORD<0-512>	Specifies the VRF by VRF ID.

The following table defines parameters for the **show ip igmp group** command.

Variable	Value
count	Specifies the number of entries.
group {A.B.C.D}	Specifies the group address.
member-subnet {A.B.C.D/X}	Specifies the IP address and network mask.

Variable	Value
vrf WORD<1-16>	Displays the multicast route configuration for a particular VRF by name.
vrfids WORD<0-512>	Displays the multicast route configuration for a particular VRF by VRF ID.

The following table defines parameters for the **show ip igmp sender** command.

Variable	Value
count	Specifies the number of entries.
group {A.B.C.D}	Specifies the group address.
member-subnet {A.B.C.D/X}	Specifies the IP address and network mask.
vrf WORD<1-16>	Displays the multicast route configuration for a particular VRF by name.
vrfids WORD<0-512>	Displays the multicast route configuration for a particular VRF by VRF ID.

View TLV Information for a Layer 3 VSN with IP Multicast over Fabric Connect

Use the following commands to check TLV information.

For a Layer 3 VSN multicast, TLV 185 on the BEB where the source is located displays the multicast source and group addresses and have the Tx bit set. Each multicast group should have its own unique data I-SID with a value between 16,000,000 to 16,512,000. TLV 144 on the BEB bridge, where the sender is located, has the Tx bit set. All BEB bridges, where a receiver exists, have the Rx bit set.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IS-IS Link State Database information by TLV:
   `show isis lsdb tlv <1-236> [sub-tlv <1-3>] [detail] [home|remote]`
3. Display IS-IS Link State Database information by Link State Protocol ID:
   `show isis lsdb lspid <xxxx.xxxx.xxxx.xx-xx> [tlv <1-236>] [sub-tlv <1-3>] [detail] [home|remote]`

Example

Display TLV information for a Layer 3 VSN with IP Multicast over Fabric Connect:

```
Switch:1# show isis lsdb tlv 185 detail
================================================================================
            ISIS LSDB (DETAIL)

        Data ISID : 16300020
        TX : 1
```

Variable Definitions

The following table defines parameters for the **show isis lsdb** command.

Variable	Value
detail	Displays detailed information about the IS-IS Link State database.
home	Displays the IS-IS LSDB information that the system configures in the home area.

Variable	Value
level {l1, l2, l12}	Displays information on the IS-IS level. The IEEE 802.1aq standard currently only defines the use of one hierarchy, Level 1. Level 2 function is disabled.
local	Displays information on the local LSDB.
lspid<xxxx.xxxx.xxxx.xx-xx>	Specifies information about the IS-IS Link State database by LSP ID.
remote	Displays the IS-IS LSDB information that the system configures in the remote area.
sub-tlv <1-3>	Specifies information about the IS-IS Link State database by sub-TLV.
sysid <xxxx.xxxx.xxxx>	Specifies information about the IS-IS Link State database by System ID.
tlv <1-236>	Specifies information about the IS-IS Link State database by TLV.

Layer 3 VSN Configuration using EDM

Enable MVPN for a VRF

Use this procedure to enable MVPN for a particular VRF. IP Multicast over Fabric Connect, constrains multicast streams of senders to all receivers in the same Layer 3 VSN. MVPN functionality is disabled by default.

Note

VLAN level configuration is also required to turn on the service on each VLAN within the VRF on which this services is required. You can turn it on under the VLAN context or the brouter context.

Before You Begin

- You must enable IP Multicast over Fabric Connect globally.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **IP-MVPN**.
3. Select the **MVPN** tab.
4. Double-click in the **Enable** field in the table.
5. Select **Enable** from the drop down menu.
6. Double-click in the **FwdCacheTimeout** field in the table, and then type the VRF timeout value.
7. Select **Apply**.

MVPN Field Descriptions

Use the data in the following table to use the **MVPN** tab.

Name	Description
VrfId	Specifies the VRF ID.
Enable	Enables Layer 3 VSN IP Multicast over Fabric Connect services for a particular VRF. The default is disabled.
FwdCacheTimeout	Specifies the VRF timeout value. The timeout value ages out the sender when there is no multicast stream on the VRF. The default is 210 seconds..

Configuring IP Multicast over Fabric Connect on a VLAN for Layer 3

Use this procedure to enable IP Multicast over Fabric Connect for a Layer 3 VSN. The default is disabled.

To configure a VLAN for IP Shortcuts with IP Multicast over Fabric Connect, see Configuring IP Multicast over Fabric Connect on a VLAN within the GRT on page 1504.

Note

On DvR Controllers in a DvR domain, you must manually configure IP multicast over Fabric Connect on Layer 3 VSNs (VRFs). This configuration is then automatically pushed to the Leaf nodes in the DvR domain.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must configure a VRF and an IP VPN instance with an I-SID configured under it on the switch. The IP VPN does not need to be enabled for Layer 3 VSN multicast to function.
- You must enable IP Multicast over Fabric Connect globally.
- If there is no IP interface on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).
- You must enable MVPN for the particular VRF.

About This Task

You must configure VLANs to turn on the service on each VLAN with in the VRF on which the service is required. You can turn it on under the VLAN context or the brouter context.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing (for Layer 3 VSN). This allows for you to more easily migrate from a PIM environment to IP Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first and then migrate unicast separately or not at all.

The switch only supports IPv4 address with IP Multicast over Fabric Connect.

Note

You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

Procedure

1. In the navigation pane, expand **Configuration** > **VRF Context View**.
2. Click **Set VRF Context View**.
3. Choose a VRF name.
4. Click **Launch VRF Context View**.
5. Select an enabled port on the Physical Device View.
6. In the navigation pane, expand **Configuration** > **VLAN**.
7. Click **VLANs**.
8. Choose a VLAN, and then click the **IP** from under the tab bar.
9. Click the **SPB Multicast** tab.
10. Check the **Enable** box.
11. Click **Apply**.

Configuring IP Multicast over Fabric Connect on a brouter port for a Layer 3 VSN

Use this procedure to enable IP Multicast over Fabric Connect on a brouter port. The default is disabled.

To configure a brouter port for IP Shortcuts with IP Multicast over Fabric Connect, see Configuring IP Multicast over Fabric Connect on a brouter port within the GRT on page 1505.

Before You Begin

- You must configure the required SPBM and IS-IS infrastructure, which includes the creation of SPBM B-VLANs.
- You must configure a VRF and an IP VPN instance with an I-SID configured under it on the switch. The IP VPN does not need to be enabled for Layer 2 VSN multicast to function.
- You must enable IP Multicast over Fabric Connect globally.
- If there is no IP interface on the VLAN, then you create one. (The IP interface must be in the same subnet as the IGMP hosts that connect to the VLAN).
- You must enable MVPN for the particular VRF.

About This Task

You must enable IP Multicast over Fabric Connect on each of the VLANs that need to support IP multicast traffic.

If you only want to use IP Multicast over Fabric Connect, you do not need to enable the Layer 3 VSN or redistribute unicast routes into or out of IS-IS. IP Multicast over Fabric Connect routing does not depend on unicast routing, which allows for you to more easily migrate from a PIM environment to Multicast over Fabric Connect. You can migrate a PIM environment to IP Multicast over Fabric Connect first, and then migrate unicast separately or not at all.

The switch only supports IPv4 address with IP Multicast over Fabric Connect.

Procedure

1. In the navigation pane, expand **Configuration** > **VRF Context View**.
2. Click **Set VRF Context View**.
3. Choose a VRF name.

4. Click **Launch VRF Context View**.
5. Select an enabled port on the Physical Device View.
6. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
7. Click **IP**.
8. Click the **SPB Multicast** tab.
9. Click **Enable**.
10. Click **Apply**.

Configuring IGMP on a VLAN interface for a Layer 3 VRF

Use this procedure to configure IGMP for each VLAN interface to enable the interface to perform multicast operations.

IGMPv2 at the VLAN level is the default setting, with no other configuration required. You only need to enable IGMPv3. You must enable SSM snoop before you configure IGMP version 3, and you must enable both ssm-snoop and snooping for IGMPv3.

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

Note

You cannot enable IP PIM when IP Multicast over Fabric Connect is enabled on the VLAN.

Before You Begin

- You must configure the required SPBM IS-IS infrastructure.
- You must configure a VRF and IP VPN instance with an I-SID on the switch.
- You must create the C-VLANs and add slots/ports.
- You must enable IP Multicast over Fabric Connect for a Layer 3 VSN.

About This Task

For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.

Procedure

1. In the navigation pane, expand **Configuration** > **VRF Context View**.
2. Click **Set VRF Context View**.
3. Choose a VRF name.
4. Click **Launch VRF Context View**.
5. In the navigation pane, expand **Configuration** > **VLAN**.
6. Click **VLANs**.
7. Select the desired VLAN from the listing.
8. Click the **IP** button.
9. Click the **IGMP** tab.
10. (Optional) If you want to enable SsmSnoopEnable, select the **SsmSnoopEnable** box.

11. (Optional) If you want to enable Snoop, select the **SnoopEnable** box.
12. (Optional) In the **Version** box, select the correct IGMP version.

    You must enable SSM snoop before you configure IGMP version 3, and you must enable both ssm-snoop and snooping for IGMPv3.
13. (Optional) Select **SnoopQuerierEnable**, to enable Snoop Querier. Only select this option, if you want to configure an address for the IGMP queries.
14. (Optional) In the **SnoopQuerierAddr** box, type an IP address, if you want to configure a snoop querier address.

Note

If the SPBM bridge connects to an edge switch, it can be necessary to add an IGMP query address. If you omit adding a query address, the SPB bridge sends IGMP queries with a source address of 0.0.0. Some edge switch models do not accept a query with a source address of 0.0.0.0.

IGMP field descriptions

Use the data in the following table to use the **IGMP** tab.

Name	Description
QueryInterval	Configures the frequency (in seconds) at which the IGMP host query packets transmit on the interface. The range is from 1–65535 and the default is 125.
QueryMaxResponseTime	Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values allow a router to prune groups faster. The range is from 0–255 and the default is 100 tenths of a second (equal to 10 seconds.) Important: You must configure this value lower than the QueryInterval.
Robustness	Configure this parameter to tune for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect the network to lose query packets, increase the robustness value. The range is from 2–255 and the default is 2. The default value of 2 means that the switch drops one query for each query interval without the querier aging out.
LastMembQueryIntvl	Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1. Decreasing the value reduces the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of a second. Configure this parameter to values greater than 3. If you do not require a fast leave process, use values greater than 10. (The value 3 is equal to 0.3 seconds, and 10 is equal to 1 second.)

Name	Description
SnoopEnable	Enables or disables snoop.
SsmSnoopEnable	Enables or disables support for SSM on the snoop interface.
ProxySnoopEnable	Enables or disables proxy snoop.
Version	Configures the version of IGMP (1, 2, or 3) that you want to use on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2. For IGMP Snooping, ensure that the IGMP version used by multicast hosts and other devices in the network is the same as the IGMP version configured on the IGMP Snooping VLAN, or that you enable compatibility mode.
FastLeaveEnable	Enables or disables fast leave on the interface.
StreamLimitEnable	Enables or disables stream limitation on this VLAN.
Maximum Number Of Stream	Configures the maximum number of streams allowed on this VLAN. The range is from 0–65535 and the default is 4.
Current Number Of Stream	Displays the current number of streams. This value is a read-only value.
FastLeavePortMembers	Selects the ports that are enabled for fast leave.
SnoopMRouterPorts	Selects the ports in this interface that provide connectivity to an IP multicast router.
DynamicDowngradeEnable	Configures if the switch downgrades the version of IGMP to handle older query messages. If the switch downgrades, the host with IGMPv3 only capability does not work. If you do not configure the switch to downgrade the version of IGMP, the switch logs a warning. The default value is selected (enabled), which means the switch downgrades to the oldest version of IGMP on the network.
CompatibilityModeEnable	Enables or disables v2-v3 compatibility mode. The default value is clear (disabled), which means IGMPv3 is not compatible with IGMPv2.
ExplicitHostTrackingEnable	Enables or disables IGMPv3 to track hosts per channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.
SnoopQuerierEnable	Enables Snoop Querier. The default is disabled. When you enable IGMP Layer 2 Querier, Layer 2 switches in your network can snoop IGMP control packets exchanged with downstream hosts and upstream routers. The Layer 2 switches then generate the Layer 2 MAC forwarding table, used for switching sessions and multicast traffic regulation, and provide the recurring queries required to maintain IGMP groups. Enable Layer 2 Querier on only one node in the VLAN.
SnoopQuerierAddr	Specifies the pseudo IP address of the IGMP Snoop Querier. The default IP address is 0.0.0.0. If the SPBM bridge connects to an edge switch, it can be necessary to add an IGMP query address. If you omit adding a query address, the SPBM bridge sends IGMP queries with a source address of 0.0.0.0. Some edge switch models do not accept a query with a source address of 0.0.0.0.

Layer 3 VSN with IP Multicast over Fabric Connect configuration example

The example below shows the configuration to enable IP Multicast over Fabric Connect support on VLANs 500 and 501 that are part of VRF Green:

```
ISIS SPBM CONFIGURATION

router isis
spbm 1 multicast enable

VRF CONFIGURATION

ip vrf green vrfid 2

VLAN CONFIGURATION - PHASE 1

vlan 110 i-sid 100
interface vlan 500
vrf green
ip address 192.0.2.1 255.255.255.0 1
ip spb-multicast enable
exit

vlan 111 i-sid 100
interface vlan 501
vrf green
ip address 192.0.2.2 255.255.0 0
ip spb-multicast enable
exit

ISIS SPBM IPVPN CONFIGURATION

router vrf green
ipvpn
i-sid 100
mvpn enable
exit
```

When using IGMPv3, the configuration is:

```

ISIS SPBM CONFIGURATION

router isis
spbm 1 multicast enable

VRF CONFIGURATION

ip vrf green vrfid 2

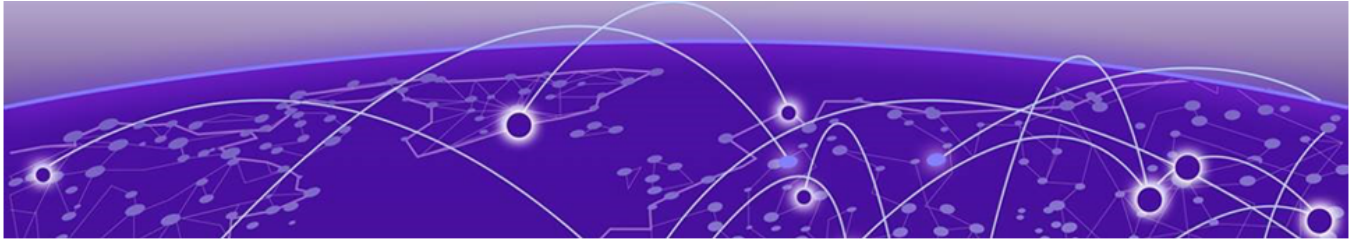
VLAN CONFIGURATION - PHASE 1

vlan 110 i-sid 100
interface vlan 500
vrf green
ip address 192.0.2.1 255.255.255.0 1
ip spb-multicast enable
ip igmp version 3
exit
```

```
vlan 111 i-sid 100
interface vlan 501
vrf green
ip address 192.0.2.2 255.255.0 0
ip spb-multicast enable
ip igmp version 3
exit

ISIS SPBM IPVPN CONFIGURATION

router vrf green
ipvpn
i-sid 100
mvpn enable
exit
```



IPFIX

Table 105: Internet Protocol Flow Information eXport (IPFIX) product support

Feature	Product	Release introduced
Internet Protocol Flow Information eXport (IPFIX)	5320 Series	Fabric Engine 8.6 5320-48P-8XE and 5320-48T-8XE only
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

IPFIX Fundamentals

Internet Protocol Flow Information eXport (IPFIX) is an Internet Engineering Task Force (IETF) standard of export for Internet Protocol flow information.

IPFIX monitors flows that pass an observation point. The switch organizes flows into a flow group, which is contained in an observation domain.

An IPFIX flow is a set of packets that pass an observation point in the network during a certain time interval. Packets that belong to a particular flow have a common set of properties. The switch defines each property using values from the following:

- Source IP address
- Destination IP address
- IP protocol
- L4 source port
- L4 destination port

A packet belongs to a flow if it completely satisfies all defined properties of the flow.

The switch logically organizes flows into a flow group, which corresponds to a single observation point. A flow can belong to only 1 flow group. A flow group is a collection of packet flows that meet match criteria. Examples of flow groups are packets ingressing a specific physical port, or packets with a destination IP address belonging to a specific subnet.

A flow group is contained in an observation domain. The switch assigns the flow group to an observation domain. The observation domain has a unique observation domain ID that you can configure. You can configure only 1 observation domain.

The IPFIX solution consists of the following processes:

- Filtering Rules process: The Filtering Rules process gathers information about flows through different ports, or the observation point. Flow information includes the following:
  - The IPv4 source address.
  - The IPv4 destination address.
  - The L4 source port.
  - The L4 destination port.
  - The transport protocol.
  - The total number of incoming packets for this flow at the observation point since the metering process (re-)initialization for this observation point.
  - The total number of octets in incoming packets for this flow at the observation point since the metering process (re-)initialization for this observation point.
  - The absolute timestamp of the first packet of this flow.
  - The absolute timestamp of the last packet of this flow.

  The Filtering Rules process runs on the switch.
- Exporting process: The Filtering Rules process sends information to the Exporting process. The Exporting process uses the UDP transport protocol for network communication with the Collecting process.

  The Exporting process runs on the switch.
- Collecting process: You can view flows and export flow information periodically to a collector. A collector can store a large number of flow records from several devices in the network. The IPFIX standard specifies the protocol for exporting the flows to a collector, including the formatting of flow records and the underlying UDP transport protocol.

  Use the collected information for network planning, troubleshooting a live network, and monitoring security threats.

  The best practice is to use the ExtremeAnalytics™ solution as the collector. The ExtremeAnalytics™ solution provides an enhanced method of collecting IPFIX flow information.

  The external collector for the IPFIX solution must support our IPFIX template, which contains the following element IDs defined by Internet Assigned Numbers Authority (IANA) IPFIX assignments.

Table 106: IPFIX element IDs

Element ID	Name	Description
0	unknown	Reserved
4	protocolIdentifier	The value of the protocol number in the IP packet header.
7	sourceTransportPort	The source port identifier in the transport header.
8	sourceIPv4Address	The IPv4 source address in the IP packet header.
11	destinationTransportPort	The destination port identifier in the transport header.

Table 106: IPFIX element IDs (continued)

Element ID	Name	Description
12	destinationIPv4Address	The IPv4 destination address in the IP packet header.
85	octetTotalCount	The total number of octets in incoming packets for this flow at the observation point since the metering process (re-)initialization for this observation point.
86	packetTotalCount	The total number of incoming packets for this flow at the observation point since the metering process (re-)initialization for this observation point.
145	templateId	The local template unique to the observation domain.
156	flowStartNanoseconds	The absolute timestamp of the last packet of this flow.
157	flowEndNanoseconds	The absolute timestamp of the last packet of this flow.
192	ipTTL	The value of the time-to-live (TTL) field in the IPv4 packet header.
234	ingressVRFID	The VRF name that receives packets for this flow.
243	dot1qVlanId	The VLAN ID in the Tag Control information of an Ethernet frame.

IPFIX is a push protocol. The Filtering Rules and Exporting processes periodically send IPFIX messages to configured receivers without interaction from the Collecting process.

IPFIX collects IPv4 flow information on the switch and conforms with the following:

- IPFIX supports only 1 collector.
- IPFIX learns only IPv4 flows.
- IPFIX sends and receives only TCP/UDP flows.
- IPFIX uses only UDP to export packets.
- You can configure only the template exporting timer.
- The Out-of-Band (OOB) port does not support IPFIX.
- IPFIX exports TCP/UDP IPv4 flows on IS-IS interfaces that are members of a VLAN. IPFIX does not capture Mac-In-Mac encapsulated flows on IS-IS interfaces.

  IPFIX processes IPv4 UDP or TCP Mac-in-Mac packet flows that are terminated by the switch. IPFIX does not process Mac-in-Mac packet flows that are only traversing the switch (Layer 2 switching).
- Layer 3 Virtual Services Network (L3 VSN) flow packets on NNI ports are not learned by IPFIX.
- The switch supports only ingress sampling. The switch does not support egress sampling.

Note

IPFIX is not supported on OOB, Circuitless IP (CLIP), or VLAN Segmented Management Instance interfaces.

IPFIX Configuration Using CLI

This section provides procedures to configure IPFIX using Command Line Interface (CLI).

Enabling IPFIX Globally

About This Task

Use the following procedure to enable IPFIX globally. IPFIX provides the ability to monitor IPv4 traffic flows.

The default global state is disabled.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Enable IPFIX:
   ```
   ip ipfix enable
   ```

Examples

Enable IPFIX globally:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#ip ipfix enable
```

Disable IPFIX globally:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#no ip ipfix enable

By disabling IPFIX globally, all the processes and traffic
sent to collector(s) will be stopped.Do you agree (y/n) ? y
```

Displaying IPFIX Global Status

About This Task

Use the following procedure to display global status information for IPFIX.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IPFIX global status:
   ```
   show ip ipfix
   ```

Example

```
Switch:1#show ip ipfix

================================================================================================
                                    IPFIX Global
================================================================================================
                      Global-State : enable
             Observation-Domain ID : 1
                        Flow Limit : 20000
```

```
                        Flow Count : 0
                    Aging Interval : 40
```

Configure the IPFIX Aging Interval

About This Task

Use the following procedure to configure an aging interval for IPFIX. The aging interval determines how long a traffic flow that is no longer being received, is retained as a flow.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure a value for the aging interval:

   ```
   ip ipfix aging-interval <100ms | 1s | 10s | 60s | 10m | 30m | 1h |10h
   |1d>
   ```

3. Configure a value for the aging interval:

   ```
   ip ipfix aging-interval <1-60>
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#ip ipfix aging-interval 1d
```

Variable Definitions

The following table defines parameters for the **`ip ipfix aging-interval`** command.

Variable	Value
<100ms | 1s | 10s | 60s | 10m | 30m | 1h |10h |1d>	Specifies (in seconds, minutes, hours, or days) the flow record aging interval. The aging interval determines how long a traffic flow that is no longer being received is retained as a flow. The default is 10 seconds.

Configuring the IPFIX Collector

About This Task

Use the following procedure to configure a collector for IPFIX. Use the ExtremeAnalytics™ solution as the collector.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure values for the collector ID, the IP address of the collector, and the IP address of the exporter. Optionally, you can configure values for the source port sending flow information and the destination port receiving flow information:

   ```
   ip ipfix collector <1-1> {A.B.C.D} exporter-ip {A.B.C.D} [dest-port
   <1-65535>] [src-port <1-65535>]
   ```

   Note

   You cannot configure collector or exporter IP addresses in the following formats:

   - 255.255.255.255
   - 127. x.x.x
   - 0.x.x.x
   - 224.0.0.0 to 239.255.255.255

   If you configure a collector or exporter IP address in any of these formats, the following error message is displayed:

   ```
   Error: Invalid IP address
   ```

3. (Optional) Configure a value for the export interval:

   ```
   ip ipfix collector 1 export-interval <1-120>
   ```

4. (Optional) Configure a value for the initial burst of template packets:

   ```
   ip ipfix collector 1 initial-burst <1-10>
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#ip ipfix collector 1 192.0.2.15 exporter-ip 192.0.2.16
dest-port 2 src-port 4
Switch:1(config)#ip ipfix collector 1 export-interval 40
Switch:1(config)#ip ipfix collector 1 initial-burst 4
```

Variable Definitions

Use the data in the following table to use the **ip ipfix collector** command.

Variable	Value
<1–1>	Specifies the IPFIX collector ID.
{A.B.C.D}	Specifies the IP address of the collector.
exporter-ip {A.B.C.D}	Specifies the IP address of the exporter.
dest-port <1-65535>	Specifies the destination port receiving flow information.
src-port <1-65535>	Specifies the source port sending flow information.
export-interval	Specifies, in seconds, the frequency of template packet exports to the collector. The default value is 60 seconds.
initial-burst	Specifies the number of template packets sent when the collector becomes reachable. The default value is 5.

Displaying IPFIX Collector Information

About This Task

Use the following procedure to display information about the IPFIX collector. The IPFIX collector can store flow information from multiple network devices.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about the IPFIX collector:

   ```
   show ip ipfix collector [<1-1>]
   ```

Example

```
================================================================================================================

                                          IPFIX Collector-Info

================================================================================================================

ID   Collector        Exporter         Source   Destination   Collector   Reachable        Exporting   Initial
     IP Address       IP Address       Port     Port          State       Via              Interval    Burst

----------------------------------------------------------------------------------------------------------------

1    20.20.20.2       20.20.20.1       2055     2055          Enabled     -                60          5
```

Variable Definitions

Use the data in the following table to use the **`show ip ipfix collector`** command.

Variable	Value
<1-1>	Specifies the IPFIX collector ID.

Configuring an IPFIX Observation Domain

About This Task

An observation domain consists of a collection of flow groups. Use this procedure to assign a unique ID to an observation domain. The default value is 0.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the observation domain ID:

   ```
   ip ipfix observation-domain <0-4294967295>
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
```

```
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#ip ipfix observation-domain 1
```

Variable Definitions

Use the data in the following table to use the **ip ipfix observation-domain** command.

Variable	Value
observation-domain <0-4294967295>	Specifies a value for the observation domain used to send IPFIX messages. The default is 0 (no observation domain). If the value is 0, data that is sent is not applied to a single observation domain.

Display IPFIX Flows

About This Task

Use the following procedure to display information about IPFIX flows. You can display information for all IPFIX flows, or you can specify a single IPFIX flow and display additional information about that flow.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about all IPFIX flows:

   ```
   show ip ipfix flows
   ```

3. Display information about an IPFIX flow learned on an ingress VRF:

   ```
   show ip ipfix flows source-addr {A.B.C.D} dest-addr {A.B.C.D} source-
   port <1-65535> dest-port <1-65535> protocol {udp|tcp} in-vrf <0-511>
   {in-vlan <1-4095> | untagged} ip-ttl <0-255>
   ```

Example

Display all IPFIX flows:

```
Switch:1>show ip ipfix flows
================================================================================================
                                IPFIX Flows
================================================================================================
Source          Destination     Source   Destination   Protocol   In
IP              IP              Port     Port                     Port
------------------------------------------------------------------------------------------------
192.0.2.1       198.51.100.1    63       63            UDP        1/17
203.0.113.2     203.0.113.1     63       63            UDP        RX-NNI
```

Variable Definitions

The following table defines parameters for the **show ip ipfix flows** command.

Variable	Value
dest-addr {A.B.C.D}	Specifies an IP address for the flow destination.
dest-port <1-65535>	Specifies a value for the destination port.
in-vlan <1-4095>	Specifies an ingress VLAN ID for the flow.

Variable	Value
in-vrf <0-511>	Specifies an ingress VRF ID for the flow.
ip-ttl <0-255>	Specifies the IP time-to-live (TTL) for the flow.
protocol {udp|tcp}	Specifies the transport protocol.
source-addr {A.B.C.D}	Specifies an IP address for the flow source.
source-port <1-65535>	Specifies a value for the source port.
untagged	Specifies ingress untagged flows.

IPFIX Configuration Using EDM

This section provides procedures to configure IPFIX in Enterprise Device Manager (EDM).

Enabling IPFIX Globally

About This Task

IPFIX allows you to monitor IPv4 traffic flows. Use the following procedure to enable IPFIX globally.

The default global state is disabled.

Procedure

1. In the navigation pane, expand the **Configuration** > **IP** folders.
2. Click **IPFIX**.
3. Click the **Globals** tab.
4. To enable IPFIX, click **enable** in the **ConfState** option box.
5. (Optional) To configure an observation domain ID, type a value in the **ObservationDomainID** field.
6. (Optional) To configure the aging interval, type a value in the **AgingInterval** field.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
ConfState	Specifies whether IPFIX is enabled or disabled. The default is disabled.
ObservationDomainID	Specifies a value for the observation domain used to send IPFIX messages. The default is 0 (no observation domain). If the value is 0, data that is sent is not applied to a single observation domain.
AgingInterval	Specifies (in seconds, minutes, hours, or days) the flow record aging interval. The aging interval determines how long a traffic flow that is no longer being received is retained as a flow. The default is 10 seconds.

Configure the IPFIX Collector

About This Task

Use the following procedure to configure a collector for IPFIX. Use the ExtremeAnalytics™ solution as the collector.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **IPFIX**.
3. Select the **Collector** tab.
4. Click **Insert**.
5. In the **Num** field, specify a value for the collector ID number.
6. In the **AddressType** field, specify a value for the IP address type of the collector.
7. In the **Address** field, specify a value for the IP address of the collector.
8. (Optional) In the **SrcPort** field, specify a value for the source port sending flow information.
9. (Optional) In the **DestPort** field, specify a value for the destination port receiving flow information.
10. In the **ExporterIpType** field, specify a value for the IP address type of the exporter for the collector.
11. In the **ExporterIp** field, specify the IP address of the exporter for the collector.
12. (Optional) In the **ExportInterval** field, specify the frequency of template packets exports to the collector.
13. (Optional) In the **InitialBurst** field, specify the number of template packets to send when the collector becomes reachable.
14. Select **Insert**.

Collector *Field Descriptions*

Use the data in the following table to use the **Collector** tab.

Name	Description
Num	Specifies the ID number of the collector
AddressType	Specifies the IP address type of the collector.
Address	Specifies the IP address of the collector.
Protocol	Specifies the protocol used to export data from the exporter to the collector.
SrcPort	Specifies the source port sending flow information. The default value is 2055.
DestPort	Specifies the destination port receiving flow information. The default value is 2055.
ExporterIpType	Specifies the IP address type of the exporter for the collector.
ExporterIp	Specifies the IP address of the exporter for the collector.
State	Specifies the state of the collector. The default value is enabled.

Name	Description
IsReachable	Specifies whether the collector is reachable. The default value is false (not reachable)
ViaNextHopName	Specifies the next-hop through which the collector is reachable.
ExportInterval	Specifies, in seconds, the frequency of template packets exports to the collector. The default value is 60 seconds.
InitialBurst	Specifies the number of template packets sent when the collector becomes reachable. The default value is 5.

IPsec Fundamentals

Internet Protocol Security (IPsec) ensures the authenticity, integrity, and confidentiality of data at the network layer of the Open System Interconnection (OSI) stack.

The IPsec feature is a set of security protocols and cryptographic algorithms that protect communication in a network. Use IPsec in scenarios where you need to encrypt packets between two hosts, or two routers, or a router and a host.

You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols.

IPsec adds support for OSPF virtual link for the security protection of the communication between the end points. You can also use IPsec with OSPFv3 on a brouter port or VLAN interface, for example, if you want to encrypt OSPFv3 control traffic on a broadcast network. You can also use IPsec with ICMPv6.

Note

- If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.
- You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols. You can continue to configure IPsec policies for IPv6 addresses for ICMPv6, OSPFv3, TCP, and UDP.

Note

- When an OSPFv3 virtual link between two end points is secured using IPsec, the IPsec status on the IPv6 interfaces is automatically updated. This is applicable only on those interfaces that have no IPSEC policies manually configured on them

The following figure displays the movement of traffic using IPsec.

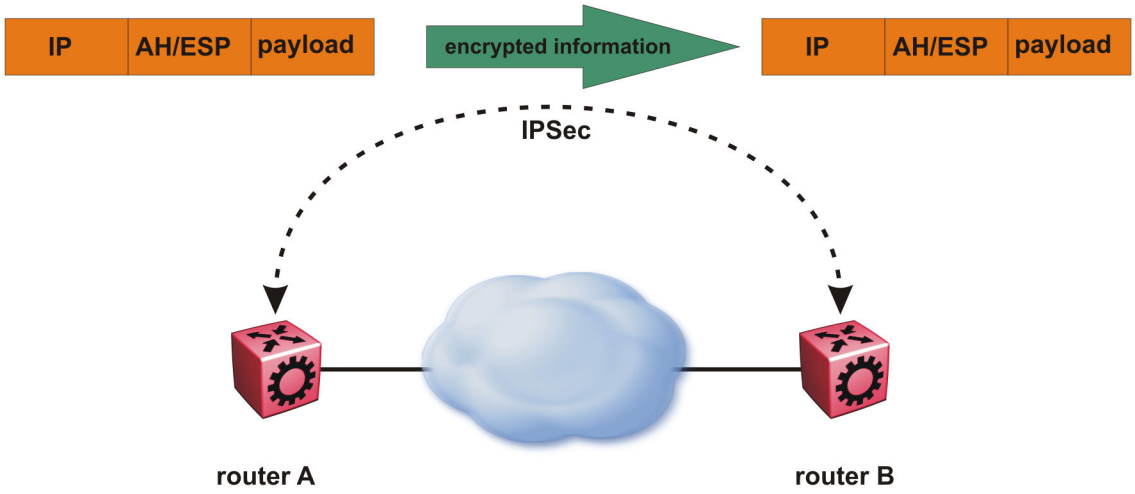

Figure 139: Internet Protocol Security (IPsec)

The IPsec feature uses security ciphers and encryption algorithms like AES, DES, and 3DES to ensure confidentiality of data, and keyed MAC for authenticity of data. The encryption algorithms require shared keys to secure the communication. The device only supports manual keying and configuration for IPsec. The IPsec feature supports IPv4 and IPv6 interfaces.

To configure IPsec, you create an IPsec policy, and then link the IPsec policy to an interface. You also link each IPsec policy to an IPsec security association. The IPsec policies define the amount of security applied to specific traffic on a specific interface. The IPsec feature supports the following security protocols:

- Encapsulating security payload (ESP)
- Authentication header (AH)

The device restricts IPsec encryption to control traffic through the CPU. The IPsec feature processes either the ingress, the egress, or both the egress and ingress control packets to and from the CPU.

The device checks every ingress or egress packet for the IPsec base protocol, either AH or ESP. The base protocol interacts with the security policy database (SPD) and security association database (SADB) to check the level of security to apply to the packet. The device consults the SPD for both ingress and egress traffic. For egress traffic, the device consults the SPD to determine if IPsec needs to apply security considerations. For ingress traffic, the device consults the SPD to determine whether the traffic received with IPsec encapsulation complies with the policies defined in the system.

For more information on IPsec, see IPsec Support with OSPFv3 on page 2189, View IPSec Statistics on page 1563, and Display IPsec Interface Statistics on page 1571.

Authentication header

The authentication header (AH) authenticates IP traffic and ensures you connect with who you want to connect. The authentication header can detect if data is altered in transit and protect against replay attacks. The authentication header does not encrypt traffic.

The authentication header provides a small header that precedes the payload with the use of the security parameters index (SPI) and sequence number. The authentication header provides:

- IP datagram sender authentication by HMAC or MAC
- IP datagram integrity assurance by HMAC or MAC
- Replay detection and protection by sequence number

The IPsec feature inserts the AH header after the IP header in transport mode. Transport mode with AH authenticates only the payload of the IP packet.

Tunnel mode authenticates the entire IP packet, including the IP header and data, to provide a secure hop between two hosts, two routers, or a router and a host.

You can apply AH alone, or in combination with the Encapsulating Security Payload (ESP).

The following figures show an original IP packet and an IP packet with an AH header.

Figure 140: Original IP packet

Figure 141: AH in transport mode

Encapsulating security payload

The encapsulating security payload (ESP) encrypts traffic with use of encryption algorithms, such as 3DES, AES-CBC, and AES-CTR. The security association specifies the algorithm and key used in ESP.

The encapsulating security payload can protect origin authenticity, integrity, and confidentiality of packets. ESP supports encryption-only and authentication-only configurations. The IPsec feature inserts the ESP header after the IP header and before the next layer protocol header in transport mode. Transport mode with ESP encrypts or authenticates only the payload of the IP packet.

Tunnel mode encrypts or authenticates the entire IP packet, including the IP header and data, to provide a secure hop between two hosts, two routers, or a router and a host.

The following figures display the original IP packet and an IP packet with ESP.

Figure 142: Original IP packet

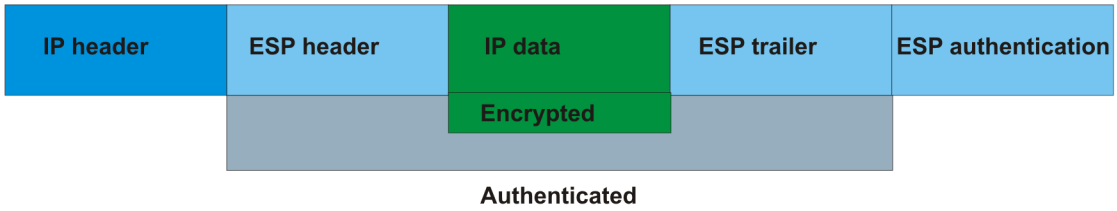

Figure 143: ESP in transport mode

IPsec modes

The IPsec feature security protocols use two different modes to protect the entire IP payload or the upper layer protocols:

- Transport mode
- Tunnel mode

Transport mode IPsec protects the upper layer protocols. In transport mode, IPsec adds an IPsec header between the IP header and upper layer protocol header.

Tunnel mode IPsec protects the whole IP packet. In tunnel mode, IPsec inserts the IPsec header between another IP datagram IP header and inner IP header.

Security association

A security association (SA) is a group of algorithms and parameters used to encrypt and authenticate the flow of IP traffic in a particular direction. An SA contains the information IPsec needs to process an IP packet. IPsec identifies SAs by:

- Security Parameter Index (SPI)
- Protocol value (either AH or ESP)
- Destination address to which the SA applies

Creation of a security association

Typically SAs exist in pairs; one in each direction, either inbound or outbound.

You can create SAs manually or dynamically. After you create an SA manually, the SA has no defined lifetime and the SA exists until you manually delete the SA.

After the device creates the SA dynamically, the SA can have a lifetime value that IPsec peers negotiate through use of a key management protocol. If the device uses the key excessively unauthorized access can occur. You must define the IPsec lifetime and other configurable parameters manually.

Security associations reside in the Security Association Database (SADB), which maintains a list of active SAs. The IPsec feature uses outbound SAs to secure the outgoing traffic and inbound SAs to process the incoming traffic. The device checks every ingress or egress packet for the IPsec base protocol, either AH or ESP. The base protocol interacts with the security policy database (SPD) and security association database (SADB) to check the level of security to apply to that packet.

The IPsec feature restricts SAs to the source and destination address of the connected router.

Security policy

Use IPsec to create IPsec security policies that define the levels of security for different types of traffic. You can use IPsec security policies to create rules to filter traffic with IPsec. IPsec policies determine what IP traffic to secure. An IPsec security policy typically consists of:

- An IP filter
- Security algorithms for authentication and key exchange
- An action

Creation of a security policy

You can configure IPsec on IPv4/IPv6 interfaces. First, create and configure an IPsec policy, and then add and enable the policy on an interface.

After you enable IPsec, the device encrypts all control traffic on the interface based on the policy. You have to specify individual policies to target a particular interface address or multiple addresses. By default, this implementation does not work on a subnet.

The Security Policy Database (SPD) maintains the IPsec security policies. The device checks every ingress or egress packet for the IPsec base protocol, either AH or ESP. The base protocol interacts with the security policy database (SPD) and security association database (SADB) to check the level of security to apply to that packet.

The IPsec feature only adds policies if the source address in the policy specified matches an interface IP address.

The IPsec feature restricts the policy match source address to the interface address of the router and destination IPv6 address.

Digital Certificates for IPsec Authentication

5720-24MXW and 5720-48MXW switches support IPsec authentication and encryption of Fabric Extend tunnels using Fabric IPsec Gateway. The default method for IPsec authentication is a pre-shared key, which is easy to configure, but does not scale well and is less secure than a certificate. You can use a digital certificate, instead of a pre-shared key, to authenticate IPsec for Fabric Extend.

Consider a hub and spoke topology with two branch locations. The network carries both private traffic and encrypted IPsec traffic. To use Public Key Infrastructure (PKI) with IPsec Fabric Extend technology, all devices must acquire the digital-signed certificates. The CA server can be accessed from the devices, a public network, or an internal network. Each device must configure a profile for the CA server. The switch uses Simple Certificate Enrollment Protocol (SCEP) to obtain the trusted, signed certificates.

5720-24MXW and 5720-48MXW

5720-24MXW and 5720-48MXW support digital certificate configuration through the Fabric IPsec Gateway virtual machine. Fabric IPsec Gateway supports both offline and online certificate management simultaneously. Use offline certificate management if the switches cannot communicate with the CA.

Fabric IPsec Gateway supports multiple CA trustpoints and multiple identity subject certificates. You can use different certificates for different IPsec tunnels. Fabric IPsec Gateway acts like a hub to isolate IPsec domains.

To use IPsec with Digital Certificates:

- Configure the Fabric Extend tunnels.
- Configure the authentication method as RSA-signature. For more information, see Configure Public Key Infrastructure for IPsec Tunnels on page 1558.
- Configure certificate information in Fabric IPsec Gateway.

For information about certificate configuration, see Extreme Integrated Application Hosting on page 770 for Fabric IPsec Gateway virtual machine configuration.

IPsec Limitations

- The IPsec feature implementation is available only in software. Hardware implementation is not available. Only control packets to and from the CPU are subject to IPsec. IPsec implements IPsec policies in the software on the control path.
- The device does not support address ranges facility for an IPsec policy.
- No fast-path support exists for IPsec.

IPsec configuration using CLI

The following section provides procedures to configure Internet Protocol Security (IPsec).

Creating an IPsec policy

Use the following procedure to configure an IPsec policy. An IPsec policy defines the level of security for different types of traffic.

Note

- You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols. You can continue to configure IPsec policies for IPv6 addresses for ICMPv6, OSPFv3, TCP, and UDP.
- If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create an IPsec policy:

   ```
   ipsec policy WORD<1-32>
   ```

3. (Optional) Delete an IPsec policy:

   ```
   no ipsec policy WORD<1-32>
   ```

Example

Create an IPsec policy named `newpolicy`:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy newpolicy
```

Variable Definitions

The following table defines parameters for the **`ipsec policy`** command.

Variable	Value
WORD<1-32>	Specifies the IPsec policy name.

Enable an IPsec Policy

Use the following procedure to enable an IPsec policy. An IPsec policy defines the level of security for different types of traffic.

Note

If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

Before You Begin

- Create an IPsec policy.

About This Task

The IPsec feature adds policies only if the admin status of the policy and the IPsec status on the interface are enabled.

If you disable the IPsec policy on an IPv4 or IPv6 interface, IPsec removes the policy-related information from the security policy database (SPD) and the security association database (SADB), but the information remains on the system. After you re-enable, the information reapplies on the interface.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable an IPsec policy:

   ```
   ipsec policy WORD<1-32> admin enable
   ```

3. (Optional) Disable an IPsec policy:

   ```
   no ipsec policy WORD<1-32> admin enable
   ```

Example

Enable an IPsec policy named `newpolicy`:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy newpolicy admin enable
```

Variable Definitions

The following table defines parameters for the **`ipsec policy`** command.

Variable	Value
`admin enable`	Enables the policy.
`WORD<1-32>`	Specifies the IPsec policy name.

Creating an IPsec security association

Use the following procedure to create an IPsec security association. A security association (SA) is a group of algorithms and parameters used to encrypt and authenticate the flow of IP traffic in a particular direction. An SA contains the information IPsec needs to process an IP packet.

About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association or to delete the security association, you must first unlink the security association from a policy.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create an IPsec security association:

   ```
   ipsec security-association WORD<1-32>
   ```

3. (Optional) Delete an IPsec security association:

   ```
   no ipsec security-association WORD<1-32>
   ```

Example

Create an IPsec security association named `newsa`:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec security-association newsa
```

Variable Definitions

The following table defines parameters for the **`ipsec security-association`** command.

Variable	Value
WORD<1-32>	Specifies the security association identifier.

Configuring an IPsec security association

Use the following procedure to configure an IPsec security association (SA). An SA is a group of algorithms and parameters used to encrypt and authenticate the flow of IP traffic in a particular direction. An SA contains the information IPsec needs to process an IP packet.

Before You Begin

- Create an IPsec security association to configure.

About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association, or to delete the security association, you must first unlink the security association from a policy. You can only unlink a security association from a policy if the policy

does not link to an interface. If a policy links to an interface, you must first unlink the policy from the interface, and then unlink the policy from the security association.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the IPsec security association key-mode:

   ```
   ipsec security-association WORD<1-32> key-mode <automatic|manual>
   ```

   This device only supports manual mode.

3. Configure the IPsec security association mode:

   ```
   ipsec security-association WORD<1-32> mode <transport|tunnel>
   ```

   This device only supports transport mode.

4. Configure the IPsec security association encapsulation protocol:

   ```
   ipsec security-association WORD<1-32> encap-proto <AH|ESP>
   ```

5. Configure the IPsec security association security parameters index:

   ```
   ipsec security-association WORD<1-32> spi <1-4294967295>
   ```

   For IPsec to function, each peer must have the same SPI value configured on both peers for a particular policy.

6. Configure the IPsec security association encryption algorithm:

   ```
   ipsec security-association WORD<1-32> Encrpt-algo <3DES|AES-CBC|AES-
   CTR|NULL> [EncrptKey WORD<1-256>][KeyLength <1-256>]
   ```

   The encryption algorithm parameters are only accessible if you configure the encapsulation protocol to ESP.

7. Configure the IPsec security association authentication algorithm:

   ```
   ipsec security-association WORD<1-32> auth-algo <AES-XCBC-MAC|MD5|
   SHA1|SHA2> [auth-key WORD<1-256>][KeyLength <1-256>]
   ```

8. Configure the IPsec security association lifetime value:

   ```
   ipsec security-association WORD<1-32> lifetime <Bytes<1-4294967295>|
   seconds<1-4294967295>
   ```

9. (Optional) Delete the IPsec security association:

   ```
   no ipsec security-association WORD<1-32>
   ```

Example

Configure an IPsec security association named new_sa to have a key-mode of `ASCII`, an SA mode of `transport`, and an encapsulation protocol of `ESP`. Configure the encryption algorithm to `3DES`, with an encryption key of `111111111111111111111111`, and a keylength of `24`. Configure the authorization algorithm to `SHA1`, the authorization key to `1111111111111111111`, and key length to `20`. Configure the SPI to `1` and the lifetime in seconds to `1000`.

```
Switch:1>enable
Switch:1#configure terminal
```

```
Switch:1(config)#ipsec security-association newsa mode transport
Switch:1(config)#ipsec security-association newsa encap-proto ESP
Switch:1(config)#ipsec security-association newsa Encrpt-algo 3DES Encrpt-key
111111111111111111111111111111111111111111111111 KeyLength 48
Switch:1(config)#ipsec security-association newsa auth-algo SHA1 auth-key
1111111111111111111 KeyLength 20
Switch:1(config)#ipsec security-association newsa key-mode manual
Switch:1(config)#ipsec security-association newsa spi 1
Switch:1(config)#ipsec security-association newsa lifetime seconds 1000
```

Variable Definitions

The following table defines parameters for the **ipsec security-association** command.

Variable	Value
WORD<1–32>	Specifies the security association.
auth-algo <AES-XCBC-MAC|MD5|SHA1|SHA2> [auth-key WORD<1–256>] [KeyLength <1–256>]	Specifies the authorization algorithm, which includes one of the following values: • AES-XCBC-MAC • MD5 • SHA1 • SHA2 The default authentication algorithm name is MD5. The parameter auth-key specifies the authentication key. The KeyLength parameter specifies a string value of 1 to 256 characters in length. The default KeyLength is 128. The KeyLength values are as follows: 3DES is 48, AES-CBC is 32, 48, or 64, AES-CTR is 32.
encap-proto <AH|ESP>	Specifies the encapsulation protocol: • AH—Specifies authentication header. • ESP—Specifies encapsulation security payload. If you configure the encapsulation protocol as AH, you cannot configure the encryption algorithms and other encryption related attributes. You can only access the encryption algorithm parameters if you configure the encapsulation protocol to ESP. The default value is ESP.
Encrpt-algo <3DES|AES-CBC|AES-CTR|NULL> [EncrptKey WORD<1–256>] [KeyLength <1–256>]	Specifies the encryption algorithm value as one of the following: • 3DES-CBC • AES-CBC • AES-CTR • NULL—Only use the NULL parameter to debug. Do not use this parameter in other circumstances. The default encryption algorithm is AES-CBC. You can only access the encryption algorithm parameters if you configure the encapsulation protocol to ESP. The EncrptKey specifies the encryption key. The KeyLength specifies the key length value in a string from 1 to 256 characters. The default KeyLength is 128. The KeyLength values are as follows: 3DES is 48, AES-CBC is 32, 48, or 64, AES-CTR is 32.

Variable	Value
key-mode <automatic | manual>	Specifies the key-mode as one of the following: • automatic • manual The default is manual.
lifetime <Bytes<1-4294967295> | seconds<1-4294967295>	Specifies the lifetime value in seconds or bytes. The default lifetime value in seconds is 28800. The default lifetime value in bytes is 4294966272.
mode <transport | tunnel>	Specifies the mode value as one of the following: • transport—Transport mode encapsulates the IP payload and provides a secure connection between two end points. • tunnel—Tunnel mode encapsulates the entire IP packet and provides a secure tunnel. The default is transport mode.
spi<1-4294967295>	Specifies the security parameters index (SPI) value, which is a unique value. SPI is a tag IPsec adds to the IP header. The tag enables the system that receives the IP packet to determine under which security association to process the received packet. For IPsec to function, each peer must have the same SPI value configured on both peers for a particular policy. The default value is 0.

Configuring an IPsec policy

Use the following procedure to configure an IPsec policy. An IPsec policy defines the level of security for different types of traffic.

Before You Begin

- Create an IPsec policy.

About This Task

You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols. You can continue to configure IPsec policies for IPv6 addresses for ICMPv6, OSPFv3, TCP, and UDP.

If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

You cannot delete or modify a policy if the policy links to a security association, or if the policy links to a port or VLAN interface. If you need to modify a policy you must first unlink the policy from the security association, and the port or VLAN interface.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the remote address:

   ipsec policy WORD<1-32> raddr WORD<1-32>

3. (Optional) Configure the local address:

   ipsec policy WORD<1-32> laddr WORD<1-32>

   The `laddr` parameter is an optional parameter that you can configure to have multiple local addresses for each remote address.

4. Configure the protocol:

   ipsec policy WORD<1-32>[protocol <icmp|icmpv6|ospfv3|tcp|udp>] [sport<1-65535|any>][dport<1-65535|any>]

5. Configure the policy action:

   ipsec policy WORD<1-32> [action <drop|permit>]

Example

Configure the remote address to `2001:db8:0:0:0:0:0:1` and local address to `2001:db8:0:0:0:0:0:15`. configure the protocol to TCP source port `4` and destination port `5`. Configure the policy to `permit`.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy Ipv6policy raddr 2001:db8:0:0:0:0:0:1
Switch:1(config)#ipsec policy Ipv6policy laddr 2001:db8:0:0:0:0:0:15
Switch:1(config)#ipsec policy Ipv6policy protocol tcp sport 4 dport 5
Switch:1(config)#ipsec policy Ipv6policy action permit
```

Configure the remote address to `192.0.1.1` and local address to `192.0.1.2`. configure the protocol to TCP source port `4` and destination port `5`. Configure the policy to `drop`.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy Ipv4policy raddr 192.0.1.1
Switch:1(config)#ipsec policy Ipv4policy laddr 192.0.1.2
Switch:1(config)#ipsec policy Ipv4policy protocol tcp sport 4 dport 5
Switch:1(config)#ipsec policy Ipv4policy action drop
```

Variable Definitions

The following table defines parameters for the **`ipsec policy`** command.

Variable	Value
action <drop|permit>	Specifies the action the policy takes. The default is permit.
laddr WORD<1-32>	Specifies the local address. The *laddr* parameter is an optional parameter that you can configure to have multiple local addresses for each remote address. The default is 0::0.

Variable	Value
protocol <icmp|icmpv6|ospfv3|tcp|udp>] [sport<1-65535>|any>] [dport<1-65535>|any>]	Specifies the protocol, as one of the following: • ICMP • ICMPv6 • OSPFv3 • TCP • UDP sport — Specifies the source port for TCP and UDP. You can specify any to configure any port as the source port. dport — Specifies the destination port for TCP and UDP. You can specify any to configure any port as the destination port. The default protocol is TCP any. IPv4 only supports ICMP, UDP, and TCP.
raddr WORD<1-32>	Specifies the remote address. The default is 0::0.
WORD<1-32>	Specifies the policy name.

Linking the IPsec security association to an IPsec policy

Use the following procedure to link the security association to an IPsec policy.

Before You Begin

- The IPsec security association and IPsec policy must exist.

About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association, or to delete the security association, you must first unlink the security association from the policy. You can only unlink a security association from a policy if the policy does not link to an interface. If a policy links to an interface, you must first unlink the policy from the interface, and then unlink the policy from the security association.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Link the IPsec security association to the IPsec policy:
   ipsec policy WORD<1-32> security-association WORD<1-32>
3. (Optional) Unlink the IPsec security association to the IPsec policy:
   no ipsec policy WORD<1-32> security-association WORD<1-32>

Example

Link the IPsec security association named `new_sa` to the IPsec policy named `newpolicy`:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ipsec policy newpolicy security-association newsa
```

Variable Definitions

The following table defines parameters for the **ipsec policy** command.

Variable	Value
WORD<1-32>	Specifies the policy ID.
security-association WORD<1-32>	Specifies the security association ID.

Enable IPsec on an Interface

Use the following procedure to enable IPsec on an interface. You can configure IPsec on a port, management port, VLAN, or loopback interface.

Note
Management interface does not support IPsec configuration.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal
   ```

   followed by one of the following:

   - `interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}`
   - `interface loopback <1-256>`
   - `interface mgmtEthernet <mgmt | mgmt2>`
   - `interface vlan <1-4059>`

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable IPsec on an IPv6 interface:

   ```
   ipv6 ipsec enable

   default ipv6 ipsec enable
   ```

3. Enable IPsec on an IPv4 interface:

   ```
   ip ipsec enable

   default ip ipsec enable
   ```

4. (Optional) Disable IPsec on an IPv6 interface:

   ```
   no ipv6 ipsec enable
   ```

5. (Optional) Disable IPsec on an IPv4 interface:

   ```
   no ip ipsec enable
   ```

Example

Enable IPsec for IPv6 on VLAN 100:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 100
Switch:1(config-if)#ipv6 ipsec enable
```

Variable Definition

The following table defines parameters for the **ip ipsec** and **ipv6 ipsec** commands.

Variable	Value
enable	Enables IPsec on the interface.

Link an IPsec Policy to an Interface

Use the following procedure to link an IPsec policy to an interface, and configure a policy direction. By default, the direction is both.

Before You Begin

- You must enable IPsec on the interface first, and then you link the IPsec policy to the interface.

About This Task

You cannot delete or modify an IPsec policy if the policy links to a port or VLAN interface. If you need to modify the policy, first unlink the policy from the port or VLAN interface.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal
   ```

   followed by one of the following:

   - `interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}`
   - `interface loopback <1-256>`
   - `interface mgmtEthernet <mgmt | mgmt2>`
   - `interface vlan <1-4059>`

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Link the IPsec policy to an IPv4 interface:

   ```
   ip ipsec policy WORD<1-32> dir <both|in|out>
   ```

3. Link the IPsec policy to an IPv6 interface:

   ipv6 ipsec policy WORD<1-32> dir <both|in|out>

4. (Optional) Unlink the IPsec policy from an IPv4 interface:

   no ip ipsec policy WORD<1-32> dir <both|in|out>

5. (Optional) Unlink the IPsec policy from an IPv6 interface:

   no ipv6 ipsec policy WORD<1-32> dir <both|in|out>

Example

Link the IPsec policy newpolicy to the IPv6 interface VLAN 100:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 100
Switch:1(config-if)#ipv6 ipsec policy newpolicy dir both
```

Variable Definitions

The following table defines parameters for the **ip ipsec policy** and **ipv6 ipsec policy** commands.

Variable	Value
WORD<1-32>	Specifies the policy ID.
dir <both|in|out>	Specifies the direction you want to protect with IPsec: • both—Specifies both ingress and egress traffic. • in—Specifies ingress traffic. • out—Specifies egress traffic. The default is both.

Configure Public Key Infrastructure for IPsec Tunnels

Note

This procedure applies to 5720-24MXW and 5720-48MXW.

Before You Begin

- Configure the Fabric Extend tunnels between the branch and hub switches.
- Configure digital certificates on the switch using Fabric IPsec Gateway virtual machine.

About This Task

5720-24MXW and 5720-48MXW switches support IPsec authentication and encryption of Fabric Extend tunnels using Fabric IPsec Gateway. You can use a digital certificate to authenticate IPsec for Fabric Extend.

The default IPsec authentication method for Fabric Extend tunnels is a pre-shared key. If you configure the authentication method to RSA signature, the tunnels use the installed digital certificate.

Procedure

On 5720-24MXW and 5720-48MXW , configure IPsec authentication in the Fabric IPsec Gateway virtual machine:

a. Enter Fabric IPsec Gateway Configuration mode:

```
enable

virtual-service WORD<1-128> console
```

Note

Type `CTRL+Y` to exit the console.

b. Configure the authentication type as RSA signature:

```
set ipsec <1-255> auth-method rsasig
```

Variable Definitions

The following table defines parameters for the **`set ipsec`** command.

Variable	Value
<1-255>	Specifies the tunnel ID.
<subject-label>	Specifies the subject identity.
cert-subject-nameWORD<1-45>	Specifies the digital certificate subject name to be used as the identity certificate. If a subject name is not specified, the default certificate subject name is Global.

Display IPsec Information on an Interface

Use the following procedure to display IPsec information on an interface.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the IPsec status on an Ethernet interface:

   show ipsec interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
3. Display the IPsec status on a VLAN interface:

   show ipsec interface vlan <1-4059>
4. Display the IPsec status on a loopback interface:

   `show ipsec interface loopback <1-256>`

Example

Display the IPsec status on a VLAN interface:

```
Switch:1>show ipsec interface vlan 22
================================================================================================
                          VLAN Interface Policy Table

================================================================================================
Vlan Interface         Policy Name            IPsec State          Direction
```

```
--------------------------------------------------------------------------------
22                  AAA                 Enable              both
22                  tcp                 Enable              both
22                  icmp                Enable              both
```

Variable Definitions

The following table defines parameters for the **show ipsec interface** command.

Variable	Value
gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
loopback <1-256>	Specifies the loopback interface.
vlan <1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Displaying configured IPsec policies

Use the following procedure to display IPsec policies.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all of the IPsec policies on the switch:

   show ipsec policy all
3. Display a specific IPsec policy based on the policy name on the interface:

   show ipsec policy interface WORD<1-32>
4. Display the IPsec policy based on the policy name:

   show ipsec policy name WORD<1-32>

Example

Display IPsec policy information:

```
Switch:1>show ipsec policy all
================================================================================
                              IPSEC Policy Table
================================================================================
PolicyName          : ospf1
LocalAddress: 0::0
RemoteAddress: 0::0
Protocol: ospfv3
src-port: 0
dest-port: 0
Action: Permit
Admin: Enable
```

```
Switch:1>show ipsec policy interface ospf1

================================================================================
                          IPsec Policy Interface Table
================================================================================
--------------------------------------------------------------------------------
POLICY NAME       InterfaceIndex            Policy State   Direction
--------------------------------------------------------------------------------
ospf1              2/3                           Enable      both

Switch:1>show ipsec policy name ospf1
================================================================================
                                IPSEC Policy Table
================================================================================
PolicyName          : ospf1
LocalAddress: 0::0
RemoteAddress: 0::0
Protocol: ospfv3
src-port: 0
dest-port: 0
Action: Permit
Admin: Enable
```

Variable Definitions

The following table defines parameters for the **show ipsec policy** command.

Variable	Value
all	Displays all of the IPsec policies on the switch.
interface WORD<1-32>	Displays a specific IPsec policy based on the policy name on the interface.
name WORD<1-32>	Displays the IPsec policy based on the name of the policy.

Displaying IPsec security association information

Use the following procedure to display IPsec security association information.

Procedure

1. Enter Privileged EXEC mode:
   `enable`
2. Display all IPsec security associations:
   `show ipsec sa all`
3. Display a specific IPsec security association:
   `show ipsec sa name WORD<1-32>`
4. Display all security associations linked to a specific policy:
   `show ipsec sa-policy`

Example

Display information on IPsec security association policies:

```
Switch:1>enable
Switch:1#show ipsec sa all
================================================================================
```

```
                        IPSEC Security Association Table
================================================================================
sa-name: ospf1

 ospf1             ospf1
--------------------------------------------------------------------------------
```

Variable Definitions

The following table defines parameters for the **show ipsec sa** command.

Variable	Value
all	Displays all security associations.
name WORD<1-32>	Displays a specific security association based on name.

Use the data in the following table to use the **show ipsec** command.

Variable	Value
sa-policy	Displays all security associations linked to a specific policy.

View IPSec Statistics

Use the following procedure to clear Internet Protocol Security (IPSec) system statistics counters and view IPSec statistics on an interface. The device only clears system statistics counters on system reboot.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View IPSec statistics for the system:

   show ipsec statistics system
3. View IPSec statistics for an Ethernet interface:

   show ipsec statistics gigabitethernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
4. View IPSec statistics for a VLAN interface:

   show ipsec statistics vlan <1-4059>
5. View statistics for IPSec on the loopback interface:

   show ipsec statistics loopback *<1-256>*
6. Clear IPSec system statistics counters:

   clear ipsec stats all

Example

View IPSec statistics. Output is partial due to length.

```
Switch:1>show ipsec statistics system

================================================================================
                            IPSEC Global Statistics

InESPFailures        = 0
OutSuccesses         = 0
OutSPViolations      = 0
OutNotEnoughMemories = 0
generalError         = 0
```

Variable Definitions

Use the data in the following table to use the **`show ipsec statistics`** command.

Variable	Value
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
loopback <1-256>	Identifies the loopback interface.
system	Shows statistics for the entire system.
vlan <1-4059>	Specifies the VLAN.

IPsec configuration using EDM

The following section provides procedures to configure Internet Protocol security (IPsec).

Create an IPsec Policy

Use the following procedure to configure an IPsec policy for an IPv4 or an IPv6 interface. An IPsec policy defines the level of security for different types of traffic.

Note

- You can only configure the IPsec policies for IPv4 addresses for UDP, TCP, and ICMPv4 protocols. You can continue to configure IPsec policies for IPv6 addresses for ICMPv6, OSPFv3, TCP, and UDP.
- If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

About This Task

You cannot delete or modify a policy if the policy links to a security association, or if the policy links to a port or VLAN interface. If you need to modify a policy you must first unlink the policy from the security association, and the port or VLAN interface.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Control Path**.
2. Select **IPSec**.
3. Select the **Policy** tab.
4. Select **Insert**.
5. In the **Name** field, type a policy name.
6. Complete the remaining optional configuration to customize the policy.
7. Select **Insert**.

Policy field descriptions

Use the data in the following table to use the **Policy** tab.

Name	Description
Name	Specifies the IPsec policy name.
DstAddress	Specifies the remote address. This field accepts IPv4 and IPv6 address, depending on the selected source address type.
SrcAddress	Specifies the local address. The local address is optional that you can configure to have multiple local addresses for each remote (destination) address. This field accepts IPv4 and IPv6 address, depending on the selected source address type.

Name	Description
SrcPort	Specifies the source port for TCP and UDP. Leave this field empty to configure any port as the source port. The default is value is 1.
DstPort	Specifies the destination port for TCP and UDP. Leave this field empty to configure any port as the destination port. The default value is 1.
AdminFlag	Enables or disables the policy. The default is disabled.
L4Protocol	Specifies the protocol, as one of the following: • tcp • udp • icmp • icmpv6 • ospfv3 IPv4 interfaces only support TCP, UDP, and ICMP. The default is TCP.
Action	Specifies the action the policy takes. The default is to permit the packet.

Create an IPsec Security Association

Use the following procedure to create an IPsec security association. A security association (SA) is a group of algorithms and parameters used to encrypt and authenticate the flow of IP traffic in a particular direction. An SA contains the information IPsec needs to process an IP packet.

About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association or to delete the security association, you must first unlink the security association from a policy.

You can only unlink a security association from a policy if the policy does not link to an interface. If a policy links to an interface, you must first unlink the policy from the interface, and then unlink the policy from the security association.

Procedure

1. In the navigation pane, expand**Configuration** > **Security** > **Control Path**.
2. Click **IPSec**.
3. Click the **Security Association** tab.
4. Click **Insert**.
5. In the **Name** field, type a name to identify the SA.
6. In the **SPI** field, type the security parameters index.

Note

For IPsec to function, each peer must have the same SPI value configured for a particular policy.

7. Complete the remaining optional configuration.
8. Click **Insert**.

Security Association field descriptions

Use the data in the following table to use the **Security Association** tab.

Name	Description
Name	Specifies the name of the security association.
Spi	Specifies the security parameters index (SPI) value, which is a unique value. SPI is a tag IPsec adds to the IP header. The tag enables the system that receives the IP packet to determine under which security association to process the received packet. For IPsec to function, each peer must have the same SPI value configured for a particular policy. The default value is 0.
HashAlgorithm	Specifies the authorization algorithm, which includes one of the following values: • AESXCBC • MD5 • SHA1 • SHA2 The default authentication algorithm name is MD5.
EncryptAlgorithm	Specifies the encryption algorithm value as one of the following: • DES3CBC • AES128CBC • AESCTR • NULL—Only use the NULL parameter to debug. Do not use this parameter in any other circumstance. The default encryption algorithm is AES128CBC. You can only access the encryption algorithm parameters if you configure the encapsulation protocol to ESP.
AuthMethod	Specifies the encapsulation protocol: • ah—Specifies authentication header. • es—Specifies encapsulation security payload. If you configure the encapsulation protocol as ah, you cannot configure the encryption algorithms and other encryption related attributes. You can only access the encryption algorithm parameters if you configure the encapsulation protocol to es. The default value is es.

Name	Description
Mode	Specifies the mode value as one of the following: • transport—Transport mode encapsulates the IP payload and provides a secure connection between two end points. This device only supports transport mode. • tunnel—Tunnel mode encapsulates the entire IP packet and provides a secure tunnel. This device does not support tunnel mode. The default is transport mode.
KeyMode	Specifies the key-mode as one of the following: • manual • auto The default is manual.
EncryptKeyName	Specifies the encryption key.
EncryptKeyLength	Specifies the numbers of bits used in the encryption key. The key length values are as follows: • DES3CBC is 48 • AES128CBC is 32, 48, 64 • AESCTR is 32
HashKeyName	Specifies the authentication key.
HashKeyLength	Specifies the numbers of bits used in the hash key. The key length values are as follows: • AESXCBC is 32 • MD5 is 32 • SHA1 is 40
LifetimeSeconds	Specifies the lifetime value in seconds. The lifetime determines the traffic that can pass between IPsec peers using a security association before that security association expires. The default lifetime value in seconds is 28800.
LifetimeKbytes	Specifies the lifetime value in kilobytes. The lifetime determines the traffic that can pass between IPsec peers using a security association before that security association expires. The default lifetime value in bytes is 4294967295.

Link the IPsec Security Association to an IPsec Policy

Use the following procedure to link the security association to an IPsec policy.

About This Task

You cannot delete or modify a security association if the security association links to a policy. To modify a parameter in the security association, or to delete the security association, you must first unlink the security association from the policy. You can only unlink a security association from a policy if the policy

does not link to an interface. If a policy links to an interface, you must first unlink the policy from the interface, and then unlink the policy from the security association.

Before You Begin

- The IPsec security association and IPsec policy must exist.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Control Path**.
2. Click **IPSec**.
3. Click the **Policy SA Link** tab.
4. Click **Insert**.
5. In the **PolicyName** field, type the IPsec policy name.
6. In the **SAName** field, type the security association name.
7. Click **Insert**.

Policy SA Link field descriptions

Use the data in the following table to use the **Policy SA Link** tab.

Name	Description
PolicyName	Specifies the name of the IPsec policy.
SAName	Specifies the name of the security association.

Enable IPsec on an IPv6 Interface

Use the following procedure to enable IPsec on an IPv6 interface.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Control Path**.
2. Select **IPSec**.
3. Select the **IPv6 Interfaces** tab.
4. In the IpsecEnable column, double-click in the **IpsecEnable** field, and select **enable** from the drop-down box.
5. Select **Apply**.

Enable IPsec on an IPv4 Interface

Use the following procedure to enable IPsec on an IPv4 interface.

Note

If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Control Path**.

2. Click **IPSec**.
3. Click the **IPv4 Interfaces** tab.
4. In the IpsecEnable column, double-click in the **IpsecEnable** field, and select **enable** from the drop-down box.
5. Click **Apply**.

IPv4 Interfaces tab field descriptions

Use the data in the following table to use the **IPv4 Interfaces** tab.

Name	Description
Interface	Specifies the interface.
IpsecEnable	Specifies if IPsec is enabled on that particular interface.

Link an IPsec Policy to an Interface

Use the following procedure to link an IPsec policy to an interface, and configure a policy direction. By default, the direction is both.

Before You Begin

- You must enable IPsec on the interface first, and then you link the IPsec policy to the interface.

About This Task

You cannot delete or modify an IPsec policy if the policy links to a port or VLAN interface. If you need to modify the policy, first unlink the policy from the port or VLAN interface.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Control Path**.
2. Select **IPSec**.
3. Select the **Interface Policy** tab.
4. Select **Insert**.
5. In the **Name** field, type the name of the IPsec policy.
6. In the **IfIndex** field, select either **Port** or **Vlan**, and then select an interface.
7. Select **Okay**.
8. Complete the remaining optional configuration.
9. Select **Insert**.

Interface Policy *Field Descriptions*

Use the data in the following table to use the **Interface Policy** tab.

Name	Description
Name	Specifies the IPsec policy name.
IfIndex	Links a policy to an interface.

Name	Description
IfEnabled	Shows if the IPsec is enabled on the interface and if the administrative state of the policy is enabled.
IfDirection	Specifies the direction you want to protect with IPsec: • inbound—Specifies ingress traffic. • outbound—Specifies egress traffic. • bothDirections—Specifies both ingress and egress traffic. The default is bothDirections.

Display IPsec Interface Statistics

Use this procedure to view IPsec statistics and counter values for each IPsec-enabled interface.

About This Task

If you select an interface on the **Stats** tab, you can click **Graph** to graph particular statistics for that interface.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Control Path**.
2. Click **IPSec**.
3. Click the **Interface Stats** tab.

Interface Stats Field Descriptions

Use the data in the following table to use the **Interface Stats** tab.

Name	Description
IfIndex	Shows the interface index for which the statistic is captured.
InSuccesses	Specifies the number of ingress packets IPsec successfully carries.
InSPViolations	Specifies the number of ingress packets IPsec discards since boot time because of a security policy violation.
InNotEnoughMemories	Specifies the number of ingress packets IPsec discards since boot time because not enough memory is available.
InAHESPReplays	Specifies the number of ingress packets IPsec discards since boot time because the AH replay check fails.
InESPReplays	Specifies the number of ingress packets IPsec discards since boot time because the ESP replay check fails.

Name	Description
InAHFailures	Specifies the number of ingress packets IPsec discards since boot time because the AH authentication check fails.
InESPFailures	Specifies the number of ingress packets IPsec discards since boot time because the ESP authentication check fails.
OutSuccesses	Specifies the number of egress packets IPsec successfully carries since boot time.
OutSPViolations	Specifies the number of egress packets IPsec discards since boot time because a security policy violation occurs.
OutNotEnoughMemories	Specifies the number of egress packets IPsec discards since boot time because not enough memory is available since boot time.
generalError	Specifies a general error.
InAhSuccesses	Specifies the number of ingress packets IPsec carries because the AH authentication succeeds.
OutAHSuccesses	Specifies the number of egress packets IPsec successfully carries since boot time.
InESPSuccesses	Specifies the number of ingress packets IPsec carries since boot time because the ESP authentication succeeds.
OutESPSuccesses	Specifies the number of egress packets IPsec successfully carries since boot time.
OutKBytes	Specifies the total number of kilobytes on egress.
OutBytes	Specifies the total number of bytes on egress.
InKBytes	Specifies the total number of bytes on ingress.
InBytes	Specifies the total number of bytes on ingress.
TotalPacketsProcessed	Specifies the total number of packets processed.
TotalPacketsByPassed	Specifies the total number of packets bypassed.
OutAHFailures	Specifies the number of egress packets IPsec discards since boot time because the AH authentication check fails.
OutESPFailures	Specifies the number of egress packets IPsec discards since boot time because the ESP authentication check fails.
InMD5Hmacs	Specifies the number of inbound HMAC MD5 occurrences since boot time.
InSHA1Hmacs	Specifies the number of inbound HMAC SHA1 occurrences since boot time.
InAESXCBCs	Specifies the number of inbound AES XCBC MAC occurrences since boot time.

Name	Description
InAnyNullAuth	Specifies the number of inbound null authentication occurrences since boot time.
In3DESCBCs	Specifies the number of inbound 3DES CBC occurrences since boot time.
InAESCBCs	Specifies the number of inbound AES CBC occurrences since boot time.
InAESCTRs	Specifies the number of inbound AES CTR occurrences since boot time.
InAnyNulEncrypt	Specifies the number of inbound null occurrences since boot time. Used for debugging purposes.
OutMD5Hmacs	Specifies the number of outbound HMAC MD5 occurrences since boot time.
OutSHA1Hmacs	Specifies the number of outbound HMAC SHA1 occurrences since boot time.
OutAESXCBCs	Specifies the number of outbound AES XCBC MAC occurrences since boot time.
OutInAnyNullAuth	Specifies the number of outbound null authentication occurrences since boot time.
Out3DESCBCs	Specifies the number of outbound 3DES CBC occurrences since boot time.
OutAESCBCs	Specifies the number of outbound AES CBC occurrences since boot time.
OutAESCTRs	Specifies the number of outbound AES CTR occurrences since boot time.
OutInAnyNullEncrypt	Specifies the number of outbound null occurrences since boot time. Used for debugging purposes.

Graphing IPsec Interface Statistics

Use this procedure to graphically view IPsec statistics and counter values for each IPsec-enabled interface.

About This Task

If you select an interface on the **Stats** tab, you can click **Graph** to graph particular statistics for that interface.

Procedure

1. In the navigation pane, expand the **Security** > **Control Path** folders.
2. Click **IPSec**.
3. Click the **Interface Stats** tab.
4. Select a row, and click **Graph**.
5. Select one of the parameters, and click the appropriate icon in the upper-left corner of the menu bar to draw a line chart, area chart, bar chart, or a pie chart.

6. To clear existing counters, and fix a reference point in time to restart the counters, click **Clear Contents**.
7. To export the statistical data to a file, click **Export**.
8. To configure a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

Display Switch Level Statistics for IPsec-Enabled Interfaces

Use this procedure to view IPsec statistics and counter values at the switch level for all IPsec-enabled interfaces.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Control Path**.
2. Click **IPSec**.
3. Click the **Global Stats** tab.

Global Stats Field Descriptions

Use the data in the following table to use the **Global Stats** tab.

Name	Description
InSuccesses	Specifies the number of ingress packets IPsec successfully carries.
InSPViolations	Specifies the number of ingress packets IPsec discards since boot time because of a security policy violation.
InNotEnoughMemories	Specifies the number of ingress packets IPsec discards since boot time because not enough memory is available.
InAHESPReplays	Specifies the number of ingress packets IPsec discards since boot time because the AH replay check fails.
InESPReplays	Specifies the number of ingress packets IPsec discards since boot time because the ESP replay check fails.
InAHFailures	Specifies the number of ingress packets IPsec discards since boot time because the AH authentication check fails.
InESPFailures	Specifies the number of ingress packets IPsec discards since boot time because the ESP authentication check fails.
OutSuccesses	Specifies the number of egress packets IPsec successfully carries since boot time.
OutSPViolations	Specifies the number of egress packets IPsec discards since boot time because a security policy violation occurs.
OutNotEnoughMemories	Specifies the number of egress packets IPsec discards since boot time because not enough memory is available since boot time.

Name	Description
generalError	Specifies a general error.
InAHSuccesses	Specifies the number of ingress packets IPsec carries because the AH authentication succeeds.
OutAHSuccesses	Specifies the number of egress packets IPsec successfully carries since boot time.
InESPSuccesses	Specifies the number of ingress packets IPsec carries since boot time because the ESP authentication succeeds.
OutESPSuccesses	Specifies the number of egress packets IPsec successfully carries since boot time.
OutKBytes	Specifies the total number of kilobytes on egress.
OutBytes	Specifies the total number of bytes on egress.
InKBytes	Specifies the total number of bytes on ingress.
InBytes	Specifies the total number of bytes on ingress.
TotalPacketsProcessed	Specifies the total number of packets processed.
TotalPacketsByPassed	Specifies the total number of packets bypassed.
OutAHFailures	Specifies the number of egress packets IPsec discards since boot time because the AH authentication check fails.
OutESPFailures	Specifies the number of egress packets IPsec discards since boot time because the ESP authentication check fails.
InMD5Hmacs	Specifies the number of inbound HMAC MD5 occurrences since boot time.
InSHA1Hmacs	Specifies the number of inbound HMAC SHA1 occurrences since boot time.
InAESXCBCs	Specifies the number of inbound AES XCBC MAC occurrences since boot time.
InAnyNullAuth	Specifies the number of inbound null authentication occurrences since boot time.
In3DESCBCs	Specifies the number of inbound 3DES CBC occurrences since boot time.
InAESCBCs	Specifies the number of inbound AES CBC occurrences since boot time.
InAESCTRs	Specifies the number of inbound AES CTR occurrences since boot time.
InAnyNulEncrypt	Specifies the number of inbound null occurrences since boot time. Used for debugging purposes.
OutMD5Hmacs	Specifies the number of outbound HMAC MD5 occurrences since boot time.
OutSHA1Hmacs	Specifies the number of outbound HMAC SHA1 occurrences since boot time.

Name	Description
OutAESXCBCs	Specifies the number of outbound AES XCBC MAC occurrences since boot time.
OutInAnyNullAuth	Specifies the number of outbound null authentication occurrences since boot time.
Out3DESCBCs	Specifies the number of outbound 3DES CBC occurrences since boot time.
OutAESCBCs	Specifies the number of outbound AES CBC occurrences since boot time.
OutAESCTRs	Specifies the number of outbound AES CTR occurrences since boot time.
OutInAnyNullEncrypt	Specifies the number of outbound null occurrences since boot time. Used for debugging purposes.

Configure IPsec for the OSPF Virtual Link

Use the following procedure to configure and enable IPsec for the OSPF virtual link.

IPsec is disabled by default.

About This Task

Until you enable IPsec on both sides of the virtual links, the links cannot exchange OSPFv3 control messages, and the system drops OSPFv3 exchange packets.

You must disable IPsec before you can perform virtual link policy configuration changes.

Before You Begin

- Configure the OSPF virtual link.
- Create the IPsec security association.

Procedure

1. In the navigation pane, expand **Configuration** > **Security** > **Control Panel**.
2. Click **IPSec**.
3. Click the **OSPF Virtual Link** tab.
4. Click **Insert**.
5. Specify the area ID.
6. Specify the neighbor address.
7. Complete the remaining optional configuration.
8. Click **Insert**.

OSPF Virtual Link field descriptions

Use the data in the following table to use the **OSPF Virtual Link** tab.

Name	Description
AreaId	Identifies the OSPF virtual link area.
Neighbor	Identifies the OSPF virtual link neighbor.
SAName	Links the security association to the OSPF virtual link.
AdminStatus	Enables the policy. The default is disabled.
Action	Configures the action of the IPsec policy under the OSPF virtual tunnel to one of the following: • permit—Permits the IP packets. • drop—Drops the IP packets. The default is permit.
Direction	Specifies the direction you want to protect with IPsec: • inBound—Specifies ingress traffic. • outBound—Specifies egress traffic. • bothDirections—Specifies both ingress and egress traffic. The default is bothDirections.
SrcAddress	Shows the address of the source interface to which the policy applies.
DstAddress	Shows the address of the destination interface to which the policy applies.
LinkID	Shows a unique ID for the OSPF virtual link. The default is 0.
IfIndex	Shows the interface index to which OSPF virtual link the policy applies.
OperStatus	Shows the operational status of the link, either up or down. The default is down.

IPsec configuration examples

The following section provides examples to configure Internet Protocol Security (IPsec).

Note

If you downgrade your software, the current IPsec configurations are no longer supported. You must boot with the factory default settings for IPsec, and then reconfigure the IPsec features.

IPsec configuration example

Review the following information to understand IPsec configuration.

Use the following steps to configure IPsec.

1. Create and configure an IPsec policy.
2. Enable the policy.
3. Create an IPsec security association to correspond with the IPsec policy.
4. Configure the key mode format.
5. Configure the security association.
6. Link the IPsec security association to the IPsec policy.
7. Enable the IPsec policy on the interface.
8. Link the IPsec policy with the interface.
9. Enable the IPsec on the interface that links to the IPsec policy.

For an example configuration and for more information on IPsec OSPFv3 and OSPFv3 virtual link, see OSPF on page 2168.

Create a policy named `newpolicy` with a security association named `new_sa` on VLAN 100.

The following displays the IPsec policy configuration:

```
ipsec policy newpolicy raddr 2001:db8:0:0:0:0:0:1
ipsec policy newpolicy laddr 2001:db8:0:0:0:0:0:15
ipsec policy newpolicy protocol tcp sport 4 dport 5
ipsec policy newpolicy action permit
```

The following example displays the IPsec security association:

```
ipsec security-association new_sa
ipsec security-association new_sa key-mode manual
ipsec security-association new_sa mode transport
ipsec security-association new_sa encap-proto ESP
ipsec security-association new_sa Encrpt-algo 3DES-CBC encrypt-key
111111111111111111111111 KeyLength 24
ipsec security-association new_sa auth-algo SHA1 auth-key 1111111111111111111 KeyLength
20
ipsec security-association new_sa spi 1
ipsec security-association new_sa lifetime seconds 1000
```

IPsec with ICMPv6 configuration example

The following displays configuration of IPsec with ICMPv6.

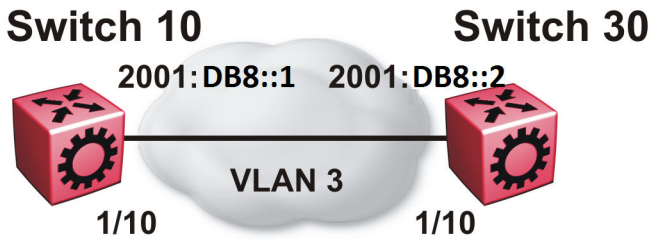

Figure 144: IPsec configuration with ICMPv6

Switch 10 security association configuration

The following example displays the configuration of the security association on Switch 10.

```
ipsec security-association icmp
ipsec security-association icmp encap-proto ESP
ipsec security-association icmp mode transport
ipsec security-association icmp spi 1
ipsec security-association icmp auth-algo SHA1 auth-key
12345678901234567890123456789012345678901234567890 keyLength 40
ipsec security-association icmp Encrpt-algo AES-CBC EncrptKey
123456789012345678901234567890123456789012 keyLength 32
ipsec security-association icmp key-mode manual
ipsec security-association icmp lifetime seconds 1
ipsec security-association icmp lifetime bytes 1
```

Switch 10 policy configuration

The following example displays the configuration of the security policy on Switch 10.

```
ipsec policy ICMP_Policy
ipsec policy ICMP_Policy admin  enable
ipsec policy ICMP_Policy raddr 2001::2
ipsec policy ICMP_Policy laddr 2001::1
ipsec policy ICMP_Policy protocol icmpv6
ipsec policy ICMP_Policy action permit
ipsec policy ICMP_Policy security-association icmp
```

Switch 10 interface configuration

The following example displays the configuration of IPsec on slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
interface vlan 3
interface address 2000::1
interface enable
ipv6 ipsec policy ICMP_Policy dir both
ipv6 ipsec enable
```

Switch 10 VLAN configuration

The following example displays the creation and configuration of VLAN 3 with IPsec.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 portmember
interface vlan 3
interface enable
interface address 2000::1
ipv6 ipsec policy ICMP_Policy dir both
ipv6 ipsec enable
```

Switch 30 security association configuration

The following example displays the configuration of the security association on Switch 30.

```
ipsec security-association icmp
ipsec security-association icmp encap-proto ESP
ipsec security-association icmp mode transport
ipsec security-association icmp spi 1
ipsec security-association icmp auth-algo SHA1 auth-key
12345678901234567890123456789012345678901234567890 keyLength 40
ipsec security-association icmp Encrpt-algo AES-CBC EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association icmp key-mode manual
ipsec security-association icmp lifetime seconds 1
ipsec security-association icmp lifetime bytes 1
```

Switch 30 policy configuration

The following example displays the configuration of the security policy on Switch 30.

```
ipsec policy ICMP_Policy
ipsec policy ICMP_Policy admin enable
ipsec policy ICMP_Policy raddr 2001::1
ipsec policy ICMP_Policy laddr 2001::2
ipsec policy ICMP_Policy action permit
ipsec policy ICMP_Policy protocol icmpv6
ipsec policy ICMP_Policy security-association icmp
```

Switch 30 interface configuration

The following example displays the configuration of IPsec on slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface enable
ipv6 interface vlan 3
ipv6 interface address 2001::2
ipv6 ipsec policy ICMP_Policy dir both
ipv6 ipsec enable
```

Switch 30 VLAN configuration

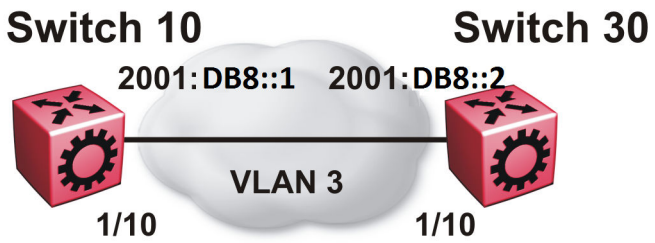
The following example displays the creation and configuration of VLAN 3 with IPsec.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 0
vlan members add 3 1/20
```

```
interface vlan 3
ipv6 interface enable
ipv6 interface address 2001::2
ipv6 ipsec policy ICMP_Policy dir both
ipv6 ipsec enable
```

OSPFv3 IPsec configuration example

The following example displays a network using IPsec used with OSPFv3.



The following example displays the configuration of IPsec with OSPFv3. For OSPFv3 conceptual and procedural information, see OSPF on page 2168.

Switch 10 security associations

The following example displays the configuration of security associations for OSPFv3 for Switch 10.

```
ipsec security-association ospf1
ipsec security-association ospf1 encap-proto ESP
ipsec security-association ospf1 mode transport
ipsec security-association ospf1 spi 1

ipsec security-association ospf6 lifetime bytes 1
```

Switch 10 policy configuration

The following example displays the configuration of policies on Switch 10. The link local address is fe80:0:0:0:b2ad:aaff:fe43:100 and the remote link local address is fe80:0:0:0:b2ad:aaff:fe43:4d00. The following displays the policy with the laddr configured to the link local address and raddr configured to the remote link local address, with the direction configured as outbound.

```
ipsec policy ospf1
ipsec policy ospf1 admin enable
ipsec policy ospf1 raddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf1 laddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf1 protocol ospfv3
ipsec policy ospf1 action permit
```

The following example displays the configuration of policies on Switch 10. The link local address is fe80:0:0:0:b2ad:aaff:fe43:100 and the remote link local address is fe80:0:0:0:b2ad:aaff:fe43:4d00. The following displays the policy with the laddr configured to the link local address and raddr configured to the remote link local address, with the direction configured as inbound.

For a policy direction of inbound, laddr and raddr are reversed before storing to the stack. Because of this, even though the policy requires you to configure the laddr as the remote link local address, you need to configure laddr as the link local address in the configuration.

```
ipsec policy ospf2
ipsec policy ospf2 admin enable
ipsec policy ospf2 raddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf2 laddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf2 protocol ospfv3
ipsec policy ospf2 action permit
```

Laddr is configured to the link local and raddr is configured to ff02::05 with the direction configured as outbound.

```
ipsec policy ospf3
ipsec policy ospf3 admin enable
ipsec policy ospf3 raddr ff02::05
ipsec policy ospf3 laddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf3 protocol ospfv3
ipsec policy ospf3 action permit
```

Laddr is configured to the remote link local and raddr is configured to ff02::05 with the direction configured as inbound.

```
ipsec policy ospf4
ipsec policy ospf4 admin enable
ipsec policy ospf4 raddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf4 laddr ff02::05
ipsec policy ospf4 protocol ospfv3
ipsec policy ospf4 action permit
```

Laddr is configured to the link local and raddr is configured to ff02::06 with the direction as outbound.

```
ipsec policy ospf5
ipsec policy ospf5 admin enable
ipsec policy ospf5 raddr ff02::06
ipsec policy ospf5 fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf5 protocol ospfv3
ipsec policy ospf5 action permit
```

Laddr is configured to the remote link local and raddr is configured to ff02::06 with the direction configured as inbound.

```
ipsec policy ospf6
ipsec policy ospf6 admin enable
ipsec policy ospf6 raddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf6 laddr ff02::06
ipsec policy ospf6 protocol ospfv3
ipsec policy ospf6 action permit
```

Switch 10 link table configuration

The following example displays the linking of the policy with the security association on Switch 10.

```
ipsec policy ospf1 security-association ospf1
ipsec policy ospf2 security-association ospf2
ipsec policy ospf3 security-association ospf3
ipsec policy ospf4 security-association ospf4
ipsec policy ospf5 security-association ospf5
ipsec policy ospf6 security-association ospf6
```

Switch 10 OSPFv3 configuration

The following example displays the OSPFv3 configuration on Switch 10.

```
router ospf ipv6-enable
router ospf
ipv6 router-id 1.1.1.1
ipv6 area 0.0.0.1
```

Switch 10 interface configuration

The following example displays the interface configuration on slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::1/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
ipv6 ipsec policy ospf1 dir out
ipv6 ipsec policy ospf2 dir in
ipv6 ipsec policy ospf3 dir out
ipv6 ipsec policy ospf4 dir in
ipv6 ipsec policy ospf5 dir out
ipv6 ipsec policy ospf6 dir in
ipv6 ipsec enable
```

Switch 10 VLAN configuration

The following example displays the creation of VLAN 3 and the configuration of IPsec on VLAN 3.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::1/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
ipv6 ipsec policy ospf1 dir out
ipv6 ipsec policy ospf2 dir in
ipv6 ipsec policy ospf3 dir out
ipv6 ipsec policy ospf4 dir in
ipv6 ipsec policy ospf5 dir out
ipv6 ipsec policy ospf6 dir in
ipv6 ipsec enable
```

Switch 30 security associations

The following example displays the configuration of security associations for OSPFv3 for Switch 30.

```
ipsec security-association ospf1
ipsec security-association ospf1 encap-proto ESP
ipsec security-association ospf1 mode transport
ipsec security-association ospf1 spi 2

Switch 30 policy configuration

In the example, the local addrress is fe80:0:0:0:b2ad:aaff:fe43:4d00, and the remote addrress is fe80:0:0:0:b2ad:aaff:fe43:100. The policy has the laddr confiugred to the link local address and the raddr is configured to the remote link local address with the direction configured to outbound.

```
ipsec policy ospf1
ipsec policy ospf1 admin enable
ipsec policy ospf1 raddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf1 laddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf1 protocol ospv3
ipsec policy ospf1 action permit
```

Laddr is configured to the remote link local address and raddr is configured to the local link local address with the direction configured to inbound.

```
ipsec policy ospf2
ipsec policy ospf2 admin enable
ipsec policy ospf2 raddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf2 laddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf2 protocol ospfv3
ipsec policy ospf2 action permit
```

Laddr is configured to the link local address and raddr is configured to ff02::05 with the direction configured to outbound.

```
ipsec policy ospf3
ipsec policy ospf3 admin enable
ipsec policy ospf3 raddr ff02::05
ipsec policy ospf3 laddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf3 protocol ospfv3
ipsec policy ospf3 action permit
```

Laddr is configured to the remote link local address and the raddr is configured to ff02::05 with the direction configured to inbound.

```
ipsec policy ospf4
ipsec policy ospf4 admin enable
ipsec policy ospf4 raddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf4 laddr ff02::05
ipsec policy ospf4 protocol ospfv3
ipsec policy ospf4 action permit
```

Laddr is configured to the link local address and raddr is configured to ff02::06 with the direction configured to outbound.

```
ipsec policy ospf5
ipsec policy ospf5 admin enable
ipsec policy ospf5 raddr ff02::06
ipsec policy ospf5 laddr fe80:0:0:0:b2ad:aaff:fe43:4d00
ipsec policy ospf5 protocol ospfv3
ipsec policy ospf5 action permit
```

Laddr is configured to the remote link local address and raddr is configured to ff02::06 with the direction configured to inbound.

```
ipsec policy  ospf6
ipsec policy  ospf6 admin enable
ipsec policy ospf6 raddr fe80:0:0:0:b2ad:aaff:fe43:100
ipsec policy ospf6 laddr ff02::06
ipsec policy ospf6 protocol ospfv3
ipsec policy ospf6 action permit
```

Switch 30 link table configuration

The following example displays the linking of the policy with the security association on Switch 30.

```
ipsec  policy ospf1 security-association ospf1
ipsec  policy ospf2 security-association ospf2
ipsec  policy ospf3 security-association ospf4
ipsec  policy ospf4 security-association ospf3
ipsec  policy ospf5 security-association ospf5
ipsec  policy ospf6 security-association ospf6
```

Switch 30 OSPFv3 configuration

The following example displays the OSPFv3 configuration on Switch 30.

```
router ospf ipv6-enable
router ospf
ipv6 router-id 2.2.2.2
ipv6 area 0.0.0.1
```

Switch 30 interface configuration

The following example displays the interface configuration on slot/port 1/10.

```
interface gigabitEthernet  1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2001::2/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
ipv6 ipsec policy ospf1 dir out
ipv6 ipsec policy ospf2 dir in
ipv6 ipsec policy ospf3 dir out
ipv6 ipsec policy ospf4 dir in
ipv6 ipsec policy ospf5 dir out
ipv6 ipsec policy ospf6 dir in
ipv6 ipsec enable
```

Switch 30 VLAN configuration

The following example displays the creation of VLAN 3 and the configuration of IPsec on VLAN 3.

```
interface gigabitEthernet 1/10
no shut
exit
minvlan create 3 type port-mstprstp 0
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2001::2/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
ipv6 ipsec policy ospf1 dir out
ipv6 ipsec policy ospf2 dir in

OSPFv3 virtual link IPsec configuration example

The following example displays a network using IPsec with OSPFv3 virtual link.

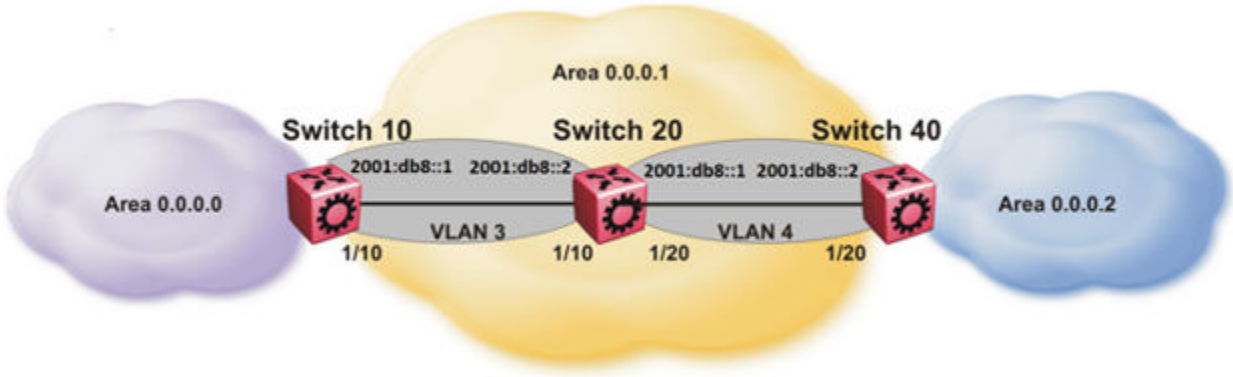

Figure 145: OSPFv3 virtual link with IPsec configuration

The following example displays the configuration of IPsec with OSPFv3 virtual link. For OSPFv3 conceptual and procedural information, see OSPF on page 2168.

Switch 10 security association configuration

The following example displays the configuration of security associations for OSPFv3 for Switch 10.

```
ipsec security-association ospf1
ipsec security-association ospf1 encap-proto ESP
ipsec security-association ospf1 mode transport
ipsec security-association ospf1 spi 1
ipsec security-association ospf1 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf1 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf1 key-mode manual
ipsec security-association ospf1 lifetime seconds 1
ipsec security-association ospf1 lifetime bytes 1
```

Switch 10 OSPFv3 configuration

The following example displays the OSPFv3 configuration on Switch 10.

```
router ospf ipv6-enable
ipv6 forwarding
router ospf
ipv6 router-id 1.1.1.1
ipv6 area 0.0.0.1
ipv6 as-boundary-router
ipv6 area 0.0.0.0
```

Switch 10 virtual link and policy configuration

The following example displays the configuration of a OSPFv3 virtual link.

```
ipv6 area virtual-link 0.0.0.1 3.3.3.3
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec security-association  ospf1
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec action permit
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec direction both
ipv6 area virtual-link 0.0.0.1 3.3.3.3 ipsec  enable
```

Switch 10 interface configuration

The following example displays the interface configuration on slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::1/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

Switch 10 VLAN configuration

The following example displays the creation of VLAN 3 and the configuration of IPsec on VLAN 3.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 port-member
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::1/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

Switch 20 OSPFv3 configuration

The following example displays the OSPFv3 configuration on Switch 20.

```
router ospf ipv6-enable
ipv6 forwarding
router ospf
ipv6 router-id 2.2.2.2
ipv6 area 0.0.0.1
```

Switch 20 interface configuration

The following example displays the interface configuration on slot/port 1/10 and 1/20.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::2/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable

interface gigabitEthernet 1/20
no shut
ipv6 interface vlan 4
ipv6 interface address 2001::1/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

Switch 20 VLAN configuration

The following example displays the creation of VLAN 3 and the configuration of IPsec on VLAN 3 and VLAN 4.

```
interface gigabitEthernet 1/10
no shut
```

```
exit
vlan create 3 type port-mstprstp 0
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::2/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable

interface gigabitEthernet 1/20
no shut
exit
vlan create 4 type port-mstprstp 0
vlan members add 4 1/20 portmember
interface vlan 4
ipv6 interface enable
ipv6 interface address 2001::1/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

Switch 40 security association configuration

The following example displays the configuration of security associations for OSPFv3 for Switch 40.

```
ipsec security-association ospf1
ipsec security-association ospf1 encap-proto ESP
ipsec security-association ospf1 mode transport
ipsec security-association ospf1 spi 1
ipsec security-association ospf1 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association ospf1 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association ospf1 key-mode manual
ipsec security-association ospf1 lifetime seconds 1
ipsec security-association ospf1 lifetime bytes 1
```

Switch 40 OSPFv3 configuration

The following example displays the OSPFv3 configuration on Switch 40.

```
router ospf ipv6-enable
ipv6 forwarding
router ospf
ipv6 router-id 3.3.3.3
ipv6 area 0.0.0.1
ipv6 area 0.0.0.2
ipv6 as-boundary-router
```

Switch 40 OSPFv3 virtual link and policy configuration

The following example displays the configuration of a OSPFv3 virtual link.

```
ipv6 area virtual-link 0.0.0.1 1.1.1.1
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec security-association  ospf1
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec action permit
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec direction both
ipv6 area virtual-link 0.0.0.1 1.1.1.1 ipsec enable
```

Switch 40 interface configuration

The following example displays the interface configuration on slot/port 1/20.

```
interface gigabitEthernet 1/20
no shut
ipv6 interface vlan 4
ipv6 interface address 2001::2/64
ipv6 interface enable
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

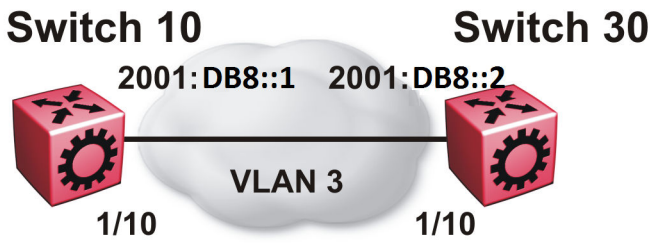
Switch 40 VLAN interface configuration

The following example displays the creation of VLAN 4 and the configuration of IPsec on VLAN 4.

```
interface gigabitEthernet 1/20
no shut
exit
vlan create 4 type port-mstprstp 0
vlan members add 4 1/20
interface vlan 4
ipv6 interface enable
ipv6 interface address 2001::2/64
ipv6 ospf area 0.0.0.1
ipv6 ospf enable
```

IPsec configuration of TCP

The following example displays the configuration of IPsec for TCP.



Switch 10 IPsec security association configuration

The following example displays the configuration of the IPsec security association for TCP for Switch 10.

```
ipsec security-association tcp1
ipsec security-association tcp1 encap-proto ESP
ipsec security-association tcp1 mode transport
ipsec security-association tcp1 spi 100
ipsec security-association tcp1 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association tcp1 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association tcp1 key-mode manual
ipsec security-association tcp1 lifetime seconds 1
ipsec security-association tcp1 lifetime bytes 1
```

Switch 10 IPsec policy configuration

The following example displays the configuration of the IPsec policy for TCP for Switch 10.

```
ipsec policy tcp1
ipsec policy tcp1 admin enable
ipsec policy tcp1 raddr 2000::2
ipsec policy tcp1 raddr 2000::2 laddr 2000::1
ipsec policy tcp1 raddr 2000::2 protocol tcp sport 23 dport 23
ipsec policy tcp1 raddr 2000::2 action permit
```

Switch 10 linking the IPsec policy with the IPsec security association

The following example displays the linking of the IPsec policy with the IPsec security association

```
ipsec policy tcp1 security-association tcp1
```

Switch 10 interface configuration

The following examples displays the configuration of IPsec for slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::1/64
ipv6 interface enable
ipv6 ipsec policy tcp1 dir both
ipv6 ipsec enable
```

Switch 10 VLAN configuration

The following example displays the creation and configuration of VLAN 3.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::1/64
ipv6 ipsec policy tcp1 dir both
ipv6 ipsec enable
```

Switch 30 IPsec security association configuration

The following example displays the configuration of the IPsec security association for TCP for Switch 10.

```
ipsec security-association tcp1
ipsec security-association tcp1 encap-proto ESP
ipsec security-association tcp1 mode transport
ipsec security-association tcp1 spi 100
ipsec security-association tcp1 auth-algo MD5 auth-key 12345678901234567890123456789012
keyLength 32
ipsec security-association tcp1 Encrpt-algo AES-CTR EncrptKey
12345678901234567890123456789012 keyLength 32
ipsec security-association tcp1 key-mode manual
ipsec security-association tcp1 lifetime seconds 1
ipsec security-association tcp1 lifetime bytes 1
```

Switch 30 IPsec policy configuration

The following example displays the configuration of the IPsec policy for TCP for Switch 10.

```
ipsec policy tcp1
ipsec policy tcp1 admin enable
ipsec policy tcp1 raddr 2000::1
ipsec policy tcp1 raddr 2000::1 laddr 2000::2
ipsec policy tcp1 raddr 2000::1 protocol tcp sport 23 dport 23
ipsec policy tcp1 raddr 2000::1 action permit
```

Switch 30 linking the IPsec policy with the IPsec security association

The following example displays the linking of the IPsec policy with the IPsec security association

```
ipsec policy tcp1 security-association tcp1
```

Switch 30 interface configuration

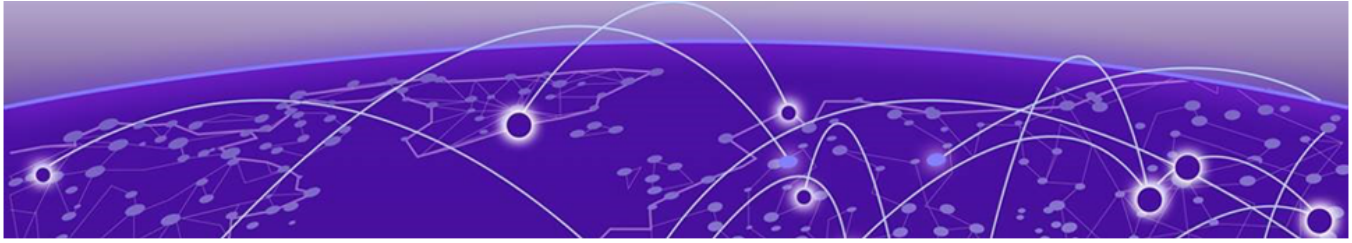
The following examples displays the configuration of IPsec for slot/port 1/10.

```
interface gigabitEthernet 1/10
no shut
ipv6 interface vlan 3
ipv6 interface address 2000::2/64
ipv6 interface enable
ipv6 ipsec policy tcp1 dir both
ipv6 ipsec enable
```

Switch 30 VLAN configuration

The following example displays the creation and configuration of VLAN 3.

```
interface gigabitEthernet 1/10
no shut
exit
vlan create 3 type port-mstprstp 3
vlan members add 3 1/10 portmember
interface vlan 3
ipv6 interface enable
ipv6 interface address 2000::2/64
ipv6 ipsec policy tcp1 dir both
ipv6 ipsec enable
```



IPv4 Routing Basics

This section provides conceptual information and procedures to configure IP Routing using Command Line Interface (CLI) and Enterprise Device Manager (EDM).

Important

For the 5320 Series, only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration.

IP routing operations fundamentals

Use the information in this section to understand IP routing.

For more information about Border Gateway Protocol (BGP), see BGP on page 355.

For more information about Open Shortest Path First (OSPF), see OSPF on page 2168. For more information about Routing Information Protocol (RIP), see RIP on page 2503.

IP addressing

An IP version 4 address consists of 32 bits expressed in dotted-decimal format (x.x.x.x). The IP version 4 address space is divided into classes, with classes A, B, and C reserved for unicast addresses and accounting for 87.5 percent of the 32-bit IP address space. Class D is reserved for multicast addressing. The following table lists the breakdown of IP address space by address range and mask.

Class	Address range	Mask	Number of addresses
A	1.0.0.0 to 126.0.0.0	255.0.0.0	126
B	128.0.0.0 to 191.0.0.0	255.255.0.0	127 * 255
C	192.0.0.0 to 223.0.0.0	255.255.255.0	31 * 255 * 255
D	224.0.0.0 to 239.0.0.0		

To express an IP address in dotted-decimal notation, you convert each octet of the IP address to a decimal number and separate the numbers by decimal points. For example, you specify the 32-bit IP address 10000000 00100000 00001010 10100111 in dotted-decimal notation as 128.32.10.167.

Each IP address class, when expressed in binary, has a different boundary point between the network and host portions of the address as illustrated in the following figure. The network portion is a network number field from 8 through 24 bits. The remaining 8 through 24 bits identify a specific host on the network.

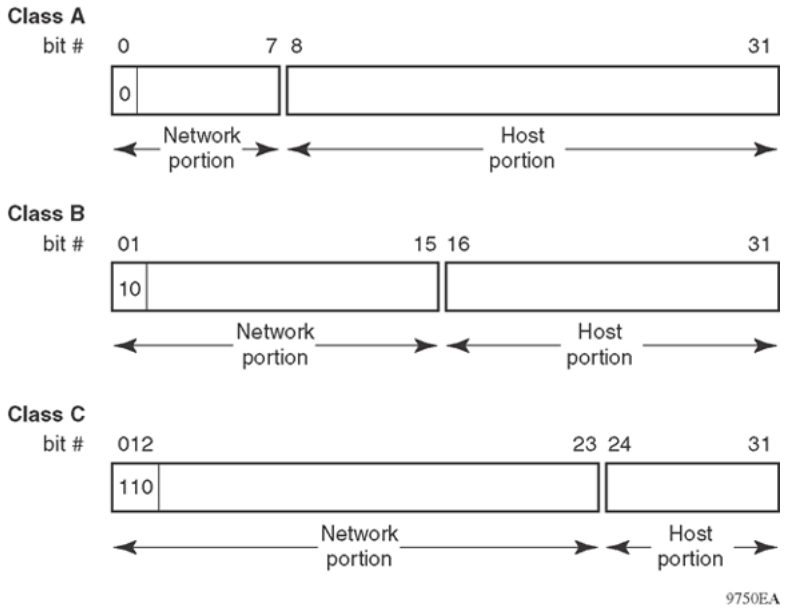


Figure 146: Network and host boundaries in IP address classes

Subnet Addressing

Subnetworks (or subnets) extend the IP addressing scheme an organization uses to one with an IP address range for multiple networks. Subnets are two or more physical networks that share a common network-identification field (the network portion of the 32-bit IP address).

You create a subnet address by increasing the network portion to include a subnet address, thus decreasing the host portion of the IP address. For example, in the address 128.32.10.0, the network portion is 128.32, while the subnet is found in the first octet of the host portion (10). A subnet mask is applied to the IP address and identifies the network and host portions of the address.

The following table illustrates how subnet masks used with class B and class C addresses can create differing numbers of subnets and hosts. This example includes the zero subnet, which is permitted on the switch.

Table 108: Subnet masks for class B and class C IP addresses

Number of bits	Subnet mask	Number of subnets	Number of hosts for each subnet
Class B			
2	255.255.192.0	2	16 382
3	255.255.224.0	6	8 190
4	255.255.240.0	14	4 094
5	255.255.248.0	30	2 046

Table 108: Subnet masks for class B and class C IP addresses (continued)

Number of bits	Subnet mask	Number of subnets	Number of hosts for each subnet
6	255.255.252.0	62	1 022
7	255.255.254.0	126	510
8	255.255.255.0	254	254
9	255.255.255.128	510	126
10	255.255.255.192	1 022	62
11	255.255.255.224	2 046	30
12	255.255.255.240	4 094	14
13	255.255.255.248	8 190	6
14	255.255.255.252	16 382	2
Class C			
1	255.255.255.128	0	126
2	255.255.255.192	2	62
3	255.255.255.224	6	30
4	255.255.255.240	14	14
5	255.255.255.248	30	6
6	255.255.255.252	62	2

You use variable-length subnet masking (VLSM) to divide your intranet into pieces that match your requirements. Routing is based on the longest subnet mask or network that matches. Routing Information Protocol version 2 and Open Shortest Path First are routing protocols that support VLSM.

Supernet Addressing and CIDR

A supernet, or classless interdomain routing (CIDR) address, is a group of networks identified by contiguous network addresses. IP service providers can assign customers blocks of contiguous addresses to define supernets as needed. You can use supernetting to address an entire block of class C addresses and avoid using large routing tables to track the addresses.

Each supernet has a unique supernet address that consists of the upper bits shared by all of the addresses in the contiguous block. For example, consider the class C addresses shown in the following figure. By adding the mask 255.255.128.0 to IP address 192.32.128.0, you aggregate the addresses 192.32.128.0 through 192.32.255.255 and 128 class C addresses use a single routing advertisement. In the bottom half of the following figure, you use 192.32.0.0/17 to aggregate the 128 addresses (192.32.0.0/24 to 192.32.127.0/24).

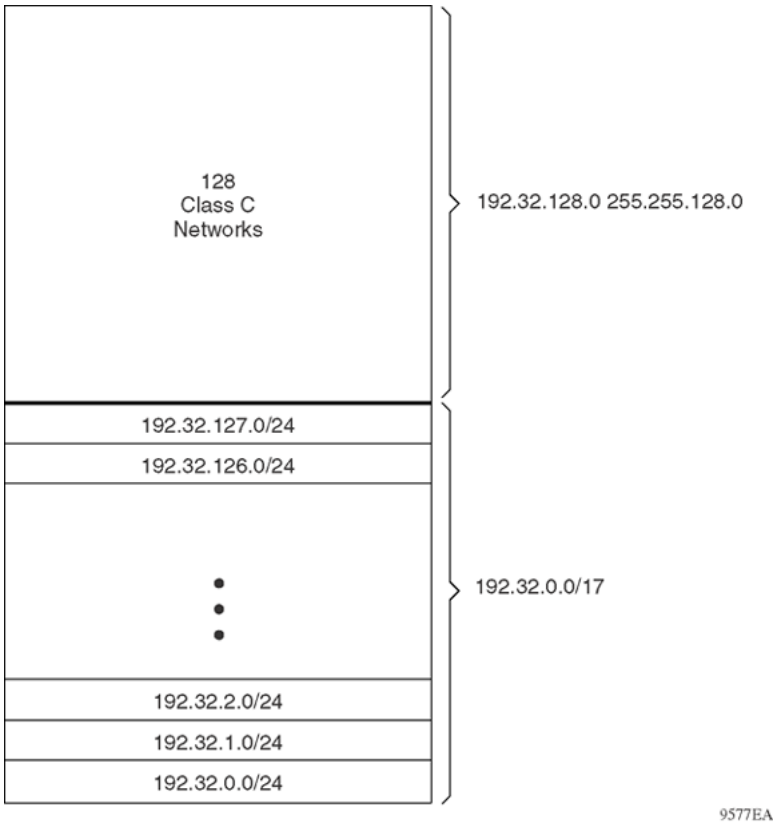

Figure 147: Class C address supernet

Another example is the block of addresses 192.32.0.0 to 192.32.7.0. The supernet address for this block is 11000000 00100000 00000, with the 21 upper bits shared by the 32-bit addresses.

A complete supernet address consists of an address and mask pair:

- The address is the first 32-bit IP address in the contiguous block. In this example, the address is 11000000 00100000 00000000 00000000 (192.32.0.0 in dotted-decimal notation).
- The mask is a 32-bit string containing a set bit for each bit position in the supernet part of the address. The mask for the supernet address in this example is 11111111 11111111 11111000 00000000 (255.255.248.0 in dotted-decimal notation).

The complete supernet address in this example is 192.32.0.0/21.

Although classes prohibit using an address mask with the IP address, you can use CIDR to create networks of various sizes using the address mask. With CIDR, the routers outside the network use the addresses.

Loopback

Circuitless IP (CLIP) is a virtual (or loopback) interface that is not associated with a physical port. You can use the CLIP interface to provide uninterrupted connectivity to your device as long as a path exists to reach the device.

For example, as shown in the following figure, a physical point-to-point link exists between R1 and R2 along with the associated addresses (195.39.1.1/30 and 195.39.1.2/30). Use an interior Border Gateway

Protocol (iBGP) session between two additional addresses, 195.39.128.1/30 (CLIP 1) and 195.39.281.2/30 (CLIP 2).

CLIP 1 and CLIP 2 represent the virtual CLIP addresses that you configure between R1 and R2. These virtual interfaces are not associated with the physical link or hardware interface, which permits the BGP session to continue as long as a path exists between R1 and R2. An IGP (such as OSPF) routes addresses that correspond to the CLIP addresses. After the routers learn all the CLIP addresses in the AS, the system establishes iBGP and exchanges routes.

The system advertises loopback routes to other routers in the domain either as external routes using the route-redistribution process, or after you enable OSPF in passive mode to advertise an OSPF internal route.

You can also use CLIP for PIM-SM, typically, as a Rendezvous Point (RP), or as a source IP address for sending SNMP traps and Syslog messages.

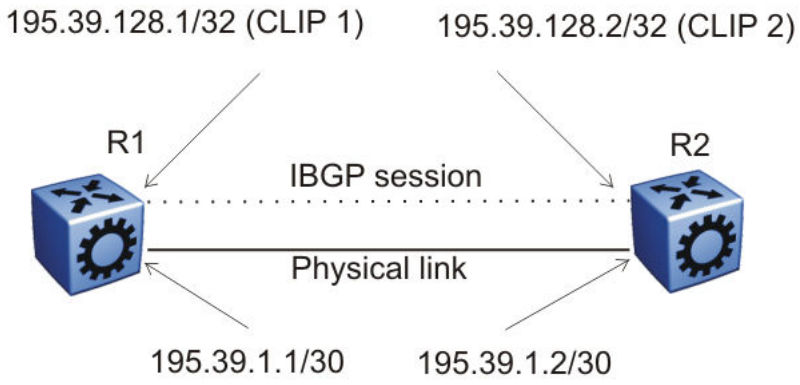

Figure 148: Routers with iBGP connections

The system treats the CLIP interface as an IP interface. The network associated with the CLIP is treated as a local network attached to the device. This route always exists and the circuit is always up because there is no physical attachment.

Static routes

Table 109: Static routing product support

Feature	Product	Release introduced
Static routing	5320 Series	Fabric Engine 8.6 Only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration.
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

A static route is a route to a destination IP address that you manually create.

Create static routes to enhance network stability. Use the local next hop option to configure a static route with or without local next hop.

You can configure static routes with a next hop that is not directly connected, but that hop must be reachable. Otherwise, the static route is not enabled.

Layer 3 redundancy supports only address resolution protocol (ARP) and static route. Static ARP must configure the nonlocal next-hop of static routes. No other dynamic routing protocols provide nonlocal next-hop.

Note

Static ARP entries are not supported for NLB Unicast or NLB Multicast operations.

You can use a default static route to specify a route to all networks for which no explicit routes exist in the forwarding information base or the routing table. This route has a prefix length of zero (RFC1812). You can configure the switch with a route through the IP static routing table.

To create a default static route, you must configure the destination address and subnet mask to 0.0.0.0.

Note

Do not configure static routes on a DvR Leaf node unless the configuration is for reachability to a management network using a brouter port.

Also, configuring the preference of static routes is not supported on a Leaf node.

Static Route Tables

A router uses the system routing table to make forwarding decisions. In the static route table, you can change static routes directly. Although the two tables are separate, the static route table manager entries are automatically reflected in the system routing table if the next-hop address in the static route is reachable, and if the static route is enabled.

The system routing table displays only active static routes with a best preference. A static route is active only if the route is enabled and the next-hop address is reachable (for example, if a valid ARP entry exists for the next hop).

You can enter multiple routes (for example, multiple default routes) that have different costs, and the routing table uses the lowest cost route that is available. However, if you enter multiple next hops for the same route with the same cost, the software does not replace the existing route. If you enter the same route with the same cost and a different next-hop, the first route is used. If the first route becomes unreachable, the second route (with a different next-hop) is activated with no connectivity loss.

Routing Protocols

Routers and routing switches use routing protocols to exchange reachability information. Routers use a routing protocol to advertise available paths on which the router can forward data. The routers use the protocol to determine the most efficient path to use. Routers use dynamic routing protocols to avoid sending data to inoperable links, and to send data to links that generally result in the fastest transmission times.

The switch routes frames using one of the following dynamic unicast IP routing protocols for path selection:

- Routing Information Protocol version 1 (RIPv1) (RFC 1058)
- RIPv2 (RFC 2453)
- Open Shortest Path First version 2 (OSPFv2) (RFC 2328)
- OSPFv3 (RFC 2740)
- Border Gateway Protocol version 4 (BGPv4) (RFC 1771)

Unlike static IP routing, where you must create a manual entry in the routing table to specify a routing path, dynamic IP routing uses a learning approach to determine the paths and routes to other routers. Dynamic routing uses two basic types of routing: distance vector and link-state. Routing Information Protocol (RIP) is a distance vector protocol and Open Shortest Path First (OSPF) is a link-state protocol.

The switch uses routing protocols like OSPF and RIP to populate routing tables. Routers use a routing protocol to exchange network topology information. A router uses the IP address of an incoming data packet to send the packet according to the routing tables.

The most commonly used unicast routing protocols include OSPF, RIP, and BGP. For more information about BGP, see BGP on page 355. For information about multicast routing protocols, see IP Multicast on page 1230. For information about OSPFv3 routing protocols, see OSPF on page 2168.

Black Hole Static Routes

A black hole static route is a route with an invalid next hop, and the device drops data packets destined for this network.

While the router aggregates or injects routes to other routers, the router does not have a path to the aggregated destination. In such cases, the result is a black hole and a routing loop. To avoid routing loops, configure a black hole static route to the destination the router is advertising.

You can configure a preference value for a black hole route. However, you must configure that preference value appropriately so that when you want to use the black hole route, it is elected as the best route.

Before you add a black hole static route, perform a check to ensure that no other static route to that identical destination is enabled. If such a route exists, you cannot add the black hole route and the system displays an error message.

If you enable a black hole route, you cannot add another static route to that destination. You must first delete or disable the black hole route before you add a regular static route to that destination.

Only black hole routes that belong to the static type protocol are supported. An inter-VRF black hole route is not installed in the routing table of the destination VRF on the same switch.

VLANs and routing

When traffic is routed on a virtual local area network (VLAN), an IP address is assigned to the VLAN and is not associated with a particular physical port. Brouter ports are VLANs that route IP packets and bridge nonroutable traffic in a single-port VLAN.

Virtual Routing Between VLANs

The switch supports wire-speed IP routing between VLANs. As shown in the following figure, VLAN 1 and VLAN 2 are on the same device, yet for traffic to flow from VLAN 1 to VLAN 2, the traffic must be routed.

When you configure routing on a VLAN, you assign an IP address to the VLAN, which acts as a virtual router interface address for the VLAN (a virtual router interface is not associated with a particular port). You can reach the VLAN IP address through the VLAN ports, and frames are routed from the VLAN through the gateway IP address. Routed traffic is forwarded to another VLAN within the device.

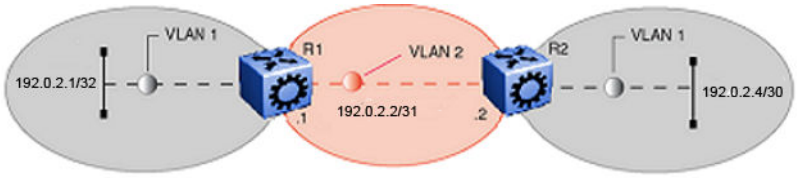

Figure 149: IP routing between VLANs

When Spanning Tree Protocol is enabled in a VLAN, the spanning tree convergence must be stable before the routing protocol begins. This requirement can lead to an additional delay in the IP traffic forwarding.

Because a port can belong to multiple VLANs (some of which are configured for routing on the device and some of which are not), a one-to-one correspondence no longer exists between the physical port and the router interface.

As with an IP address, virtual router interface addresses using Virtual Router Redundancy Protocol (VRRP) are also used for device management. For Simple Network Management Protocol (SNMP) or Telnet management, you can use virtual router interface address to access the device as long as routing is enabled on the VLAN.

Brouter Ports

The switch also supports brouter ports. A brouter port is a single-port VLAN that routes IP packets and bridges all nonroutable traffic. The difference between a brouter port and a standard IP protocol-based VLAN configured to route traffic is that the routing interface of the brouter port is not subject to the spanning tree state of the port. A brouter port can be in the blocking state for nonroutable traffic and still route IP traffic. This feature removes interruptions caused by Spanning Tree Protocol recalculations in routed traffic.

Because a brouter port is a single-port VLAN, each brouter port decreases the number of available VLANs by one and uses one VLAN ID.

The switch allows IP routing to be enabled on VLANs and brouter ports. For the maximum number of interfaces, see the Software scaling capabilities section of the *Fabric Engine Release Notes*.

Equal Cost Multipath

Table 110: Equal Cost Multiple Path for IPv4 product support

Feature	Product	Release introduced
Equal Cost Multiple Path (ECMP) for IPv4	5320 Series	Fabric Engine 8.6 Only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration.
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

With Equal Cost Multipath (ECMP), the switch can determine up to eight equal-cost paths to the same destination prefix. You can use multiple paths for load sharing of traffic. These multiple paths provide faster convergence to other active paths in case of network failure. By maximizing load sharing among equal-cost paths, you can use links between routers more efficiently when sending IP traffic. Equal Cost Multipath is formed using routes from the same source or protocol.

All IP ECMP routes that share the same combination of ECMP next hops consume the same ECMP group resource. The following list illustrates how shared next hops affect resource consumption:

- Prefix 3.1.1.0/16 is learned as an ECMP route with next hops A and B, and consumes one entry in the ECMP GROUP table.
- Prefix 4.1.1.0/16 is learned as an ECMP route with the same next hops, A and B. No additional resource is taken in the ECMP GROUP table.
- Prefix 5.1.1.0/16 is learned as an ECMP route with next hops B and C, and consumes one additional entry in the ECMP GROUP table.

ECMP is supported on both the Global Routing Table (GRT) and Virtual Routing and Forwarding (VRF).

The ECMP feature supports and complements the following protocols and route types:

- Border Gateway Protocol (BGP)
- Default route
- Intermediate System-to-Intermediate System (IS-IS)
- Open Shortest Path First (OSPF)
- Routing Information Protocol (RIP)
- Static route
- VRF

ECMP Pathlist

Use the ECMP Pathlist feature to control how many equal-cost paths to add to the routing manager for the same destination.

Note

Product Notice: Not all products support Equal Cost Multipath Pathlist with Fabric Connect. For more information, see *Fabric Engine Feature Support Matrix*.

IP Source Routing

Table 111: IP Source Routing product support

Feature	Product	Release introduced
IP Source Routing enable or disable	5320 Series	Fabric Engine 8.6 Only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration.
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

IP Source Routing allows the sender of a packet to specify the route that the packet must travel through the network. When the Source Route option is not enabled, the router chooses the primary routing path to send the packets. If IP Source Routing flag is on, the source host dictates the datapath for the packet to reach the destination using the information contained in the IP header.

IP Source Routing is considered a security risk because it allows the users to specify their own path through the network outside of the primary forwarding path. This can cause packets to bypass the security devices. Therefore, IP Source Routing is disabled by default.

Multihoming

The switch uses the multihoming feature to support clients or servers that have multiple IP addresses associated with a single MAC address. Multihomed hosts can be connected to port-based and policy-based VLANs.

The IP addresses associated with a single MAC address on a host must be in the same IP subnet.

IPv4 ICMP Broadcast

Table 112: Internet Control Message Protocol product support

Feature	Product	Release introduced
Internet Control Message Protocol (ICMP)	5320 Series	Fabric Engine 8.6 Only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration.
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
ICMP broadcast and multicast enable or disable	5320 Series	Fabric Engine 8.6 Only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration.
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Fragmented ICMP Packet Filtering for IPv4	5320 Series	Fabric Engine 8.6 Only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration.
	5420 Series	VOSS 8.5
	5520 Series	VOSS 8.5
	5720 Series	Fabric Engine 8.7
Fragmented ICMP Packet Filtering for IPv6	5320 Series	Fabric Engine 8.6 Only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration.
	5420 Series	VOSS 8.5
	5520 Series	VOSS 8.5
	5720 Series	Fabric Engine 8.7

On IPv4 networks, a packet can be directed to an individual machine or broadcast to an entire network. When a packet is sent to an IP broadcast address from a machine on the local network, that packet is delivered to all machines on that network.

If a packet that is broadcast is an ICMP echo request packet, the machines on the network receive this ICMP echo request packet and send an ICMP echo reply packet back. When all the machines on a network respond to this ICMP echo request, the result can be severe network congestion or outages.

The switch always responds to IPv4 ICMP packets sent to a broadcast address. You can disable the processing of these IPv4 ICMP packets sent to the broadcast address. On disabling the ICMP broadcast processing, all the packets containing ICMP sent to the broadcast addresses will be dropped when the packets reach the control plane.

You can disable or enable the IPv4 ICMP broadcast processing at the VRF level.

Fragmented ICMP Packet Filtering

ICMP fragmentation distributed denial-of-service (DDoS) attacks flood the destination resources with fragmented packets and overwhelm the network because of massive volumes of traffic. With Fragmented ICMP packet filtering, the system inspects each incoming IPv4 ICMP packet to determine if it should drop the packet or forward it.

You can configure ICMP drop packet filtering globally, on a specific VRF, and on the following management interfaces:

- Out-of-Band (OOB) management
- Circuitless IP (CLIP) management
- VLAN management

IP routing configuration using the CLI

Configure the IP router interface so that you can configure and use routing protocols and features on the interface. This section contains instructions for both the Global Router and Virtual Router Forwarding (VRF) instances.

Enabling routing globally or on a VRF instance

Use IP forwarding (routing) on a global level so that the device supports routing. You can use the IP address of an interface for IP-based network management.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`
2. Activate IP forwarding:

   ```
   ip routing
   ```
3. View the forwarding configuration:

   ```
   show ip routing [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

Example

Activate IP forwarding and view the forwarding configuration:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf green
```

```
Switch:1(router-vrf)#ip routing
Switch:1(router-vrf)#show ip routing

================================================================================
                                IP - GlobalRouter
================================================================================

 IP Forwarding is enabled
 IP ECMP feature is disabled
 Maximum ECMP paths number is 1
 ECMP 1 pathlist :
 ECMP 2 pathlist :
 ECMP 3 pathlist :
 ECMP 4 pathlist :
 ECMP 5 pathlist :
 ECMP 6 pathlist :
 ECMP 7 pathlist :
 ECMP 8 pathlist :
 Gratuitous-Arp  :  enable
 IP Alternative Route feature is enabled
 IP More Specific Non Local Route feature is disabled
 IP ICMP Unreachable Message is disabled
 IP Supernetting is disabled
 IP Icmp-echo-broadcast-request is enabled

 IP Default TTL is 255 seconds
 IP ARP life time is 360 minutes
 IP Source Route Option is disabled
```

Variable Definitions

Use the data in the following table to use the **show ip routing** command.

Variable	Value
vrf WORD<1-16>	Specifies a VRF instance by VRF name.
vrfids WORD<0-512>	Specifies a VRF instance by VRF number.

Enabling routing on an IP interface

About This Task

You can enable or disable routing capabilities on a VLAN or brouter port.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable routing:

   ```
   routing enable
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 1/2
Switch:1(config-if)#routing enable
```

Deleting a dynamically learned route

About This Task

Delete a dynamically learned route from the routing table if you do not want the switch to use the route. Exercise caution when you delete entries from the routing table.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. View IP route information:

   ```
   show ip route [<A.B.C.D>] [-s default|-s <A.B.C.D/X>] [alternative] [count-summary] [spbm-nh-as-mac][preference] [vrf WORD<1-16>] [vrfids WORD<0-512>] [static]
   ```

3. Delete the dynamically learned route:

   ```
   no ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> dynamic
   ```

Example

Delete a dynamically learned route:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#no ip route 192.0.2.32 255.255.255.0 198.51.100.31 dynamic
```

Variable Definitions

Use the data in the following table to use the **show ip route** commands.

Variable	Value
<A.B.C.D>	Specifies the IP address of the route to the network.
alternative	Displays the alternative routes.
count-summary	Displays a summary of the number of routes learned from each routing protocol for each VRF.
preference	Displays the route preference.
-s <A.B.C.D/X>	Indicates the IP address and subnet mask for which to display routes.
-s default	Indicates the default subnet.
static	Displays the static route information.
vrf WORD<1-16>	Displays the route for a particular VRF.
vrfids WORD<0-512>	Displays the route for a particular VRF number.
spbm-nh-as-mac	Displays the spbm route next hop as mac.

Use the data in the following table to use the **no ip route** command.

Variable	Value
<A.B.C.D> <A.B.C.D> <A.B.C.D>	Specifies the IP address, the subnet mask, and the next-hop IP address, respectively.
dynamic	Specifies that a dynamic route is to be deleted.
enable	Disables the route.
local-next-hop enable	Disables the local-next-hop option.
preference	Deletes the value of the route preference.
next-hop-vrf WORD<1-16>	Specifies the name of the next-hop VRF router.

Configuring IP route preferences

Before You Begin

- Disable ECMP before you configure route preferences

Important

Changing route preferences can affect system performance and network accessibility while you perform the procedure. You must therefore change a prefix list or a routing protocol before you activate the protocols.

About This Task

Configure IP route preferences to give preference to routes learned for a specific protocol. You must disable ECMP before you configure route preferences.

To configure route preferences for a VRF, access VRF Router Configuration mode, rather than Global Configuration mode.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`
2. Configure the route preference:

   ```
   ip route preference protocol <static|ospf-intra|ospf-inter|ebgp|ibgp|
   rip|ospf-extern1|ospf-extern2|spbm-level1> <0-255>
   ```
3. Confirm that the configuration is correct:

   ```
   show ip route preference [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

Example

Configure the route preference to SPBM Level 1 and confirm the configuration is correct.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip route preference protocol spbm-level1 7
Switch:1(config)#show ip route preference
================================================================================
                      IP Route Preference - GlobalRouter
================================================================================
PROTOCOL        DEFAULT    CONFIG
--------------------------------------------------------------------------------
LOCAL           0          0
STATIC          5          5
SPBM_L1         7          7
OSPF_INTRA      20         20
OSPF_INTER      25         25
EBGP            45         45
RIP             100        100
OSPF_E1         120        120
OSPF_E2         125        125
IBGP            175        175
```

View the route preference configuration for a specific VRF, for example `444`.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf test
Switch:1(router-vrf)#show ip route preference vrf 444

================================================================================
                        IP Route Preference - VRF 444

================================================================================
PROTOCOL        DEFAULT    CONFIG
--------------------------------------------------------------------------------
LOCAL           0          0
STATIC          5          5
SPBM_L1         7          7
OSPF_INTRA      20         20
```

```
OSPF_INTER      25          25
EBGP            45          45
RIP             100         100
OSPF_E1         120         120
OSPF_E2         125         125
IBGP            175         175
```

Variable definitions

Use the data in the following table to use the **ip route preference protocol** command.

Variable	Value
ebgp	Protocol type eBGP
ibgp	Protocol type iBGP
ospf-extern1	Protocol type ospf-extern1
ospf-extern2	Protocol type ospf-extern2
ospf-intra	Protocol type ospf-intra
ospf-inter	Protocol type ospf-inter
rip	Protocol type rip
spbm-level1	Protocol type spbm-level1
static	Protocol type static

Flushing routing tables by VLAN or port

About This Task

For administrative and troubleshooting purposes, flush the routing tables.

To flush tables on a VRF instance for a port or VLAN, ensure that the VRF is associated with the port or VLAN.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Flush the routing tables:

   ```
   action flushIp
   ```

Example

Flush the routing tables:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 3/6
Switch:1(config-if)#action flushIp
```

Assign an IP address to a Port

Assign an IP address to a port so that it supports routing operations.

About This Task

Use a brouter port to route IP packets and to bridge all nonroutable traffic. The routing interface of the brouter port is not subject to the spanning tree state of the port. A brouter port can be in the blocking state for nonroutable traffic and still route IP traffic. This feature removes interruptions caused by Spanning Tree Protocol recalculations in routed traffic.

If an IP interface is configured without specifying the VRF instance, it maps to VRF 0 by default.

Use the `vrf` parameter to associate the port or VLAN with a VRF instance.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Assign an IP address to the port:

   ```
   brouter port {slot/port[/sub-port]} vlan <2-4059> subnet <A.B.C.D/X>
   [mac-offset <MAC-offset> | [name WORD <0-64>]
   ```

3. If required, associate the port with a VRF:

   ```
   vrf WORD<1-16>
   ```

4. Confirm that the configuration is correct:

   ```
   show brouter [<1-4059>]
   ```

Example

Assign an IP address to a port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 1/11
Switch:1(config-if)#brouter port 1/11 vlan 2202 subnet 47.17.10.31/255.255.255.0
```

Variable Definitions

Use the data in the following table to use the **brouter port** command.

Variable	Value
mac-offset <MAC-offset>	Specifies a number by which to offset the MAC address from the chassis MAC address. This ensures that each IP address has a different MAC address. If you omit this variable, a unique MAC offset is automatically generated. Different hardware platforms support different ranges. To see which range is available on the switch, use the CLI command completion Help.
name WORD <0-64>	Specifies the IP address name in the range of 0 to 64 characters.
{slot/port[/sub-port]}	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
subnet <A.B.C.D/X>	Specifies the IP address and subnet mask (0–32).
<2-4059>	Specifies the VLAN ID that is used if the port is tagged (802.1q encapsulation). The VLAN ID is unique to the switch and is not used if the port is untagged.

Use the data in the following table to use the **show brouter** command.

Variable	Value
<1-4059>	Specifies the VLAN ID that is used if the port is tagged (802.1q encapsulation). The VLAN ID is unique to the switch and is not used if the port is untagged.

Viewing IP addresses for all router interfaces

About This Task

Perform the following procedure to display information about all IP interfaces configured on the device.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Show the IP interfaces and addresses on the device:
   ```
   show ip interface
   ```

Example

Show the IP interfaces and addresses on the device:

```
Switch:1>enable
Switch:1#show ip interface

================================================================================
                          IP Interface - GlobalRouter
================================================================================
INTERFACE    IP              NET            BCASTADDR  REASM    VLAN  BROUTER
             ADDRESS         MASK           FORMAT     MAXSIZE  ID    PORT
```

```
--------------------------------------------------------------------------------
Port1/6      192.0.2.6        255.255.255.0  ones       1500     200   true
Vlan100      192.0.2.5        255.255.255.0  ones       1500     100   false
Vlan4000     198.51.100.21    255.255.255.0  ones       1500     4000  false
```

Variable Definitions

Use the data in the following table to **`show ip interface`** command.

Variable	Value
gigabitethernet	Displays IP interface information for Gigabit Ethernet ports.
vrf	Displays interface information for a particular VRF.
vrfids	Displays interface information for particular VRF IDs.

Configure IP Routing Globally or for a VRF

Configure the IP routing protocol stack to specify which routing features the device can use. You can configure global parameters before or after you configure the routing protocols.

About This Task

To configure IP routing globally for a VRF instance, use VRF Router Configuration mode rather than Global Configuration mode.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`
2. Configure the default TTL for all routing protocols to use:

   ```
   ip ttl <1-255>
   ```

   This value is placed into routed packets that have no TTL specified.
3. Activate the alternative route feature globally:

   ```
   ip alternative-route
   ```
4. Configure the remaining global parameters as required.

Variable Definitions

The following table defines parameters for the **ip** command.

Variable	Value
alternative-route	Enables or disables the alternative route feature. The default value is enabled. If the alternative-route parameter is disabled, all existing alternative routes are removed. After you enable the parameter, all alternative routes are readded. The default form of this command is `default ip alternative-route`. The no form of this command is `no ip alternative-route`.
max-routes-trap enable	Enables the device to send a trap after the maximum number of routes is exceeded. The no form of this command is `no max-routes-trap enable`. The default form of this command is `default max-routes-trap enable`.
more-specific-non-local-route	Enables the more-specific-non-local-route feature. If enabled, the device can enter a more-specific nonlocal route into the routing table. The default is disabled. The default form of this command is `default ip more-specific-non-local-route`. The no form of this command is `no ip more-specific-non-local-route`.
routing	Enables routing. The no form of this command is `no ip routing`.
supernet	Enables or disables supernetting. If you globally enable supernetting, the device can learn routes with a route mask of less then eight bits. Routes with a mask length less than eight bits cannot have ECMP paths, even if the ECMP feature is globally enabled. The default is disabled. The default form of this command is `default ip supernet`. The no form of this command is `no ip supernet`.
ttl <1-255>	Configures the default time-to-live (TTL) value for a routed packet. The TTL is the maximum number of seconds before a packet is discarded. The default value of 255 is used whenever a time is not supplied in the datagram header. The default form of this command is `default ip ttl`.

The following table defines parameters for the **ip icmp** commands.

Variable	Value
unreachable	Enables the device to send ICMP unreachable messages. When enabled, this variable generates Internet Control Message Protocol (ICMP) network unreachable messages if the destination network is not reachable from this router. These messages help determine if the device is reachable over the network. The default is disabled. The default form of this command is `default ip icmp unreachable`.

Configure ECMP

Enable Equal Cost MultiPath (ECMP) to permit routers to determine up to eight equal-cost paths to the same destination prefix. You can use the multiple paths for load-sharing of traffic, which provides fast convergence to alternative paths. By maximizing load sharing among equal-cost paths, you can maximize the efficiency of links between routers.

About This Task

To configure ECMP for a VRF instance, after you enable ECMP globally, use VRF Router Configuration mode rather than Global Configuration mode.

Different hardware platforms can support a different number of ECMP paths. For more information, see *Fabric Engine Release Notes*.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable ECMP globally:

   ```
   ip ecmp
   ```

3. (Optional) Configure the maximum number of ECMP paths:

   ```
   ip ecmp max-path <ECMP-Paths>
   ```

4. (Optional) Configure a prefix-list for the target destination:

   ```
   ip prefix-list WORD<1-64> <A.B.C.D/X> [ge <0-32>] [le <0-32>]
   ```

5. (Optional) Configure an ECMP pathlist to specify routes with the required number of paths:

   ```
   ip ecmp pathlist-<1-8> WORD<1-64>
   ```

6. (Optional) Return to Privileged EXEC mode:

   ```
   end
   ```

7. (Optional) Apply changes to all ECMP pathlist configurations:

   ```
   ip ecmp pathlist-apply [vrf WORD<1-16>]
   ```

Example

Define which IP prefixes use ECMP and which do not.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#ip ecmp
Switch:1(config)#ip prefix-list ecmpAllowed 192.0.2.0/24 ge 24 le 24
Switch:1(config)#ip prefix-list ecmpDenied 0.0.0.0/0 ge 0 le 32
Switch:1(config)#ip ecmp pathlist-2 ecmpAllowed
Switch:1(config)#ip ecmp pathlist-1 ecmpDenied
Switch:1(config)#end
Switch:1#ip ecmp pathlist-apply
```

Variable Definitions

The following table defines parameters for the **ip ecmp** command.

Variable	Value
max-path <ECMP-Paths>	Specifies the maximum number of ECMP paths. Different hardware platforms can support a different number of ECMP paths. For more information on the maximum number of ECMP paths supported on the switch, see the scaling information in *Fabric Engine Release Notes*.
pathlist-1 WORD<0-64>	Specifies one equal-cost path to the same destination prefix. To remove the policy, enter a blank string.
pathlist-2 WORD<0-64>	Specifies up to two equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.
pathlist-3 WORD<0-64>	Specifies up to three equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.
pathlist-4 WORD<0-64>	Specifies up to four equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.
pathlist-5 WORD<0-64>	Specifies up to five equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.
pathlist-6 WORD<0-64>	Specifies up to six equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.
pathlist-7 WORD<0-64>	Specifies up to seven equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.
pathlist-8 WORD<0-64>	Specifies up to eight equal-cost paths to the same destination prefix. To remove the policy, enter a blank string.
pathlist-apply [vrf WORD<1-16>]	Applies the pathlist configuration changes. You can optionally specify a VRF name.

The following table defines parameters for the **ip prefix-list** command.

Variable	Value
WORD<0-64>	Specifies the prefix list name.
<A.B.C.D/X>	Specifies the IP address and network mask in one of the following formats: • a.b.c.d/x • a.b.c.d/x.x.x.x • default
ge <0-32>	Specifies the minimum length to match. Lower bound and higher bound mask lengths together can define a range of networks.
le <0-32>	Specifies the maximum length to match. Lower bound and higher bound mask lengths together can define a range of networks.

Configure Static Routes

Perform the steps in this task to:

- Create static routes for data traffic in either the GRT or a specific VRF context for any platform.
- Create static routes for a VRF associated with a Segmented Management Instance CLIP interface. Specify the name of the VRF context in Step 1.

Before You Begin

- Ensure no black hole static route exists. If a black hole route is enabled, you must first delete or disable it before you can add a regular static route to that destination.

Note

Only black hole routes that belong to the static type protocol are supported. An inter-VRF black hole route is not installed in the routing table of the destination VRF on the same switch.

About This Task

When you configure a static route with a next-hop-vrf context, you can specify a next-hop IP address that is a locally owned VRRP IP address of the system itself. However, this is not a supported configuration. The best practice is to implement an alternative method of inter-vrf route sharing, such as route redistribution or ISIS accept polices.

For route scaling information and for information on the maximum number of static routes supported on your hardware platform, see *Fabric Engine Release Notes*.

Note

As a best practice, do not configure static routes on a DvR Leaf node unless the configuration is for reachability to a management network using a Brouter port.

You cannot configure the preference of static routes on a Leaf node.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`
2. Create an IP static route:

   ```
   ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> weight <1-65535>
   ```
3. Enable an IP static route:

   ```
   ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> enable
   ```
4. Use the following variable definitions table to configure other static route parameters as required.
5. View existing IP static routes for the device, or for a specific network or subnet:

   ```
   show ip route static
   ```

Example

Create an IP static route, enable a static route, and view the existing IP static routes for the device, or for a specific network or subnet.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip route 192.0.2.2 255.255.0.0 198.51.100.24 weight 20 name ExtSer 10 preference 1
Switch:1(config)#ip route 192.0.2.2 255.255.0.0 198.51.100.24 enable
Switch:1(config)#show ip route static
================================================================================================
                          IP Static Route - GlobalRouter
================================================================================================

DEST       MASK          NEXT           NH-VRF      COST PREF LCLNHOP STATUS ENABLE NAME
------------------------------------------------------------------------------------------------

192.0.2.2  255.255.255.0 198.51.100.24  GlobalRouter 20   1   TRUE    ACTIVE TRUE   ExtSer 10
```

Variable Definitions

Use the data in the following table to use the **ip route** command.

Variable	Value
<A.B.C.D> <A.B.C.D> <A.B.C.D>	The first and second *<A.B.C.D>* specify the IP address and mask for the route destination. The third *<A.B.C.D>* specifies the IP address of the next-hop router (the next router at which packets must arrive on this route). When you create a black hole static route, configure this parameter to 255.255.255.255 as the IP address of the router through which the specified route is accessible.
disable	Disables a route to the router or VRF.
enable	Adds a static route to the router or VRF. The no form of this command is `no ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> enable`. The default form of this command is `default ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> enable`.
local-next-hop enable	Enables the local next hop for this static route. The default form of this command is `default ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> local-next-hop enable`. The no form of this command is `no ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> local-next-hop enable`.
next-hop-vrf <WORD 1-16>	Specifies the next-hop VRF instance by name. After you configure the *next-hop-vrf* parameter, the static route is created in the local VRF, and the next-hop route is resolved in the next-hop VRF instance (next-hop-vrf). The default form of this command is `default ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> next-hop-vrf <WORD 1-16>`. The no form of this command is `no ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> next-hop-vrf <WORD 1-16>`.

Variable	Value
weight <1-65535>	Specifies the static route cost. The default form of this command is `default ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> weight`. Note: Do not configure a static interface subnet route with a weight of 1.
name <1-64>	Specifies the name of the static route. You can name the route before or after it is created. Only 32 characters display. The tilde (~) symbol indicates that the name is truncated.
preference <1-255>	Specifies the route preference. The default form of this command is `default ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> preference`.

Use the data in the following table to use the **`show ip route static`** command.

Variable	Value
<A.B.C.D>	Specifies the route by IP address.
-s { <A.B.C.D> <A.B.C.D> | default}	Specifies the route by IP address and subnet mask.
vrf WORD<1-16>	Specifies a VRF by name.
vrfids WORD<0-512>	Specifies a range of VRF IDs.
name <1-64>	Specifies the name of the static route. You can name the route before or after it is created. Only 32 characters display. The tilde (~) symbol indicates that the name is truncated.

Configure a Black Hole Static Route

About This Task

Configure a black hole static route to the destination a router advertises to avoid routing loops after the router aggregates or injects routes to other routers.

If a black hole route is enabled, you must first delete or disable it before you can add a regular static route to that destination.

Note

Only black hole routes that belong to the static type protocol are supported. An inter-VRF black hole route is not installed in the routing table of the destination VRF on the same switch.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`
2. Create a black hole static route:

   `ip route <A.B.C.D> <A.B.C.D> 255.255.255.255 weight <1-65535>`
3. Enable a black hole static route:

   `ip route <A.B.C.D> <A.B.C.D> 255.255.255.255 enable [next-hop-vrf WORD<1-16>]`
4. Configure other black hole static route parameters as required.

   When you specify a route preference, appropriately configure the preference so that when the black-hole route is used, it is elected as the best route.

Example

Create a black hole static route and enable the black hole static route.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip route 192.0.2.0 255.255.0.0 255.255.255.255 weight 200
Switch:1(config)#ip route 192.0.2.0 255.255.0.0 255.255.255.255 enable
```

Variable Definitions

Use the data in the following table to use the **`ip route`** command.

Variable	Value
<A.B.C.D>	The first and second *<A.B.C.D>* specify the IP address and mask for the route destination. 255.255.255.255 is the destination of the black hole route.
enable	Adds a static route to the router or VRF. The no form of this command is `no ip route <A.B.C.D> <A.B.C.D> 255.255.255.255 enable`.
local-next-hop enable	Enables the local next hop for this static route. The default form of this command is `default ip route <A.B.C.D> <A.B.C.D> <A.B.C.D> local-next-hop enable`. The no form of this command is `no ip route <A.B.C.D> <A.B.C.D> 255.255.255.255 local-next-hop enable`.

Variable	Value
next-hop-vrf WORD<1-16>	Specifies the next-hop VRF instance by name. The default form of this command is `default ip route <A.B.C.D> <A.B.C.D> 255.255.255.255 next-hop-vrf <WORD 1-16>`. The no form of this command is `no ip route <A.B.C.D> <A.B.C.D> 255.255.255.255 next-hop-vrf <WORD 1-16>`.
weight <1-65535>	Specifies the static route cost. The default form of this command is `default ip route <A.B.C.D> <A.B.C.D> 255.255.255.255 weight`. Note: Do not configure a static interface subnet route with a weight of 1.
preference <1-255>	Specifies the route preference. The default form of this command is `default ip route <A.B.C.D> <A.B.C.D> 255.255.255.255 preference`.

Configuring a default static route

About This Task

The default route specifies a route to all networks for which there are no explicit routes in the forwarding information base or the routing table. This route has a prefix length of zero (RFC 1812). You can configure the switch with a static default route, or they can learn it through a dynamic routing protocol.

To create a default static route, you configure the destination address and subnet mask to 0.0.0.0.

Note

When you configure a static route with a next-hop-vrf context, you can specify a next-hop IP address that is a locally owned VRRP IP address of the system itself. However, this is not a supported configuration. The best practice is to implement an alternative method of inter-vrf route sharing, such as route redistribution or ISIS accept polices.

Note

As a best practice, do not configure static routes on a DvR Leaf node unless the configuration is for reachability to a management network using a Brouter port.

You cannot configure the preference of static routes on a Leaf node.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`

2. Create a default static route:

   ```
   ip route 0.0.0.0 0.0.0.0 <A.B.C.D> weight <1-65535>
   ```

3. Enable a default static route:

   ```
   ip route 0.0.0.0 0.0.0.0 <A.B.C.D> enable [next-hop-vrf WORD<1-16>]
   ```

4. Configure other default static route parameters as required.

Example

Create a default static route and enable the default static route.

```
Switch:1>enable
Switch:1>configure terminal
Switch:1(config)#ip route 0.0.0.0 0.0.0.0 192.0.2.128 weight 100
Switch:1(config)#ip route 0.0.0.0 0.0.0.0 192.0.2.128 enable
```

Variable Definitions

Use the data in the following table to use the **ip route** command.

Variable	Value
<A.B.C.D>	*<A.B.C.D>* specifies the IP address of the next-hop router (the next router at which packets must arrive on this route).
enable	Adds a static or default route to the router or VRF. The no form of this command is `no ip route 0.0.0.0 0.0.0.0 <A.B.C.D> enable`.
local-next-hop enable	Enables the local next hop for this static route. The default form of this command is `default ip route 0.0.0.0 0.0.0.0 <A.B.C.D> local-next-hop enable`. The no form of this command is `no ip route 0.0.0.0 0.0.0.0 <A.B.C.D> local-next-hop enable`.
next-hop-vrf WORD<1-16>	Specifies the next-hop VRF instance by name. The default form of this command is `default ip route 0.0.0.0 0.0.0.0 <A.B.C.D> next-hop-vrf WORD<1-16>`. The no form of this command is `no ip route 0.0.0.0 0.0.0.0 <A.B.C.D> next-hop-vrf WORD<1-16>`.
weight <1-65535>	Specifies the static route cost. The default form of this command is `default ip route 0.0.0.0 0.0.0.0 <A.B.C.D> weight`. Note: Do not configure a static interface subnet route with a weight of 1.
preference <1-255>	Specifies the route preference. The default form of this command is `default ip route 0.0.0.0 0.0.0.0 <A.B.C.D> preference`.

Configure IPv4 Fragmented ICMP Packet Filtering

About This Task

Use this task to enable IPv4 Fragmented ICMP packet filtering globally or on a specific VRF. This feature is disabled by default.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`
2. Enable Fragmented ICMP packet filtering:

   ```
   ip icmp drop-fragments
   ```

Enabling ICMP Router Discovery globally

About This Task

Enable Router Discovery globally so that the device supports Router Discovery. Use ICMP Router Discovery to enable hosts attached to the broadcast network to discover the IP addresses of their neighboring routers.

If you enable ICMP Router Discovery globally, you automatically enable it for all VLANs. If you do not require ICMP Router Discovery on a specific VLAN, you must manually disable the feature.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`
2. Enable ICMP Router Discovery on the device:

   ```
   ip irdp
   ```
3. Confirm that Router Discovery is enabled:

   ```
   show ip irdp [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

Example

Enable ICMP router discovery on the device and confirm that router discovery is enabled.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip irdp
Switch:1(config)#show ip irdp
        VRF "GlobalRouter" (Global Routing Table) : Router Discovery Enabled
```

Variable Definitions

Use the data in the following table to **show ip irdp** command.

Variable	Value
interface	Displays route discovery interface information.
vrf WORD<1-16>	Displays route discovery for particular VRF.
vrfids WORD<0-512>	Displays route discovery for particular VRF IDs.

Enabling or disabling IPv4 ICMP broadcast globally

On disabling the ICMP broadcast processing, all the packets containing ICMP sent to broadcast addresses, will be dropped when they reach the control plane.

About This Task

Use these commands to enable or disable the IPv4 ICMP broadcast feature on the global router.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable IPv4 ICMP broadcast feature, enter:

   ```
   ip icmp echo-broadcast-request
   ```

3. Disable IPv4 ICMP broadcast feature, enter:

   ```
   no ip icmp echo-broadcast-request
   ```

4. Set the IPv4 ICMP broadcast feature to default state, enter:

   ```
   default ip icmp echo-broadcast-request
   ```

   Note

   By default, the IPv4 ICMP broadcast feature is enabled.

5. View the IPv4 ICMP broadcast feature state:

   ```
   show ip routing
   ```

Enabling or disabling IPv4 ICMP broadcast per VRF

On disabling the ICMP broadcast processing, all the packets containing ICMP sent to broadcast addresses, will be dropped when they reach the control plane.

About This Task

Use these commands to enable or disable the IPv4 ICMP broadcast feature on the VRF router.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:
   ```
   enable

   configure terminal

   router vrf WORD<1-16>
   ```
2. Enable IPv4 ICMP broadcast feature, enter:
   ```
   ip icmp echo-broadcast-request
   ```
3. Disable IPv4 ICMP broadcast feature, enter:
   ```
   no ip icmp echo-broadcast-request
   ```
4. Set the IPv4 ICMP broadcast feature to default state, enter:
   ```
   default ip icmp echo-broadcast-request
   ```

   Note
   By default, the IPv4 ICMP broadcast feature is enabled.

5. View the IPv4 ICMP broadcast feature state:
   ```
   show ip routing
   ```

View IPv4 ICMP Statistics

View the collective IPv4 ICMP statistics for all VRF instances.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View IPv4 ICMP statistics:
   ```
   show ip icmp statistics
   ```

Example

View IPv4 ICMP statistics:

```
Switch:1#show ip icmp statistics

 Icmp Statistics:
-------------------------------------------------------------
ICMP IN STATISTICS (includes GRT and all VRF instances) :
IcmpInMsgs           = 0
IcmpInErrors         = 0
IcmpInDestUnreachs   = 0
IcmpInTimeExcds      = 0
IcmpInParmProbs      = 0
IcmpInSrcQuenchs     = 0
IcmpInRedirects      = 0
IcmpInEchos          = 0
IcmpInEchoReps       = 0
IcmpInTimestamps     = 0
IcmpInTimestampReps  = 0
IcmpInAddrMasks      = 0
IcmpInAddrMaskReps   = 0
ICMP OUT STATISTICS (includes GRT and all VRF instances) :
IcmpOutMsgs          = 0
```

```
IcmpOutErrors         = 0
IcmpOutDestUnreachs   = 0
IcmpOutTimeExcds      = 0
IcmpOutParmProbs      = 0

IcmpOutSrcQuenchs     = 0

IcmpOutRedirects      = 0

IcmpOutEchos          = 0

IcmpOutEchoReps       = 0

IcmpOutTimestamps     = 0

IcmpOutTimestampReps  = 0

IcmpOutAddrMasks      = 0

IcmpOutAddrMaskReps   = 0

0  messages dropped due to rate limiting
```

Configuring Router Discovery on a port or VLAN

Enable Router Discovery so that the device forwards Router Discovery Advertisement packets to the VLAN or port.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable
   ```

   ```
   configure terminal
   ```

   ```
   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```
   or
   ```
   interface vlan <1-4059>
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Specify the address placed in advertisement packets:

   ```
   ip irdp address <A.B.C.D>
   ```

3. Enable the interface to send the advertisement packets:

   ```
   ip irdp multicast
   ```

4. Configure other Router Discovery parameters for the interface as required.

Example

Log on to the GigabitEthernet Interface mode:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/16
```

Specify the address placed in advertisement packets to the all-systems multicast address:

```
Switch:1(config-if)# ip irdp address 244.0.0.1
```

Enable the interface to send the advertisement packets:

```
Switch:1(config-if)# ip irdp multicast
```

Configure the lifetime for advertisements:

```
Switch:1(config-if)# ip irdp holdtime 180
```

Variable Definitions

Use the data in the following table to use the **`ip irdp`** command.

Variable	Value
address <A.B.C.D>	Specifies the IP destination address use for broadcast or multicast router advertisements sent from the interface. The address is the all-systems multicast address, 224.0.0.1, or the limited-broadcast address, 255.255.255.255. The default address is 255.255.255.255. The default form of this command is `default ip irdp address`.
holdtime <4-9000>	Configures the lifetime for advertisements. The default form of this command is `default ip irdp holdtime`.
maxadvertinterval <4-1800>	Specifies the maximum time (in seconds) that elapses between unsolicited router advertisement transmissions from the router interface. The default is 600 seconds. The default form of this command is `default ip irdp maxadvertinterval`.
minadvertinterval <3-1800>	Specifies the minimum time (in seconds) that elapses between unsolicited router advertisement transmissions from the interface. The range is 3 seconds to maxadvertinterval. The default is 450 seconds. The default form of this command is `default ip irdp minadvertinterval`.
multicast	Specifies if multicast advertisements are sent. The no form of this command is `no ip irdp multicast`.
preference <-2147483648-2147483647>	Specifies the preference (a higher number indicates more preferred) of the address as a default router address relative to other router addresses on the same subnet The default is 0. The default form of this command is `default ip irdp preference`.

Configure a CLIP Interface

About This Task

Configure a circuitless IP (CLIP) interface to provide a virtual interface that is not associated with a physical port. You can use a CLIP interface to provide uninterrupted connectivity to your device.

For scaling information and for information on the maximum number of CLIP interfaces you can configure on your device, see *Fabric Engine Release Notes*.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create or access a CLIP interface:

   ```
   interface loopback <1-256>
   ```

   <1-256> indicates the identification number for the CLIP.

   The command prompt changes to indicate you now access the Loopback Interface Configuration mode.

3. Configure an IP address and name for the interface:

   ```
   ip address [<1-256>] <A.B.C.D/X> [vrf WORD<1-16>] [name WORD <0-64>]
   ```

4. Enable OSPF on the CLIP interface:

   ```
   ip ospf [<1-256>] [vrf WORD<1-16>]
   ```

   You can configure other protocols on the CLIP interface; OSPF is the most common. See the following variable definitions table for other options.

5. View the IP address on the CLIP interface:

   ```
   show ip interface
   ```

Example

Create a CLIP interface.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface loopback 3
Switch:1(config-if)#ip address 23.23.23.23 255.255.255.0 name ExtNet
Switch:1>show ip interface
================================================================================================
                          IP Interface - GlobalRouter
================================================================================================
INTERFACE  IP            NET            BCASTADDR  REASM    VLAN  BROUTER  IPSEC    IP
           ADDRESS       MASK           FORMAT     MAXSIZE  ID    PORT     STATE    NAME
------------------------------------------------------------------------------------------------
Port1/2    10.3.4.2      255.255.255.0  ones       1500     3     true     disable  address1
Clip1      1.2.3.4       255.255.0.0    ones       1500     --    false    disable
Clip2      2.3.4.5       255.255.255.0  ones       1500     --    false    disable
Clip23     23.23.23.23   255.255.255.0  ones       1500     --    false    disable  ExtNet
Vlan2      192.0.2.5     255.255.255.0  ones       1500     2     false    disable
Vlan55     55.55.55.55   255.255.255.0  ones       1500     55    false    disable  Boston

All 6 out of 6 Total Num of IP interfaces displayed
```

Variable Definitions

Use the data in the following table to use the **ip** commands.

Variable	Value
address [<1-256>] <A.B.C.D/X> [vrf WORD<1-16>] [name WORD<0-64]	Specifies the IP address for the CLIP interface. *<1-256>* specifies the interface. *<A.B.C.D/X>* specifies the IP address and mask (0-32). *vrf WORD<1-16>* specifies an associated VRF by name. The no form of this command is `no ip address [<1-32>] <A.B.C.D> [vrf WORD<1-16>]`. *name WORD<1-16>* specifies a name for the IP address.
area <1-256> <A.B.C.D> [vrf WORD<1-16>]	Designates an area for the CLIP interface. *vrf WORD<1-16>* specifies an associated VRF by name The default form of this command is `default ip area <1-256> <A.B.C.D> [vrf WORD<1-16>]`. The no form of this command is `no ip area <1-256> vrf WORD<1-16>]`.

Display BFD Configurations on the Loopback Interface

About This Task

Use the following procedure to display all BFD configurations on the loopback interface.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the BFD configurations:

   ```
   show ip bfd interfaces loopback
   ```

Example

The following example displays BFD configurations on the Loopback Interface:

```
Switch:1>enable
Switch:1#show ip bfd interfaces loopback
================================================================================
                          Circuitless IP Interface Bfd
================================================================================
INTF ID    STATUS     MIN_RX     INTERVAL   MULTIPLIER      VRF-ID
--------------------------------------------------------------------------------
1          enable     200        200        3               0
2          enable     200        200        3               2
```

Display the IPv4 Global Configuration

About This Task

Use this task to view Fragmented ICMP packet filtering on a IPv4 network.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. Display the ICMP IPv4 information:
   ```
   show ip global [vrf WORD<1-16> | vrfids WORD<0-512>]
   ```

Viewing TCP and UDP information

Use this procedure to view TCP and UDP configuration information for IPv4.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. View the IPv4 TCP connection information:
   ```
   show ip tcp connections
   ```
3. View the IPv4 TCP connection information for a specific vrf or vrfids:
   ```
   show ip tcp connections vrf WORD<0-16>

   show ip tcp connections vrfids WORD<0-512>
   ```
4. View IPv4 TCP properties:
   ```
   show ip tcp properties
   ```
5. View IPv4 TCP statistics
   ```
   show ip tcp statistics
   ```
6. View IPv4 udp endpoints
   ```
   show ip udp endpoints
   ```
7. View IPv4 udp statistics
   ```
   show ip udp statistics
   ```

Example

```
Switch:1#show ip tcp connections

================================================================================================
                          TCP connection table info

HCOutDatagrams:     887
```

Variable definitions

Use the data in the following table to use the **`show ip tcp`** command.

Variable	Value
connections	Specifies the TCP connection information. Use the following parameters: • vrf WORD<0–16> Specifies a virtual routing and forwarding (VRF) by name. • vrfids WORD<0–512> Specifies the IDs of a VRF path as an integer from 1 to 512. Example: `show ip tcp connections vrf 0`
properties	Specifies the TCP global properties information.
statistics	Specifies the TCP global statistics.

Use the data in the following table to use the **`show ip udp`** command.

Variable	Value
endpoints	Specifies the IP UDP endpoint information.
statistics	Specifies IP UDP statistics information.

IP routing configuration using Enterprise Device Manager

Configure the IP router interface so that you can use routing protocols and features on the interface. This section contains instructions for both the Global Router and Virtual Router Forwarding (VRF) instances.

Enabling routing for a router or a VRF instance

About This Task

Enable IP forwarding (routing) on a router or a Virtual Router Forwarding (VRF) instance so that they support routing. You can use the IP address of any physical or virtual router interface for an IP-based network management.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IP**.
2. Click **IP**.
3. Click the **Globals** tab.
4. To enable routing, select **Forwarding**.
5. Click **Apply**.

Deleting a dynamically-learned route

About This Task

Use the Routes tab to view and manage the contents of the system routing table. You can also delete a dynamically learned route using this table. Exercise caution if you delete entries from the route table.

To delete a static route, use the **StaticRoute** tab.

To delete dynamic routes from the table for a VRF instance, first select the appropriate instance.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IP**.
2. Click **IP**.
3. Click the **Routes** tab.
4. To delete a route, select the route and click **Delete**.

***Routes** field descriptions*

Use the data in the following table to use the **Routes** tab.

Name	Description
Dest	Specifies the destination IP network of this route. An entry with a value of 0.0.0.0 is a default route. The system can display multiple routes to a single destination in the table, but access to multiple entries depends on the table access mechanisms defined by the network management protocol in use.
Mask	Indicates the network mask to logically add with the destination address before comparison to the destination IP network.
NextHop	Specifies the IP address of the next hop of this route.
AltSequence	Indicates the alternative route sequence. The value of 0 denotes the best route.
NextHopId	Specifies the identifier of the next-hop, hostname or MAC address.
HopOrMetric	Specifies the primary routing metric for this route. The semantics of this metric are specific to various routing protocols.
Interface	Specifies the router interface for this route. • Virtual router interfaces are identified by the VLAN number of the VLAN followed by the (VLAN) designation. • Brouter interfaces are identified by the slot and port number of the brouter port.
Proto	Specifies the routing mechanism through which this route was learned: • local—nonprotocol information, for example, manually configured entries • static • isis • inter-vrf redistributed route
Age	Specifies the number of seconds since this route was last updated or otherwise determined correct.

Name	Description
PathType	Indicates the route type, which is a combination of direct, indirect, best, alternative, and ECMP paths. • iA indicates Indirect Alternative route without an ECMP path • iAE indicates Indirect Alternative ECMP path • iB indicates Indirect Best route without ECMP path • iBE indicates Indirect Best ECMP path • dB indicates Direct Best route • iAN indicates Indirect Alternative route not in hardware • iAEN indicates Indirect Alternative ECMP route not in hardware • iBN indicates Indirect Best route not in hardware • iBEN indicates Indirect Best ECMP route not in hardware • dBN indicates Direct Best route not in hardware • iAU indicates Indirect Alternative Route Unresolved • iAEU indicates Indirect Alternative ECMP Unresolved • iBU indicates Indirect Best Route Unresolved • iBEU indicates Indirect Best ECMP Unresolved • dBU indicates Direct Best Route Unresolved • iBF indicates Indirect Best route replaced by FTN • iBEF indicates Indirect Best ECMP route replaced by FTN • iBV indicates Indirect best IPVPN route • iBEV indicates Indirect best ECMP IP VPN route • iBVN indicates Indirect best IP VPN route not in hardware • iBEVN indicates Indirect best ECMP IP VPN route not in hardware
Pref	Specifies the preference.
NextHopVrfId	Specifies the VRF ID of the next-hop address.

Configuring IP route preferences

Before You Begin

- Disable ECMP before you configure route preferences.

About This Task

Change IP route preferences to force the routing protocols to prefer a route over another. Configure IP route preferences to override default route preferences and give preference to routes learned for a specific protocol.

Important

Changing route preferences is a process-oriented operation that can affect system performance and network reachability while you perform the procedures. Therefore, if you want to change default preferences for routing protocols, you do so before you enable the protocols.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IP**.

2. Click **IP**.
3. Click the **RoutePref** tab.
4. In the **ConfiguredValue** column, change the preference for the given protocol.
5. Click **Apply**.

***RoutePref** field descriptions*

Use the data in the following table to use the **RoutePref** tab.

Name	Description
DefaultValue	Specifies the default preference value for the specified protocol.
Protocol	Specifies the protocol name.
ConfiguredValue	Configures the preference value for the specified protocol.

Flushing routing tables by VLAN

About This Task

For administrative and troubleshooting purposes, sometimes you must flush the routing tables. You can use Enterprise Device Manager (EDM) to flush the routing tables by VLAN or by port. Use this procedure to flush the IP routing table for a VLAN.

To flush routing tables by VLAN for a VRF instance, first select the appropriate instance.

Procedure

1. In the navigation tree, expand the following folders:**Configuration** > **VLAN**.
2. Click **VLANS**.
3. Click the **Advanced** tab.
4. In the **Vlan Operation Action** column, select a flush option.

   In a VLAN context, all entries associated with the VLAN are flushed. You can flush the ARP entries and IP routes for the VLAN.
5. Click **Apply**.

Flushing routing tables by port

For administrative and troubleshooting purposes, sometimes you must flush the routing tables. You can use EDM to flush the routing tables by VLAN or flush them by port. Use this procedure to flush the IP routing table for a port.

About This Task

To flush routing tables by port for a VRF instance, first select the appropriate instance.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation tree, expand the following folders: **Configuration** > **Edit** > **Port**.
3. Click **General**.

4. Click the **Interface** tab.
5. In the **Action** section, select **flushAll**.

   In a port context, all entries associated with the port are flushed. You can flush the ARP entries and IP routes for a port.

   After you flush a routing table, it is not automatically repopulated. The repopulation time delay depends on the routing protocols in use.
6. Click **Apply**.

Assigning an IP address to a port

Assign an IP address to a port so that it acts as a routable VLAN (a brouter port) and supports IP routing.

To configure a brouter port, assign an IP address to an IP policy-based single-port VLAN.

Before You Begin

- Ensure routing (forwarding) is globally enabled.
- Ensure the VLAN is configured.
- If required, ensure the VRF instance exists.

About This Task

Important

After you configure the IP address, you cannot edit the IP address, and you can assign only one IP address to any router interface (brouter or virtual).

You cannot assign an IP address to a brouter port that is a member of a routed VLAN. To assign an IP address to the brouter port, you must first remove the port from the routed VLAN.

If you want to assign a new IP address to a VLAN or brouter port that already has an IP address, first delete the existing IP address and then insert the new IP address.

Procedure

1. In Device Physical View, select the port.
2. In the navigation tree, expand the **Configuration** > **Edit** > **Port** folders.
3. Click **IP**.
4. Click the **IP Address** tab.
5. Click **Insert**.
6. In the **Insert IP Address** dialog box, type the IP address, network mask, and VLAN ID.
7. Click **Insert**.

IP Address *Field Descriptions*

Use the data in the following table to help use the **IP Address** tab.

Name	Description
Interface	Specifies the router interface. • The name of the VLAN followed by the VLAN designation identifies virtual router interfaces. • The slot and port number of the brouter port identifies brouter interfaces.
Ip Address	Specifies the IP address of the brouter interface on this port. You can define only one IP address on a given port interface.
Net Mask	Specifies the subnet mask of the brouter interface on this port. The mask is an IP address with all the network bits set to 1 and all the hosts bits set to 0.
Name	Specifies the name of the brouter interface. The value ranges from 0 to 64 characters.
BcastAddrFormat	Specifies the IP broadcast address format used on this interface.
ReasmMaxSize	Specifies the size of the largest IP packet which the interface can reassemble from fragmented incoming IP packets.
VlanId	Specifies the ID of the VLAN associated with the brouter port. This parameter is used to tag ports.
BrouterPort	Indicates whether this is a brouter port.
MacOffset	Specifies a number by which to offset the MAC address of the VLAN from the chassis MAC address. This ensures that each IP address has a different MACaddress.
VrfId	Specifies the associated VRF interface. The VrfId associates VLANs or brouter ports to a VRF after the creation of VLANs or brouter ports. VRF ID 0 is reserved for the Global Router.

Assigning an IP Address to a VLAN

Before You Begin

- Ensure routing (forwarding) is globally enabled.
- Ensure VLAN is configured.
- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504.

About This Task

Specify an IP address for a VLAN so that the VLAN can perform IP routing.

Important

You can assign only one IP address to any router interface (brouter or VLAN).

You cannot assign an IP address to a VLAN if a brouter port is a member of the VLAN. To assign an IP address to the VLAN, you must first remove the brouter port member.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **VLAN**.
2. Click **VLANs** > **Basic**.
3. Select a VLAN.
4. Click **IP**.
5. Click **Insert**.
6. In the **Insert IP Address** dialog box, type the IP address and network mask.
7. Click **Insert**.

Viewing IP addresses for all router interfaces

About This Task

Use the Addresses tab to view IP addresses (and their associated router interfaces) from one central location.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IP**.
2. Click **IP**.
3. Click the **Addresses** tab.

Addresses *field descriptions*

Use the data in the following table to use the **Addresses** tab.

Name	Description
Interface	Specifies the router interface. • The name of the VLAN followed by the VLAN designation identifies virtual router interfaces. • The slot and port number of the brouter port identifies brouter interfaces.
Ip Address	Specifies the IP address of the router interface.
Net Mask	Specifies the subnet mask of the router interface.
BcastAddrFormat	Specifies the IP broadcast address format used on this interface; that is, whether 0 (zero) or one is used for the broadcast address. The switch uses 1.
ReasmMaxSize	Specifies the size of the largest IP packet that this interface can reassemble from incoming fragmented IP packets.
VlanId	Identifies the VLAN associated with this entry. This value corresponds to the lower 12 bits in the IEEE 802.1Q VLAN tag.
BrouterPort	Indicates whether this is a brouter port (as opposed to a routable VLAN).
MacOffset	Specifies a number by which to offset the MAC address of the VLAN from the chassis MAC address. This ensures that each IP address has a different MAC address.

Configure IP Routing Features Globally

About This Task

Configure the IP routing protocol stack to determine which routing features the switch can use.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IP**.
2. Select **IP**.
3. Select the **Globals** tab.
4. To globally enable routing, select **Forwarding**.
5. To globally configure the default TTL parameter type a value in the **DefaultTTL** field.

   This value is placed into routed packets that have no TTL specified.
6. To globally enable IPv4 ICMP broadcast, select **IcmpEchoBroadcastRequestEnable**.
7. To globally enable IPv4 Fragmented ICMP packet filtering, select **IcmpDropFragmentsEnable**.
8. To globally enable the Alternative Route feature, select **AlternativeEnable**.
9. To globally enable ICMP Router Discovery, select **RouteDiscoveryEnable**.
10. To globally enable IP Sorce Routing, select **SourceRouteEnable**.
11. To globally enable ECMP, select **EcmpEnable**.
12. Configure the remaining parameters as required.
13. Select **Apply**.

Globals *Field Descriptions*

Use the data in the following table to use the **Globals** tab.

Name	Description
Forwarding	Configures the system for forwarding (routing) or for dropping. The default value is forwarding.
DefaultTTL	Configures the default time-to-live (TTL) value for a routed packet. TTL indicates the maximum number of seconds elapsed before a packet is discarded. Enter an integer from 1 to 255. The default value of 255 is used if a value is not supplied in the datagram header.
ReasmTimeout	Specifies the maximum number of seconds that received fragments are held while they wait for reassembly. The default value is 30 seconds.

Name	Description
ICMPUnreachableMsgEnable	Enables the generation of Internet Control Message Protocol (ICMP) network unreachable messages if the destination network is not reachable from this system. These messages help determine if the system is reachable over the network. The default is disabled. Important: As a best pactice, enable icmp-unreach-msg only if it is absolutely required. If icmp-unreach-msg is enabled and a packet is received for which there is no route in the routing table, CPU utilization can dramatically increase.
ICMPRedirectMsgEnable	Enables or disables the system sending ICMP destination redirect messages.
IcmpEchoBroadcastRequestEnable	Enables or disables IP ICMP echo broadcast request feature. The default is enabled.
IcmpDropFragmentsEnable	Enables or disables IPv4 Fragmented ICMP packet filtering globally. The default is disabled.
AlternativeEnable	Globally enables or disables the Alternative Route feature. If the alternative-route parameter is disabled, all existing alternative routes are removed. After the parameter is enabled, all alternative routes are re-added. The default is enabled.
RouteDiscoveryEnable	Enables the ICMP Router Discovery feature. The default is disabled (not selected). Use ICMP Router Discovery to enable hosts attached to multicast or broadcast networks to discover the IP addresses of neighboring routers.
AllowMoreSpecificNonLocalRouteEnable	Enables or disables a more-specific nonlocal route. If enabled, the system can enter a more-specific nonlocal route into the routing table. The default is disabled.
SuperNetEnable	Enables or disables supernetting. If supernetting is globally enabled, the system can learn routes with a route mask less than 8 bits. Routes with a mask length less than 8 bits cannot have ECMP paths, even if you globally enable the ECMP feature. The default is disabled.
UdpCheckSumEnable	Enables or disables the UDP checksum calculation. The default is enable.
SourceRouteEnable	Enables or disables IP Source Routing globally. It is disabled by default.

Name	Description
ARPLifeTime	Specifies the lifetime of an ARP entry within the system, global to the switch. The default value is 360 minutes.
EcmpEnable	Globally enables or disables the Equal Cost Multipath (ECMP) feature. The default is disabled. After ECMP is disabled, the EcmpMaxPath is reset to the default value of 1.
EcmpMaxPath	Globally configures the maximum number of ECMP paths. You cannot configure this feature unless ECMP is enabled globally. Different hardware platforms can support a different number of ECMP paths. For more information, see *Fabric Engine Release Notes*.
Ecmp1PathList	Selects a preconfigured ECMP path.
Ecmp2PathList	Selects a preconfigured ECMP path.
Ecmp3PathList	Selects a preconfigured ECMP path.
Ecmp4PathList	Selects a preconfigured ECMP path.
Ecmp5PathList	Selects a preconfigured ECMP path.
Ecmp6PathList	Selects a preconfigured ECMP path.
Ecmp7PathList	Selects a preconfigured ECMP path.
Ecmp8PathList	Selects a preconfigured ECMP path.
EcmpPathListApply	Applies changes in the ECMP pathlist configuration, or in the prefix lists configured as the pathlists.
TcpAdjustMssEnable	Adjusts the TCP maximum segment size (MSS) to improve the throughput for the TCP session over a Fabric Extend (FE) adjacency. The default is disabled.
TcpAdjustMssStatus	Displays the activation status of the MSS adjustment functionality.
TcpAdjustMssType	Displays if the MSS adjustment value is manually configured or auto-derived. The software does not support auto-derived values for this feature.
TcpAdjustMssValue	Configures the MSS adjustment value. • The default value is 1300.

Configure ECMP

Enable Equal Cost MultiPath (ECMP) to permit routers to determine up to eight equal-cost paths to the same destination prefix. You can use the multiple paths for load-sharing of traffic, which allows fast

convergence to alternative paths. By maximizing load sharing among equal-cost paths, you can maximize the efficiency of links between routers.

Before You Begin

- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504.
- To configure an ECMP pathlist, you must first configure a prefix list that you reference in the pathlist configuration.

About This Task

Different hardware platforms can support a different number of ECMP paths. For more information, see *Fabric Engine Release Notes*.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **IP**.
3. Select the **Globals** tab.
4. Select **EcmpEnable**.
5. (Optional) In **EcmpMaxPath**, type the preferred maximum number of equal-cost paths.
6. (Optional) Configure an ECMP pathlist to specify routes with the required number of paths.
7. (Optional) If you modified the ECMP pathlist configuration, select **EcmpPathListApply**.
8. Select **Apply**.

Configure Static Routes

Perform the steps in this task to:

- Create static routes for data traffic in either the GRT or a specific VRF context for any platform.
- Create static routes for a VRF associated with a Segmented Management Instance CLIP interface.

Before You Begin

- Ensure no black hole static route exists. If a black hole route is enabled, you must first delete or disable it before you can add a regular static route to that destination.

  Note

  Only black hole routes that belong to the static type protocol are supported. An inter-VRF black hole route is not installed in the routing table of the destination VRF on the same switch.

- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504.

About This Task

When you configure a static route with a next-hop-vrf context, you can specify a next-hop IP address that is a locally owned VRRP IP address of the system itself. However, this is not a supported configuration. The best practice is to implement an alternative method of inter-vrf route sharing, such as route redistribution or IS-IS accept polices.

For route scaling information, see *Fabric Engine Release Notes*.

Note

Do not configure static routes on a DvR Leaf node unless the configuration is for reachability to a management network using a brouter port.

Also, configuring the preference of static routes is not supported on a Leaf node.

Procedure

1. In the navigation tree, expand **Configuration** > **IP**.
2. Select **IP**.
3. Select the **Static Routes** tab.
4. Select **Insert**.
5. If required, in the **OwnerVrfId** check box, select the appropriate VRF ID. By default, the VRF is the GlobalRouter VRF 0.
6. In the **Dest** field, type the IP address.
7. In the **Mask** field, type the subnet mask.
8. In the **NextHop** field, type the IP address of the router through which the specified route is accessible.
9. (Optional) In the **NextHopVrfId** field, select the appropriate value.
10. (Optional) To enable the static route, select the **Enable** check box.
11. (Optional) In the **Metric** field, type the metric.
12. (Optional) In the **Preference** field, type the route preference.
13. (Optional) If required, select the **LocalNextHop** check box.

    Use this option to create Layer 3 static routes.
14. Select **Insert**.

    The system displays the new route in the **IP** dialog box, **Static Routes** tab.

Static Routes *Field Descriptions*

Use the data in the following table to use the **Static Routes** tab.

Name	Description
OwnerVrfId	Specifies the VRF ID for the static route.
Dest	Specifies the destination IP address of this route. A value of 0.0.0.0 is a default route. The system can display multiple routes to a single destination in the table, but access to such multiple entries is dependent on the table-access mechanisms defined by the network management protocol in use.

Name	Description
Mask	Indicates the mask that the system operates a logically AND function on, with the destination address, to compare the result to the Route Destination. For systems that do not support arbitrary subnet masks, an agent constructs the Route Mask by determining whether it belongs to a class A, B, or C network, and then uses one of: 255.0.0.0—Class A 255.255.0.0—Class B 255.255.255.0—Class C If the Route Destination is 0.0.0.0 (a default route) then the mask value is also 0.0.0.0.
NextHop	Specifies the IP address of the next hop of this route. In the case of a route bound to an interface which is realized through a broadcast media, the Next Hop is the IP address of the agent on that interface. When you create a black hole static route, configure this parameter to 255.255.255.255.
NextHopVrfId	Specifies the next-hop VRF ID in interVRF static route configurations. Identifies the VRF in which the ARP entry resides.
Name Note: This field does not apply to all hardware platforms.	Specifies the name for the static route.
Enable	Determines whether the static route is available on the port. The default is enable. If a static route is disabled, it must be enabled before it can be added to the system routing table.
Status	Specifies the status of the route. The default is enabled.
Metric	Specifies the primary routing metric for this route. The semantics of this metric are determined by the routing protocol specified in the route RouteProto value. If this metric is not used, configure the value to 1. The default is 1. Note: Do not configure a static interface subnet route with a metric of 1.
IfIndex	Specifies the route index of the Next Hop. The interface index identifies the local interface through which the next hop of this route is reached.
Preference	Specifies the routing preference of the destination IP address. If more than one route can be used to forward IP traffic, the route that has the highest preference is used. The higher the number, the higher the preference.
LocalNextHop	Enables and disables LocalNextHop. If enabled, the static route becomes active only if the system has a local route to the network. If disabled, the static route becomes active if the system has a local route or a dynamic route.

Deleting a static route

About This Task

Delete static routes that are no longer needed to prevent routing errors.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IP**.
2. Click **IP**.
3. Click the **Static Routes** tab.
4. Select the static route you want to delete.
5. Click **Delete**.

Configure a Default Static Route

Before You Begin

- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504.

About This Task

The default route specifies a route to all networks for which there no explicit routes exist in the Forwarding Information Base or in the routing table. This route has a prefix length of zero (RFC 1812). You can configure the switch with a static default route, or they can learn it through a dynamic routing protocol.

To create a default static route, you configure the destination address and subnet mask to 0.0.0.0.

Tip

As a best practice, do not configure static routes on a DvR Leaf node unless the configuration is for reachability to a management network using a brouter port.

Also, configuring the preference of static routes is not supported on a Leaf node.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **IP**.
3. Select the **Static Routes** tab.
4. Select **Insert**.
5. In the **OwnerVrfId** check box, select the appropriate VRF ID.
6. In **Dest**, type 0.0.0.0.
7. In **Mask**, type 0.0.0.0.
8. In **NextHop**, type the IP address of the router through which the specified route is accessible.
9. In **Metric**, type the HopOrMetric value.
10. Select **Insert**.

Configure a Black Hole Static Route

Before You Begin

- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504.

About This Task

Create a black hole static route to the destination that a router advertises to avoid routing loops when aggregating or injecting routes to other routers.

If an existing black hole route is enabled, you must first delete or disable it before you can add a regular static route to that destination.

Note

Only black hole routes that belong to the static type protocol are supported. An inter-VRF black hole route is not installed in the routing table of the destination VRF on the same switch.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IP**.
2. Select **IP**.
3. Select the **Static Routes** tab.
4. Select **Insert**.
5. In the **OwnerVrfId** check box, select the appropriate VRF ID.
6. In the **Dest** field, enter the IP address.
7. In the **Mask** field, enter the network mask.
8. In the **NextHop** field, type 255.255.255.255.

   To create a black hole static route, you must configure the NextHop address to 255.255.255.255.
9. Select the **enable** option.
10. In the **Metric** box, type the HopOrMetric value.
11. In the **Preference** check box, select the route preference.

    When you specify a route preference, be sure to appropriately configure the preference so that when the black hole route is used, it is elected as the best route.
12. Select **Insert**.

Viewing IP routes

View IP routes learned on the device.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IP**.
2. Click **IP**.
3. Click the **Routes** tab to view IP routes learned on the device.
4. If you want to limit the routes displayed, click **Filter** to show a smaller subset of the learned routes.
5. In the Filter dialog box, select an option, or options, and enter information to limit the routes to display in the Routes table.

6. Click **Filter** and the Routes table displays only the routes that match the options and information that you enter.

Routes *Field Descriptions*

Use the data in the following table to use the **Routes** tab.

Name	Description
Dest	Specifies the destination IP network of this route. An entry with a value of 0.0.0.0 is a default route. The system can display multiple routes to a single destination in the table, but access to multiple entries depends on the table access mechanisms defined by the network management protocol in use.
Mask	Indicates the network mask to logically add with the destination address before comparison to the destination IP network.
NextHop	Specifies the IP address of the next hop of this route.
AltSequence	Indicates the alternative route sequence. The value of 0 denotes the best route.
NextHopId	Displays the MAC address or hostname of the next hop.
HopOrMetric	Displays the primary routing metric for this route. The semantics of this metric are specific to different routing protocols.
Interface	Specifies the router interface for this route. • Virtual router interfaces are identified by the VLAN number of the VLAN followed by the (VLAN) designation. • Brouter interfaces are identified by the slot and port number of the brouter port.
Proto	Specifies the routing mechanism through which this route was learned: • other—none of the following • local—nonprotocol information, for example, manually configured entries • static • ICMP • EGP • GGP • Hello • RIP • IS-IS • ES-IS • Cisco IGRP • bbnSpfIgp • OSPF • BGP • Inter-VRF Redistributed Route
Age	Displays the number of seconds since this route was last updated or otherwise determined to be correct.

Name	Description
PathType	Indicates the route type, which is a combination of direct, indirect, best, alternative, and ECMP paths. • iA indicates Indirect Alternative route without an ECMP path • iAE indicates Indirect Alternative ECMP path • iB indicates Indirect Best route without ECMP path • iBE indicates Indirect Best ECMP path • dB indicates Direct Best route • iAN indicates Indirect Alternative route not in hardware • iAEN indicates Indirect Alternative ECMP route not in hardware • iBN indicates Indirect Best route not in hardware • iBEN indicates Indirect Best ECMP route not in hardware • dBN indicates Direct Best route not in hardware • iAU indicates Indirect Alternative Route Unresolved • iAEU indicates Indirect Alternative ECMP Unresolved • iBU indicates Indirect Best Route Unresolved • iBEU indicates Indirect Best ECMP Unresolved • dBU indicates Direct Best Route Unresolved • iBF indicates Indirect Best route replaced by FTN • iBEF indicates Indirect Best ECMP route replaced by FTN • iBV indicates Indirect best IPVPN route • iBEV indicates Indirect best ECMP IP VPN route • iBVN indicates Indirect best IP VPN route not in hardware • iBEVN indicates Indirect best ECMP IP VPN route not in hardware
Pref	Displays the preference.
NextHopVrfId	Specifies the VRF ID of the next-hop address.

Configuring ICMP Router Discovery globally

About This Task

Enable ICMP Router Discovery so that it can operate on the system.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IP**.
2. Click **IP**.
3. Click the **Globals** tab.
4. Select **RouteDiscoveryEnable**.
5. To select a preconfigured ECMP path, click the **EcmpPathList** ellipsis button.
6. Click **OK**.
7. Click **Apply**.

Configure the ICMP Router Discovery Table

Before You Begin

- ICMP Router Discovery must be globally enabled.
- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504.

About This Task

Configure the ICMP Router Discovery table to ensure correct ICMP operation for all interfaces that use Router Discovery.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IP**.
2. Click **IP**.
3. Click the **Router Discovery** tab.
4. Configure the Router Discovery parameters to suit your network.
5. Click **Apply**.

Router Discovery *field descriptions*

Use the data in the following table to use the **Router Discovery** tab.

Name	Description
Interface	Indicates the VLAN ID or the port.
AdvAddress	Specifies the IP destination address used for broadcast or multicast router advertisements sent from the interface. The address is the all-systems multicast address 224.0.0.1, or the limited-broadcast address 255.255.255.255. The default value is 255.255.255.255.
AdvFlag	Indicates whether (true) or not (false) the address is advertised on the interface. The default value is true (advertise address).
AdvLifetime	Specifies the time to-live-value (TTL) of router advertisements (in seconds) sent from the interface. The range is MaxAdvInterval to 9000 seconds. The default value is 1800 seconds.
MaxAdvInterval	Specifies the maximum time (in seconds) that elapses between unsolicited broadcast or multicast router advertisement transmissions from the interface. The range is 4 to 1800 seconds. The default value is 600 seconds.

Name	Description
MinAdvInterfal	Specifies the minimum time (in seconds) that elapses between unsolicited broadcast or multicast router advertisement transmissions from the interface. The range is 3 seconds to MaxAdvInterval. The default value is 450 seconds.
PreferenceLevel	Specifies the preference value (a higher number indicates more preferred) of the address as a default router address relative to other router addresses on the same subnet. The range is –2147483648 to 2147483647. The default value is 0.

Configuring ICMP Router Discovery for a Port

Before You Begin

- You must globally enable ICMP Router Discovery.
- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504.

About This Task

Use this procedure to configure Router Discovery on a port. When enabled, the port sends Router Discovery advertisement packets.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand the following folders: **Configuration** > **Edit** > **Port**.
3. Click **IP**.
4. Click the **Router Discovery** tab.
5. To enable Router Discovery, select **AdvFlag**.
6. Configure other parameters as required for proper operation.
7. Click **Apply**.

Router Discovery *field descriptions*

Use the data in the following table to use the **Router Discovery** tab.

Name	Description
AdvAddress	Specifies the destination IP address used for broadcast or multicast router advertisements sent from the interface. The accepted values are the all-systems multicast address 224.0.0.1, or the limited-broadcast address 255.255.255.255. The default value is 255.255.255.255.
AdvFlag	Indicates whether (true) or not (false) the address is advertised on the interface. The default value is True (advertise address).

Name	Description
AdvLifetime	Specifies the time to live value (TTL) of router advertisements (in seconds) sent from the interface. The range is MaxAdvInterval to 9000 seconds. The default value is 1800 seconds.
MaxAdvInterval	Specifies the maximum time (in seconds) that elapses between unsolicited broadcast or multicast router advertisement transmissions from the interface. The range is 4 seconds to 1800 seconds. The default value is 600 seconds.
MinAdvInterval	Specifies the minimum time (in seconds) that elapses between unsolicited broadcast or multicast router advertisement transmissions from the interface. The range is 3 seconds to MaxAdvInterval. The default value is 450 seconds.
PreferenceLevel	Specifies the preference value (a higher number indicates more preferred) of the address as a default router address relative to other router addresses on the same subnet. The accepted values are –2147483648 to 2147483647. The default value is 0.

Configure ICMP Router Discovery on a VLAN

Before You Begin

- You must globally enable ICMP Router Discovery.
- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504.

About This Task

Configure Router Discovery on a VLAN so that the ICMP Router Discovery feature can run over the VLAN. When enabled, the system sends Router Discovery advertisement packets to the VLAN.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **VLAN**.
2. Click **VLANs**.
3. Select the VLAN ID that you want to configure to participate in Router Discovery.
4. Click **IP**.
5. Click the **Router Discovery** tab.
6. To enable Router Discovery for the VLAN, select **AdvFlag**.
7. Configure other parameters as required for proper operation.
8. Click **Apply**.

***Router Discovery** field descriptions*

Use the data in the following table to use the **Router Discovery** tab.

Name	Description
AdvAddress	Specifies the destination IP address used for broadcast or multicast router advertisements sent from the interface. The address is the all-systems multicast address, 224.0.0.1, or the limited-broadcast address, 255.255.255.255. The default value is 255.255.255.255.
AdvFlag	Indicates whether (true) or not (false) the address is advertised on the interface. The default value is true (advertise address).
AdvLifetime	Specifies the time to-live-value (TTL) of router advertisements (in seconds) sent from the interface. The range is MaxAdvInterval to 9000 seconds. The default value is 1800 seconds.
MaxAdvInterval	Specifies the maximum time (in seconds) allowed between sending unsolicited broadcast or multicast router advertisements from the interface. The range is 4 seconds to 1800 seconds. The default value is 600 seconds.
MinAdvInterval	The minimum time (in seconds) allowed between unsolicited broadcast or multicast router advertisements sent from the interface. The range is 3 seconds to MaxAdvInterval. The default value is 450 seconds.
PreferenceLevel	Specifies the preference value (a higher number indicates more preferred) of the address as a default router address, relative to other router addresses on the same subnet. The range is –2147483648 to 2147483647. The default value is 0.

Configure a Circuitless IPv4 Interface

About This Task

You can use a circuitless IPv4 (CLIPv4) interface to provide uninterrupted connectivity to your system.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **IP**.
3. Select the **Circuitless IP** tab.
4. Select **Insert**.
5. In the **Interface** field, assign a CLIP interface number.
6. Enter the IP address.
7. Enter the network mask.
8. Select **Insert**.
9. To delete a CLIP interface, select the interface and select **Delete**.

Circuitless IP *Field Descriptions*

Use the data in the following table to use the **Circuitless IP** tab.

Name	Description
Interface	Specifies the number assigned to the interface.
Ip Address	Specifies the IP address of the CLIP.
Net Mask	Specifies the network mask.
Name	Specifies the name assigned to the IPv4 CLIP address.

Enabling OSPF on a CLIP interface

Before You Begin

- You must globally enable OSPF.
- The OSPF area must already exist.

About This Task

Enable Open Shortest Path First (OSPF) on a CLIP interface so that it can participate in OSPF routing.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IP**.
2. Click **IP**.
3. Click the **Circuitless IP** tab.
4. Select the required CLIP interface.
5. Click **OSPF**.
6. Select the **Enable** check box.

   You must enable OSPF on the CLIP interface for CLIP to function.
7. In the current **AreaId** field, enter the IP address of the OSPF backbone area.
8. Click **Apply**.

Circuitless OSPF *field descriptions*

Use the data in the following table to use the **Circuitless OSPF** tab.

Name	Description
Enable	Enables OSPF on the CLIP interface.
AreaId	Specifies the OSPF area ID.

Enabling PIM on a CLIP interface

Enable Protocol Independent Multicasting (PIM) on a CLIP interface so that it can participate in PIM routing.

Before You Begin

- You must globally enable PIM.

About This Task

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IP**.
2. Click **IP**.
3. Click the **Circuitless IP** tab.
4. Select the required CLIP interface.
5. Click **PIM**.
6. Select the **Enable** check box.

   You must enable PIM on the CLIP interface for PIM to function. The mode is indicated on this tab.
7. Click **Apply**.

Circuitless PIM *field descriptions*

Use the data in the following table to use the **Circuitless PIM** tab.

Name	Description
Enable	Enables PIM on the CLIP interface.
Mode	Specifies the PIM mode.

Enable BFD on a CLIP interface

Before You Begin

- The CLIP Interface must already exist.

About This Task

Enable Bidirectional Forwarding Detection (BFD) over Fabric Extend tunnels on a CLIP interface.

Note

Procedure

1. In the navigation pane, expand the **Configuration** > **IP** folders.
2. Click **IP**.
3. Click the **Circuitless IP** tab.
4. Select the required CLIP interface.
5. Click **BFD**.
6. Select the **Enable** check box.
7. (Optional) In the **MinRxInterval** field, specify the minimum receive interval.
8. (Optional) In the **TxInterval** field, specify the transmit interval.
9. (Optional) In the **Multiplier** field, specify the multiplier used to calculate a receive timeout.

BFD Field Descriptions

Use the data in the following table to use the **BFD** tab.

Name	Description
Enable	Enable BFD on the CLIP interface.
MinRxInterval	Specifies the minimum interval, in milliseconds, between received BFD control packets that the local system is capable of supporting. The default is 200 ms. Note: The minimum value you can configure for the receive interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the receive interval. You can configure any remaining BFD sessions with a receive interval that is greater than or equal to the 200 ms default value.
TxInterval	Specifies the transmit interval in milliseconds. The default is 200 ms. Note: The minimum value you can configure for the transmit interval is 100 ms. You can configure a maximum of 4 BFD sessions with the minimum value for the transmit interval. You can configure any remaining BFD sessions with a transmit interval that is greater than or equal to the 200 ms default value.
Multiplier	Specifies a value for the multiplier used to calculate a receive timeout. The default is 3. Note: If you configure the transmit interval or the receive interval as 100 ms, you must configure a value of 4 or greater for the multiplier.

Viewing TCP global information

View TCP and UDP information to view the current configuration.

About This Task

The fields on the TCP global tab provide information about the handshake (SYN) configuration and the maximum number of TCP connections you can create on your system.

When you initiate a TCP connection, both end points send handshake information to create the channel.

The retransmission algorithm and fields display the configured timeout value and minimum and maximum retransmission times that your system uses to terminate a connection attempt that falls outside your specified parameters.

Procedure

1. In the navigation pane, expand the **Configuration** > **IP** folders.
2. Click **TCP/UDP**.
3. Click the **TCP Globals** tab.

TCP Global field descriptions

Use the data in the following table to use the **TCP Globals** tab.

Name	Description
RtoAlgorithm	Determines the timeout value used for retransmitting unacknowledged octets.
RtoMin	Displays the minimum time (in milliseconds) permitted by a TCP implementation for the retransmission timeout.
RtoMax	Displays the maximum time (in milliseconds) permitted by a TCP implementation for the retransmission timeout.
MaxConn	Displays the maximum connections for the device.

Viewing TCP connections information

View information about TCP connections.

About This Task

Among other things, the fields on the TCP connections tab provide important information about the health of connections that traverse your switch.

In particular, the state column lets you know the state of each TCP connection. Of these, synSent, synReceived, and established indicate whether or not a channel is established and listen indicates when an end system is waiting for a returning handshake (SYN).

Procedure

1. In the navigation pane, expand the : **Configuration** > **IP** folders.
2. Click **TCP/UDP**.
3. Click the **TCP Connections** tab.

TCP Connections field descriptions

Use the data in the following table to use the **TCP Connections** tab.

Name	Description
LocalAddressType	Displays the type (IPv6 or IPv4) for the address in the LocalAddress field.
LocalAddress	Displays the IPv6 address for the TCP connection.
LocalPort	Displays the local port number for the TCP connection.
RemAddressType	Displays the type (IPv6 or IPv4) for the remote address of the TCP connection.
RemAddress	Displays the IPv6 address for the remote TCP connection.

Name	Description
RemPort	Displays the remote port number for the TCP connection.
State	Displays an integer that represents the state for the connection: • closed • listen • synSent • synReceived • established • finWait1 • finWait2 • closeWait • lastAck(9) • closing • timeWait • deleteTCB
Process	Displays the process ID for the system process associated with the TCP connection.

Viewing TCP listeners information

View TCP listener information.

About This Task

The TCP listeners table provides a detailed list of systems that are in the listening state.

When a connection is in the listen state an end point system is waiting for a returning handshake (SYN).The normal listening state should be very transient, changing all of the time.

Two or more systems going to a common system in an extended listening state indicates the need for further investigation.

End systems in an extended listening state can indicate a broken TCP connection or a DOS attack on a resource.

This type of DOS attack, known as a SYN attack, results from the transmission of SYNs with no response to return replies.

While many systems can detect a SYN attack, the TCP listener statistics can provide additional forensic information.

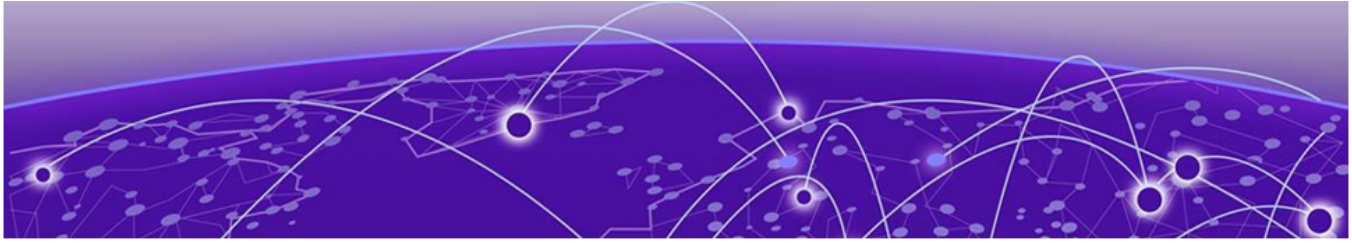
Procedure

1. In the navigation pane, expand the **Configuration** > **IP** folders.
2. Click**TCP/UDP**.
3. Click the **TCP Listeners** tab.

TCP Listeners *field descriptions*

Use the data in the following table to use the **TCP Listeners** tab.

Name	Description
LocalAddressType	Displays the type (IPv6 or IPv4) for the address in the LocalAddress field.
LocalAddress	Displays the IPv6 address for the TCP connection.
LocalPort	Displays the local port number for the TCP connection.
Process	Displays the process ID for the system process associated with the TCP connection.



IPv6 Routing Basics

The following sections provide concepts and procedures to complete basic IPv6 configuration, for example, IPv6 forwarding and static routes.

Important

For the 5320 Series, only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration.

Origins of IPv6

The growth of IP address use is exponential.

Predictions indicated that the IPv4 address pool could be exhausted as early as 1994.

So, in July 1991, the Internet Engineering Task Force (IETF) began researching a replacement for IPv4.

That replacement is IPv6.

The Internet Assigned Numbers Authority (IANA) free pool of IPv4 addresses reached 0% in February 2011, according to the American Registry for Internet Numbers (ARIN).

While IPv4 addresses may remain available for some time within reserved pools, no further IPv4 addresses are available for reservation.

Although IPv6 is designed to replace IPv4, IPv6 is not backward-compatible and IPv4 and IPv6 need to coexist within your network during and after the transition to IPv6.

Advantages of IPv6

IPv6 can provide more addresses and support more networks than IPv4. For example, IPv6 offers enough addresses for every person on Earth to have 1 million addresses.

Because IPv6 offers a larger address space it offers improved scalability.

Following are additional advantages of IPv6 over IPv4:

- With 128 bit addresses, the larger IPv6 address space offers global access and scalability and solves the pending exhaustion of IP addresses.
- Network Address Translation (NAT) is no longer required.

  Flat address space and transparency are restored by IPv6 because NAT is eliminated.
- Routing efficiency is improved due to the hierarchical network architecture.

  IPv6 allows for hierarchical routing and effective route summarization.
- IPv6 supports Auto-configuration.
- IPv6 supports plug-and-play.
- Enhanced support is included for mobile IP and mobile computing devices.

  Addresses can be permanently assigned to end devices such as DSL, PDAs, mobile terminals and PCs.
- Neighbor discovery (ND) replaces ARP in IPv6.

  ND combines the IPv4 services for IPv4 Address Resolution Protocol (ARP) and router discovery.

Comparison of IPv4 and IPv6

The following table compares the key differences between IPv4 and IPv6.

Note
This information may not reflect IPv6 support in the current release.

Table 113: IPv4 and IPv6 key differences compared

Feature	IPv4	IPv6
Address length	32 bits	128 bits
IPsec support	Optional	Required
QoS support	Limited	Improved
Fragmentation	Hosts and routers	Hosts only
Minimum MTU packet size	576 bytes	1280 bytes
Checksum in header	Yes	No
Options in header	Yes	Yes
Link-layer address resolution	ARP (broadcast)	Multicast neighbor discovery messages
Multicast membership	IGMP	Multicast Listener Discovery
Router discovery	Optional	Optional
Uses broadcasts	Yes	No
Address configuration	Manual, DHCP	Automatic, DHCP

IPv6 packet

Each IPv6 packet can include mandatory and non-mandatory components.

An IPv6 packet includes:

- The basic header, which has a fixed length and is mandatory
- Extension header(s) , which has a variable length and is not mandatory
- Payload, which has a variable length and is not mandatory

The following figure illustrates the components of an IPv6 packet.

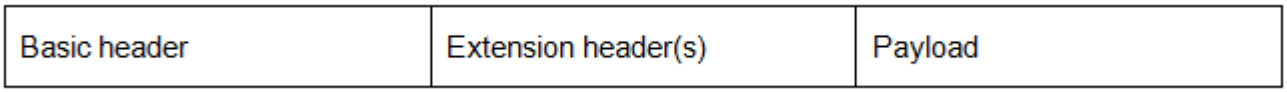


Figure 150: IPv6 packet components

Note
Nodes must be able to handle packets up to 1,280 octets in length.

IPv6 header

The IPv6 header basic length is fixed at 40 octets (bytes) and it contains the following fields:

Table 114: Fields in the IPv6 header

Field	Size in bits
Ver—Internet Protocol version number, with a value of 6	4
DS byte—Traffic class field, similar to Type of Service in IPv4	8
Flow label—identifies traffic flow for additional Quality of Service (QoS)	20
Payload Length—Unsigned integer, the length of the IPv6 payload	16
Next header selector—identifies the next header	8
Hop limit unsigned integer—decrements by 1 each time a node forwards the packet (nodes discard packets with hop limit values of 0)	8
Source address	128
Destination address	128

The following figure illustrates the basic IPv6 header, without extension headers.

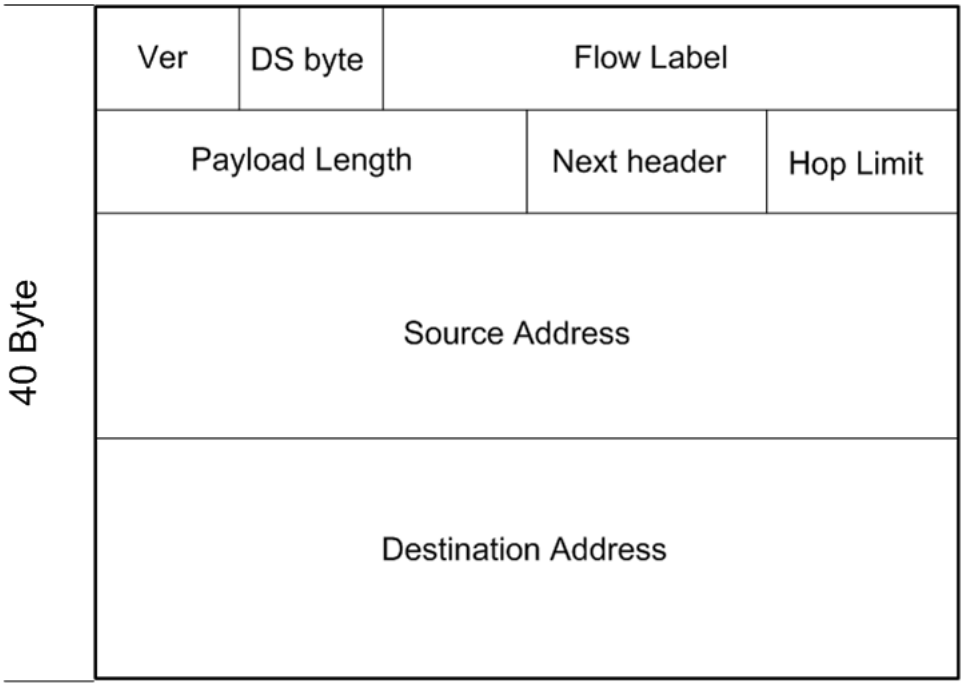

Figure 151: IPv6 header

IPv6 extension headers

IPv6 extension headers describe processing options.

Each extension header contains a separate category of options and is identified by a number, similar to protocol identification numbers.

An IPv6 packet can include extension headers, but they are not mandatory.

The following figure illustrates the IPv6 header with extension headers.

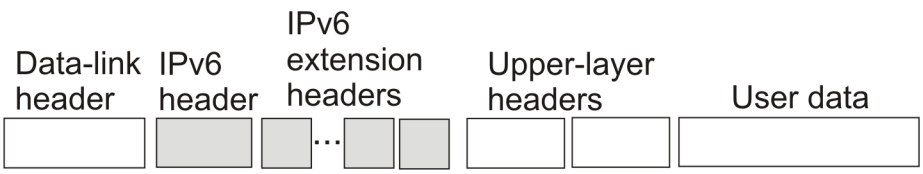

Figure 152: IPv6 header with extension headers

IPv6 examines the destination address in the main header of each packet it receives.

This examination determines whether the router is

- the packet destination - if the router is the packet destination, IPv6 examines the header extensions that contain options for destination processing.
- an intermediate node in the packet data path - if the router is an intermediate node, IPv6 examines the header extensions that contain forwarding options.

By examining only the extension headers that apply to the operations it performs, IPv6 reduces the amount of time and resources required to process a packet.

IPv6 defines the following extension headers as described in the following table:

Table 115: IPv6 extension headers

Extension header name	Description
hop-by-hop	Contains optional information, and sub-options for Router Alert and Jumbo Payload, that all intermediate IPv6 routers examine between the source and the destination.
destinations-options	Contains optional information for the destination node. The system can display this option twice, once for way points and once for final destination.
source-routing	Contains a list of one or more intermediate nodes that define a path for the packet to follow through the network to the destination. The packet source creates this list. The source-routing function is similar to the IPv6 source routing options.
fragmentation	Uses an IPv6 source to send packets larger than the size specified for the path maximum transmission unit (MTU).
authentication	provides security for IPv6 datagrams
encapsulated security payload (ESP)	provides security for IPv6 datagrams
The authentication extension header and the encapsulated security payload extension header can be used together to provide security services for IPv6 datagrams.	

The following extension header order is:

- Hop-by-hop
- Destination option 1
- Routing
- Fragmentation
- Authentication/ESP
- Destination Option 2

The presence of particular extension headers within a packet can cause slower packet processing if the IPv6 implementation handles only certain headers and diverts others to a slow path. For example, many IPv6 implementations usually process Hop-by-Hop extension headers on the control plane.

IPv6 address component summary

The IPv6 Internet is divided into addressing zones and IPv6 addresses can be categorized by type and scope.

IPv6 addressing is represented in RFC 4291.

Address types

IPv6 addresses are divided into the following types:

- Unicast

  Unicast addresses provide one-to-one communication.
- Multicast

  Multicast addresses are similar in operation to IPv4 and provide one-to-many communication.
- Anycast

  An Anycast address is a Unicast address used for several devices to allow them to communicate with the device closest to the source; one-to-nearest communication.
- Broadcast

  In IPv6, broadcast addresses have been superseded by multicast addresses per RFC 4291.

For more information about address types and scopes, see IPv6 Address Types.

Address scopes

Following are IPv6 address scopes:

- node-local
- link-local
- global

The switch does not support site-local addresses and, according to RFC 4193, site-local addresses will be replaced by unique-local addresses.

For more information about address types and scopes, see IPv6 address formats.

Address zones

The IPv6 Internet is divided into zones.

For example:

- Each node is a separate zone of the node-local scope.
- Each link is a separate zone of the link-local scope.
- The entire Internet is a single zone of global scope.

Zones of the same scope do not overlap.

IPv6 address formats

IPv6 addresses are 128 bits long. In comparison, IPv4 addresses are 32 bits in length.

The IPv6 address contains an

- address type
- address prefix
- interface ID

The following figure illustrates the IPv6 address format.

Figure 153: IPv6 address format

Address types

IPv6 uses three main address types to help route packets.

Address types are:

- Unicast: global, link—local, special unspecified, special loopback
- Multicast
- Anycast

Difference between multicast and anycast

Anycast address delivery is from one to one-of-many, whereas multicast address delivery is from one to many.

Unicast addresses

Unicast addresses provide one-to-one communication

Unicast addresses provide one-to-one communication.

Global

A Unicast global address identifies a single interface and is similar to an IPv4 public address.

Unicast global addresses are globally routable in the same manner as IPv4 addresses.

The following figure illustrates the Unicast global address parts.

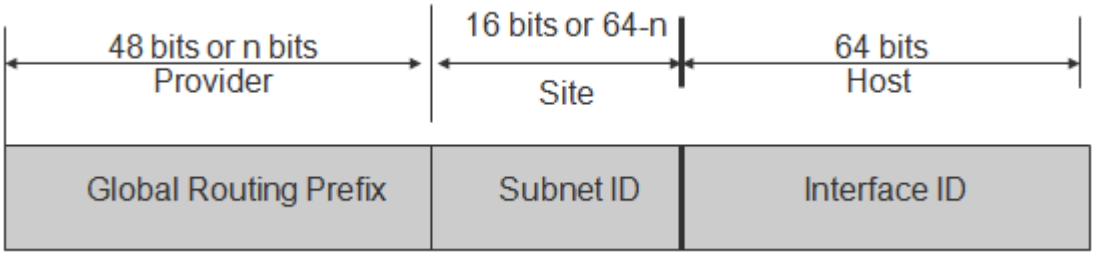

Figure 154: Unicast global address parts

An IPv6 Unicast global address is composed of the following 3 levels:

- public topology (48 bit Global Routing Prefix)
  - 001, specifies an IPv6 Unicast global address
  - Top Level Aggregation Identifier (TLA ID), the highest level in routing hierarchy
  - Res, reserved for future use
  - Next Level Aggregation Identifier (NLA ID), specifies a customer site
- site topology (16 bit Subnet ID)
  - Site Level Aggregation Identifier (SLA ID); assigned within the site, an ISP cannot affect the SLA ID, enables up to 65,536 subnets within a site
- interface ID (64 bits)
  - specifies the interface for a node on a subnet

The system uses the 48 bit global routing prefix for the route prefix exchange.

The IPv6 Prefix for Unicast global is 2000::/3 (RFC3513).

Link-local

Hosts on the same link/subnet use automatically configured IPv6 Unicast link-local addresses to communicate with each other.

Link-local addresses are automatically configured on all interfaces.

Routers do not forward packets containing a destination or source address with a link-local address.

IPv6 uses neighbor discovery (ND) for address resolution.

The IPv6 prefix for link-local Unicast addresses is FE80::/10 (RFC3513).

The following figure illustrates the parts of a Unicast Link-local address.

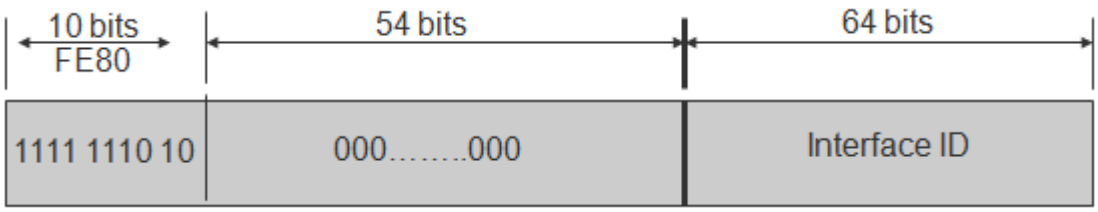

Figure 155: Unicast Link-local address

Special addresses

The Unicast/special/unspecified address indicates the absence of an address and is the only valid SRC address for IPv6 Duplicate Address Detection (DAD).

Equivalent to the IPv4 unspecified address 0.0.0.0, represented as 0:0:0:0:0:0:0:0: or ::1; an IPv6 host that does not have a valid address uses the unspecified address as its source address when it sends a packet to discover whether an address is used by another node (during the boot process when the host requests address configuration information).

Note

Do not assign an unspecified address, either statically or dynamically, to an interface.

The Unicast/special/loopback address is a special case Unicast address only found inside a single node.

The switch does not support the loopback address.

Equivalent to the IPv4 loopback address 127.0.0.1, represented as 0:0:0:0:0:0:0:1 or ::1; a node uses a loopback address to send a packet to itself.

The loopback address is beneficial in troubleshooting and testing the IP stack because you can use it to send a packet to the protocol stack without sending it onto the subnet.

Note

Do not assign a loopback address, either statically or dynamically, to an interface.

Both Loopback and Unspecified addresses are not valid destination addresses.

An example of a unicast IPv6 address is 1080:0:0:0:8:8000:200C:417A

An example of a link-local Unicast IPv6 address is FE80::4445:4eff:fe54:1212

Multicast addresses

Multicast addresses provide one-to-many communication

Multicast addresses provide one-to-many communication.

An IPv6 multicast address identifies a group of nodes.

The scope is built into the multicast address structure.

The system uses a multicast address to send traffic to multiple destinations. In this situation traffic experiences less delay with a multicast address than it would with Unicast address.

The following figure shows the format of an IPv6 multicast address.

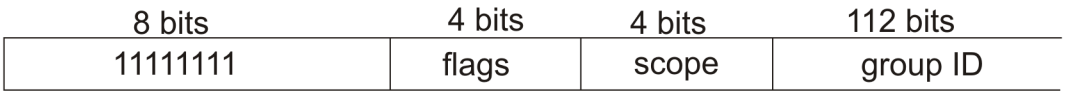

Figure 156: IPv6 multicast address format

A value of FF (11111111) in the 8 high-order bits of an IPv6 address indicates that the address is an IP multicast address.

The Multicast IPv6 Prefix is FF00::/8 (RFC3513).

Flags

The 4-bit flags field indicates whether the group is permanent or transient. The first 3 bits are reserved and the 4th bit represents the Transient flag. Currently only the Transient (T) flag is defined. A T flag set to 0 specifies a permanently assigned multicast address. A T flag set to 1 specifies a transient address.

Group ID

The 112 bit group ID identifies the multicast group.

An example of a multicast address is FF01:0:0:0:0:0:0:101

Scope field

The 4-bit scope field within the group ID specifies the multicast traffic scope.

Following is a list of the scope options that limit the scope of the multicast address:

- 1 - node-local
- 2 - link-local
- 3 - subnet local
- 4 - admin local
- 5 - site-local – not supported
- 8 - organization-local
- B - community-local
- E - global

Examples of multicast addresses

All-nodes addresses look like this:

FF01::1 (Node Local), FF02::1 (Link Local)

All-routers addresses look like this:

FF01::2 (Node Local), FF02::2 (Link Local)

A solicited node or host address looks like this:

FF02::1:FF1E:8329.

In this case the MAC is 00-02-B3-1E-83-29 and the IPv6 address is fe80::202:B3FF:FE1E:8329.

The following table lists some well-known multicast IPv6 addresses

Table 116: Well-known multicast IPv6 addresses

Name	Address
All Nodes	FF02:0:0:0:0:0:0:1
All Routers	FF02:0:0:0:0:0:0:2
OSPFIGP	FF02:0:0:0:0:0:0:5
OSPFIGP Designated Routers	FF02:0:0:0:0:0:0:6
All PIM Routers	FF02:0:0:0:0:0:0:D
VRRP	FF02:0:0:0:0:0:0:12
All MLDv2–capable routers	FF02:0:0:0:0:0:0:16
All DHCP agents	FF02:0:0:0:0:0:0:2
Solicited Node address	FF02::1:FF00:0000/104

Anycast

Anycast addresses provide one-to-nearest (one to one-of-many) communication.

Anycast addresses provide one-to-nearest (one to one-of-many) communication.

An anycast address designates a set of interfaces that share an address.

A packet sent to an anycast address goes only to the nearest member of the group. Considering routing distance, the system delivers packets with anycast addresses only to the nearest member of a group of multiple interfaces.

Restrictions

An anycast address must not be:

- used as the source address in an IPv6 packet
- assigned to an IPv6 host (you can assign an anycast address to an IPv6 router)

Anycast address scopes

Anycast addresses have the following scopes:

- Link-local—the local link; nodes on the same subnet
- Global—IPv6 Internet addresses

Similar to anycast IPv4 addresses, IPv6 anycast addresses are more efficient. They use the unicast address space but identify multiple interfaces.

IPv6 delivers a packet bearing an anycast address to the nearest interface identified by the address.

Currently anycast addresses are assigned to routers and are used as destination addresses. Because packets bearing anycast addresses are delivered to the closest router, you can also access the closest name server or time server with an anycast address.

Visually there is no distinction between an anycast address and a unicast address.

Note

The switch supports only the subnet-router anycast address.

You cannot configure any specific anycast addresses beyond the automatic, generic subnet-router anycast address.

IP address prefix

Address prefixes represent one of the following:

- network identifier
- fixed address part

Examples of IP address prefixes

2001:10F2::/48 represents a summarized route prefix

2001:10F2:0:102F::/64 represents a subnet or link prefix

FF00::/8 represents Multicast IPv6

Interface ID

Interface identifiers identify interfaces on a link.

As long as the interfaces are attached to different subnets, you can use the same identifier on more than one interface on a single node.

The IPv6 interface ID is as unique as the MAC address.

The interface ID is derived by a formula that uses the link layer 48-bit MAC address. In most cases, the interface ID is a 64-bit interface ID that contains the 48-bit MAC address. If you enter less than 64 bits, the system adds leading zeroes to extend the interface ID length to 64 bits.

You can configure the interface ID in the following ways:

- Manual configuration
- DHCPv6 (can configure the whole address)
- Automatic derivation from EUI-64 (MAC address or other HW serial)—enables serverless or stateless auto-configuration when combined with high order part of address learned from router advertisements
- Pseudo-random generation (client privacy)—enables serverless or stateless auto-configuration when combined with high order part of address learned from router advertisements

The switch supports manual interface ID configuration or automatic derivation from EUI-64.

Note

You must manually specify the network prefix, regardless of the interface ID formation method.

For stateless autoconfiguration, the ID is 64 bits in length.

For more information about stateless autoconfiguration, see Host autoconfiguration on page 1747.

How to write an IPv6 address

The appearance of IPv6 addresses differs from IPv4 addresses and you express them differently.

Hexadecimal IPv6 address representations

The 128 bits in an IPv6 address are divided into 8 blocks of 16 bits each.

Following is the preferred IPv6 address format:

XXXX:XXXX:XXXX:XXXX:XXXX:XXXX:XXXX:XXXX

Each 16 bit block in an IPv6 address is converted into a 1 to 4 digit hexadecimal number separated by colons (:).

The format to represent an IPv6 address is n:n:n:n:n:n:n:n, where n is the hexadecimal representation of 16 bits in the address; for example, 2001:0:0:0:0:0:0:43.

Each nonzero field must contain at least one numeral.

Within a hexadecimal field, you do not need leading zeros.

Certain classes of IPv6 addresses commonly include multiple adjacent fields that contain hexadecimal 0.

The sample address—2001::43—includes six adjacent fields that contain zeroes represented by a double colon (::) .

You can use a double colon to compress the leading zero fields in a hexadecimal address.

The system can display a double colon only once in an address.

Four more ways to write an IPv6 address

```
2001:DB8:0000:0000:25AB:0000:0000:0001
2001:DB8:0:0:25AB:0:0:1
2001:DB8:0:0:25AB::1
2001:DB8::25AB:0:0:1
```

ICMPv6

Internet Control Message Protocol version 6 (ICMPv6) maintains and improves on features from ICMP for IPv4.

ICMPv6 reports the delivery of forwarding errors.

For example:

- Destination unreachable
- Packet too big (path MTU)
- Time exceeded (fragmentation)
- Parameter problem

ICMPv6 also delivers information messages such as ping, otherwise known as

- Echo request
- Echo reply

Important

By providing a framework for informational messages, ICMPv6 plays an important role in IPv6 features such as

- Neighbor discovery (ND)
- Path MTU discovery
- Multicast Listener Discovery (MLD)

You can identify an IPv6 ICMP packet because the Next Header field in the IPv6 packet header is 58.

Internet Protocol Security (IPsec) with ICMPv6

You can configure IPsec with ICMPv6. For a configuration example of IPsec with ICMPv6, see IPsec with ICMPv6 configuration example on page 1578.

Fragmented ICMP Packet Filtering

ICMP fragmentation distributed denial-of-service (DDoS) attacks flood the destination resources with fragmented packets and overwhelm the network because of massive volumes of traffic. With Fragmented ICMP packet filtering, the system inspects each incoming IPv6 ICMP packet to determine if it should drop the packet or forward it.

You can configure ICMP packet filtering globally, on a specific VRF, and on the following management interfaces:

- Out-of-Band (OOB) management
- Circuitless IP (CLIP) management
- VLAN management

Path MTU discovery

IPv6 routers do not fragment packets.

The source node can send packets less than or equal to the maximum transmission unit (MTU) of the link layer.

As the packet travels through the network to the source it can encounter a link with a smaller MTU. If so, the router sends the source node an ICMP error message that contains the MTU size of the next link. The source IPv6 node then resends a packet equal to the size of the MTU included in the ICMP message.

The default Layer 3 IPv6 MTU value is 1500 where the system MTU default value is 1950.

The default IPv6 MTU value is always less than the default System MTU value.

You can configure the MTU for each IPv6 interface.

Note

The MTU value for an IPv6 interface is not configurable on 5320 Series, 5420 Series, and 5720 Series.

Note

To configure separate Layer 3 MTU values for IPv4 and IPv6 packets on the same VLAN interface, you must disable Unicast Reverse Path Forwarding (uRPF) mode. If you enable the uRPF mode using the command **boot config flags urpf-mode**, the MTU values for both IPv4 and IPv6 packets on the same VLAN are matched. Different Layer 3 MTU sizes on the same VLAN are not allowed in uRPF mode.

Routing

A routing table is present on all nodes.

The routing table stores information about IPv6 network prefixes and how to reach them.

Note

The switch requires routing protocols, such as OSPFv3 to exchange IPv6 routing prefixes.

For each incoming packet, the switch checks the destination neighbor cache first. If the destination is not in the destination neighbor cache, the routing table determines:

- the next-hop interface (the interface used for forwarding)
- the next-hop address

Note

The system uses the IPv6 Neighbor Cache for on-link, directly-connected destinations only. Off-link destinations go through a next-hop router, as determined by the next-hop address lookup.

IPv6 routes in a routing table can be:

- directly attached network routes using a 64-bit prefix
- remote network routes using a 64-bit or lower prefix
- host routes using a 128-bit prefix length
- the default route using a prefix of ::/0

The switch supports the following IPv6 routing protocols:

- BGP+ (over 6in4 tunnels)
- BGPv6
- IPv6 Shortcuts (over Fabric Connect)
- OSPFv3
- RIPng

You can redistribute IPv6 routes between any of these routing protocols.

To configure IPv6 routing on a VLAN, an IP address is assigned to the VLAN. This IP address is not associated with any particular physical port, but is used on all ports where this VLAN is a member.

On a brouter port, a single port VLAN is used to route the traffic. IPv4 and IPv6 traffic is routed in the single-port brouter VLAN.

Other VLANs (which are multiple port VLANs) can bridge and route the traffic.

Virtual routing between IPv6 subnets

The switch supports IPv6 routing between subnets.

When you add an IP address to the VLAN, the system maps an IP subnet to the VLAN.

As shown in the following figure, although VLAN 1 and VLAN 2 reside on the same switch, for traffic to flow from VLAN 1 to VLAN 2, you must route the traffic.

You must enable IPv6 forwarding to route IPv6 traffic between VLANs. And you must enable IPv6 both globally and on a specific VLAN basis in order for forwarding to function. You can enable or disable IPv6, either globally or on a specific VLAN basis.

IPv6 forwarding is enabled by default.

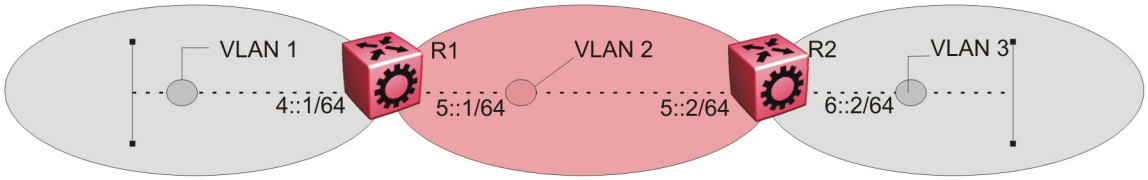

Figure 157: IPv6 routing between VLANs

When you configure routing on a VLAN, an IPv6 address assigned to the VLAN is the VLAN IP interface.

The VLAN IPv6 address can be reached through any VLAN port, and frames route from the VLAN through the gateway IPv6 address.

You can forward traffic to any IPv6 subnet in the switch. A VLAN can be reached only if it has an IPv6 interface configured on it.

Because a port can belong to multiple VLANs, a one-to-one correspondence no longer exists between the physical port and the router interface when VLAN tagging is enabled.

If you do not enable VLAN tagging a single port can belong only to one port-based VLAN, but that same single port can belong to multiple policy-based VLANs.

As with any IPv6 address, you can use any VLAN IP interface for device management.

For the Simple Network Management Protocol (SNMP) or Telnet management, you can use any VLAN IP interface to access the switch while routing is enabled on the VLAN.

Brouter ports

A brouter port is a single-port VLAN that can route IP packets and bridge all nonroutable traffic.

The difference between a brouter port and a standard protocol-based VLAN configured for routing is that the routing interface of the brouter port is not subject to the spanning tree state of the port. A brouter port can be in the blocking state for nonroutable traffic while it routes IP traffic.

Note

Because a brouter port is a one-port VLAN, each brouter port decreases the number of available VLANs by one and uses one VLAN ID.

Static routes

Static routes provide an alternative method for establishing route reachability.

Static routes, with dynamic routes, provide routing information from the forwarding database.

Only enabled static routes whose nexthop address is reachable are submitted to the Route Table Manager (RTM), which determines the best route based on reachability, route preference, and cost.

The RTM communicates all updates to best routes.

If the nexthop is not reachable you can use the **`show ipv6 route static`** command to display the status. If the nexthop is not reachable, the status is `TryToResolve` and the system does not display the route in the RTM until the nexthop address is resolved.

For directly-connected IPv6 Subnets you do not need to specify a nexthop address; you can specify outgoing Tunnel-ID, VLAN, or port. If you use outgoing Tunnel-ID, VLAN, or port, the implied nexthop value is 0::0.

When you configure IPv6 static routes only by interface (VLAN or brouter), it lets the traffic to reach IPv6 prefixes configured on the link that is directly connected to the interface provided in the static route configuration. For example: ipv6 route 180:0:0:0:0:0:0:0/64 cost 1 vlan 631.

When you configure static routes with a link-local nexthop, you must also specify the outgoing Tunnel-ID, VLAN, or port because link-local addresses are ambiguous unless the proper interface binding is attached. For example: ipv6 route 1234::/64 cost 1 next-hop fe80::1 vlan 1900.

You must provide the following options to configure a static route:

- local or nonlocal hop option

Configure a static route either with a next hop that exists on a locally attached network or a next hop that is reachable through a dynamic route. The static route is available as long as the next hop is reachable.

- route preference

  You can specify the route preference for the static routes as follows:

  - Global value for all static routes: the preference is either static or dynamic routes.
  - Preference for each static route entry: if specified, this value overrides the global value for the entry which provides flexibility to change the general behavior of a specific static route.

- Administrative status

  Controls when the static route is considered for forwarding. Administrative status differs from the operational status. An admin-enabled static route can still be unreachable and not used for forwarding. An admin-disabled static route is operationally a nonexistent route.

- Multiple static routes

  Specify alternative paths to the same destination. Multiple static routes provide stability and load balancing.

To configure a default static route, supply a value of 0 for the prefix and the prefix length.

The following table describes events that affect static route operation.

Table 117: Events and their affects on static route operation

Action	Result
Change the administrative status of the static route	Makes the static route unavailable for forwarding You can use one CLI command to administratively enable or disable all static routes as follows `ipv6 route static enable`. You can administratively disable all routes but preserve the static route configuration when you use the CLI command: `no ipv6 static route enable`.
Delete the IPv6 addresses of a VLAN or brouter port	Permanently deletes the static routes with the corresponding local neighbors from the RTM, the forwarding database, and the configuration database
Delete a VLAN	Removes static routes with a local next-hop option from the configuration database. Static routes with a nonlocal next-hop option become inactive (they are removed from the forwarding database).
Disable forwarding on a VLAN or brouter port	Static routes reachable through the locally attached network become inactive
Disable a VLAN or brouter port	Makes the static route inactive
Disable IPv6 forwarding globally	Stops forwarding all IPv6 traffic
Learn changes about a dynamically learned neighbor	After a neighbor becomes unreachable or is deleted, the static route with the neighbor becomes inactive, and the configuration is not affected. The static route with the neighbor becomes active in the configuration and is added to the RTM and forwarding database when the neighbor becomes reachable.
Enable a static route	Adds the route to the RTM to change certain static routes to active.

Table 117: Events and their affects on static route operation (continued)

Action	Result
Delete a static route	Permanently deletes a static route from the configuration.
Disable a static route	Stops traffic on the static route but does not remove the route from the configuration.
Change a route preference	After the static route preference changes, the best routes for the entries use both static and dynamic paths.
Delete or disable a tunnel	Removes the tunnel entry from the forwarding table
Enable a tunnel	Activates the tunnel static routes and adds an entry to the forwarding table.

The local-nexthop flag is not required for IPv6.

An IPv4 device cannot learn a neighbor ARP entry unless the device uses a local route entry.

In IPv6, a host can learn a neighbor entry if the device is physically connected to the neighbor (one hop).

The static route becomes active when the next hop is reachable by a dynamic route neighbor resolution. The static route takes the forwarding information from the dynamic route. If the next hop is reachable using a local route, the neighbor resolution is required.

Static route table

The static route table is separate from the system routing table that the router uses to make forwarding decisions.

You can use the static route table to directly change static routes.

Although the tables are separate, the system routing table automatically reflects the static routing table manager entries if the next-hop address in the static route is reachable and if the static route is enabled.

The static route table is indexed by four attributes:

- destination network
- destination mask
- next hop
- interface

You can insert static routes by using the static route table, and you can delete static routes by using either the static route table or the system routing table. For information on route scaling, see *Fabric Engine Release Notes*.

Important

The system routing table stores only active static routes with the best route preference. A static route is active only if the route is enabled and if the next-hop address is reachable; for example, if a valid IPv6 neighbor cache entry exists for the next hop.

You can enter multiple routes (for example, multiple default routes) that use different costs and the lowest cost route that is reachable, the system displays the lowest cost route in the routing table.

If you enter multiple next hops for the same route with the same cost, the switch does not replace the existing route.

If you enter the same route with the same cost and a different next hop, the switch uses the first route. If that first route becomes unreachable, the system activates the second route, with a different next-hop, with no connectivity loss.

Route scaling

IPv4 and IPv6 route scaling depends on the combination of the ipv6-mode and urpf-mode boot config flags. For more information, see *Fabric Engine Release Notes*.

IPv6 Circuitless IP

IPv6 Circuitless IP (CLIP) is a virtual interface that is not associated with any physical port. You can use an IPv6 CLIP interface to provide uninterrupted connectivity to your switch as long as an actual path exists to reach the device. The system treats the IPv6 CLIP interface like an IPv6 interface and treats the network associated with the IPv6 CLIP as a local network attached to the device. This route always exists and the circuit is always up because no physical attachment exists.

You can use an IPv6 CLIP address as a logical IPv6 address for network management, as well as for other purposes. The IPv6 CLIP is typically a host address with any prefix length. You can redistribute this address as part of any other routing protocol update, so that the CLIP address is known to neighbors and available for use in routing or other types of connectivity. You can use IPv6 CLIP for many kinds of management connectivity, such as Telnet or SSH. You can also use IPv6 CLIP as a source IP address for sending Syslog messages.

For scaling information on IPv6 CLIP, see *Fabric Engine Release Notes*.

IPv6 CLIP restrictions and limitations

This section describes the restrictions and limitations associated with IPv6 CLIP.

- Stateless address autoconfiguration (SLAAC) is not supported on IPv6 CLIP interfaces.
- IPv6 CLIP does not support link-local address configuration.
- To configure an IPv6 address with a prefix length from 65 to 127 on a CLIP interface, you must enable the IPv6 mode flag.
- Neighbor discovery (ND) does not run on an IPv6 CLIP interface. Therefore, the system does not detect duplicate IPv6 address assignment to this interface.
- Multiple IPv6 address configuration on an IPv6 CLIP interface is not supported.
- IPv6 CLIP interface is enabled by default and it cannot be disabled.
- You cannot configure an IPv6 CLIP interface as the source or destination endpoint of an IPv6-in-IPv4 tunnel.

Equal Cost Multipath

Table 118: Equal Cost Multiple Path for IPv6 product support

Feature	Product	Release introduced
ECMP for IPv6	5320 Series	Fabric Engine 8.6 Only 5320-48P-8XE and 5320-48T-8XE support more than one VRF with IP configuration.
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

With Equal Cost Multipath (ECMP), the switch can determine equal-cost paths to the same destination prefix. You can use multiple paths for load sharing of traffic. These multiple paths allow faster convergence to other active paths in case of network failure. By maximizing load sharing among equal-cost paths, you can use your links between routers more efficiently when sending IP traffic. ECMP is formed using routes from the same source or protocol, and the ECMP routes are evaluated within each routing protocol.

The ECMP feature supports and complements the following protocols and route types:

- OSPFv3
- Static routes
- BGP+
- RIPng
- IPv6 Shortcuts

ECMP with static routes

ECMP supports and complements static routes.

The following points need to be considered while configuring ECMP with static routes:

- When ECMP is globally enabled, the equal cost static routes are added in the Routing Table Manager (RTM).
- Static routes that are configured only using an interface, such as VLAN or port, do not support ECMP as these routes have a preference value of 0 and are treated like local routes.
- If your switch supports a management interface, then static routes configured on the management interface do not support ECMP.
- Static routes configured by next-hop are not considered equal cost with routes that are configured by tunnel even if the routes have the same cost and preference.
- A static route configured by tunnel is the least preferred and is programmed only when a next-hop or an interface does not configure a static route.

- Static routes configured by next-hop that resolves their next-hop using another static route will be in the `notReachable` state even if the next-hop can be pinged.
- If there are two static routes configured by next-hop, and both next-hops are resolved via a dynamic protocol to the same value, then only one route will be in the `reachableInRtm` state. The state of the other route will be `reachableNotInRtm`.

Disable IPv6 ICMP multicast

On IPv6 networks, a packet can be directed to an individual machine or multicasted to a set of hosts. When a packet is sent to an IPv6 multicast address from a machine on the local network, that packet is delivered to a subset or all machines on that network.

If the packet that is sent to the multicast address is an ICMP Echo Request packet, the machines on the network will receive this ICMPv6 echo request packet and send an ICMP echo reply packet back. When all the machines on a network respond to this ICMPv6 echo request, the result can be severe network congestion or outages.

Network devices always respond to the IPv6 ICMP packets sent to a multicast address. However, you can disable the processing of IPv6 ICMP packets sent to a multicast address on the device. On disabling the ICMP multicast processing, all the packets containing ICMP sent to multicast addresses are dropped when the packets reach the control plane.

Viewing IPv6 Connections

You can establish network connectivity with the following protocols:

- Transmission Control Protocol (TCP), for connection-oriented sessions
- User Datagram Protocol (UDP), for connectionless sessions

When you view TCP information you can:

- check the health of the connections, from the switch perspective, as they traverse the network
- detect intermittent connectivity
- detect attacks on resources
- determine which applications are active by checking the port numbers

UDP endpoint information tells you about local and remote UDP activity.

When you view UDP information you can:

- determine which applications are active by checking the local and remote port numbers
- identify processes within a UDP session to enable multiplexing of a port mapping for UDP

IPv6 Basic Configuration using CLI

Use the procedures in this section to configure IPv6 basics using CLI.

Enable the IPv6-Mode Boot Config Flag

Enable this flag to support IPv6 routes with prefix-lengths greater than 64 bits.

This flag is disabled by default. Use this procedure to enable (set to true) the IPv6-mode boot config flag.

When the IPv6-mode boot config flag is enabled, the maximum number of IPv4 routing table entries decreases. For scaling information, see *Fabric Engine Release Notes*.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Enable the IPv6-mode boot config flag:
   ```
   boot config flags ipv6-mode
   ```
3. Save the configuration, and then reboot the switch for the change to the IPv6-mode boot config flag to take effect.
4. After you reboot the switch, verify that the IPv6-mode boot config flag is set to true:
   ```
   show boot config flags
   ```

Configure an IPv6 Static Neighbor Address

You can use static IPv6 neighbors to manually specify the link-layer address for a given IPv6 endpoint.

About This Task

Under normal operation you do not need to configure static IPv6 neighbors.

However, IPv6 static neighbors can be used to:

- avoid the overhead associated with dynamic neighbor discovery protocol traffic
- help troubleshoot specific network scenarios

Note

- IPv6 static neighbors are not supported on SMLT.
- When you add or remove IPv6 static neighbors that point to a nexthop router, make sure that you have disabled the IPv6 interface.

Not all parameters are available in non-default VRFs.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:
   ```
   enable

   configure terminal
   ```
   Optional: `router vrf WORD<1-16>`
2. Configure an IPv6 neighbor address:
   ```
   ipv6 neighbor WORD<0-128> port {slot/port[sub-port]} mac
   <0x00:0x00:0x00:0x00:0x00:0x00> [vlan <1-4059>
   ```

3. Configure optional parameters if the default values do not meet your requirements:
   a. Configure the hop limit:

      ```
      ipv6 hop-limit <0-255>
      ```

      The default is 64.
   b. Configure ICMP network address unreachable messages:

      ```
      ipv6 icmp addr-unreach
      ```
   c. Configure the ICMP error interval:

      ```
      ipv6 icmp error-interval <1-2147483647>
      ```

      The interval is in milliseconds. An interval of 0 results in no error messages. The default is 1000.
   d. Configure the ICMP error quota:

      ```
      ipv6 icmp error-quota <0-2000000>
      ```

      The default is 50.
   e. Configure ICMP port unreachable messages:

      ```
      ipv6 icmp port-unreach
      ```
   f. Enable response to icmp echo multicast packets:

      ```
      ipv6 icmp echo-multicast-request
      ```

      The default is disabled.
   g. Enable ICMP network unreachable messages:

      ```
      ipv6 icmp unreach-msg
      ```

      The default is disabled.

Examples

Add an IPv6 neighbor for a brouter port:

```
Switch:1(config)#ipv6 neighbor 3000:0:0:0:0:0:0:2 port 1/11 mac 00:0c:42:07:35:90
```

Add an IPv6 neighbor for a VLAN:

```
Switch:1(config)#ipv6 neighbor 3000::3 port 1/12 mac 01:02:03:04:05:06 vlan 20
```

Variable Definitions

Use the data in the following table to use the **ipv6** commands in this procedure.

Variable	Value
forwarding	Configures whether this entity is an IPv6 router with respect to the forwarding of datagrams received by, but not addressed to, this entity. Enable forwarding to act as a router. The default is enabled.
hop-limit <0-255>	Configures the hop limit. The default is 64.
icmp addr-unreach	Enables ICMP address unreachable messages. The default is enabled.

Variable	Value
icmp echo-multicast-request	Enable response to icmp echo multicast packets. The default is enable.
icmp error interval <1-2147483647>	Configures the interval (in milliseconds) for sending ICMPv6 error messages. The default is 1000.
icmp error-quota <0-2000000>	Configures the number of ICMP error messages that can be sent during the ICMP error interval. A value of zero instructs the system not to send an ICMP error messages. The default value is 50.
icmp port-unreach	Enables ICMP port unreachable messages. The default is enabled.
icmp unreach-msg	Enables ICMP network unreachable messages. The default is disabled.
neighbor WORD<0-128> port {slot/port[sub-port]} mac <0x00:0x00:0x00:0x00:0x00:0x00> [vlan <1-4059>]	Creates a static IPv6 neighbor with the following variables: • *WORD<0-128>* specifies the IPv6 addressof the neighbor in hexadecimal colon format. • *{slot/port[/sub-port]}* specifies the brouter port to use for the neighbor. Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. • *mac <0x00:0x00:0x00:0x00:0x00:0x00>* specifies the MAC address of the neighbor. • *vlan <1-4059>* specifies the VLAN ID to use for the neighbor. Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. Static IPv6 neighbors do not maintain any state machine and the system assumes that they are always reachable.

Configure an IPv6 Interface

The information in this section can help you configure an IPv6 interface to make IPv6 active on the interface and fine-tune IPv6 neighbor discovery to control the frequency of protocol traffic.

By default, IPv6 forwarding is enabled on an interface.

Compared to IPv4/ARP, the IPv6 neighbor discovery mechanism maintains more protocol state, timers, and protocol traffic overhead.

There are two important tunable parameters for IPv6 ND that can control the frequency of protocol traffic:

- ipv6 interface reachable-time
- ipv6 interface retransmit-timer

Before You Begin

- Before you can assign an IPv6 address to the interface, you must configure an IPv6 interface for a VLAN or brouter port.

  You must configure a VLAN before you can give the VLAN an interface identifier or an IPv6 address.

  The switch supports port-based and IPv6 protocol-based VLANs.

  For information about how to configure VLANs, see the followings:

  - VLAN Configuration Using CLI on page 3422
  - MultiLink Trunking and Split MultiLink Trunking on page 2090

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```
   or `interface vlan <1-4059>`

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create IPv6 interface:

   ```
   ipv6 interface
   ```
3. Configure optional parameters to meet your requirements:
   a. Enable IPv6 router advertisement on the interface:

      ```
      ipv6 nd send-ra
      ```
   b. Configure the maximum number of hops before packets drop:

      ```
      ipv6 interface hop-limit <1-255>
      ```
   c. Configure the link-local address:

      ```
      ipv6 interface link-local WORD<0-19>
      ```
   d. Configure the mac offset:

      ```
      ipv6 interface mac-offset <MAC-offset>
      ```

e. Configure the maximum transmission unit (MTU):

Note
Product Notice: This step does not apply to 5320 Series or 5420 Series.

```
ipv6 interface mtu <1280-9500>
```

f. Configure an interface description:

```
ipv6 interface name WORD<0-255>
```

g. Configure the time a neighbor is considered reachable after receiving a reachability confirmation:

```
ipv6 interface reachable-time <1-3600000>
```

h. Configure the time between retransmissions of neighbor solicitation messages to a neighbor when resolving the address or when probing the reachability of a neighbor:

```
ipv6 interface retransmit-timer <1-4294967295>
```

i. Configure a brouter port as part of an IPv6 VLAN:

```
ipv6 interface vlan <1-4059>
```

j. Configure the interface to perform IPv6 unicast reverse path forwarding:

- To enable urpf-mode boot flag, enter:

```
boot config flags urpf-mode
```

- To configure unicast reverse path forwarding, enter:

```
ipv6 rvs-path-chk mode {strict|exist-only}
```

Example

Note
In contrast to IPv6 interface creation and address assignment in EDM, you use the **ipv6 interface** CLI command to create an interface and specify a single global address in one step.

Create and administratively enable the interface:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/4
Switch:1(config-if)#ipv6 interface enable
```

Variable Definitions

Use the data in the following table to use the **ipv6 interface** command.

Variable	Value
hop-limit <1-255>	Configures the maximum hops. The default is 64.
link-local WORD<0-19>	Specifies the 64-bit interface ID used to calculate the actual link-local address as a name up to 19 characters long.

Variable	Value
mac-offset <MAC-offset>	Use *mac-offset* to request a particular MAC for an IPv6 VLAN. Note: This parameter applies only to VLANs. You can specify a MAC offset when you configure IPv6 on a VLAN, or the system can assign a MAC address from within the available range. Specifies a number by which to offset the MAC address from the chassis MAC address. This ensures that each IP address has a different MAC address. If you omit this variable, a unique MAC offset is automatically generated. Different hardware platforms support different ranges. To see which range is available on the switch, use the CLI command completion Help.
mtu <1280-9500>	Configures the maximum transmission unit for the interface: 1280–1500, 1850, or 9500. This value must be the same for all addresses defined on this interface. The default is 1500. Different hardware platforms support different MTU values. To see what values your switch supports, use the CLI command completion help.
name WORD<0-255>	Assigns a descriptive name. The network management system also configures this string.
reachable-time <0-3600000>	Controls how long IPv6 neighbor entries learned on an interface remain in the REACHABLE state (as described in RFC 4861). The system randomizes the value you configure, per RFC specifications, to be 50%-150% of the configured value. By default the reachable-time base value is 30 seconds, with an actual 15-45 second range when you consider the randomization factor. The default is 3000 milliseconds
retransmit-timer <0-4294967295>	Controls the time, in milliseconds, between retransmission of Neighbor Solicitation messages when the system attempts to resolve or reconfirm the reachability of an IPv6 neighbor. By default, the system sends three Neighbor Solicitation messages with a one second interval between each message. If the system does not receive a corresponding Neighbor Advertisement within an interval equal to 3 X retransmit-timer milliseconds, the system declares the IPv6 neighbor unreachable. Tip: You can increase the retransmit-timer to extend the interval that the switch waits until it declares the neighbor unreachable. For example: a retransmit-timer value of 5000 means the switch waits 3 X 5000 milliseconds which equals 15000 milliseconds or 15 seconds. The default is 1000 milliseconds
vlan <1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. This value corresponds to the lower 12 bits of the IEEE 802.1Q VLAN tag.

Use the data in the following table to use the **ipv6 rvs-path-chk** command.

Variable	Value
mode {strict| exist-only}	Specifies the mode for Unicast Reverse Path Forwarding (uRPF). In strict mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. If the incoming interface is not the best reverse path, the packet check fails and uRPF drops the packet. In exist-only mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. The packet is dropped only if the source address is not reachable via any interface on that router.

Use the data in the following table to use the **interface** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Assign IPv6 Addresses to a Brouter Port or VLAN

Assign IPv6 addresses to interfaces to configure IPv6 routing for the interface.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Assign an IPv6 address:

   ```
   ipv6 interface address WORD<0-255>
   ```

Example

Assign an IPv6 address specifying the full 128 bits of the address:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/5
Switch:1(config-if)#ipv6 interface address 30:0:0:0:0:0:0:ffff/64
```

Variable Definitions

The following table defines parameters for the **ipv6 interface address** command.

Variable	Value
WORD<0-255>	Specifies the IPv6 address for the port or VLAN.

The following table defines parameters for the **interface** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configure IPv6 Route Preferences

Configure IPv6 route preferences to give preference to routes learned for a specific protocol.

Before You Begin

Important

Changing route preferences can affect system performance and network accessibility while you perform the procedure. Change a prefix list or a routing protocol before you activate the protocols.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   `enable`

   `configure terminal`

   Optional: `router vrf WORD<1-16>`

2. Configure the route preference:

   ```
   ipv6 route preference protocol <static|ebgp|ibgp|ospfv3-intra|ospfv3-inter|ospfv3-extern1|ospfv3-extern2|ripng|spbm-level1> <0-255>
   ```

3. Confirm that the configuration is correct:

   ```
   show ipv6 route preference [vrf WORD<1-16> | vrfids WORD<0-512>]
   ```

Example

Configure the route preference to RIPng and confirm the configuration is correct.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#ipv6 route preference protocol ripng 10
Switch:1(config)#show ipv6 route preference
================================================================================================
                                  IPv6 Route Preference - GlobalRouter
================================================================================================
PROTOCOL        DEFAULT    CONFIG
------------------------------------------------------------------------------------------------
LOCAL           0          0
STATIC          5          5

OSPFv3_INTRA    20         20
OSPFv3_INTER    25         25
EBGP            45         45
RIPNG           100        100
OSPFv3_E1       120        120
OSPFv3_E2       125        125
IBGP            175        175
```

Variable definitions

Use the data in the following table to use the **ipv6 route preference** and the **show ipv6 route preference** commands.

Variable	Value
<0-255>	Assigns a route preference value.
ebgp	Configures the preference for protocol type EBGP.
ibgp	Configures the preference for protocol type IBGP.
ospfv3-extern1	Configures the preference for protocol type OSPFv3 external type 1.
ospfv3-extern2	Configures the preference for protocol type OSPFv3 external type 2.
ospfv3-intra	Configures the preference for protocol type OSPFv3 intra-area.
ospfv3-inter	Configures the preference for protocol type OSPFv3 inter-area.
ripng	Configures the preference for protocol type RIPng.
spbm-level1	Configures the preference for protocol type spbm-level1.
static	Configures the preference for protocol type static.

View Global IPv6 Information

View and manage general IPv6 information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display IPv6 information for an interface:

   ```
   show ipv6 interface [gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}] [loopback <1-256>][tunnel <1-2000>][vlan <1-4059>] [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```
3. Display IPv6 tunnel information:

   ```
   show ipv6 interface tunnel <1-2000>
   ```
4. Display IPv6 address information for the specified slot and port:

   ```
   show ipv6 address interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```
5. Display IPv6 address information for the specified IPv6 address:

   ```
   show ipv6 address interface ip WORD<0-46> [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```
6. Display IPv6 address information for the specified tunnel:

   ```
   show ipv6 address interface tunnel <1-2000>
   ```
7. Display IPv6 address information for the specified VLAN:

   ```
   show ipv6 address interface vlan <1-4059>
   ```
8. Display the current state of IPv6 forwarding:

   ```
   show ipv6 forwarding [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```
9. Display information on the current state of IPv6 functionality:

   ```
   show ipv6 global [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```
10. Display IPv6 Gigabit Ethernet (GbE) router advertisement information:

    ```
    show ipv6 nd interface gigabitethernet [{slot/port[-slot/port][,...]}]
    ```
11. Display IPv6 Gigabit Ethernet (GbE) router advertisement information:

    ```
    show ipv6 nd interface gigabitethernet [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
    ```
12. Display IPv6 VLAN router advertisement information:

    ```
    show ipv6 nd interface vlan [<1-4059>]
    ```
13. Display detailed information in IPv6 router advertisements:

    ```
    show ipv6 nd-prefix detail [vrf WORD<1-16> | vrfids WORD<0-512>]
    ```
14. Display GbE interface information in IPv6 router advertisements:

    ```
    show ipv6 nd-prefix interface gigabitethernet [{slot/port[-slot/port][,...]}]
    ```
15. Display GbE interface information in IPv6 router advertisements:

    ```
    show ipv6 nd-prefix interface gigabitethernet [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
    ```
16. Display VLAN interface information in IPv6 router advertisements:

    ```
    show ipv6 nd-prefix interface vlan [<1-4059>]
    ```

17. Display VLAN information in IPv6 router advertisements:

    `show ipv6 nd-prefix vlan <1-4059>`

18. Display IPv6 neighbor entries with specific brouter port numbers:

    `show ipv6 neighbor interface gigabitethernet {slot/port[/sub-port]}`

19. Display IPv6 neighbor information for neighbors of the specified type:

    `show ipv6 neighbor type <1-4>`

20. Display IPv6 neighbor information:

    `show ipv6 neighbor [WORD<0-46>]`

Examples

```
Switch:1(config)#show ipv6 interface vlan

Variable Definitions

Use the data in the following table to use the **show ipv6** commands.

Variable	Value
address interface ip WORD<0-46>	Specifies the IPv6 address.
neighbor [WORD<0-46>]	Specifies the IPv6 address of the neighbor.
loopback <1-256>	Specifies the loopback interface ID value. If you do not specify a value, the output includes all IPv6 loopback interfaces.
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
type <1-4>	Specifies the neighbor type as one of the following: • 1 - other • 2 - dynamic • 3 - static • 4 - local
tunnel <1-2000>	Specifies the tunnel ID.
vlan <1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
vrfWORD<1-16>	Specifies the VRF name.
vrfidsWORD<1-256>	Specifies the VRF ID.

Create IPv6 Static Routes

Perform the steps in this task to:

- Create static routes for data traffic in either the GRT or a specific VRF context for any platform.
- Create static routes for a VRF associated with a Segmented Management Instance CLIP interface. Specify the name of the VRF context in Step 1.

About This Task

Not all parameters are available in non-default VRFs.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`
2. Enable IPv6 static routes globally:

   ```
   ipv6 route static enable
   ```

   If you disable static routes globally, the system removes all enabled static routes from the RTM and does not add new static routes to the RTM.
3. Configure a static route:

   ```
   ipv6 route WORD<0-46> [enable] [cost <1-65535>] [next-hop WORD<0-46>]
   [preference <1-255>] [tunnel <1-2000>] [port {slot/port[sub-port]}]
   [vlan <1-4059>]
   ```
4. (Optional) Disable all IPv6 static routes:

   ```
   no ipv6 route static enable
   ```
5. (Optional) Permanently delete the IPv6 static route configuration:

   ```
   clear ipv6 route static [vrf WORD<1-16> | vrfids WORD<0-512>]
   ```

Examples

Enable IPv6 static routes globally:

```
Switch:1(config)#ipv6 route static enable
```

Create and enable a static route through a global nexthop:

```
Switch:1(config)#ipv6 route 4000::/64 cost 1 next-hop 3000::2 enable
```

Create and enable a static route through an outgoing interface (VLAN or brouter port):

```
Switch:1(config)# ipv6 route 4000::/64 cost 1 vlan 1900 enable
```

Create and enable a static route through a link local nexthop and an outgoing interface:

```
Switch:1(config)# ipv6 route 4000::/64 cost 1 next-hop fe80::1 vlan 1900
enable
```

In the preceding example, you must specify the outgoing interface so that the system can apply the correct context to the link-local address.

Variable Definitions

Use the data in the following table to use the **ipv6 route** command.

Variable	Value
WORD <0-46>	Specifies the IPv6 destination address and prefix.
enable	Enables the static route. The default is enabled.
cost <1-65535>	Specifies the cost or distance ratio to reach the destination for this static route. The default is 1.
next-hop Word <0-46>	Specifies the IPv6 address of the next hop on this route. You do not need to specify the next hop if the devices directly connect to one another. Configure the next hop if the two nodes do not share the same network prefix but reside on the same link.
preference <1-255>	Specifies the routing preference of the destination IPv6 address. The default is 5.
{slot/port[/sub-port]}	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
tunnel <1-2000>	Specifies the tunnel ID.
vlan <1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

View Routes Information

View routes information to view the current configuration.

About This Task

Not all parameters are available in non-default VRFs.

IPv6 host routes created for the IPv6 local interfaces do not display in the routing table.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show route information for alternative routes:

   ```
   show ipv6 route alternative [vrf WORD<1-16> | vrfids WORD<1-256>]
   ```
3. Show the number of OSPF, RIP, static, and local routes:

   ```
   show ipv6 route count-summary [vrf WORD<1-16> | vrfids WORD<1-256>]
   ```
4. Show route information for a destination:

   ```
   show ipv6 route dest WORD<0-46> [vrf WORD<1-16> | vrfids WORD<1-256>]
   ```
5. Show route information for a port:

   ```
   show ipv6 route gigabitethernet {slot/port[sub-port]}
   ```

6. Show route information for a next-hop address:
   `show ipv6 route next-hop WORD<0-46> [vrf WORD<1-16> | vrfids WORD<1-256>]`
7. Show route information for an SPBM IPv6 route:
   `show ipv6 route spbm-nh-as-mac`
8. Show route information for a static route:
   `show ipv6 route static [vrf WORD<1-16> | vrfids WORD<1-256>]`
9. Show route information for a tunnel:
   `show ipv6 route tunnel <1-2000>`
10. Show route information for a VLAN:
    `show ipv6 route vlan <1-4059>`

Example

```
Switch:1(config-if)#show ipv6 route

```

Variable Definitions

Use the data in the following table to use the **show ipv6 route** command.

Variable	Value
count-summary	Shows the total number of OSPF, static, and local routes.
dest WORD<0-46>	Specifies the IPv6 destination network address. The prefix value must match the prefix length.
next-hop WORD<0-46>	Specifies the IPv6 address of the next hop on this route.
spbm-nh-as-mac	Shows the B-MAC address as the next hop rather than the host name.
{slot/port[/sub-port]}	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
static	Shows static IPv6 routes.
tunnel <1-2000>	Shows route entries for a specific tunnel ID.
vlan<1-4059>	Shows route entries for a specific VLAN ID.
vrfWORD<1-16>	Shows the VRF name.
vrfidsWORD<1-256>	Shows the VRF ID.

Creating an IPv6 CLIP interface

About This Task

Perform this procedure to create an IPv6 CLIP interface and associate it with a specific VRF.

Procedure

1. Enter Loopback Interface Configuration mode
   ```
   enable

   configure terminal

   interface Loopback <1-256>
   ```
2. Create an IPv6 loopback interface address:
   ```
   ipv6 interface address WORD <0-255> vrf WORD <1-16>
   ```
3. (Optional) Enter a name for the IPv6 address:
   ```
   ipv6 interface name WORD <0-64>
   ```

4. Ensure the configuration is correct:

   ```
   show ipv6 interface loopback <1-256>
   ```

Example

```
Switch:1#show ipv6 interface loopback

1 out of 1 Total Num of Address Entries displayed.
```

Variable Definitions

Use the data in the following table to use the **ipv6** commands.

Variable	Value
WORD<1-256>	Specifies the CLIP interface ID.
WORD<0-255>	Specifies the IPv6 address.
vrf WORD<1-16>	Specifies the VRF name.
WORD<0-64>	Specifies the I-SID name associated with the IPv6 address.

Enabling IPv6 ECMP

About This Task

Use the following procedure to enable IPv6 ECMP globally or on a specific VRF. IPv6 ECMP is disabled by default.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`
2. Enter the following command to enable IPv6 ECMP:

   ```
   ipv6 ecmp enable
   ```
3. Set the default value, IPv6 ECMP is disabled by default.

   ```
   default ipv6 ecmp enable
   ```

4. Disable IPv6 ECMP globally:

   ```
   no ipv6 ecmp enable
   ```

Variable definitions

Use the data in the following table to use the **ipv6 ecmp** command.

Variable	Value
enable	Enables IPv6 ECMP globally. Note: • Enabling IPv6 ECMP sets the maximum number of paths configured to its default value. This value is either 4 or 8 depending on your hardware platform. • Disabling IPv6 ECMP sets the maximum number of paths configured to 1.

Configuring maximum number of ECMP paths

Before You Begin

Enable ECMP on the switch before configuring the max-path value. For more information, see Enabling IPv6 ECMP on page 1699.

About This Task

Use the following procedure to configure the maximum number of ECMP paths.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`
2. Configure the maximum number of ECMP paths.

   ```
   ipv6 ecmp max-path <ECMP-Paths>
   ```
3. Set the configured maximum number of ECMP paths to its default value:

   ```
   default ipv6 ecmp max-path
   ```

   Note

   The default value for max-path is the maximum value, which varies depending on your hardware platform.

Example

```
Switch:1>enable
Switch:1#configure terminal
```

Enable ECMP on the switch:

```
Switch:1(config)#ipv6 ecmp enable
```

Configure the maximum number of ECMP paths to 4:

```
Switch:1(config)#ipv6 ecmp max-path 4
```

Variable definitions

Use the data in the following table to use the **ipv6 ecmp max-path** command.

Variable	Value
<ECMP-Paths>	Specifies the maximum number of ECMP paths. Different hardware platforms can support a different number of ECMP paths. For more information on the maximum number of ECMP paths supported on the switch, see the scaling information in *Fabric Engine Release Notes*. When ECMP is enabled, the default value is either 4 or 8 depending on your hardware platform.

Enabling or disabling IPv6 ICMP multicast

On disabling the ICMP multicast processing, ICMPv6 Echo Request packets sent to IPv6 multicast addresses are dropped when they reach the control plane.

About This Task

Use this procedure to enable or disable the IPv6 ICMP multicast on the global router.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

   ```
   enable

   configure terminal
   ```

   Optional: `router vrf WORD<1-16>`
2. Enable IPv6 ICMP multicast, enter:

   ```
   ipv6 icmp echo-multicast-request
   ```
3. Disable IPv6 ICMP multicast, enter:

   ```
   no ipv6 icmp echo-multicast-request
   ```
4. Set IPv6 ICMP multicast to default state, enter:

   ```
   default ipv6 icmp echo-multicast-request
   ```

   Note

   By default, the IPv6 ICMP multicast feature is enabled.
5. View the IPv6 ICMP multicast state:

   ```
   show ipv6 global [vrf WORD<1-16> | vrfids WORD<0-512>]
   ```

Configure IPv6 Fragmented ICMP Packet Filtering

About This Task

Use this task to enable Fragmented ICMP packet filtering on IPv6 network globally or on a specific VRF.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:
   ```
   enable

   configure terminal
   ```
   Optional: `router vrf WORD<1-16>`
2. Enable Fragmented ICMP packet filtering:
   ```
   ipv6 icmp drop-fragments
   ```

View IPv6 ICMP Statistics

View IPv6 ICMP statistics on an interface for ICMP messages sent over a particular interface.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View IPv6 ICMP statistics:
   ```
   show ipv6 interface icmpstatistics [gigabitethernet <slot/port[/sub-port]> | loopback <1-256> | tunnel <1-2000> | vlan <1-4059> ] [vrf WORD<1-16>] [vrfids WORD<0-512>]
   ```

Example

View ICMP statistics:

```
Switch:1>show ipv6 interface icmpstatistics
================================================================================
                                  Icmp Stats
================================================================================

Icmp stats for IfIndex = 192

```

Variable Definitions

Use the data in the following table to use the **show ipv6 interface icmpstatistics** command

Variable	Value
<1-4059>	Shows ICMP statistics for the specific interface index. If you do not specify an interface index, the command output includes all IPv6 ICMP interfaces. Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
gigabitethernet {slot/port[/sub-port]}	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
loopback <1-256>>	Identifies a loopback interface.
tunnel <1-2000>	Identifies a 6in4 tunnel ID.
vrf WORD<1-16>	Specifies the VRF name.
vrfids WORD<0-512>	Specifies the VRF ID.

Enabling Stateless Address Autoconfiguration

Enable IPv6 Stateless Address Autoconfiguration to generate addresses using a combination of locally available information and information advertised by routers.

The default is disabled.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable IPv6 autoconfiguration:

   ```
   ipv6 autoconfig
   ```

Example

```
Switch:1(config)#ipv6 autoconfig
```

The following example shows a sample output for the **show ipv6 global** command.

```
Switch:1#show ipv6 global
        forwarding                    : disable
        default-hop-cnt               : 64
        number-of-interfaces          : 2
        icmp-error-interval           : 1000
        icmp-error-quota              : 50
        icmp-unreach-msg              : disable
        icmp-addr-unreach-msg         : enable
```

```
        icmp-port-unreach-msg          : enable
        icmp-echo-multicast-request    : enable
        static-route-admin-status      : enable
        alternative-route              : enable
        ecmp                           : disable
        ecmp-max-path                  : 1
        source-route                   : disable
        host-autoconfig                : enable
```

Configure Route Advertisement on the Management Port

Configure route advertisement in IPv6 on the management port for neighbor discovery (ND).

Procedure

1. Enter mgmtEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface mgmtEthernet <mgmt | mgmt2>
   ```

2. Configure the number of neighbor solicitation messages from duplicate address detection:

   ```
   ipv6 nd dad-ns <0-600>
   ```

3. Configure the hop limit sent in router advertisements:

   ```
   ipv6 nd hop-limit <0-255>
   ```

Example

```
Switch:1(config-if)#ipv6 nd dad-ns 2
Switch:1(config-if)#ipv6 nd hop-limit 2
```

Variable definitions

Use the data in the following table to use the **ipv6 nd** command.

Variable	Value
dad-ns <0-600>	Specifies the number of neighbor solicitation messages for duplicate address detection (DAD). A value of 0 disables the DAD process on this interface. A value of 1 sends one advertisement without retransmissions. The default is 1.
hop-limit <0-255>	Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a hop-limit value. The default is 64.

Enable the Processing of Redirect Messages on the Management Port

Perform this procedure to honor or ignore redirect messages for the management port. Redirect messages are visible only when Stateless Address Autoconfiguration is configured on switches capable of routing IPv6 traffic.

The default is disabled.

Before You Begin

- Disable IPv6 forwarding.
- Enable Stateless Address Autoconfiguration
- Create an IPv6 interface.
- Configure an IPv6 address.

Procedure

1. Enter mgmtEthernet Interface Configuration mode:
   ```
   enable

   configure terminal

   interface mgmtEthernet <mgmt | mgmt2>
   ```
2. Enable processing redirect messages:
   ```
   ipv6 interface process-redirect
   ```
3. Verify that configuration on the management port:
   ```
   show ipv6 interface process-redirect
   ```

Example

The following example shows a sample output of the **`show ipv6 interface process-redirect`** command.

```
Switch:1#show ipv6 interface process-redirect

================================================================================
                      Process ICMP redirect status
================================================================================
IFINDX                DESCR               VLAN               STATUS
--------------------------------------------------------------------------------
64                    PORT-mgmt           4092               Enabled

192                   VLAN-5              5                  Disabled

2050                  VLAN-2              2                  Disabled
```

Viewing IPv6 default routers

View the table of default routers learned from router advertisement messages.

A maximum of four routers are visible in the default routers list.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show IPv6 default routers:
   ```
   show ipv6 default-routers
   ```

Example

```
Switch:1#show ipv6 default-routers
```

```
=======================================================
                  Default Routers
NET ADDRESS                     VLAN   LIFETIME     IS ACTIVE
-------------------------------------------------------------
fe80::211:58ff:fe2b:fc00        mgmt     1778            YES
fe80::215:e8ff:fe6e:2800        mgmt     1657             NO
```

Configuring an IPv6 prefix list

Use IPv6 prefix lists to allow or deny specific IPv6 route updates. A prefix list policy specifies route prefixes to match. When there is a match, the route is used.

About This Task

You configure prefix lists on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create an IPv6 prefix list:

   ```
   ipv6 prefix-list <WORD 1-64> <WORD 1-256> [ge <0-128>] [le <0-128>]
   [id <1-2147483647>]
   ```

   Use the same command to add additional prefixes to the list.

3. To rename the list:

   ```
   ipv6 prefix-list <WORD 1-64> name <WORD 1-64>
   ```

4. Display the prefix list:

   ```
   show ipv6 prefix-list <WORD 1-256> [vrf WORD<1-16>] [vrfids
   WORD<1-512>] [WORD <1-64>]
   ```

Example

Create an IPv6 prefix list:

```
Switch:1<config>#ipv6 prefix-list list4 2001:DB8::/32  ge 32 le 32
```

To rename the list:

```
Switch:1<config>#ipv6 prefix-list list4 name list5
```

Variable Definitions

Use the data in the following table to use the **ipv6 prefix-list** command.

Variable	Value
<WORD 1-64>	Specifies the IPv6 prefix-list name.
<WORD 1-256>	Specifies the IPv6 prefix and length.

Variable	Value
ge <0-128>	Specifies the minimum length to match. Lower bound and higher bound mask lengths together can define a range of networks.
id <1-2147483647>	Specifies the Prefix list ID.
le <0-128>	Specifies the maximum length to match. Lower bound and higher bound mask lengths together can define a range of networks.
name <WORD 1-64>	Names the prefix list. The default value is none.

Use the data in the following table to use the **show ipv6 prefix-list** command.

Variable	Value
<WORD 1-256>	Specifies the IPv6 prefix and length.
vrf WORD<1-16>	Specifies the name of the VRF.
vrfids WORD<0-512>	Specifies the ID of the VRF and is an integer in the range of 0–512.
WORD<1-64>	Specifies a prefix list, by name, to use for the command output.

Clear IPv6 Statistics

Clear all IPv6 statistics if you do not require previous statistics.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Clear all the IPv6 statistics:

   ```
   clear ipv6 statistics all [vrf WORD<1-16> | vrfids WORD<0-512>]
   ```

3. Clear interface statistics:

   ```
   clear ipv6 statistics interface [general|icmp] [gigabitethernet {slot/port[/sub-port]}>| loopback <1-256> | tunnel <1-2000> | vlan <1-4059>] [vrf WORD<1-16> | vrfids WORD<0-512>]
   ```

4. Clear TCP statistics:

   ```
   clear ipv6 statistics tcp [vrf WORD<1-16> | vrfids WORD<0-512>]
   ```

5. Enter the following command to clear UDP statistics:

   ```
   clear ipv6 statistics udp [vrf WORD<1-16> | vrfids WORD<0-512>]
   ```

Variable Definitions

Use the information in the following table to use the **clear ipv6 statistics** commands.

Variable	Value
gigabitethernet {slot/port[/sub-port]}	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
loopback <1-256>	Identifies a loopback interface.
tunnel <1-2000>	Identifies a 6in4 tunnel ID.
vlan<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
vrf WORD<1-16>	Specifies the VRF name.
vrfids WORD<0-512>	Specifies the VRF ID.

View IPv6 Statistics on an Interface

View IPv6 statistics to view information about the IPv6 datagrams on an interface.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View statistics:
   ```
   show ipv6 interface statistics [gigabitethernet <slot/port[/sub-port]>
   | loopback <1-256> | tunnel <1-2000> | vlan <1-4059>] [vrf WORD<1-16>]
   [vrfids WORD<0-512>]
   ```

Example

View IPv6 statistics on an interface:

```
Switch:1>enable
Switch:1#show ipv6 interface statistics

================================================================================
                                Interface Stats
================================================================================

If Stats for mgmt, IfIndex = 64

InReceives: 404
InHdrErrors: 0
InTooBigErrors : 0
InNoRoutes : 0
InAddrErrors : 0
InUnknownProtos : 0
InTruncatedPkts : 0
InDiscards : 0
InDelivers : 404
OutForwDatagrams : 0
```

```
OutRequests : 417
OutDiscards : 0
OutFragOKs : 0
OutFragFails : 0
OutFragCreates : 0

--More-- (q = quit)
```

Variable Definitions

Use the data in the following table to use the **show ipv6 interface statistics** command

Variable	Value
gigabitethernet {slot/port[/sub-port]}	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
loopback <1-256>>	Identifies a loopback interface.
tunnel <1-2000>	Identifies a 6in4 tunnel ID.
vlan <1-4059>	Shows statistics for the specific interface index. If you do not specify an interface index, the command output includes all IPv6 interfaces. Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
vrf WORD<1-16>	Specifies the VRF name.
vrfids WORD<0-512>	Specifies the VRF ID.

Viewing IPv6 Connections using CLI

Use the procedures in this section to view IPv6 connections using CLI.

View TCP and UDP Information

Perform this procedure to view the TCP and UDP configuration information for IPv6.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display IPv6 TCP connection information:

   ```
   show ipv6 tcp connections [vrf WORD<1-16> | vrfids WORD<0-512>]
   ```

3. Display IPv6 TCP listener information for the specified IPv6 address:

   ```
   show ipv6 tcp listener [vrf WORD<1-16> | vrfids WORD<0-512>]
   ```

4. Display IPv6 TCP properties

   ```
   show ipv6 tcp properties [vrf WORD<1-16> | vrfids WORD<0-512>]
   ```

5. Display IPv6 TCP statistics
   `show ipv6 tcp statistics [vrf WORD<1-16> | vrfids WORD<0-512>]`
6. Display IPv6 UDP information:
   `show ipv6 udp endpoints [vrf WORD<1-16> | vrfids WORD<0-512>]`

Example

```
Switch:1>show ipv6 tcp connections

================================================================================
                     TCP connection table info - GlobalRouter
================================================================================
LOCALPORT    LOCALADDR         REMOTEPORT   REMOTEADDR           STATE
--------------------------------------------------------------------------------
21           0:0:0:0:0:0:0:0   0            0:0:0:0:0:0:0:0      listen
23           0:0:0:0:0:0:0:0   0            0:0:0:0:0:0:0:0      listen
Switch:1>show ipv6 tcp listener

```

IPv6 Basic Configuration using EDM

Use the procedures in this section to configure IPv6 basics using EDM.

Enable the IPv6–Mode Boot Config Flag

Enable this flag to support IPv6 routes with prefix-lengths greater than 64 bits.

This flag is disabled by default. Use this procedure to enable (set to true) the IPv6-mode boot config flag.

When the IPv6-mode boot config flag is enabled, the maximum number of IPv4 routing table entries decreases. For scaling information, see *Fabric Engine Release Notes*.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**,
2. Select **Chassis**.
3. Select the **Boot Config** tab.
4. Select the **EnableIpv6Mode** check box.
5. Select **Apply**.
6. Save the configuration, and then reboot the switch for the change to the IPv6-mode boot config flag to take effect.

Configure IPv6 Globally

Global configuration includes the following:

- IPv6 alternative routes: To avoid traffic interruption, enable alternative routes globally on the switch, to replace the best route with the next-best route if the best route becomes unavailable. By default, this feature is enabled.

Before You Begin

Change the VRF instance as required to configure IPv6 globally on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation tree, expand the **Configuration** > **IPv6** folders.
2. Select **IPv6**.
3. Select the **Globals** tab.
4. In the **DefaultHopLimit** box, enter the preferred number of hops before packets drop.
5. To enable ICMP network unreachable messages, select **IcmpNetUnreach**.
6. In the **IcmpErrorInterval** box, enter the preferred interval for sending ICMPv6 error messages.
7. In the **IcmpErrorQuota** box, enter the preferred number of ICMP error messages that the system can send during the ICMP error interval.

8. To enable IPv6 multicast, select **IcmpMulticastRequestEnable**.
9. To enable IPv6 ICMP address unreachable messages, select **IcmpAddrUnreach**.
10. To enable IPv6 ICMP port unreachable messages, select **IcmpPortUnreach**.
11. To enable IPv6 Fragmented ICMP packet filtering, select **IcmpDropFragmentsEnable**.
12. To enable IPv6 autoconfiguration, select **Autoconfig**.
13. To enable IPv6 static routes globally, select **StaticRouteGlobalAdminEnabled**.
14. To enable IPv6 Source Routing, select **SourceRouteEnable**.
15. To clear all IPv6 static routes, select **RouteStaticClear**.
16. To enable IPv6 alternative routes, select **AlternativeRouteEnable**.
17. To configure IPv6 ECMP globally, select **enable** or **disable**, in the **EcmpEnable** option box.
18. In the **EcmpMaxPath** box, enter the preferred number of equal-cost paths.
19. Select **Apply**.

Globals *Field Descriptions*

Use the data in the following table to use the **Globals** tab.

Name	Description
Forwarding	Configures whether this switch is an IPv6 router with respect to the forwarding of datagrams received by, but not addressed to, the switch. Select **forwarding** for the switch to act as a router for IPv6 traffic. Select **notForwarding** to not act as a router for IPv6 traffic. The default is **forwarding**. You must enable forwarding to use Telnet or Ping with IPv6.
DefaultHopLimit	Configures the hop limit. The default is 64.
Interfaces	Shows the number of interfaces.
IfTableLastChange	Shows the date of the last interface table change.
IcmpNetUnreach	Enables ICMP network unreachable messages. The default is disabled.
IcmpErrorInterval	Configures the interval (in milliseconds) for sending ICMPv6 error messages. The default is 1000. An entry of 1 seconds results in no sent ICMPv6 error messages.
IcmpErrorQuota	Configures the number of ICMP error messages that the system can send during the ICMP error interval. A value of zero specifies not to send any. The default value is 50.
IcmpMulticastRequestEnable	Globally enables or disables the IPv6 ICMP echo multicast request feature. This is enabled by default.
IcmpAddrUnreach	Enables or disabled ICMP address unreachable messages. This is enabled by default.

Name	Description
IcmpPortUnreach	Enables or disables ICMP port unreachable messages. This is enabled by default.
IcmpDropFragmentsEnable	Enables or disables the Fragmented ICMP packet filtering globally. The default is disabled.
Autoconfig	Enables or disables stateless address autoconfiguration. This is disabled by default.
StaticRouteGlobalAdminEnabled	Enables IPv6 static routes globally. If you disable static routes globally, the system removes all enabled static routes from the RTM and does not add new static routes to the RTM. The default is enabled.
RouteStaticClear	Clears all IPv6 static routes.
SourceRouteEnable	Globally enables or disables the IPv6 Source Routing feature. It is disabled by default.
PrefixListTableSize	Displays the prefix list table size.
RoutePrefTableSize	Displays the route preference table size.
AlternativeRouteEnable	Globally enables or disables the IPv6 alternative route feature. By default, this feature is enabled.
EcmpEnable	Enables or disables the IPv6 ECMP globally. By default, it is disabled.
EcmpMaxPath	Globally configures the maximum number of ECMP paths. The number of paths supported is either 1 to 4 or 1 to 8, depending on your hardware platform. When ECMP is enabled, the default value is either 4 or 8 depending on your hardware platform. You cannot configure this feature unless ECMP is enabled globally.

Viewing ICMP Statistics

View ICMP statistics for ICMP configuration information.

Procedure

1. In the navigation pane, expand the **Configuration** > **IPv6** folders.
2. Click **IPv6**.
3. Click **Interfaces** tab.
4. Select the interface on which you want to view the ICMP statistics.
5. Click **ICMPstats** option from the menu.

ICMP stats *Field Descriptions*

Use the data in the following table to use the ICMP **Statistics** tab.

Name	Description
InMsgs	Specifies the total number of ICMP messages which the entity received. Note: This counter includes all those counted by icmpInErrors.
InErrors	Specifies the number of ICMP messages which the entity received but determined as having ICMP-specific errors (bad ICMP checksums, bad length, etc.).
InDestUnreachs	Specifies the number of ICMP Destination Unreachable messages received by the interface.
InAdminProhibs	Specifies the number of ICMP destination unreachable/communication administratively prohibited messages received by the interface.
InTimeExcds	Specifies the number of ICMP Time Exceeded messages by the interface.
InParmProblems	Specifies the number of ICMP Parameter Problem messages received by the interface.
InPktTooBigs	Specifies the number of ICMP Packet Too Big messages received by the interface.
InEchos	Specifies the number of ICMP Echo (request) messages received by the interface.
InEchoReplies	Specifies the number of ICMP Echo Reply messages received by the interface.
InRouterSolicits	Specifies the number of ICMP Router Solicit messages received by the interface.
InRouterAdvertisements	Specifies the number of ICMP Router Advertisement messages received by the interface
InNeighborSolicits	Specifies the number of ICMP Neighbor Solicit messages received by the interface.
InNeighborAdvertisements	Specifies the number of ICMP Neighbor Advertisement messages received by the interface.
InRedirects	Specifies the number of ICMP Redirect messages received by the interface.
InGroupMembQueries	Specifies the number of ICMPv6 Group Membership Query messages received by the interface
InGroupMembResponses	Specifies the number of ICPv6 Group Membership Response messages received by the interface.

Name	Description
InGroupMembReductions	Specifies the number of ICMPv6 Group Membership Reduction messages received by the interface.
OutMsgs	Specifies the total number of ICMP messages which this interface attempted to send. Note that this counter includes all those counted by icmpOutErrors.
OutErrors	Specifies the number of ICMP messages which this interface did not send due to problems discovered within ICMP such as a lack of buffers. This value should not include errors discovered outside the ICMP layer such as the inability of IPv6 to route the resultant datagram. In some implementations there may be no types of error which contribute to this counter's value.
OutDestUnreachs	Specifies the number of ICMP Destination Unreachable messages sent by the interface.
OutAdminProhibs	Specifies the number of ICMP destination unreachable/communication administratively prohibited messages sent.
OutTimeExcds	Specifies the number of ICMP Time Exceeded messages sent by the interface.
OutParmProblems	Specifies the number of ICMP Parameter Problem messages sent by the interface.
OutPktTooBigs	Specifies the number of ICMP Packet Too Big messages sent by the interface.
OutEchos	Specifies the number of ICMP Echo (request) messages sent by the interface.
OutEchoReplies	Specifies the number of ICMP Echo Reply messages sent by the interface.
OutRouterSolicits	Specifies the number of ICMP Router Solicitation messages sent by the interface.
OutRouterAdvertisements	Specifies the number of ICMP Router Advertisement messages sent by the interface.
OutNeighborSolicits	Specifies the number of ICMP Neighbor Solicitation messages sent by the interface.
OutNeighborAdvertisements	Specifies the number of ICMP Neighbor Advertisement messages sent by the interface.
OutRedirects	Specifies the number of Redirect messages sent. For a host, this object will always be zero, since hosts do not send redirects.
OutGroupMembQueries	Specifies the number of ICMPv6 Group Membership Query messages sent.

Name	Description
OutGroupMembResponses	Specifies the number of ICMPv6 Group Membership Response messages sent.
OutGroupMembReductions	Specifies the number of ICMPv6 Group Membership Reduction messages sent.

Configure an IPv6 Interface

You must configure an IPv6 interface for a VLAN or brouter port before you can assign an IPv6 address to the interface.

Before You Begin

- You must configure a VLAN before you can give the VLAN an interface identifier or an IPv6 address. The switch supports port-based, protocol-based, and MAC-source-based VLANs.

  For information about how to configure VLANs, see VLAN Configuration using EDM on page 3454.
- Change the VRF instance as required to configure an IPv6 interface on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

You can also configure an IPv6 interface for a brouter port through the **Edit** > **Port** > **IPv6** navigation path, and for a VLAN through the **VLAN** > **VLANs** > **Basic** > **IPv6** navigation path. This procedure uses the main IPv6 navigation path where you can create both types of interfaces.

Procedure

1. In the navigation pane, expand the **Configuration** > **IPv6** folders.
2. Select **IPv6**.
3. Select the **Interfaces** tab.
4. Select **Insert**.
5. In the **Interface** field, select **Port** or **VLAN**.
6. Select a port or VLAN.
7. Select **OK**.
8. Select the **AdminStatus** field to activate the interface.
9. Configure the remaining parameters as required.
10. Select **Insert**.
11. Select **Apply**.

Interfaces *Field Descriptions*

Use the data in the following table to use the **Interfaces** tab.

Name	Description
Interface	Specifies the port or VLAN.
Identifier	Shows the IPv6 address interface identifiers. This value is a binary string of up to 8 octets in network byte-order.

Name	Description
IdentifierLength	Shows the length of the identifier, in bits.
Descr	Specifies a description of the interface. The network management system also configures this string.
VlanId	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. This value corresponds to the lower 12 bits of the IEEE 802.1Q VLAN tag.
Type	Shows the interface type.
ReasmMaxSize(MTU)	Specifies the maximum size of the MTU of this IPv6 interface. This value must be the same for all the IP addresses defined on this interface. The default value is 1500. Different hardware platforms support different MTU values.
PhysAddress	Specifies the media-dependent physical address. For Ethernet, this is a MAC address.
AdminStatus	Specifies if IPv6 is active on this interface. The default is false (disabled).
OperStatus	Specifies the current operational status of the interface.
ReachableTime	Specifies the time, in milliseconds, that a neighbor is considered reachable after receiving a reachability confirmation. The default is 30000.
RetransmitTimer	Specifies the time, in milliseconds, between retransmissions of neighbor solicitation messages to a neighbor when resolving the address, or when probing the reachability of a neighbor. The default is 1000.
CurHopLimit	Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a value for CurHopLimit. The default is 64.
MulticastAdminStatus	The option to select **MulticastAdminStatus** is disabled. You cannot configure the administrative status for multicast in this context.
MacOffset	Requests a particular MAC for an IPv6 VLAN. You can specify a MAC offset when you configure IPv6 on a VLAN, or the system can assign a MAC address from within the available range. Different hardware platforms support different MAC offset ranges.
RSMLTEnable	Shows whether RSMLT is enabled on the interface. The default value is disabled (false).
ProcessRedirect	Shows whether ND Redirect messages processing is enabled or disabled on this interface. The default value is disabled (false).

Viewing IPv6 Statistics for an Interface

View IPv6 statistics to view information about the IPv6 datagrams on an interface.

Procedure

1. In the navigation pane, expand the **Configuration** > **IPv6** folders.
2. Click **IPv6**.
3. Click the **Interfaces** tab.
4. Select an interface.
5. Click **IfStats**.
6. (Optional) Select one or more values, and then click on the type of graph to graph the data.

Statistics *Field Descriptions*

Use the data in the following table to use the **Statistics** tab.

Name	Description
InReceives	Shows the total number of input datagrams received by the interface, including those received in error.
InHdrErrors	Shows the number of input datagrams discarded due to errors in their IPv6 headers, including version number mismatch, other format errors, hop count exceeded, and errors discovered in processing the IPv6 options.
InTooBigErrors	Shows the number of input datagrams that could not be forwarded because their size exceeded the link MTU of the outgoing interface.
InNoRoutes	Shows the number of input datagrams discarded because no route could be found to transmit them to their destination.
InAddrErrors	Shows the number of input datagrams discarded because the IPv6 address in the IPv6 header destination field was not a valid address to be received at this entity. This count includes invalid addresses, for example, ::0, and unsupported addresses, for example, addresses with unallocated prefixes. For entities which are not IPv6 routers and do not forward datagrams, this counter includes datagrams discarded because the destination address was not a local address.
InUnknownProtos	Shows the number of locally-addressed datagrams received successfully but discarded because of an unknown or unsupported protocol. This counter is incremented at the interface to which these datagrams were addressed, which is not always the input interface for some of the datagrams.
InTruncatedPkts	Shows the number of input datagrams discarded because the datagram frame did not carry enough data.

Name	Description
InDiscards	Shows the number of input IPv6 datagrams for which no problems were encountered to prevent their continued processing, but which were discarded, for example, for lack of buffer space. This counter does not include datagrams discarded while awaiting re-assembly.
InDelivers	Shows the total number of datagrams successfully delivered to IPv6 user-protocols (including ICMP). This counter is incremented at the interface to which these datagrams were addressed which is not always the input interface for some of the datagrams.
OutForwDatagrams	Shows the number of output datagrams which this entity received and forwarded to their final destinations. In entities which do not act as IPv6 routers, this counter includes only those packets which were Source-Routed using this entity, and the Source-Route processing was successful. For a successfully forwarded datagram the counter of the outgoing interface is incremented.
OutRequests	Shows the total number of IPv6 datagrams which local IPv6 user-protocols (including ICMP) supplied to IPv6 in requests for transmission. This counter does not include datagrams counted in **OutForwDatagrams**.
OutDiscards	Shows the number of output IPv6 datagrams for which no problem was encountered to prevent their transmission to their destination, but which were discarded, for example , for lack of buffer space. This counter includes datagrams counted in **OutForwDatagrams** if such packets met this (discretionary) discard criterion.
OutFragOKs	Shows the number of IPv6 datagrams that have been successfully fragmented at this output interface.
OutFragFails	Shows the number of IPv6 datagrams that have been discarded because they needed to be fragmented at this output interface but could not be.
OutFragCreates	Shows the number of output datagram fragments that have been generated as a result of fragmentation at this output interface.
ReasmReqds	Shows the number of IPv6 fragments received which needed to be reassembled at this interface. This counter is incremented at the interface to which these fragments were addressed, which is not always the input interface for some of the fragments.

Name	Description
ReasmOKs	Shows the number of IPv6 datagrams successfully reassembled. This counter is incremented at the interface to which these datagrams were addressed, which is not always the input interface for some of the fragments.
ReasmFails	Shows the number of failures detected by the IPv6 re- assembly algorithm). This value is not necessarily a count of discarded IPv6 fragments because some algorithms can lose track of the number of fragments by combining them as they are received. This counter is incremented at the interface to which these fragments were addressed, which is not always the input interface for some of the fragments.
InMcastPkts	Shows the number of multicast packets received by the interface.
OutMcastPkts	Shows the number of multicast packets transmitted by the interface.

Configuring an IPv6 brouter port interface

You must configure an IPv6 interface for a brouter port before you can assign an IPv6 address to the interface.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration** > **Edit** > **Port** folders.
3. Click **IPv6**.
4. Click the **IPv6 Interface** tab.
5. Click **Insert**.
6. Enter the interface identifier.
7. Select the **AdminStatus** field to activate the interface.
8. Configure the remaining parameters as required.
9. Click **Insert**.
10. Click **Apply**.

Interfaces *Field Descriptions*

Use the data in the following table to use the **Interfaces** tab.

Name	Description
Interface	Specifies the port or VLAN.
Identifier	Shows the IPv6 address interface identifiers. This value is a binary string of up to 8 octets in network byte-order.
IdentifierLength	Shows the length of the identifier, in bits.

Name	Description
Descr	Specifies a description of the interface. The network management system also configures this string.
VlanId	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. This value corresponds to the lower 12 bits of the IEEE 802.1Q VLAN tag.
Type	Shows the interface type.
ReasmMaxSize(MTU)	Specifies the maximum size of the MTU of this IPv6 interface. This value must be the same for all the IP addresses defined on this interface. The default value is 1500. Different hardware platforms support different MTU values.
PhysAddress	Specifies the media-dependent physical address. For Ethernet, this is a MAC address.
AdminStatus	Specifies if IPv6 is active on this interface. The default is false (disabled).
OperStatus	Specifies the current operational status of the interface.
ReachableTime	Specifies the time, in milliseconds, that a neighbor is considered reachable after receiving a reachability confirmation. The default is 30000.
RetransmitTimer	Specifies the time, in milliseconds, between retransmissions of neighbor solicitation messages to a neighbor when resolving the address, or when probing the reachability of a neighbor. The default is 1000.
CurHopLimit	Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a value for CurHopLimit. The default is 64.
MulticastAdminStatus	The option to select **MulticastAdminStatus** is disabled. You cannot configure the administrative status for multicast in this context.
MacOffset	Requests a particular MAC for an IPv6 VLAN. You can specify a MAC offset when you configure IPv6 on a VLAN, or the system can assign a MAC address from within the available range. Different hardware platforms support different MAC offset ranges.
RSMLTEnable	Shows whether RSMLT is enabled on the interface. The default value is disabled (false).
ProcessRedirect	Shows whether ND Redirect messages processing is enabled or disabled on this interface. The default value is disabled (false).

Configure an IPv6 VLAN Interface

You must configure an IPv6 interface for a VLAN before you can assign an IPv6 address to the interface.

Before You Begin

- You must configure a VLAN before you can give the VLAN an interface identifier or an IPv6 address. The switch supports port-based, protocol-based, and MAC-source-based VLANs.

For information about how to configure VLANs, see VLAN Configuration using EDM on page 3454.

Procedure

1. In the navigation pane, expand the **Configuration** > **VLAN** folders.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select a VLAN.
5. Select **IPv6**.
6. Select the **IPv6 Interface** tab.
7. Select **Insert**.
8. Enter the interface identifier.
9. Select the **AdminStatus** field to activate the interface.
10. Configure the remaining parameters as required.
11. Select **Insert**.
12. Select **Apply**.

IPv6 Interfaces *Field Descriptions*

Use the data in the following table to use the **IPv6 Interfaces** tab.

Name	Description
Interface	Specifies the port or VLAN.
Identifier	Shows the IPv6 address interface identifiers. This value is a binary string of up to 8 octets in network byte-order.
IdentifierLength	Shows the length of the identifier, in bits.
Descr	Specifies a description of the interface. The network management system also configures this string.
VlanId	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. This value corresponds to the lower 12 bits of the IEEE 802.1Q VLAN tag.
Type	Shows the interface type.
ReasmMaxSize(MTU)	Specifies the maximum size of the MTU of this IPv6 interface. This value must be the same for all the IP addresses defined on this interface. The default value is 1500.
PhysAddress	Specifies the media-dependent physical address. For Ethernet, this is a MAC address.
AdminStatus	Specifies if IPv6 is active on this interface. The default is false (disabled).
OperStatus	Specifies the current operational status of the interface.
ReachableTime	Specifies the time, in milliseconds, that a neighbor is considered reachable after receiving a reachability confirmation. The default is 30000.

Name	Description
RetransmitTimer	Specifies the time, in milliseconds, between retransmissions of neighbor solicitation messages to a neighbor when resolving the address, or when probing the reachability of a neighbor. The default is 1000.
CurHopLimit	Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a value for CurHopLimit. The default is 64.
MulticastAdminStatus	The option to select **MulticastAdminStatus** is disabled. You cannot configure the administrative status for multicast in this context.
MacOffset	Requests a particular MAC for an IPv6 VLAN. You can specify a MAC offset when you configure IPv6 on a VLAN, or the system can assign a MAC address from within the available range. Different hardware platforms support different MAC offset ranges.
RSMLTEnable	Shows whether RSMLT is enabled on the interface. The default value is disabled (false).
ProcessRedirect	Shows whether ND Redirect messages processing is enabled or disabled on this interface. The default value is disabled (false).

Assigning IPv6 addresses to interfaces

Assign IPv6 addresses to interfaces to configure IPv6 routing for the interface.

You can assign an IPv6 address to a VLAN or brouter port.

Before You Begin

Change the VRF instance as required to assign IPv6 addresses to interfaces on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

To create MLT and LAG interfaces with IPv6, you must configure VLAN-based connections and you cannot use brouter ports.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6**.
3. Click the **Addresses** tab.
4. Click **Insert**.
5. In the **Interface** field, click **Port** or **VLAN**.
6. Select the interface.
7. Click **OK**.
8. Type the IPv6 address and prefix length.
9. Click **Insert**.
10. Click **Apply**.

Addresses *field descriptions*

Use the data in the following table to use the **Addresses** tab.

Name	Description
Interface	Specifies the interface to which this entry applies.
Addr	Specifies the IPv6 address to which this entry applies. Important: If the IPv6 address exceeds 116 octets, the object identifiers (OIDS) of instances of columns in this row are more than 128 subidentifiers and you cannot use SNMP-v1, SNMPv2c, or SNMPv3 to access them.
AddrLen	Specifies the prefix length value for this address. You cannot change the address length after you create it. You must provide this value to create an entry in this table.
Type	Specifies the type of address. The default is unicast.
Origin	Specifies the origin of the address. The following list shows the possible origins: • other • manual • dhcp • linklayer • random
Status	Specifies the status of the address, describing whether the address is used for communication. The following list shows the possible statuses: • prefered (default) • deprecated • invalid • inaccessible • unknown • tentative • duplicate
Created	Specifies the sysUpTime of the creation of this entry. If the entry was created prior to the last reinitialization of the local management subsystem, the object contains a zero value.
LastChanged	Specifies the value of sysUpTime of the last modification to this entry. If the entry was created prior to the last reinitialization of the local management subsystem, the object contains a zero value.

Name	Description
ValidLifetime	Shows how long, in seconds, the address is valid.
PrefLifetime	Shows how long, in seconds, the address is in use.

Assigning IPv6 addresses to a brouter port interface

Assign IPv6 addresses to interfaces to configure IPv6 routing for the interface.

You can assign an IPv6 address to a VLAN or brouter port.

Before You Begin

Change the VRF instance as required to assign IPv6 addresses to a brouter port interface on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

To create MLT and LAG interfaces with IPv6, you must configure VLAN-based connections and you cannot use brouter ports.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **Edit** > **Port**.
2. Click **IPv6**.
3. Click the **Ipv6 Addresses** tab.
4. Click **Insert**.
5. Click **Insert**.
6. Click **Apply**.

IPv6 Addresses field descriptions

Use the data in the following table to use the **IPv6 Addresses** tab.

Name	Description
Interface	Specifies the port.
Addr	Specifies the IPv6 address to which this entry applies. Note: If the IPv6 address exceeds 116 octets, the object identifiers (OIDS) of instances of columns in this row are more than 128 subidentifiers and you cannot use SNMP-v1, SNMPv2c, or SNMPv3 to access them.
AddrLen	Specifies the prefix length value for this address. You cannot change the address length after you create it. You must provide this value to create an entry in this table.

Name	Description
Type	Specifies the type of address. The default is unicast.
Origin	Specifies the origin of the address.
Status	Specifies the status of the address, describing whether the address is used for communication.
Created	Specifies the sysUpTime of the creation of this entry. If the entry was created prior to the last reinitialization of the local management subsystem, the object contains a zero value.
LastChanged	Specifies the value of sysUpTime of the last modification to this entry. If the entry was created prior to the last reinitialization of the local management subsystem, the object contains a zero value.

Assigning an IPv6 address to a VLAN

Assign an IPv6 address to a VLAN.

Procedure

1. In the navigation pane, expand the **Configuration** > **VLAN** folders.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN interface.
5. Click **IPv6**.
6. Click the **IPv6 Addresses** tab.
7. Click **Insert**.
8. Type the IPv6 address and length in the fields.
9. Click **Insert**.
10. Click **Apply**.

IPv6 Addresses *field descriptions*

Use the data in the following table to use the **IPv6 Addresses** tab.

Name	Description
Interface	Identifies the address to which the address is assigned.
Addr	Specifies an IP address that is associated with a VLAN.
AddrLen	Specifies the prefix address length value for this address.
Type	Specifies the type of address: either unicast or anycast.

Name	Description
Origin	Specifies the origin of the address as one of the following: • other • manual • dhcp • linklayer • random
Status	Shows the status of the address and if it can be used for communication.
Created	Shows the time this address entry was created.
LastChanged	Shows the time this address entry was last updated.

Create IPv6 Static Routes

Perform the steps in this task to:

- Create static routes for data traffic in either the GRT or a specific VRF context for any platform.
- Create static routes for a VRF associated with a Segmented Management Instance CLIP interface.

Static routes for the management OOB and management VLAN, if supported, must use the Segmented Management Instance. For more information, see Segmented Management Instance Configuration for Fabric Engine using EDM on page 102. The management CLIP can use the Segmented Management Instance or routes in the associated VRF routing table manager (RTM).

Before You Begin

- Enable IPv6 forwarding.
- Change the VRF instance as required. For information about how to use EDM for a non-default VRF, see Select and Launch a VRF Context View on page 3504. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Select **IPv6**.
3. Select the **Globals** tab.
4. Select the **StaticRouteGlobalAdminEnabled** check box.

   If you disable static routes globally, the system removes all enabled static routes from the RTM and does not add new static routes to the RTM. The default is enabled.
5. Select **Apply**.
6. Select the **Static Routes** tab.
7. Select **Insert**.
8. In the **Dest** field, type the IPv6 address.
9. In the **PrefixLength** field, type the length of the prefix for the IPv6 address.
10. In the **NextHop** field, type the IPv6 address of the router through which the specified route is accessible.

11. Beside the **Interface** field, select **Port** or **Vlan** or **Tunnel**.
12. Select the interface, and then select **OK**.
13. In the **Cost** field, type a number for the distance.
14. Select the **Enable** check box.
15. Select **Insert**.

Static Routes *Field Descriptions*

Use the data in the following table to use the **Static Routes** tab.

Name	Description
Dest	Specifies the IPv6 destination network address. The prefix value must match the PrefixLength.
PrefixLength	Specifies the number bits you want to advertise from the prefix. The prefix value must match the value in the Dest field. The range is 0 to 128.
NextHop	Specifies the IPv6 address of the next hop on this route. You do not need to specify the next hop if the devices directly connect to one another. Configure the next hop if the two nodes do not share the same network prefix but reside on the same link.
Interface	Specifies the interface to which this entry applies. You must specify the port or VLAN if the next hop is a link-local address.
Cost	Specifies the cost or distance ratio to reach the destination for this node. The range is 1-65535. The default value is 1.
Name Note: This field does not apply to 5320 Series switches.	Specifies the name for the static route.
Enable	Enables the static route on the port. The default value is enable.

Name	Description
Status	Shows the status of the static route as one of the following: • notReachable: The route is not reachable and no neighbor request entry is built to resolved the next-hop. The system displays this status if no route or neighbor exists to reach the next-hop of the static route. • tryToResolve: The route is not reachable but a neighbor request entry is built to resolve the next-hop. The system displays this status if a local equivalent route exists in the system to reach the next-hop but the neighbor is not learned. • reachableNotInRtm: The static route is reachable but it is not in RTM. The system displays this status if the static route is reachable, but it is not the best among alternative static routes. • reachableInRtm: The static route is reachable and it is in RTM. The system displays this status if the static route is reachable, and it is the best among alternative static routes to be added into RTM.
Preference	Specifies the routing preference of the destination IPv6 address. The range is 1-255. The default value is 5.

Configuring IPv6 route preferences

Change IPv6 route preferences to force the routing protocols to prefer one route over another. Configure route preferences to override default route preferences and give preference to routes learned for a specific protocol.

Before You Begin

Change the VRF instance as required to configure IPv6 route preferences on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

Important

Changing route preferences is a process-oriented operation that can affect system performance and network reachability while you perform the procedures. If you want to change default preferences for routing protocols, do so before you enable the protocols.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6**.
3. Click the **RoutePref** tab.

4. In the **ConfiguredValue** column, double-click a parameter to change the preference for the given protocol.
5. Click **Apply**.

RoutePref *field descriptions*

Use the data in the following table to use the **RoutePref** tab.

Name	Description
DefaultValue	Specifies the default preference value for the specified protocol.
Protocol	Specifies the protocol name.
ConfiguredValue	Configures the preference value for the specified protocol.

View Route Information

View routes information to view the current configuration.

About This Task

IPv6 host routes created for the IPv6 local interfaces do not display in the routing table.

Before You Begin

Change the VRF instance as required to view route information on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Select **IPv6**.
3. Select the **Routes** tab.

Routes *Field Descriptions*

Use the data in the following table to use the **Routes** tab.

Name	Description
Dest	Specifies the IPv6 destination network address. The prefix value must match the PrefixLength.
PfxLength	Specifies the number bits you want to advertise from the prefix. The prefix value must match the value in the Dest field.
Index	Specifies the unique value that identifies the route among the routes to the same network layer destination.
Interface	Specifies the interface to which this entry applies.
NextHop	Specifies the IPv6 address of the next hop on this route.
Protocol	Specifies the routing protocol, such as OSPF.

Name	Description
Metric	Specifies the metric assigned to this interface. The default value of the metric is the reference bandwidth or ifSpeed. The value of the reference bandwidth is configured by the rcOspfv3ReferenceBandwidth object. For more information about reference bandwidth, see Globals field descriptions on page 2299.
NextHopId	Identifier of the next-hop, hostname, or mac address.
Age	Specifies the number of seconds since the route was last updated or is last active.
Type	Specifies the type of route.
PathType	Specifies the type of path.
SrcVrfId	Specifies the source VRF instance.
Pref	Specifies the preference.

Viewing IPv6 Default Routers

View the table of default routers learned from router advertisement messages.

A maximum of four routers are visible in the default routers list.

Procedure

1. In the navigation tree, expand the **Configuration** > **IPv6** folders.
2. Click **IPv6**.
3. Click the **Default Routers** tab.

Default Routers field descriptions

Use the data in the following table to use the **Default Routers** tab.

Name	Description
Address	Specifies the learned router address for an IPv6 default routers entry.
IfIndex	Specifies the interface number for an IPv6 default routers entry.
Lifetime	Specifies the remaining router lifetime.
Active	Specifies if the default router is active for an IPv6 default routers entry.

Configure a Circuitless IPv6 Interface

Before You Begin

Change the VRF instance as required to configure a Circuitless IPv6 interface on a specific VRF instance.

About This Task

You can use a circuitless IPv6 (CLIPv6) interface to provide uninterrupted connectivity to your system.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Click **IPv6**.
3. Click the **Circuitless IP** tab.
4. Click **Insert**.
5. In the **Interface** field, assign a CLIP interface number.
6. Type the IPv6 address and prefix length.

Circuitless IPv6 *Field Descriptions*

Use the data in the following table to use the **Circuitless IPv6** tab.

Name	Description
Interface	Specifies the interface to which this entry applies.
Addr	Specifies the IPv6 address to which this entry applies.
AddrLen	Specifies the prefix length value for this address. You cannot change the address length after you create it. You must provide this value to create an entry in this table.
Name Note: This filed does not apply to 5320 Series switches.	Specifies the name assigned to the IPv6 CLIP address.

Configuring IPv6 Prefix List

Use IPv6 prefix lists to allow or deny specific route updates. A prefix list policy specifies route prefixes to match. When there is a match, the route is used.

Before You Begin

- Change the VRF instance as required to configure a prefix list on a specific VRF instance.

Procedure

1. In the navigation pane, open the following folders: **Configuration** > **IPv6**.
2. Click **Policy**.
3. In the **Ipv6-Prefix List** tab, click **Insert**.
4. Edit the parameters as required.
5. Click **Insert**.

Ipv6–Prefix list *field descriptions*

Use the data in the following table to use the **Ipv6–Prefix List** tab.

Name	Description
Id	Specifies the list identifier. The range is 1 to 2147483647.
Prefix	Specifies the prefix IPv6 address.
PrefixMaskLen	Specifies the length of the prefix mask. You must enter the full 128-bit mask to exact a full match of a specific IPv6 address (for example, when creating a policy to match the next-hop).
Name	Names a specified prefix list during the creation process or renames the specified prefix list. The name can be from 1 to 64 characters in length.
MaskLenFrom	Specifies the lower bound on the mask length. The default is the mask length. Lower bound and higher bound mask lengths together can define a range of networks.
MaskLenUpto	Specifies the higher bound mask length. The default is the mask length. Lower bound and higher bound mask lengths together can define a range of networks.

Configuring an IPv6 Route Policy

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **Policy**.
3. Click the **Route Policy** tab.
4. Click **Insert**.
5. Enter the appropriate information for your configuration in the Insert Route Policy dialog box.
6. Click **Insert**.

Route Policy *Field Descriptions*

Use the data in the following table to use the **Route Policy** tab.

Name	Description
Id	Specifies the ID of an entry in the Prefix list table.
SequenceNumber	Specifies a policy within a route policy group.
Name	Specifies the name of the policy. This command changes the name field for all sequence numbers under the given policy.
Enable	Indicates whether this policy sequence number is enabled or disabled. If disabled, the policy sequence number is ignored. The default is disabled.

Name	Description
Mode	Specifies the action to take when a policy is selected for a specific route. Select permit (allow the route) or deny (ignore the route). The default is permit.
MatchProtocol	Selects the appropriate protocol. If configured, matches the protocol through which the route is learned. This field is used only for RIP Announce purposes. The default is to enable all match protocols.
MatchNetwork	Specifies if the system matches the destination network against the contents of the specified prefix list.
MatchIpRouteSource	Specifies if the system matches the next-hop IP address for RIP routes and advertising router IDs for OSPF routes against the contents of the specified prefix list. This option is ignored for all other route types. Select the ellipsis and choose from the list in the Match Route Source dialog box. You can select up to four entries. To clear an entry, use the ALT key. You can also change this field in the Route Policy tab of the Policy dialog box.
MatchIpRouteDest	Specifies if the system matches the next-hop IP address for RIP routes and advertising router IDs for OSPF routes against the contents of the specified prefix list. This option is ignored for all other route types.
MatchNextHop	Specifies if the system matches the next-hop IP address of the route against the contents of the specified prefix list. This field applies only to nonlocal routes. Select the ellipsis and choose from the list in the Match Next Hop dialog box. You can select up to four entries. To clear an entry, use the ALT key.
MatchInterface	Specifies if the system matches the IP address of the interface by which the RIP route was learned against the contents of the specified prefix list. This field is used only for RIP routes and ignored for all other type of route. Select the ellipsis and choose from the list in the Match Interface dialog box. You can select up to four entries. To clear an entry, use the ALT key.
MatchRouteType	Configures a specific route type to match (applies only to OSPF routes). Externaltype1 and Externaltype2 specify the OSPF routes of the specified type only. OSPF internal refers to intra- and inter-area routes. The default is any.
MatchMetric	Specifies if the system matches the metric of the incoming advertisement or existing route against the specified value (1 to 65535). If 0, this field is ignored. The default is 0.
MatchMetricTypeIsis	Specifies the match metric type field in the incoming ISIS routes in accept policy.
MatchAsPath	Configures if the system matches the BGP autonomus system path. Applicable to BGP only. This overrides the BGP neighbor filter list information.

Name	Description
MatchCommunity	Filters incoming and outgoing updates based on a Community List. Applicable to BGP only. The default is disable.
MatchCommunityExact	Indicates if the match must be exact (that is, all of the communities specified in the path must match). Applicable to BGP only. The default is disabled.
MatchTag	Specifies a list of tags used during the match criteria process. Applicable to BGP only. It contains one or more tag values.
MatchVrf	Identifies the source VRFs that leaks routes to the local VRF (applies only to RIP routes).
MatchLocalPref	Specifies the local preference value to be matched.
NssaPbit	Configures or resets the P bit in specified type 7 link state advertisements (LSA). By default, the Pbit is always configured in case the user configures the Pbit to a disable state for a particular route policy other than all type 7. LSAs associated with that route policy have the Pbit cleared. With this intact, not so stubby area (NSSA) area border router (ABR) does not perform translation of these LSAs to type 5. The default is enable.
SetRoutePreference	Configures a value from 0 to 255. The default value is 0. If the default is configured, the global preference value is used. When configured to a value greater than zero, specifies the route preference value assigned to the routes that matches the policy. This feature applies to accept policies only.
SetMetricTypeInternal	Identifies the MED value for routes advertised to BGP numbers to the Interior Gateway Protocol (IGP) metric value. The value must be 0 or 1. The default is 0.
SetMetricTypeIsis	Sets the metric type IS-IS.
SetMetric	Configures the system to use the metric value for the route while announcing or redistributing. The default-import-metric is 0. If the default is configured, the original cost of the route is advertised into OSPF; for RIP, the original cost of the route or the default value is used (applies to IS-IS routes also). The default is 0.
SetMetricType	Configures the metric type for the routes to announce into the OSPF routing protocol that matches this policy. Applicable to OSPF protocol only. The default is type 2. This field is applicable only for OSPF announce policies. The default is type2.
SetNextHop	Configures the IP address of the next-hop router. Applicable to BGP only. The default is 0.0.0.0.
SetInjectNetList	Configures the destination network of the route that matches this policy with the contents of the specified prefix list. Select the ellipsis and choose from the list in the Set Inject NetList dialog box.
SetMask	Configures the mask of the route that matches this policy. This applies only to RIP accept policies.

Name	Description
SetAsPath	Indicates the AS path value to use whether the SetAsPathMode field is Tag or Prepend. Applicable to BGP only. Note: Prepend is not applicable to an internal BGP (iBGP) peer with outbound route policy.
SetAsPathMode	Configures if the system converts the tag of a route into an AS path. Applicable to BGP protocol only. The mode is either Tag or Prepend tag. The value is applicable only while redistributing routes to BGP The default is prepend. Note: Prepend is not applicable to an iBGP peer with outbound route policy.
SetAutomaticTag	Enables the automatic tag feature. Applicable to BGP protocol only. The default is disable.
SetCommunityNumber	Configures the community number for BGP advertisements. This value can be a number (1 to 42949672000) or no-export or no-advertise.
SetCommunityMode	Configures the community mode for the BGP protocol. This value can be either append, none, or unchanged. The default is unchanged. • Unchanged—keeps the community attribute in the route path as it is. • None—removes the community in the route path additive. • Append—adds the community number specified in SetCommunityNumber to the community list attribute.
SetExtCommunity	Configures a BGP community. The values are 0 to 256.
SetExtCommunityMode	Configures the extended-community mode. The value can be append, unchanged, or overwrite. The default value is unchanged. • append — creates another community string. • unchanged — keeps the community attribute as it is. • overwrite — changes the current value.
SetOrigin	Configures the origin for the BGP protocol to IGP, EGP, incomplete, or unchanged. If not configured, the system uses the route origin from the IP routing table (protocol). The default is unchanged.
SetLocalPref	Configures the local preference for the BGP protocol only. The system uses this value during the route decision process for the BGP protocol. The default is 0.
SetOriginEgpAs	Indicates the remote autonomous system number for the BGP protocol. The default is 0.

Name	Description
SetWeight	Configures the weight value for the routing table for the BGP protocol. This field must be used with the match as-path condition. For BGP, this value overrides the weight configured through the NetworkTableEntry, FilterListWeight, or NeighborWeight. The default is 0.
SetTag	Configures the list of tags used during the match criteria process for the BGP protocol. The default is 0.
Ipv6SetNextHop	Specifies the address of the IPv6 next hop router.

Configuring IPv6 Route Redistribution Policies

About This Task

Configure route redistribution so that a VRF interface can announce routes that other protocols learn, for example, OSPF or BGP. Use a route policy to control the redistribution of routes. You can redistribute routes for the Global router (VRF 0) and within a user-defined VRF but not between different VRFs.

Before You Begin

- Ensure VRF instances exist.
- Configure route policies, if required.
- Change the VRF instance as required.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Click **Policy**.
3. Click the **Route Redistribution** tab.
4. Click **Insert**.
5. Choose the protocol and route source.
6. Select **Enable**.
7. Choose the route policy to apply to the redistributed routes.
8. Configure other parameters as required.
9. Click **Insert**.

Route Redistribution *Field Descriptions*

Use the data in the following table to use the **Route Redistribution** tab.

Name	Description
DstVrfId	Specifies the destination VRF ID.
Protocol	Specifies the protocols for which you want to receive external routing information.
SrcVrfId	Specifies the source VRF ID.
RouteSource	Indicates if the protocol receives notification about the routes this source learns. The route source is equivalent to the owner in the routing table.

Name	Description
Enable	Enables or disables route redistribution. The default is disabled.
RoutePolicy	Specifies the route policies to apply to the redistributed routes from the source VRF. Use the route policy to determine whether the system advertises a specific route to the specified protocol.
Metric	Specifies the metric announced in advertisements. The default is 0.
MetricType	Specifies the metric type (applies to OSPF and BGP only). Specifies a type 1 or a type 2 metric. For metric type 1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type 2, the cost of the external routes is equal to the external cost alone. The default is type2.

Viewing IPv6 Connections using EDM

Use the procedures in this section to view IPv6 connections using EDM.

Viewing TCP global information

View TCP and UDP information to view the current configuration.

Before You Begin

Change the VRF instance as required to view TCP global information on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

The fields on the TCP global tab provide information about the handshake (SYN) configuration and the maximum number of TCP connections you can create on your system.

When you initiate a TCP connection, both end points send handshake information to create the channel.

The retransmission algorithm and fields display the configured timeout value and minimum and maximum retransmission times that your system uses to terminate a connection attempt that falls outside your specified parameters.

Procedure

1. In the navigation pane, expand the **Configuration** > **IPv6** folders
2. Click **TCP/UDP**.
3. Click the **TCP Globals** tab.

TCP Global *field descriptions*

Use the data in the following table to use the **TCP Globals** tab.

Name	Description
RtoAlgorithm	Determines the timeout value used for retransmitting unacknowledged octets.
RtoMin	Displays the minimum time (in milliseconds) permitted by a TCP implementation for the retransmission timeout.
RtoMax	Displays the maximum time (in milliseconds) permitted by a TCP implementation for the retransmission timeout.
MaxConn	Displays the maximum connections for the device.

Viewing TCP connections information

View information about TCP connections.

Before You Begin

Change the VRF instance as required to view TCP connections information on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

Among other things, the fields on the TCP connections tab provide important information about the health of connections that traverse your switch.

In particular, the state column lets you know the state of each TCP connection. Of these, synSent, synReceived, and established indicate whether or not a channel is established and listen indicates when an end system is waiting for a returning handshake (SYN).

Procedure

1. In the navigation pane, expand the **Configuration** > **IPv6** folders.
2. Click **TCP/UDP**.
3. Click the **TCP Connections** tab.

TCP Connections *field descriptions*

Use the data in the following table to use the **TCP Connections** tab.

Name	Description
LocalAddressType	Displays the type (IPv6 or IPv4) for the address in the LocalAddress field.
LocalAddress	Displays the IPv6 address for the TCP connection.
LocalPort	Displays the local port number for the TCP connection.

Name	Description
RemAddressType	Displays the type (IPv6 or IPv4) for the remote address of the TCP connection.
RemAddress	Displays the IPv6 address for the remote TCP connection.
RemPort	Displays the remote port number for the TCP connection.
State	Displays an integer that represents the state for the connection: • closed • listen • synSent • synReceived • established • finWait1 • finWait2 • closeWait • lastAck(9) • closing • timeWait • deleteTCB
Process	Displays the process ID for the system process associated with the TCP connection.

Viewing TCP listeners information

View TCP listener information.

Before You Begin

Change the VRF instance as required to view TCP listeners information on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

The TCP listeners table provides a detailed list of systems that are in the listening state.

When a connection is in the listen state an end point system is waiting for a returning handshake (SYN).The normal listening state should be very transient, changing all of the time.

Two or more systems going to a common system in an extended listening state indicates the need for further investigation.

End systems in an extended listening state can indicate a broken TCP connection or a DOS attack on a resource.

This type of DOS attack, known as a SYN attack, results from the transmission of SYNs with no response to return replies.

While many systems can detect a SYN attack, the TCP listener statistics can provide additional forensic information.

Procedure

1. In the navigation pane, expand the **Configuration** > **IPv6** folders.
2. Click**TCP/UDP**.
3. Click the **TCP Listeners** tab.

TCP Listeners *field descriptions*

Use the data in the following table to use the **TCP Listeners** tab.

Name	Description
LocalAddressType	Displays the type (IPv6 or IPv4) for the address in the LocalAddress field.
LocalAddress	Displays the IPv6 address for the TCP connection.
LocalPort	Displays the local port number for the TCP connection.
Process	Displays the process ID for the system process associated with the TCP connection.

Viewing UDP endpoint information

View UDP Endpoints to confirm correct configuration.

Before You Begin

Change the VRF instance as required to view UDP endpoint information on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

You can use UDP endpoint information to display local and remote UDP activity.

Since UDP is a protocol used to establish connectionless network sessions, you need to monitor local and remote UDP activity and to know which applications are running over UDP.

You can determine which applications are active by checking the port number.

Processes are further identified with a UDP session to allow for the multiplexing of a port mapping for UDP.

Procedure

1. In the navigation pane, expand the **Configuration** > **IPv6** folders.
2. Click **TCP/UDP**.
3. Click the **UDP Endpoints** tab.

UDP Endpoints *field descriptions*

Use the data in the following table to use the **UDP Endpoints** tab.

Name	Description
LocalAddressType	Displays the local address type (IPv6 or IPv4).
LocalAddress	Displays the local IPv6 address.
LocalPort	Displays the local port number.
RemoteAddressType	Displays the remote address type (IPv6 or IPv4).
RemoteAddress	Displays the remote IPv6 address.
RemotePort	Displays the remote port number.
Instance	Distinguishes between multiple processes connected to the UDP endpoint.
Process	Displays the ID for the UDP process.

IPv6 Neighbor Discovery

The following sections provide concepts and procedures to complete IPv6 neighbor discovery configuration.

Neighbor Discovery

IPv6 nodes (routers and hosts) on the same link use neighbor discovery (ND) to discover link-layer addresses and to obtain and advertise various network parameters and reachability information. ND combines the services for IPv4 with the Address Resolution Protocol (ARP) and router discovery. In IPv6 ND performs a function similar to ARP (Address Resolution Protocol) in IPv4.

Hosts use ND to discover the routers in the network that you can use as the default routers, and to determine the link-layer address of neighbors attached to local links. Routers also use ND to discover neighbors and link-layer information. ND updates the neighbor database with valid entries, invalid entries, and entries migrated to various locations.

The ND protocol provides the following services:

- address and prefix discovery

  Hosts determine the set of addresses that are on-link for the given link. Nodes determine which addresses or prefixes are locally reachable or remote with address and prefix discovery.
- router discovery

  Hosts discover neighboring routers with router discovery. Hosts establish neighbors as default packet-forwarding routers.
- parameter discovery

  Hosts and routers discover link parameters such as the link MTU or the hop-limit value placed in outgoing packets.
- address autoconfiguration

  Hosts configure an address for an interface with address autoconfiguration.
- duplicate address detection

  Hosts and nodes determine if an address is assigned to another router or a host.

- address resolution

  Hosts determine link-layer addresses (MAC for Ethernet) of the local neighbors (attached on the local network), provided the IP address is known.
- next-hop determination

  Hosts determine how to forward local or remote traffic with next-hop determination. The next hop can be a local or remote router.
- neighbor unreachability detection

  Hosts determine if the neighbor is unreachable, and if address resolution must be performed again to update the database. For neighbors you use as routers, hosts attempt to forward traffic through alternative default routers.
- redirect

  Routers inform the host of more efficient routes with redirect messages.

Neighbor discovery uses three components:

- host-router discovery

  Host-router discovery performs the following functions:
  - router discovery
  - prefix discovery
  - parameter discovery
  - address autoconfiguration
- host-host communication

  Host-host communication performs the following functions:
  - address resolution
  - next-hop determination
  - neighbor unreachability detection
  - duplicate address detection

- route redirect

Note

When a neighbor transitions to the STALE state, to initiate Neighbor Unreachability detection (NUD), a duplicate copy of the traffic destined to this neighbor is sent to the switch Control Processor (CP) on a low priority queue (queue 0). The original packet is forwarded to this neighbor. After NUD is initiated, the hardware records are updated and the traffic is no longer sent to the CP. When a high rate of such traffic is sent to the CP, the switch can drop some of these packets due to the built-in CP rate limiting feature, which protects the CP from DOS attacks.

Use the command **`show qos cosq-stats cpu-port`** to view drop statistics on the CPU queue. This design does not result in loss of traffic.

Use the command **`ipv6 nd reachable-time <0-3600000>`** to increase the default value of 3000 milliseconds, which in turn delays the scenario of data path sending STALE neighbor destined packets to the CP.

As a best practice, configure a reachable time value of 180000 and retransmit interval of 5000.

ND messages

The following table compares the ICMP message types.

Table 119: IPv4 and IPv6 neighbor comparison

IPv4 Function	IPv6 Function	Description
ARP request message	Neighbor solicitation message	A node sends this message to determine the link-layer address of a neighbor or to verify that a neighbor is still reachable through a cached link-layer address. You can also use neighbor solicitations for duplicate address detection.
ARP reply message	Neighbor advertisement	A node sends this message either in response to a received neighbor solicitation message or to communicate a link-layer address change.
ARP cache	Neighbor cache	The neighbor cache contains information about neighbor types on the network.
Gratuitous ARP	Duplicate address detection New VRRP master interface announcement	A host or node sends a request with its own IP address to determine if another router or host uses the address. If the sender receives a reply, then there is a device with a duplicate address. Both hosts and routers use this function. Gratuitous ARP can also be used to announce the new VRRP master interface so that all switches can adjust their MAC tables.

Table 119: IPv4 and IPv6 neighbor comparison (continued)

IPv4 Function	IPv6 Function	Description
Router solicitation message (optional)	Router solicitation message (required)	The host sends this message after it detects a change in a network interface operational state. The message includes a request for routers to generate router advertisement immediately rather than at the scheduled time.
Router advertisement message (optional)	Router advertisement message (required)	Routers send this message to advertise their presence with various links and Internet parameters either periodically or in response to a router solicitation message. Router advertisements contain prefixes that you use for on-link determination or address configuration, and a suggested hop limit value.
Redirect message	Redirect message	Routers send this message to inform hosts of a better first hop for a destination.

Neighbor discovery cache

The neighbor discovery cache lists information about neighbors in the network and can contain the following types of neighbors:

- static: a configured neighbor
- local: a device on the local system
- dynamic: a discovered neighbor

The following table describes the states in the neighbor cache.

Table 120: Neighbor cache states

State	Description
Incomplete	Address resolution is in progress and the system has not yet determined the link-layer address of the neighbor. The neighbor cache may also enter the Incomplete state when the switch cannot confirm subsequent reachability during the ND process for router neighbors. By contrast, the system deletes host neighbors, rather than enter the Incomplete state, if ND fails to confirm reachability. Tip: Router neighbors: when the R bit is set in the received neighbor advertisement Host neighbors: when the R bit is not set in the received neighbor advertisement
Reachable	A node receives positive confirmation within the last reachable time period.
Stale	Reachability of the neighbor is unknown. Until the system sends traffic to the neighbor, make no attempt to verify its reachability.

Table 120: Neighbor cache states (continued)

State	Description
Delay	A time period longer than the reachable time period passes since the node received the last positive confirmation, and a packet was sent within the last DELAY_FIRST_PROBE_TIME period. If no reachability confirmation is received within the DELAY_FIRST_PROBE_TIME period after entering the DELAY state, neighbor solicitation is sent and the state changes to probe.
Probe	Reachability confirmation is sought from the device every retransmit timer period.

The following events involve Layer 2 and Layer 3 interaction during processing and affect the neighbor cache:

- flushing the virtual LAN (VLAN) MAC
- removing a VLAN or brouter port
- performing an action on all VLANs
- removing a port from a VLAN
- removing a port from a spanning tree group (STG)
- removing a multilink trunk (MLT) group from a VLAN
- removing an MLT port from a VLAN
- removing an MLT port from an STG
- performing an action that disables a VLAN, such as removing all ports from a VLAN
- disabling a tagged port that is a member of multiple routable VLANs

Router discovery

IPv6 nodes discover routers on the local link with router discovery.

IPv6 nodes discover routers on the local link with router discovery.

Router advertisement

Configured interfaces on an IPv6 router send router-advertisement messages. Interfaces also send router advertisements in response to router-solicitation messages from IPv6 nodes on the link.

Router solicitation

An IPv6 host without a configured unicast address sends router solicitation messages.

Host autoconfiguration

The switch can automatically configure a host (node), and assign IPv6 addresses automatically. This process is called stateless address autoconfiguration (SLAAC). The neighbor discovery (ND) protocol performs autoconfiguration.

Stateless autoconfiguration enables serverless basic configuration of IPv6 nodes and renumbering from a mathematical perspective.

Stateless autoconfiguration uses the following equation:

Stateless autoconfiguration = *network prefix (router advertisement)* + *IPv6 interface identifiers*

Stateless autoconfiguration uses the network prefix information in the router advertisement and integrates this with the interface ID to form the node global address(es).

Note

The switch cannot autoconfigure an IPv6 address local to itself because IPv6 routers do not process router advertisements in the same manner as hosts. That is, routers check only for consistency in information advertised in IPv6 Router Advertisements on the same link.

Tip

You must manually assign all addresses/prefixes local to the switch.

Assuming an EUI-64 based interface ID is used, the IPv6 interface address is created from the 48-bit (6-byte) MAC address as follows:

1. EUI-64 hexadecimal digits 0xff-fe are inserted between the third and fourth bytes of the MAC address to obtain the EUI-64.
2. The universal or local bit, the second lower-order bit of the first byte of the MAC address, is complemented.

For example, the IPv6 identifier for host A uses the MAC address 00-AA-00-3F-2A-1C.

To automatically assign an address, the following occurs:

1. Convert to EUI-64 format

   00-AA-00-FF-FE-3F-2A-1C
2. Complement the Universal/Local (U/L) bit.

   The first byte in binary form is 00000000. When the seventh bit is complemented, it becomes 00000010 (0x02).

   The result is 02-AA-00-FF-FE-3F-2A-1C or 2AA:FF:FE3F:2A1C.

Host A with MAC address 00-AA-00-3F-2A-1C, combined with network prefix 2001::/64 provided by router advertisement, uses an IPv6 address 2001::2AA:FF:FE3F:2A1C.

A host generates a link-local address with the prefix FE80 regardless of whether an IPv6 router is present or not.

The link-local address for a node with the MAC address 00-AA-00-3F-2A-1C is FE80::2AA:FF:FE3F:2A1C.

The following list explains the states of an autoconfiguration address:

- Tentative: the address is being verified as unique (link-local address)
- Valid: an address from which unicast traffic can be sent and received; can be in one of two states—either preferred or deprecated

- Preferred: an address for which uniqueness was verified for unrestricted use; can be in one of three states—either tentative, preferred, or deprecated
- Deprecated: an address that remains valid but is withheld for new communication
- Invalid: an address for which a node can no longer send or receive unicast traffic

Neighbor Discovery Configuration using CLI

Use the procedures in this section for neighbor discovery configuration using CLI.

Configuring an IPv6 discovery prefix

Configure the discovery prefixes to send in router advertisement.

About This Task

Hosts on the link use router advertisements to perform IPv6 autoconfiguration.

The discovery prefix controls which IPv6 addresses will be automatically configured, and for how long they are valid.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create neighbor discovery prefixes for an interface:

   ```
   ipv6 nd prefix-interface WORD<0-255> [eui <1-3>] [no-advertise] [no-autoconfig] [no-onlink]
   ```

3. Modify an existing neighbor discovery prefix:

   ```
   ipv6 nd prefix WORD<0-255> infinite [no-advertise] [preferred-life <0-4294967295>] [valid-life <0-4294967295>]
   ```

Example

Create a new neighbor discovery prefix:

```
Switch:1(config-if)#ipv6 nd prefix-interface fd48:bfb6:4c09:9499::1/64
```

Variable Definitions

Use the data in the following table to use the **ipv6 nd prefix** and **ipv6 nd prefix-interface** commands.

Variable	Value
eui <1–3>	Configures the EUI address. The values are: • (1) EUI not used • (2) EUI with Universal/Local bit (U/L) complement enabled • (3) EUI used without U/L Use an EUI-64 interface ID in the address field. If enabled, use EUI, or use EUI-64 and the complement Universal/Local (U/L) bit. This operation provides for both global– and link-local addresses. After you create the entry, you cannot modify this value. This value is valid for use only when the prefix length is 64 or less. The default is EUI not used. If you select EUI not used, this configuration creates an IPv6 ND prefix but no associated IPv6 address on the router. IF you select either EUI used with UL complement or EUI used without UL complement, an associated IPv6 adress is created by concatenating the specified prefix with the EUI-64 interface ID.
infinite	Configures the prefix valid lifetime so it never expires. The default is disabled, which means the prefix expires.
no-advertise	Removes the prefix from the neighbor advertisement. The default is disabled, which means the prefix is advertised.
no-autoconfig	Configures the prefix for use as the autonomous address configuration. This value is placed in the autoflag field in the prefix information option. The value is a 1-bit flag. The default is enabled.
no-onlink	Configures the prefix for use when determining if a node is online. This value is placed in the L-bit field in the prefix information option. The value is a 1-bit flag. The default is enabled.
preferred-life <0–4294967295>	Configures the preferred lifetime in seconds that indicates the length of time this prefix is advertised. The default value is 604800. The preferred lifetime is the length of time for the tentative, preferred, and depreciated state of an autoconfiguration address. The preferred lifetime value must be less than the valid lifetime value. If you must configure the valid lifetime value to a value lower than the current preferred lifetime, you must lower the preferred lifetime value first.

Variable	Value
valid-life <0-0-4294967295>	Configures the valid lifetime in seconds that indicates the length of time this prefix is advertised. The default is 2592000. A valid lifetime is the length of time of the preferred and depreciated state of an autoconfiguration address. The preferred lifetime value must be less than the valid lifetime value. If you must configure the valid lifetime to a value lower than the current preferred lifetime, you must lower the preferred lifetime value first.
WORD <0-255>	Specifies the IPv6 address and prefix.

Use the data in the following table to use the **interface** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configuring route advertisement

Configure route advertisement in IPv6 for neighbor discovery (ND).

About This Task

IPv6 nodes on the same link use ND to discover link-layer addresses and to obtain and advertise various network parameters and reachability information. ND combines the services provided by Address Resolution Protocol (ARP) and router discovery for IPv4.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the number of neighbor solicitation messages from duplicate address detection:

   ```
   ipv6 nd dad-ns <0-600>
   ```

3. Configure the hop limit sent in router advertisements:

   ```
   ipv6 nd hop-limit <0-255>
   ```

4. Enable managed address configuration (M-bit) on the router:

   ```
   ipv6 nd managed-config-flag
   ```

5. Configure the MTU for router advertisements:

   ```
   ipv6 nd mtu <0-9500>
   ```

6. Enable other stateful configuration (O-bit) on the router:

   ```
   ipv6 nd other-config-flag
   ```

7. Configure the router lifetime included in router advertisement:

   ```
   ipv6 nd ra-lifetime <0-9000>
   ```

8. Configure the neighbor reachable time:

   ```
   ipv6 nd reachable-time <0-3600000>
   ```

9. Configure the time between neighbor solicitation messages:

   ```
   ipv6 nd retransmit-timer <0-4294967295>
   ```

10. Configure the maximum time allowed between sending unsolicited multicast router advertisements:

    ```
    ipv6 nd rtr-advert-max-interval <4-1800>
    ```

11. Configure the minimum time allowed between sending unsolicited multicast router advertisements:

    ```
    ipv6 nd rtr-advert-min-interval <3-1350>
    ```

12. Enable periodic router advertisement messages:

    ```
    ipv6 nd send-ra
    ```

Example

Configure the maximum time between sending unsolicited router advertisements:

```
Switch:1(config-if)#ipv6 nd rtr-advert-max-interval 700
```

Configure the minimum time between sending unsolicited router advertisements:

```
Switch:1(config-if)#ipv6 nd rtr-advert-min-interval 500
```

Enable periodic router advertisement messages:

```
Switch:1(config-if)#ipv6 nd send-ra
```

Variable Definitions

Use the data in the following table to use the **ipv6 nd** commands.

Variable	Value
dad-ns <0-600>	Specifies the number of neighbor solicitation messages for duplicate address detection (DAD). A value of 0 disables the DAD process on this interface. A value of 1 sends one advertisement without retransmissions.
hop-limit <0-255>	Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a hop-limit value. The default is 64.
managed-config-flag	Enables the system to configure the M-bit, or managed address configuration flag, in the router advertisements When set, the M-bit flag indicates that addresses are available through DHCPv6. If the M flag is set, the O flag is redundant because DHCPv6 returns all available configuration information. If neither the M nor O flags are set, no information is available through DHCPv6. The default is disabled.
mtu <0-9500>	Shows the MTU value sent in router advertisements on this interface. A value of zero indicates that the system sends no MTU options. The default is 0.
other-config-flag	Enables the O-bit, or other stateful configuration, flag in the router advertisement. Other stateful configuration autoconfigures received information without addresses. When set, the O-bit flag indicates that other configuration information is available through DHCPv6; for example, DNS-related information or information about other servers within the network. If neither the M nor O flags are set, no information is available through DHCPv6. The default is disabled.

Variable	Value
ra-lifetime <0-9000>	Specifies a value placed in the router lifetime field of router advertisements sent from this interface. This value must be either 0, or 4 to 9000 seconds. A value of zero indicates that the system is not a default router. The default is 1800.
reachable-time <0-3600000>	Specifies a value (in milliseconds) placed in the router advertisement message sent by the router. The value zero means unspecified (by this system). Configure the amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event. The default is 0.
retransmit-timer <0-4294967295>	Specifies a value (in milliseconds) placed in the retransmit timer field in the router advertisement message sent from this interface. The value zero means unspecified (by this system). The value configures the amount of time the system waits for the transmission to occur. The default is 0.
rtr-advert-max-interval <4-1800>	Specifies the maximum interval (in seconds) at which the transmission of route advertisements occurs on this interface. The default is 600.
rtr-advert-min-interval <3-1350>	Specifies the minimum interval (in seconds) at which the transmission of route advertisements occurs on this interface. The default is 200.
send-ra	Specifies whether the router sends periodic router advertisements and responds to router solicitations on this interface. The default is enabled.

Use the data in the following table to use the **interface** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

System Interface Values Versus Advertised Values

There are differences in the relationship between the system interface values and advertised values related to Neighbor Disovery (ND). The information in this section describes differences and similarities and provides examples for important IPv6 interface and IPv6 ND commands.

Comparison of Default Values per Interface and as Advertised

The following table compares the default behavior of values per interface and advertised values.

Default values per interface	Default advertised values
hop-limit 64	hop-limit 64
mtu 1500	mtu 0 (unspecified)
reachable-time 30000 ms	reachable-time 0 (unspecified)
retransmit-timer 1000 ms	retransmit-timer 0 (unspecified)

What Happens When You Change the per Interface Value and the Advertised Value?

When you change per-interface values from default to non-default values, the system changes the advertised values to match the interface values.

For example, when you enter the `ipv6 interface mtu 1300` command the values become

- interface mtu 1300
- advertised mtu 1300

Then, when you enter the `show ipv6 nd interface` command, the system marks the mtu value with an (i) which signifies that the ND advertised value is inherited from the interface configuration.

Example: Changing both values

```
Switch:1(config-if)#ipv6 interface mtu 1300
```

```
Switch:1(config-if)#
show ipv6 nd interface GigabitEthernet 1/1
```

```
================================================================================
                              Port Ipv6 Nd
================================================================================
IFID BTR RTR- MAX- MIN-    LIFE- MANAG  OTHER DAD-NS MTU    HOP  REACH- RETRANS-
         ADV  INT  INT     TIME        LIMIT TIME   TIME        ABLE   MIT
                   FLAG    CONF
--------------------------------------------------------------------------------
320  1/1 True 600  200      0    False False   1    1300(i) 64(d) 0(d)   0(d)
Note: (s) = Set, (d) = Default, (i) = inherit
--------------------------------------------------------------------------------
```

What Happens When You Change the per Interface Value but do not Change the Advertised Value?

To change the per-interface value from the default value to a non-default value but retain the advertised value of 0 (unspecified), you must enter two commands.

For example, to set the reachable-time to 60000 but retain the advertised value of the reachable-time parameter at 0, enter the following commands:

```
ipv6 interface reachable-time 6000
```

```
ipv6 nd reachable-time 0
```

When you enter the `show ipv6 nd interface` command, the system marks the reachable-time value with an (s) to signify that this value is explicitly set by the ND configuration.

Example: Changing only the per interface value

```
Switch:1(config-if)#ipv6 interface reachable-time 60000

Switch:1(config-if)#ipv6 nd reachable-time 0
```

```
Switch:1(config-if)#
show ipv6 nd interface GigabitEthernet 1/1
```

```

```

Configure the Neighbor Cache

Configure the address translation table used to map IPv6 addresses to physical addresses. You can manually add static neighbors to the cache.

Note

IPv6 static neighbors are not supported on SMLT.

About This Task

Neighbor cache in IPv6 is similar to the IPv4 Address Resolution Protocol (ARP) table.

The neighbor cache is a set of entries for individual neighbors to which traffic was recently sent.

You make entries on the neighbor on-link unicast IP address, including information such as the link-layer address.

A neighbor cache entry contains information used by the Neighbor Unreachability Detection algorithm, including the reachability state, the number of unanswered probes, and the time the next Neighbor Unreachability Detection event is scheduled.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create a static neighbor:

   ```
   ipv6 neighbor WORD<0-128> port {slot/port[sub-port]} mac
   <0x00:0x00:0x00:0x00:0x00:0x00> [vlan <1-4059> ]
   ```

   When you create a static neighbor, it always remains in the reachable state. This differs from the general neighbor cache behavior where, among other things, timers and neighbor unreachability detection events can be generated.

Example

Create a static neighbor:

```
Switch:1(config)#ipv6 neighbor 3000::3 port 1/11 mac 00-1A-4B-8A-FB-6B
```

Variable Definitions

Use the data in the following table to use the **ipv6 neighbor** command.

Variable	Value
mac <0x00:0x00:0x00:0x00:0x00:0x00>	Specifies the MAC address.
{slot/port[/sub-port]}	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
vlan <1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
WORD<0-128>	Specifies the IPv6 address in hexadecimal colon format.

View Cached Destination Information

View the destination cache to see next-hop addresses for destinations.

The destination cache is only populated or updated when IPv6 packets originate locally on the central processor of the switch.

The main purpose of the destination cache is to store, on a per-destination basis, the dynamic Path MTU value currently used when transmitting packets from the local system to the remote destination.

The system uses the PMTU value to calculate how many bytes can fit into an individual packet before fragmentation should be applied.

About This Task

The command output shows the following information:

- the IPv6 destination address
- the IPv6 address for the next hop to the destination
- the path maximum transmission unit (MTU) for the destination
- the time, in seconds, since an ICMPv6 packet-too-big message was received

Not all parameters are available in non-default VRFs.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the destination cache for all interfaces:

   ```
   show ipv6 dcache [vrf WORD<1-16> | vrfids WORD<0-512>]
   ```
3. View the destination cache for a brouter port:

   ```
   show ipv6 dcache gigabitethernet {slot/port[/sub-port]}
   ```
4. View the destination cache for a specific tunnel ID:

   ```
   show ipv6 dcache tunnel <1-2000>
   ```
5. View the destination cache for a VLAN:

   ```
   show ipv6 dcache vlan <1-4059>
   ```
6. Clear the destination cache:

   ```
   clear ipv6 dcache [gigabitethernet {slot/port[/sub-port]}][tunnel <1-2000>][vlan <1-4059>] [vrf WORD<1-16> | vrfids WORD<0-512>]
   ```

Example

```
Switch:1(config-if)#show ipv6 dcache
================================================================================================
                       IPv6 Destination Cache Information - GlobalRouter
================================================================================================
Destination Address    NEXT HOP         VID/BID/TID  IF_TYPE   IF_DATA   PMTU    PMTU_AGE
------------------------------------------------------------------------------------------------
ff02:0:0:0:0:0:0:1    0:0:0:0:0:0:0:0     V-22         real      -        1500     0
------------------------------------------------------------------------------------------------

1 out of 1 Total Num of Destinaton Cache Entries displayed.
```

Variable Definitions

Use the data in the following table to use the **show ipv6 dcache** and **clear ipv6 dcache** commands.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
{slot/port[/sub-port]}	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
vrf WORD<1-16>	Specifies the VRF name.
vrfids WORD<0-512>	Specifies the VRF ID.

Neighbor Discovery Configuration using EDM

Use the procedures in this section for neighbor discovery configuration using EDM.

Configuring an IPv6 discovery prefix

Configure the discovery prefixes to send in router advertisement.

Before You Begin

Change the VRF instance as required to configure an IPv6 discovery prefix on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

Hosts on the link use router advertisements to perform IPv6 autoconfiguration. The discovery prefix controls what IPv6 addresses to autoconfigure and how long they are valid.

You can also configure an IPv6 interface for a brouter port through the **Edit** > **Port** > **IPv6** navigation path, and for a VLAN through the **VLAN** > **VLANs** > **Basic** > **IPv6** navigation path. This procedure uses the main IPv6 navigation path where you can configure both types of interfaces.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6**.
3. Click the **Discovery Prefix** tab.
4. Click **Insert**.
5. Beside the **Interface** field, click **Port** or **VLAN**.
6. Select a port or VLAN.
7. Click **OK**.

8. Specify the prefix and prefix length.
9. Click **Insert**.
10. Click **Apply**.

Discovery Prefix *Field Descriptions*

Use the data in the following table to use the **Discovery Prefix** tab.

Name	Description
Interface	Shows a read-only value that indicates an IPv6 interface. For the brouter port, it is the ifindex of the port and, in the case of the VLAN, it is the ifindex of the VLAN.
Prefix	Configures the prefix to create an IPv6 prefix entry as either advertised or suppressed.
PrefixLen	Configures the mask to create an IPv6 address in the IPv6 interface table.
VLanId	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
UseDefaultVal	Specifies one included value to use the default value, or use all bits to configure all options to their default value.
ValidLifetime	Configures the valid lifetime in seconds that indicates the length of time this prefix is advertised. The default is 2592000. A valid lifetime is the length of time of the preferred and depreciated state of an autoconfiguration address. The preferred lifetime value must be less than the valid lifetime value. If you must configure the valid lifetime value to a value lower than the current preferred lifetime, you must lower the preferred lifetime value first.
PreferedLifetime	Configures the preferred lifetime in seconds that indicates the length of time this prefix is advertised. The default value is 604800. The preferred lifetime is the length of time for the tentative, preferred, and depreciated state of an autoconfiguration address. The preferred lifetime value must be less than the valid lifetime value. If you must configure the valid lifetime value to a value lower than the current preferred lifetime, you must lower the preferred lifetime value first.

Name	Description
Infinite	Configures the prefix valid lifetime so it never expires. The default is false.
OnLinkFlag	Configures the prefix for use when determining if a node is online. This value is placed in the L-bit field in the prefix information option. It is a 1-bit flag. The default is true.
AutoFlag	Configures the prefix for use as the autonomous address configuration. This value is placed in the autoflag field in the prefix information option. It is a 1-bit flag. The default is true.
AddressEui	Configures the EUI address. Use an EUI-64 interface ID in the address field. If enabled, use EUI, or use EUI-64 and the complement Universal/Local (U/L) bit. This operation provides for both gloal and link-local addresses. After you create the entry, you cannot modify this value. This value is valid for use only when the PrefixLength is 64 or less. The default is eui-not-used. If you select eui-not-used, this configuration creates an IPv6 ND prefix but no associated IPv6 address on the router. IF you select either eui-used-with-ul-complement or eui-used-without-ul-complement, an associated IPv6 adress is created by concatenating the specified prefix with the EUI-64 interface ID.
NoAdvertise	Configures if the prefix is included in the router advertisement. Select true to not include the prefix in the router advertisement. The default is false.

Configuring an IPv6 discovery prefix port

Configure the discovery prefixes to send in router advertisement.

About This Task

Hosts on the link use router advertisements to perform IPv6 autoconfiguration. The discovery prefix controls what IPv6 addresses to autoconfigure and how long they are valid.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **Edit** > **Port**.
2. Click **IPv6**.
3. Click **Discovery Prefix**.
4. Click **Insert**.
5. Click **OK**.
6. Specify the prefix and prefix length.
7. Click **Insert**.
8. Click **Apply**.

IPv6 Discovery Prefix *field descriptions*

Use the data in the following table to use the **IPv6 Discovery Prefix** tab.

Name	Description
Interface	Shows a read-only value that indicates an IPv6 interface. For the brouter port, it is the ifindex of the port and, in the case of the VLAN, it is the ifindex of the VLAN.
Prefix	Configures the prefix to create an IPv6 prefix entry as either advertised or suppressed.
PrefixLen	Configures the mask to create an IPv6 address in the IPv6 interface table.
VLanId	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
UseDefaultVal	Specifies one included value to use the default value, or use all bits to configure all options to their default value.
ValidLifetime	Configures the valid lifetime in seconds that indicates the length of time this prefix is advertised. The default is 2592000. A valid lifetime is the length of time of the preferred and depreciated state of an autoconfiguration address. The preferred lifetime value must be less than the valid lifetime value. If you must configure the valid lifetime value to a value lower than the current preferred lifetime, you must lower the preferred lifetime value first.
PreferedLifetime	Configures the preferred lifetime in seconds that indicates the length of time this prefix is advertised. The default value is 604800. The preferred lifetime is the length of time for the tentative, preferred, and depreciated state of an autoconfiguration address. The preferred lifetime value must be less than the valid lifetime value. If you must configure the valid lifetime value to a value lower than the current preferred lifetime, you must lower the preferred lifetime value first.
Infinite	Configures the prefix valid lifetime so it never expires. The default is false.

Name	Description
OnLinkFlag	Configures the prefix for use when determining if a node is online. This value is placed in the L-bit field in the prefix information option. It is a 1-bit flag. The default is true.
AutoFlag	Configures the prefix for use as the autonomous address configuration. This value is placed in the autoflag field in the prefix information option. It is a 1-bit flag. The default is true.
AddressEui	Configures the EUI address. Use an EUI-64 interface ID in the address field. If enabled, use EUI, or use EUI-64 and the complement Universal/Local (U/L) bit. This operation provides for both gloal and link-local addresses. After you create the entry, you cannot modify this value. This value is valid for use only when the PrefixLength is 64 or less. The default is eui-not-used. If you select eui-not-used, this configuration creates an IPv6 ND prefix but no associated IPv6 address on the router. IF you select either eui-used-with-ul-complement or eui-used-without-ul-complement, an associated IPv6 adress is created by concatenating the specified prefix with the EUI-64 interface ID.
NoAdvertise	Configures if the prefix is included in the router advertisement. Select true to not include the prefix in the router advertisement. The default is false.

Configuring an IPv6 discovery prefix on a VLAN

Configure the discovery prefixes to send in router advertisement.

About This Task

Hosts on the link use router advertisements to perform IPv6 autoconfiguration. The discovery prefix controls what IPv6 addresses to autoconfigure and how long they are valid.

Procedure

1. In the navigation pane, expand the following folders: **VLAN** > **VLANs**.
2. Click the **Basic** tab.
3. Select an interface row.
4. Click **IPv6**.
5. Click the **IPv6 Discovery Prefix** tab.
6. Click **Insert**.
7. Specify the prefix and prefix length.
8. Configure the remaining parameters, as required.
9. Click **Insert**.
10. Click **Apply**.

IPv6 Discovery Prefix *Field Descriptions*

Use the data in the following table to use the **IPv6 Discovery Prefix** tab.

Name	Description
Interface	Shows a read-only value that indicates an IPv6 interface. For the brouter port, it is the ifindex of the port and, in the case of the VLAN, it is the ifindex of the VLAN.
Prefix	Configures the prefix to create an IPv6 prefix entry as either advertised or suppressed.
PrefixLen	Configures the mask to create an IPv6 address in the IPv6 interface table.
VLanId	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
UseDefaultVal	Specifies one included value to use the default value, or use all bits to configure all options to their default value.
ValidLifetime	Configures the valid lifetime in seconds that indicates the length of time this prefix is advertised. The default is 2592000. A valid lifetime is the length of time of the preferred and depreciated state of an autoconfiguration address. The preferred lifetime value must be less than the valid lifetime value. If you must configure the valid lifetime value to a value lower than the current preferred lifetime, you must lower the preferred lifetime value first.
PreferedLifetime	Configures the preferred lifetime in seconds that indicates the length of time this prefix is advertised. The default value is 604800. The preferred lifetime is the length of time for the tentative, preferred, and depreciated state of an autoconfiguration address. The preferred lifetime value must be less than the valid lifetime value. If you must configure the valid lifetime value to a value lower than the current preferred lifetime, you must lower the preferred lifetime value first.
Infinite	Configures the prefix valid lifetime so it never expires. The default is false.

Name	Description
OnLinkFlag	Configures the prefix for use when determining if a node is online. This value is placed in the L-bit field in the prefix information option. It is a 1-bit flag. The default is true.
AutoFlag	Configures the prefix for use as the autonomous address configuration. This value is placed in the autoflag field in the prefix information option. It is a 1-bit flag. The default is true.
AddressEui	Configures the EUI address. Use an EUI-64 interface ID in the address field. If enabled, use EUI, or use EUI-64 and the complement Universal/Local (U/L) bit. This operation provides for both gloal and link-local addresses. After you create the entry, you cannot modify this value. This value is valid for use only when the PrefixLength is 64 or less. The default is eui-not-used. If you select eui-not-used, this configuration creates an IPv6 ND prefix but no associated IPv6 address on the router. IF you select either eui-used-with-ul-complement or eui-used-without-ul-complement, an associated IPv6 adress is created by concatenating the specified prefix with the EUI-64 interface ID.
NoAdvertise	Configures if the prefix is included in the router advertisement. Select true to not include the prefix in the router advertisement. The default is false.

Configuring route advertisement

Configure route advertisement in IPv6 for neighbor discovery (ND).

Before You Begin

Change the VRF instance as required to configure route advertisement on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

IPv6 nodes on the same link use ND to discover link-layer addresses and to obtain and advertise various network parameters and reachability information. ND combines the services provided by Address Resolution Protocol (ARP) and router discovery for IPv4.

Note

You only use the ND level configuration when you want to create advertised values that differ from the interface values for reachable-time, retransmit-timer, mtu, or hop-limit.

You can also configure an IPv6 interface for a brouter port through the **Edit** > **Port** > **IPv6** navigation path, and for a VLAN through the **VLAN** > **VLANs** > **Basic** > **IPv6** navigation path. This procedure uses the main IPv6 navigation path where you can configure both types of interfaces.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6**.
3. Click the **Route Advertisement** tab.
4. Double-click a parameter to change the current value.

   You cannot modify the parameters in gray shading.
5. Click **Apply**.

Route Advertisement *field descriptions*

Use the data in the following table to use the **Route Advertisement** tab.

Name	Description
Interface	Specifies the interface to which this entry applies.
SendAdverts	Specifies whether the router sends periodic router advertisements and responds to router solicitations on this interface. The default is True.
UseDefaultVal	Specifies one included value to use the default value, or use all bits to configure all options to their default value.
MaxInterval	Specifies the maximum interval (in seconds) at which the transmission of route advertisements occurs on this interface. The value must be between 4 seconds and 1800 seconds. The default is 600.
MinInterval	Specifies the minimum interval (in seconds) at which the transmission of route advertisements occurs on this interface. The value must be between 3 seconds and 0.75 x max-interval. The default is 200.
ReachableTime	Shows a value (in milliseconds) placed in the router advertisement message sent by the router. The value zero means unspecified (by this system). Configure the amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event. You cannot modify this parameter; use the **Interfaces** tab to change the value for the interface.
RetransmitTime	Shows a value (in milliseconds) placed in the retransmit timer field in the router advertisement message sent from this interface. The value zero means unspecified (by this system). The value configures the amount of time the system waits for the transmission to occur. You cannot modify this parameter; use the **Interfaces** tab to change the value for the interface.

Name	Description
DefaultLifeTime	Specifies a value placed in the router lifetime field of router advertisements sent from this interface. This value must be either 0 or between 4 and 9000 seconds. A value of zero indicates that the system is not a default router. The default is 1800.
CurHopLimit	Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a value for CurHopLimit. The default is 64.
ManagedFlag	Enables the system to configure the M-bit or managed address configuration in the router advertisements. The default is false.
DadNsNum	Specifies the number of neighbor solicitation messages for duplicate address detection (DAD). A value of 0 disables the DAD process on this interface. A value of 1 sends one advertisement without retransmissions.
LinkMTU	Shows the MTU value sent in router advertisements on this interface. A value of zero indicates that the system sends no MTU options.
OtherConfigFlag	Enables the O-bit (other stateful configuration) in the router advertisement. Other stateful configuration autoconfigures received information without addresses. The default is disabled.

Configuring route advertisement on an IPv6 interface for a brouter port

Configure route advertisement in IPv6 for neighbor discovery (ND).

About This Task

IPv6 nodes on the same link use ND to discover link-layer addresses and to obtain and advertise various network parameters and reachability information. ND combines the services provided by Address Resolution Protocol (ARP) and router discovery for IPv4.

Note

You only use the ND level configuration when you want to create advertised values that differ from the interface values for reachable-time, retransmit-timer, mtu, or hop-limit.

You can also configure an IPv6 interface for a VLAN through the **VLAN** > **VLANs** > **Basic** > **IPv6** navigation path.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **Edit** > **Port**.
2. Click **IPv6**.
3. Click the **Route Advertisement** tab.

4. Double-click a parameter to change the current value.

   You cannot modify the parameters in gray shading.
5. Click **Apply**.

Route Advertisement *field descriptions*

Use the data in the following table to use the **Route Advertisement** tab.

Name	Description
Interface	Specifies the interface to which this entry applies.
SendAdverts	Specifies whether the router sends periodic router advertisements and responds to router solicitations on this interface. The default is True.
UseDefaultVal	Specifies one included value to use the default value, or use all bits to configure all options to their default value.
MaxInterval	Specifies the maximum interval (in seconds) at which the transmission of route advertisements occurs on this interface. The value must be between 4 seconds and 1800 seconds. The default is 600.
MinInterval	Specifies the minimum interval (in seconds) at which the transmission of route advertisements occurs on this interface. The value must be between 3 seconds and 0.75 x max-interval. The default is 200.
ReachableTime	Shows a value (in milliseconds) placed in the router advertisement message sent by the router. The value zero means unspecified (by this system). Configure the amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event. You cannot modify this parameter; use the **Interfaces** tab to change the value for the interface.
RetransmitTime	Shows a value (in milliseconds) placed in the retransmit timer field in the router advertisement message sent from this interface. The value zero means unspecified (by this system). The value configures the amount of time the system waits for the transmission to occur. You cannot modify this parameter; use the **Interfaces** tab to change the value for the interface.
DefaultLifeTime	Specifies a value placed in the router lifetime field of router advertisements sent from this interface. This value must be either 0 or between 4 and 9000 seconds. A value of zero indicates that the system is not a default router. The default is 1800.

Name	Description
CurHopLimit	Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a value for CurHopLimit. The default is 64.
ManagedFlag	Enables the system to configure the M-bit or managed address configuration in the router advertisements. The default is false.
DadNsNum	Specifies the number of neighbor solicitation messages for duplicate address detection (DAD). A value of 0 disables the DAD process on this interface. A value of 1 sends one advertisement without retransmissions.
LinkMTU	Shows the MTU value sent in router advertisements on this interface. A value of zero indicates that the system sends no MTU options.
OtherConfigFlag	Enables the O-bit (other stateful configuration) in the router advertisement. Other stateful configuration autoconfigures received information without addresses. The default is disabled.

Configuring route advertisement on an IPv6 interface for a VLAN

Configure route advertisement in IPv6 for neighbor discovery (ND).

About This Task

IPv6 nodes on the same link use ND to discover link-layer addresses and to obtain and advertise various network parameters and reachability information. ND combines the services provided by Address Resolution Protocol (ARP) and router discovery for IPv4.

Note

You only use the ND level configuration when you want to create advertised values that differ from the interface values for reachable-time, retransmit-timer, mtu, or hop-limit.

Procedure

1. In the navigation pane, expand the following folders: **VLAN** > **VLANs**.
2. Click the **Basic** tab.
3. Select an interface row, and click **IPv6**.
4. Click **Route Advertisement**.
5. Double-click a parameter to change the current value.

   You cannot modify the parameters in gray shading.
6. Click **Apply**.

Route Advertisement *field descriptions*

Use the data in the following table to use the **Route Advertisement** tab.

Name	Description
Interface	Specifies the interface to which this entry applies.
SendAdverts	Specifies whether the router sends periodic router advertisements and responds to router solicitations on this interface. The default is True.
UseDefaultVal	Specifies one included value to use the default value, or use all bits to configure all options to their default value.
MaxInterval	Specifies the maximum interval (in seconds) at which the transmission of route advertisements occurs on this interface. The value must be between 4 seconds and 1800 seconds. The default is 600.
MinInterval	Specifies the minimum interval (in seconds) at which the transmission of route advertisements occurs on this interface. The value must be between 3 seconds and 0.75 x max-interval. The default is 200.
ReachableTime	Shows a value (in milliseconds) placed in the router advertisement message sent by the router. The value zero means unspecified (by this system). Configure the amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event. You cannot modify this parameter; use the **Interfaces** tab to change the value for the interface.
RetransmitTime	Shows a value (in milliseconds) placed in the retransmit timer field in the router advertisement message sent from this interface. The value zero means unspecified (by this system). The value configures the amount of time the system waits for the transmission to occur. You cannot modify this parameter; use the **Interfaces** tab to change the value for the interface.
DefaultLifeTime	Specifies a value placed in the router lifetime field of router advertisements sent from this interface. This value must be either 0 or between 4 and 9000 seconds. A value of zero indicates that the system is not a default router. The default is 1800.
CurHopLimit	Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a value for CurHopLimit. The default is 64.
ManagedFlag	Enables the system to configure the M-bit or managed address configuration in the router advertisements. The default is false.

Name	Description
DadNsNum	Specifies the number of neighbor solicitation messages for duplicate address detection (DAD). A value of 0 disables the DAD process on this interface. A value of 1 sends one advertisement without retransmissions.
LinkMTU	Shows the MTU value sent in router advertisements on this interface. A value of zero indicates that the system sends no MTU options.
OtherConfigFlag	Enables the O-bit (other stateful configuration) in the router advertisement. Other stateful configuration autoconfigures received information without addresses. The default is disabled.

Configuring the neighbor cache

Configure the address translation table used to map IPv6 addresses to physical addresses. You can manually add static neighbors to the cache.

Note

IPv6 static neighbors are not supported on SMLT.

Before You Begin

Change the VRF instance as required to configure neighbor cache on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

Neighbor cache in IPv6 is similar to the IPv4 Address Resolution Protocol (ARP) table. The neighbor cache is a set of entries for individual neighbors to which traffic was sent recently. You make entries on the neighbor on-link unicast IP address, including information such as the link-layer address. A neighbor cache entry contains information used by the Neighbor Unreachability Detection algorithm, including the reachability state, the number of unanswered probes, and the time the next Neighbor Unreachability Detection event is scheduled.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6**.
3. Click the **Neighbors** tab.
4. Click **Insert**.
5. Beside the **Interface** field, click **Port** or **Port in Vlan**.
6. Select a port or VLAN.
7. Configure the remaining parameters as required.
8. Click **Insert**.
9. Click **Apply**.

Neighbors *Field Descriptions*

Use the data in the following table to use the **Neighbors** tab.

Name	Description
Interface	Specifies the interface to which this entry applies.
NetAddress	Specifies the IP address of the media-dependent physical address.
PhyAddress	Specifies the MAC address.
Interface	Specifies a physical port ID or an MLT port ID.
LastUpdated	Specifies the value of sysUpTime of the last modification to this entry. If the entry was created prior to the last reinitialization of the local management subsystem, the object contains a zero value.
Type	Specifies the mapping type from manually configured entries. While the selection of either dynamic, static, or local is allowed; static is currently the only valid selection.
State	Specifies the Neighbor Unreachability Detection state for the interface after the address mapping in this entry is used. If Neighbor Unreachability Detection is not in use (for example, for IPv4), this object is always unknown. The options include the following: • reachable: confirmed reachability • stale: unconfirmed reachability • delay: waiting for reachability confirmation before entering the probe state • probe: actively probing • invalid: an invalidated mapping • unknown: state cannot be determined. • incomplete: address resolution is being performed
BMac	Specifies the backbone MAC address.
Cvid	Specifies the customer VID.

Viewing cached destination information

View the destination cache to see next-hop addresses for destinations.

The destination cache is only populated or updated when IPv6 packets are locally originated on the central processor of the switch.

The main purpose of the destination cache is to store, on a per-destination basis, the dynamic Path MTU value currently used when transmitting packets from the local system to the remote destination. The PMTU value itself is used to calculate how many bytes can fit into an individual packet before fragmentation should be applied.

Before You Begin

Change the VRF instance as required to view cached destination information on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6.**
2. Click **IPv6**.
3. Click the **Destination Cache** tab.

Destination Cache *Field Descriptions*

Use the data in the following table to use the **Destination Cache** tab.

Name	Description
DestAddr	Shows the IPv6 destination address.
Interface	Shows the interface number that is used to reach the destination.
NextHop	Shows the IPv6 address for the next hop to the destination.
IfType	Specifies the interface type (tunel, VLAN, or brouter) or virtual circuit (VRRP, RSMLT).
IfData	Displays additional information about virtual circuits. For instance, for a VRRP or RSMLT the virtual router ID displays. If the interface type is tunnel, VLAN, or brouter, no additional information displays.
Pmtu	Shows the path maximum transmission unit (MTU) for the destination.
PmtuAge	Shows the time, in seconds, since an ICMPv6 packet too big message was received.

IPv6-in-IPv4 Tunneling

Table 121: IPv6-in-IPv4 tunnels product support

Feature	Product	Release introduced
IPv6-in-IPv4 tunnels	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Tunneling

Tunneling provides a mechanism to transfer IPv6 traffic through an IPv4–only network.

How tunneling works

IPv6 tunneling encapsulates IPv6 packets in IPv4 packets for delivery across an IPv4 infrastructure.

At the tunnel source, or head end, the system encapsulates an IPv6 packet into an IPv4 packet and sends it to the remote tunnel destination.

The tunnel destination strips the IPv4 packet header and forwards the original IPv6 packet further into an IPv6 cloud.

These types of tunnels are called dual-stack tunnels because they support both IPv4 and IPv6.

Manually configured tunnels

Manually configured tunnels can provide communication between two isolated IPv6 domains over an IPv4 network.

Manually configured tunnels are point-to-point.

You can configure tunnel endpoints to create a point-to-point connection between two isolated IPv6 domains by configuring IPv6 and IPv4 addresses at each end of the tunnel.

Note

The router or host at the source and destination ends of the tunnel must support both IPv4 and IPv6 protocol stacks.

Caution

Ensure that all single-homed point-to-point traffic ingresses and egresses a configured tunnel. Otherwise the traffic is dropped.

IPv6 reachability enables tunnel forwarding but tunnel operational status depends on the IPv4 reachability of the tunnel endpoint.

The IPv4 tunnel endpoint configuration must be symmetrical; that is, if you configure a tunnel with a source of 10.10.10.1 and a destination of 11.11.11.1 from switch A, then Switch B must have a source of 11.11.11.1 and a destination of 10.10.10.1.

Tunnel interfaces are logical point-to-point interfaces.

You can enable dynamic routing when you enable a routing protocol, for example OSPFv3, on the tunnel interfaces.

Unicast routing protocols can detect link loss and redirect IPv6 route information

There is no explicit signaling protocol applied to IPv6-in-IPv4 configured tunnels (refer to RFC 4213).

Therefore, if the remote endpoint of a tunnel that terminates several Layer 3 hops away in the network fails, the local state of the tunnel remains active even though the endpoint has failed.

However, you can enable unicast routing protocols over tunnels, for example OSPFv3. These unicast routing protocols introduce their own protocol-specific signaling and, when a unicast routing protocol is present over the tunnel link, the routing protocol can detect link loss and re-direct the IPv6 route information to use an alternate, reachable nexthop.

Operational events that trigger tunnel state transition

The switch must be able to locally detect operational events that can trigger a tunnel state transition.

These events include:

- deletion of local IPv4 interface
- change or loss of the IPv4 route to the remote tunnel endpoint
- change in the nexthop of the IPv4 route to the remote tunnel endpoint
- loss of the ARP entry for the nexthop router that is used to reach the IPv4 tunnel endpoint

Tunnels and MTU

You cannot configure the MTU for tunnels.

The default MTU value for tunnels is 1280.

Packets are forwarded through the tunnel using the line card network processing units (NPUs) only. Since the packets are not forwarded through the central processing unit (CPU) they do not impact the CPU load.

Tunnels and BGP+

You must configure an IPv6 tunnel and static routes on BGP+ peers when you use BGP+. For more information on IPv6 tunnel configuration for BGP+, see IPv6 Tunnel Configurations for BGP+ on page 462.

Limitations

The following list identifies tunnel configuration limitations.

- You cannot configure IPv6 CLIP addresses for IPv6-in-IPv4 tunnels. Also, you cannot configure an IPv6 CLIP interface as the source or destination endpoint of an tunnel.
- You cannot configure SMLT on the switch terminating a tunnel.
- Termination of tunnels on vIST peers is not supported.

Tunneling Configuration using CLI

Use the procedures in this section to configure Tunnel using CLI.

Configuring a tunnel

Configure a tunnel for IPv6 VLANs or brouter ports to communicate through an IPv4–only network. Create a point-to-point connection between the two isolated IPv6 devices by configuring the tunnel endpoints.

Do not create tunnels in a native IPv6 network.

Before You Begin

- The router or host at the source and destination of the tunnel must support both IPv4 and IPv6 protocol stacks.

About This Task

Manual tunnels are point-to-point, so you configure both source and destination addresses. You must configure both IPv6 and IPv4 addresses for both source and destination devices. The IPv6 addresses must represent the same network, for example 6666::1/96 and 6666::2/96.

Tunnel interfaces are automatically configured with a link-local address in the format fe80::<local_ipv4_source_address>.

You cannot configure the maximum transmission unit (MTU) for tunnels. The default MTU value for tunnels is 1280.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create a tunnel:

   ```
   ipv6 tunnel <1-2000> source {A.B.C.D} address WORD<0-46> destination
   {A.B.C.D}
   ```

Example

Create tunnel 2:

```
Switch:1(config)#ipv6 tunnel 2 source 11.11.11.1 address
3000:0:0:0:0:0:0:1/64 destination 12.12.12.2
```

Variable definitions

Use the data in the following table to use the **`ipv6 tunnel`** command.

Variable	Value
<1-2000>	Configures the ID for the tunnel.
address WORD<0-46>	Assigns an IPv6 address and prefix to the tunnel.
destination {A.B.C.D}	Configures the address of the remote endpoint of the tunnel.
source {A.B.C.D}	Configures the address of the local endpoint of the tunnel.

View Tunnel Interfaces

View tunnel interfaces to verify the current configuration and operational status of IPv6 tunnels.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Show IPv6 tunnel information:

   ```
   show ipv6 tunnel [<1-2000>] [detail] [local {A.B.C.D}] [remote
   {A.B.C.D}]
   ```

Example

```
Switch:1#show ipv6 tunnel detail

```

Variable definitions

Use the data in the following table to use the **show ipv6 tunnel** command.

Variable	Value
<1-2000>	Shows information for a specific tunnel ID.
detail	Shows detailed address information for the tunnel.
local {A.B.C.D}	Shows information for a specific local address (the local endpoint of the tunnel).
remote {A.B.C.D}	Shows information for a specific remote address (the remote endpoint of the tunnel).

Modifying tunnel hop limits

Modify tunnel hop limits to update hop-limit values on previously configured tunnels.

About This Task

The tunnel hop limit configures the value of the time-to-live (TTL) for IPv4 packets.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Modify the hop limit:

   ```
   ipv6 tunnel <1-2000> hop-limit <0-255>
   ```

Example

Modify the hop limit for tunnel ID 5:

```
Switch:1(config)#ipv6 tunnel 5 hop-limit 200
```

Variable definitions

Use the data in the following table to use the **ipv6 tunnel** command.

Variable	Value
<0–255>	Configures the maximum number of hops in the tunnel. The default value is 255.
<1–2000>	Specifies the tunnel ID.

Tunneling Configuration using EDM

Use the procedures in this section to configure Tunnel using EDM.

Configuring a tunnel

Configure a tunnel for IPv6 VLANs or brouter ports to communicate through an IPv4–only network. Create a point-to-point connection between the two isolated IPv6 devices by configuring the tunnel endpoints.

Do not create tunnels in a native IPv6 network.

Before You Begin

- The router or host at the source and destination of the tunnel must support both IPv4 and IPv6 protocol stacks.

About This Task

Manual tunnels are point-to-point, so you configure both source and destination addresses. You must configure both IPv6 and IPv4 addresses for both source and destination devices. The IPv6 addresses must represent the same network, for example 6666::1/96 and 6666::2/96.

Tunnel interfaces are automatically configured with a link-local address in the format fe80::<local_ipv4_source_address>.

You cannot configure the maximum transmission unit (MTU) for tunnels. The default MTU value for tunnels is 1280.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Click **Tunnel**.
3. Click the **Tunnel Config** tab.
4. Click **Insert**.
5. Beside the **LocalAddress** field, click the button, and then select the IPv4 address for the local VLAN or brouter port.
6. In the **RemoteAddress** field, type the IPv4 address for the destination VLAN or brouter port.
7. In the **ID** field, type a number to represent the tunnel.
8. In the **IPv6AddressAddr** field, type the IPv6 address for the tunnel VLAN or brouter port.
9. In the **IPv6AddressPrefixLength** field, type the number of bits to advertise in the IPv6 address.
10. Click **Insert**.

Tunnel Config *field descriptions*

Use the data in the following table to use the **Tunnel Config** tab.

Name	Description
AddressType	Shows the address type over which the tunnel encapsulates packets.
LocalAddress	Configures the address of the local endpoint of the tunnel.
RemoteAddress	Configures the address of the remote endpoint of the tunnel.
EncapsMethod	Configures the tunnel mode, which is manual for manually configured tunnels.
ID	Configures the ID for the tunnel.
IfIndex	Shows the value of ifIndex that corresponds to the tunnel interface. A value of 0 indicates that the interface index has not yet been assigned. The system displays this field only on the **Tunnel Config** tab.
Ipv6AddressAddr	Specifies the IPv6 address for the local VLAN or brouter port. The system displays this field only on the **Insert Tunnel Config** dialog box.
Ipv6AddressPrefixLength	Specifies the number of bits to advertise in the IPv6 address. The system displays this field only on the **Insert Tunnel Config** dialog box.

Modifying tunnel hop limits

Modify tunnel hop limits to update hop-limit values on previously configured tunnels.

Use this procedure to modify the hop limits for multiple tunnels simultaneously.

About This Task

The tunnel hop limit configures the value of the time-to-live (TTL) for IPv4 packets.

Procedure

1. In the navigation pane, expand the **Configuration** > **IPv6** folders.
2. Click **Tunnel**.
3. Click the **Tunnel Interface** tab.
4. Double-click the **HopLimit** value to modify the information as required.
5. Click **Apply**.

Tunnel Interface *field descriptions*

Use the data in the following table to use the **Tunnel Interface** tab.

Name	Description
Index	Identifies the tunnel interface internally. The value is derived from the tunnel ID.
EncapsMethod	Displays the encapsulation method for the tunnel: manual for manually configured tunnels and 6to4 for automatically configured tunnels.
HopLimit	Configures the maximum number of hops in the tunnel. The default value is 255.
Security	Indicates the type of security on the tunnel interface.
TOS	Displays the method used to configure the high 6 bits (the differentiated services codepoint) of the IPv4 type of service (TOS) or IPv6 traffic class in the outer IP header. A value of -1 indicates that the bits are copied from the payload header. A value of -2 indicates that a traffic conditioner is invoked and more information can be available in a traffic conditioner MIB module. A value from 0 to 63 indicates that the bit field is configured to the indicated value.
FlowLabel	Displays the method used to configure the IPv6 flow label value. This object is not required where AddressType indicates the tunnel is not over IPv6. A value of -1 indicates that a traffic conditioner is invoked and more information can be available in a traffic conditioner MIB. Any other value indicates that the flow label field is configured to the indicated value.
AddressType	Displays manual for a manually configured tunnel, or sixToFour for autoconfigured tunnels.
LocalInetAddress	Identifies the local endpoint address of the tunnel.
RemoteInetAddress	Identifies the remote endpoint of the tunnel.
EncapsLimit	Displays the maximum number of additional encapsulations permitted for packets undergoing encapsulation at this node. A value of -1 indicates that no limit exists, except as a result of the packet size.

Modifying tunnel hop limits for a specific tunnel

Modify tunnel hop limits to update hop-limit values on previously configured tunnels.

Use this procedure to modify the hop limits for a specific tunnel interface.

About This Task

The tunnel hop limit configures the value of the time-to-live (TTL) for IPv4 packets.

Procedure

1. In the navigation pane, expand the **Configuration** > **IPv6** folders.
2. Click **Tunnel**.
3. Click the **Tunnel Config** tab.
4. Select the tunnel row.
5. Click **Tunnel Interface**.
6. Double-click the **HopLimit** value to modify the information as required.
7. Click **Apply**.

Tunnel Interface *field descriptions*

Use the data in the following table to use the **Tunnel Interface** tab.

Name	Description
Index	Identifies the tunnel interface internally. The value is derived from the tunnel ID.
EncapsMethod	Displays the encapsulation method for the tunnel: manual for manually configured tunnels and 6to4 for automatically configured tunnels.
HopLimit	Configures the maximum number of hops in the tunnel. The default value is 255.
Security	Indicates the type of security on the tunnel interface.
TOS	Displays the method used to configure the high 6 bits (the differentiated services codepoint) of the IPv4 type of service (TOS) or IPv6 traffic class in the outer IP header. A value of -1 indicates that the bits are copied from the payload header. A value of -2 indicates that a traffic conditioner is invoked and more information can be available in a traffic conditioner MIB module. A value from 0 to 63 indicates that the bit field is configured to the indicated value.
FlowLabel	Displays the method used to configure the IPv6 flow label value. This object is not required where AddressType indicates the tunnel is not over IPv6. A value of -1 indicates that a traffic conditioner is invoked and more information can be available in a traffic conditioner MIB. Any other value indicates that the flow label field is configured to the indicated value.
AddressType	Displays manual for a manually configured tunnel, or sixToFour for autoconfigured tunnels.
LocalInetAddress	Identifies the local endpoint address of the tunnel.

Name	Description
RemoteInetAddress	Identifies the remote endpoint of the tunnel.
EncapsLimit	Displays the maximum number of additional encapsulations permitted for packets undergoing encapsulation at this node. A value of -1 indicates that no limit exists, except as a result of the packet size.

Viewing IPv6 addresses on a tunnel

View a tunnel for IPv6 addresses.

You can assign an IPv6 address to a VLAN or brouter port.

About This Task

To create MLT and LAG interfaces with IPv6, you must configure VLAN-based connections and you cannot use brouter ports.

You can also assign an IPv6 address through the **Edit** > **Port** > **IPv6** navigation path, and through the **VLAN** > **VLANs** > **Basic** > **IPv6** navigation path.

Procedure

1. In the navigation pane, expand the following folders: **Configuration** > **IPv6**.
2. Click **Tunnel**.
3. Click the **Tunnel Config** tab.
4. Click **IPv6 Address**.

Tunnel Config *field descriptions*

Use the data in the following table to use the **Tunnel Config** tab.

Name	Description
AddressType	Shows the address type over which the tunnel encapsulates packets.
LocalAddress	Configures the address of the local endpoint of the tunnel.
RemoteAddress	Configures the address of the remote endpoint of the tunnel.
EncapsMethod	Configures the tunnel mode, which is manual for manually configured tunnels.
ID	Configures the ID for the tunnel.
IfIndex	Shows the value of ifIndex that corresponds to the tunnel interface. A value of 0 indicates that the interface index has not yet been assigned. The system displays this field only on the **Tunnel Config** tab.

IPv6 Tunnel Configuration Example

This section shows examples of manually configured tunnels between brouter ports and VLANs.

Between brouter ports

The following figure shows the tunnel configuration between brouter ports.

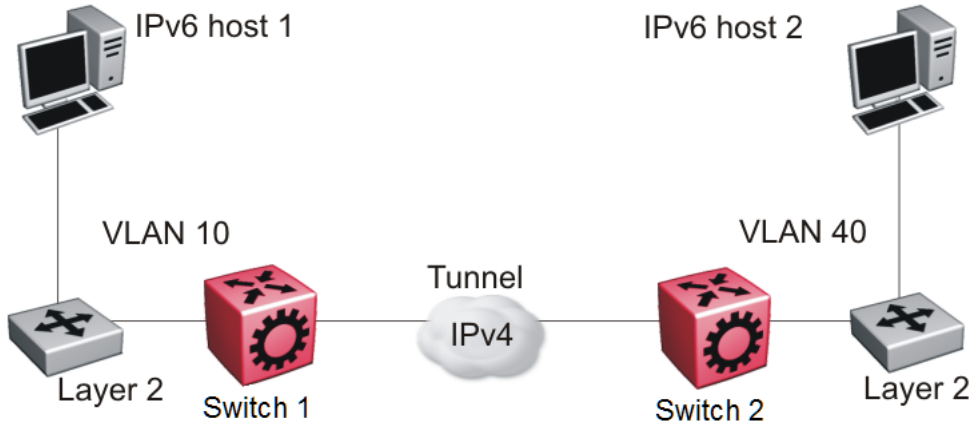

Figure 158: Tunnel configuration between brouter ports

You must configure static routes, RIP, or OSPF on both the source (Switch 1) and destination (Switch 2) IPv4 interfaces to communicate on the IPv4 network. You must configure IPv4 addresses on the source and destination.

Configuring Switch 1

Create an IPv6 VLAN and add ports to the VLAN.

```
vlan create 10 type port-mstprstp 0
vlan mlt 10 4
vlan members 10 1/1 portmember
interface vlan 10
ipv6 interface
ipv6 interface enable
ipv6 interface address 4000:0:0:0:0:0:0:1/64
exit
```

Create an IPv4 brouter port and enable OSPF on the port.

```
interface GigabitEthernet 1/30
brouter port 1/30 vlan 1000 subnet 172.21.80.1/255.255.255.0 mac-offset
6
```

Create the tunnel from the source to the destination.

```
ipv6 tunnel 1 source 172.21.80.1 address 2500:0000:0000:0000:0000:0000:0000:0001/64
destination 192.168.20.1
```

Configure a static route on the source.

```
ipv6 route 4000:0:0:0:0:0:0:2/64 cost 1 tunnel 1
```

Optionally, you can create an OSPFv3 interface through the tunnel.

```
router ospf ipv6-enable
router ospf
ipv6 tunnel 1 area 0.0.0.0
ipv6 tunnel 1 enable
exit
```

Configuring Switch 2

Create an IPv6 VLAN and add ports to the VLAN.

```
vlan create 40 type port-mstprstp 0
vlan mlt 40 4
vlan members 40 1/2 portmember
interface vlan 40
ipv6 interface
ipv6 interface enable
ipv6 interface address 4000:0:0:0:0:0:0:2/64

exit
```

Create an IPv4 brouter port and enable OSPF on the port.

```
interface GigabitEthernet 1/30
brouter port 1/30 vlan 2000 subnet 192.168.20.1/255.255.255.0 mac-offset 6
```

Create the tunnel from the destination to the source.

```
ipv6 tunnel 1 source 192.168.20.1 address 2500:0000:0000:0000:0000:0000:0000:0002/64
destination 172.21.80.1
```

Configure a static route on the destination.

```
ipv6 route 4000:0:0:0:0:0:0:1/64 cost 1 tunnel 1
```

Optionally, you can create an OSPFv3 interface through the tunnel.

```
router ospf ipv6-enable
router ospf
ipv6 tunnel 1 area 0.0.0.0
ipv6 tunnel 1 enable
exit
```

Between VLANs

The following figure shows the tunnel configuration between VLANs.

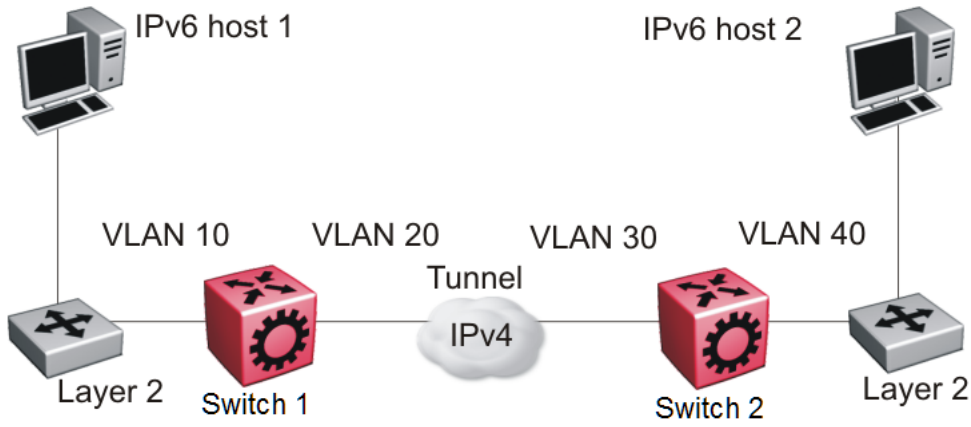

Figure 159: Tunnel configuration between VLANs

You must configure static routes, and either RIP or OSPF on both the source (Switch 1) and destination (Switch 2) IPv4 interfaces to communicate on the IPv4 network. You must configure IPv4 addresses on the VLANs.

Configuring Switch 1

Create an IPv6 VLAN and add ports to the VLAN.

```
vlan create 10 type port-mstprstp 0
vlan mlt 10 4
vlan members 10 1/1 portmember
interface vlan 10
ipv6 interface
ipv6 interface enable
ipv6 interface address 4000:0:0:0:0:0:0:1/64
exit
```

Create an IPv4 VLAN, add ports to the VLAN, and enable OSPF on the VLAN.

```
vlan create 20 type port-mstprstp 0
vlan mlt 20 4
vlan members 20 1/30 portmember
interface vlan 20
ip address 172.21.80.1 255.0.0.0
ip ospf enable
exit
```

Create the tunnel from the source to the destination.

```
ipv6 tunnel
1 source 172.21.80.1 address 2500:0000:0000:0000:0000:0000:0000:0001/64
destination 192.168.20.1
```

Configuring Switch 2

Create an IPv6 VLAN and add ports to the VLAN.

```
vlan create 40 type port-mstprstp 0
vlan mlt 40 4
vlan members 40 1/2 portmember
interface vlan 40
ipv6 interface
```

```
ipv6 interface enable
ipv6 interface address 4000:0:0:0:0:0:0:2/64
exit
```

Create an IPv4 VLAN , add ports to the VLAN, and enable OSPF on the VLAN.

```
vlan create 30 type port-mstprstp 0
vlan mlt 30 4
vlan members 30 1/30 portmember
interface vlan 30
ip address 192.168.20.1 255.0.0.0
ip ospf enable
exit
```

Create the tunnel from the destination to the source.

```
ipv6 tunnel 1 source 192.168.20.1 address 2500:0000:0000:0000:0000:0000:0000:0002/64
destination 172.21.80.1
```

Verification

Use the following show command to verify tunnel creation on the source device:

```
Switch:1(config)#show ipv6 tunnel 1 detail
================================================================================
                          Tunnel Interface Information
================================================================================
ID          LOCAL ADDRESS   REMOTE ADDRESS  OPER STATUS TYPE
--------------------------------------------------------------------------------
1           172.21.80.1     192.168.20.1    active    manual

1 out of 1 Total number of entries displayed.

--------------------------------------------------------------------------------

================================================================================
                             Address Information
================================================================================

Key Health Indicators (KHI)

Table 122: Key Health Indicator product support

Feature	Product	Release introduced
Key Health Indicator (KHI)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

The Key Health Indicators (KHI) feature provides a subset of health information that allows for quick assessment of the overall operational state of the device.

Note

KHI was not designed to provide a comprehensive debugging solution. Instead, KHI identifies key information that could lead support personnel towards discovery of a specific failure. After the technician assesses the KHI information, further debugging is required to determine the specific reason for the fault.

You should capture KHI information during normal operations to provide a baseline for support personnel when detecting fault situations.

Key Health Indicators Using the CLI

Use the procedures in this section to display Key Health Indicator (KHI) information using the CLI.

Display KHI Performance Information

Use the following commands to display KHI information about the performance of the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display buffer performance and utilization statistics:

```
show khi performance buffer-pool [{slot[-slot][,...]}]
```

3. Show current utilization, 5-minute average utilization, and 5-minute high water mark with date and time of event:

   ```
   show khi performance cpu [{slot[-slot][,...]}]
   ```

4. Display memory performance and utilization statistics on the specified slot or all slots:

   ```
   show khi performance memory [history | {slot[-slot][,...]}]
   ```

   

   Note

   Depending on the hardware platform, you can display virtual memory history.

5. Display process performance and utilization statistics on the specified slot or all slots:

   ```
   show khi performance process [{slot[-slot][,...]}]
   ```

6. Display thread performance and utilization statistics on the specified slot or all slots:

   ```
   show khi performance pthread [{slot[-slot][,...]}]
   ```

7. Display the queue performance and utilization statistics on the switch:

   ```
   show khi performance rx-queue
   ```

8. Display internal memory management resource performance and utilization statistics on the specified slot or all slots:

   ```
   show khi performance slabinfo [{slot[-slot][,...]}]
   ```

Example

```
Switch:1>show khi performance buffer-pool 1
    Slot:1
      CPP:
         UsedFBuffs: 12
         FreeFBuffs: 3060
         RxQ0FBuffs: 0
         RxQ1FBuffs: 0
         RxQ2FBuffs: 0
         RxQ3FBuffs: 0
         RxQ4FBuffs: 0
         RxQ5FBuffs: 0
         RxQ6FBuffs: 0
         RxQ7FBuffs: 0
         TxQueueFBuffs: 0
         NoFbuff: 0
      Network stack system:
         UsedMbuf: 244
         FreeMbuf: 47606
         SocketMbuf: 19
      Network stack data:
         UsedMbuf: 4
         FreeMbuf: 10748
      Letter API message queue:
         QHigh: 0
         QNormal: 0
         FreeQEntries: 51200

Switch:1>show khi performance cpu 1
    Slot:1
         Current utilization: 9
         1-minute average utilization: 9
         1-minute high water mark: 14 (06/20/16 06:03:08)
         5-minute average utilization: 8
         5-minute high water mark: 10 (06/19/16 08:35:58)
```

Depending on the switch hardware, any one of the following output can display for **show khi performance memory [{slot[-slot][,...]}]**.

```
Switch:1>show khi performance memory 1
    Slot:1
         Used: 514560 (KB)
         Free: 521260 (KB)
         Current utilization: 49 %
         5-minute average utilization: 49 %
         5-minute high water mark: 22 (10/08/14 14:48:01)

Switch:1>show khi performance memory 1
    Slot:1
         Used: 1684000 (KB)
         Free: 2321704 (KB)
         Current utilization: 42 %
         5-minute average utilization: 41 %
         5-minute high water mark: 41 (%)
         10-minute average utilization: 41 %
         10-minute high water mark: 41 (%)
         1-Hour average utilization: 41 %
         1-Hour high water mark: 41 (%)
         1-Day average utilization: 41 %
         1-Day high water mark: 41 (%)
         1-Month average utilization: 39 %
         1-Year average utilization: 0 %
```

The following example shows partial output for the **show khi performance memory history** command and depending on the hardware platform, you can also display virtual memory history.

```
Switch:1>show khi performance memory history
    Slot:1

Variable Definitions

Use the data in the following table to use the **show khi performance** command.

Variable	Value
{slot[-slot][,...]}	Specifies the slot number. Valid slot is 1.
history Note: Depending on the hardware platform, the system displays this parameter in **show khi performance memory**.	Specifies virtual memory consumed for each process.
rx-queue	Specifies the queue performance and utilization statistics on the switch.

Displaying KHI Control Processor Information

Display key health information about the type of packets and protocols received on a port. This command helps debug high CPU utilization issues.

About This Task

You can use the packets-per-second information in the output to identify where the bulk of packets destined for the CPU enter the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display statistics for control packets that go to the control processor:

   `show khi cpp port-statistics [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]`

Example

```
Switch:1>show khi cpp port-statistics
=================================================================================================================
        KHI CPP Details - Port Statistics
```

```
================================================================================================================

2/4       LLC_BPDU(128)                                 2         0         0        33508       837         0
2/4       LLC_TDP(134)                              11100       278         0        11090       278         0
```

Variable Definitions

Use the data in the following table to use the **show khi cpp port-statistics** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port).

View KHI Segmented Management Instance Information

Use the following commands to view Key Health Indicator (KHI) for segmented management instance interface information of the switch.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View KHI management instance statistics:

Note

The type of management interface supported varies by platform. For information about supported Segmented Management Instance interface types, see *Fabric Engine Feature Support Matrix*.

```
show khi mgmt statistics [clip | oob | vlan]
```

Example

```
Switch:1>show khi mgmt statistics
================================================================================================
                                Packet Counters - Interface Mgmt-oob

Arp-request                 59915                74                   0
IcmpV6-nd-nbr-solicit       0                    1                    0
IcmpV6-nd-router-advert     27                   0                    0
```

Clear KHI Information

KHI information can be cleared globally across the whole device. Use the command to clear the CPP port statistics or Segmented Management Instance statistics.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Clear CPP statistics:
   ```
   clear khi cpp port-statistics
   ```
3. Clear segmented management instance statistics:
   ```
   clear khi mgmt statistics
   ```

Key Health Indicators Using EDM

Use the procedures in this section to display KHI information using EDM.

Clearing KHI Statistics

About This Task

Clear KHI statistics.

Procedure

1. In the Device Physical View tab, select the Device.
2. In the navigation pane, expand the **Configuration** > **Edit** folders.
3. Click **Chassis**.
4. Click the **CPP Stats Control** tab.
5. Select the statistics you want to clear.
6. Click **Apply**.

CPP Stats Control *Field Descriptions*

Use the data in the following table to use the **CPP Stats Control** tab.

Name	Description
PortStatsClear	Clears port statistics.

Displaying KHI Port Information

About This Task

Use the following commands to display key health information about the types of control packets and protocols received on a port and sent to the control processor.

Procedure

1. In the Device Physical View, select a port.

2. In the navigation pane, expand the **Configuration** > **Graph** folders.
3. Click **Port**.
4. Click the **CPP Stats** tab.

CPP Stats *Field Descriptions*

Use the data in the following table to use the **CPP Stats** tab.

Name	Description
Port	Identifies the slot and port.
Packet	Shows the packet type.
PacketName	Shows the name of the packet.
RxPackets	Indicates the number of received packets on the port for the packet type.
TxPackets	Indicates the number of transmitted packets on the port for the packet type.

View KHI Segmented Management Instance Statistics Information

About This Task

Use the following procedure to view key health information about the types of control packets and protocols received on a port and sent to the segmented management instance interace.

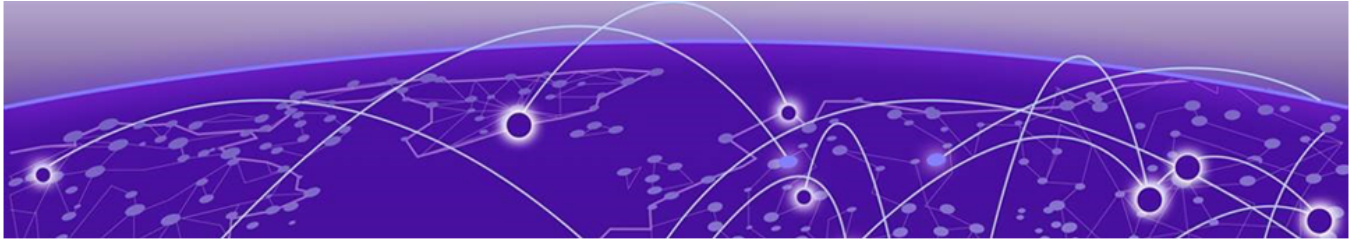
Procedure

1. In the navigation pane, expand the **Configuration** > **Edit** folders.
2. Expand **Mgmt Instance**.
3. Select **Stats**
4. Select the **KHI** tab.
5. To clear KHI statistics for a management interface, select an **InstanceId** and select **Clear Stats**.

KHI *Field Descriptions*

Use the data in the following table to use the **KHI** tab.

Name	Description
InstanceId	Shows the management interface instance.
PacketType	Shows the packet type.
PacketName	Shows the name of the packet.
RxPackets	Shows the number of received packets on the port for the packet type.
TxPackets	Shows the number of transmitted packets on the port for the packet type.
RxDropped	Shows the number of received packets dropped on the port for the packet type.



Layer 2 Security

Layer 2 Security for IPv4 and IPv6 Deployments

This section describes Layer 2 security concerns and the security features you can use to mitigate them.

Security Features for IPv4 Deployments:

- DHCP Snooping
- Dynamic ARP Inspection
- IP Source Guard for IPv4 addresses

Security Features for IPv6 Deployments:

- First Hop Security (FHS)
- DHCP Snooping and IPv6 Neighbor Discovery Inspection
- IP Source Guard for IPv6 addresses

Dynamic ARP Inspection (DAI)

Table 123: Dynamic ARP Inspection (DAI) product support

Feature	Product	Release introduced
Dynamic ARP Inspection (DAI)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Dynamic ARP Inspection (DAI) is a security feature that validates ARP packets in the network.

Without DAI, a malicious user can attack hosts, switches, and routers connected to the Layer 2 network by poisoning the ARP caches of systems connected to the subnet, and intercepting traffic intended for

other hosts on the subnet. DAI prevents these attacks by intercepting, logging, and discarding the ARP packets with invalid IP to MAC address bindings.

The switch dynamically builds the address binding table from the information gathered from the DHCP requests and replies when DHCP Snooping is enabled. The switch pairs the MAC address from the DHCP request with the IP address from the DHCP reply to create an entry in the DHCP binding table. For more information, see Create DHCP Binding Table Entries on page 1875.

When you enable DAI, the switch filters ARP packets on untrusted ports based on the source MAC and IP addresses seen on the switch port. The switch forwards an ARP packet when the source MAC and IP address matches an entry in the address binding table. Otherwise, the switch drops the ARP packet.

Note

- For DAI to function, you must enable DHCP Snooping globally.
- Configure DAI on a VLAN to VLAN basis.

DAI cannot be enabled on:

- Private VLANs (Etree)
- SPBM B-VLANs
- MLT port members

First Hop Security

First Hop Security (FHS) improves local network security by employing a number of mitigation techniques. This section describes the base set functionality which provides protection from a wide host of rogue or mis-configured users, and this can be extended with additional features for different deployment scenarios. For example, see the following topology.

Sample Topology

In the following topology, Layer 2 switch SW-1 is connected to another Layer 2 switch SW-2. SW-2 is connected to three hosts and SW-1 is connected to two hosts.

In this network, if FHS is enabled only on SW-1, then it can only save the nodes which are directly connected to it. To protect the good node connected to SW-2, the FHS must be enabled on SW-2.

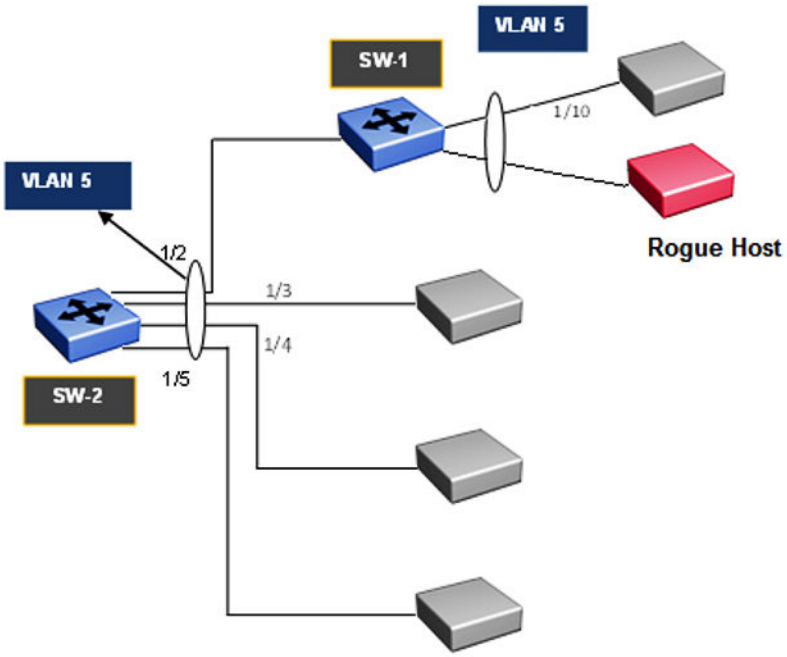


Figure 160: First Hop Security topology

First Hop Security contains the majority of the RIPE 554 mandatory requirements for Layer 2 switches. This includes the following:

- DHCPv6 Guard or DHCPv6 filtering
- RA Guard or Router Advertisement filtering

DHCPv6 security concerns

The enhancements in IPv6 provide better security in certain areas, but some of these areas are still open to exploitation by attackers. This section identifies the IPv6 FHS concerns associated with Dynamic Host Configuration Protocol version 6 (DHCPv6).

DHCPv6 (RFC 3315) describes how a host can acquire an IPv6 address and other configuration options from a server that is available on its local link. DHCPv6 is described as a stateful protocol. In other words, DHCPv6 can operate in a stateless fashion where it provides configuration information to nodes and does not perform address assignments (RFC 3736). In addition, it can operate in a stateful manner, where it assigns IPv6 addresses and configuration information to hosts that request it.

As in IPv4 DHCP, DHCPv6 is susceptible to rogue server attacks. In other words, if DHCPv6 is used to provide IPv6 addresses to the hosts, an attacker that managed to insert a rogue DHCPv6 server in the link can potentially assign addresses and configuration options to the link hosts. In turn, the attacker can deploy man-in-the-middle, traffic interception, or blackhole traffic, similar to those in the stateless address autoconfiguration scenario. Therefore, it is important to use DHCP protections for both IPv4 and IPv6.

DHCPv6 Guard

Table 124: DHCPv6 Guard product support

Feature	Product	Release introduced
DHCPv6 Guard	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

DHCPv6 Guard is a type of security for IPv6 deployments in an enterprise environment, it provides Layer 2 security to DHCPv6 clients by protecting them against rogue DHCPv6 servers. The basic concept of DHCPv6 Guard is that a Layer 2 device filters DHCPv6 messages meant to DHCPv6 clients, based on a number of different criteria. The basic filtering criterion is, the DHCPv6 server generated packets which are received on non-server ports or from an untrusted server will be dropped by the Layer 2 device.

Various levels of granularity are provided. Following are the policies that are supported:

- Port based filtering using device role (server or client)
- Server or relay agent IPv6 address based filtering
- Advertising IPv6 prefix based filtering
- DHCPv6 packet filtering based on Server Preference checks

The following figures are DHCPv6 topology samples:

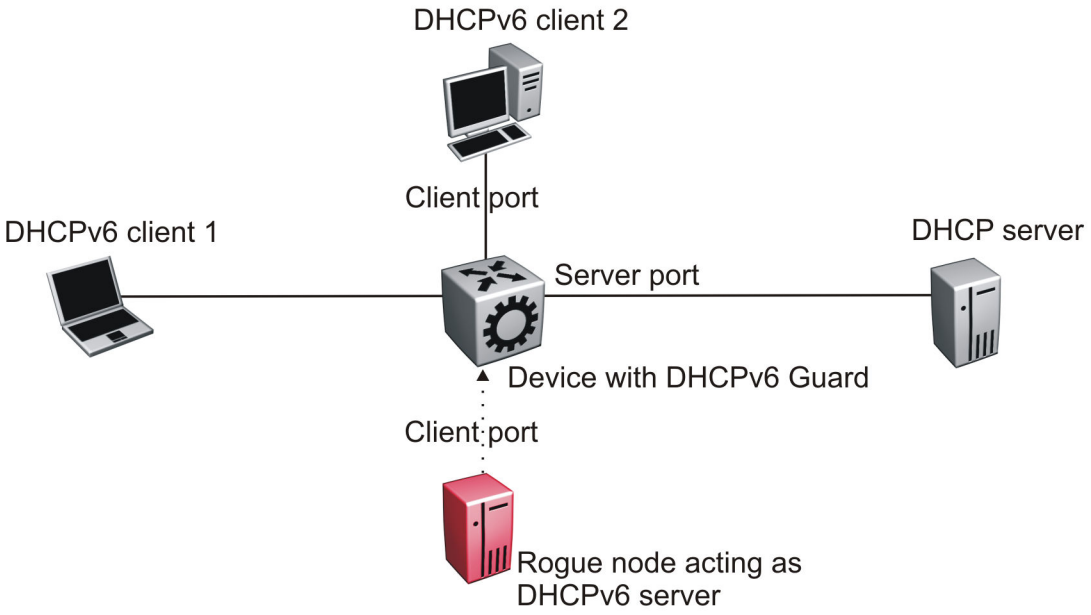

Figure 161: DHCPv6 Topology 1

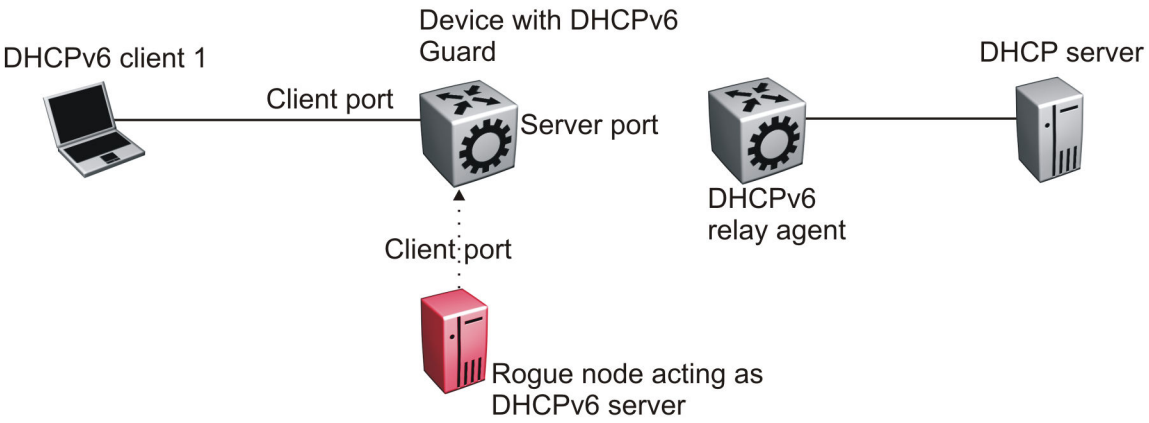

Figure 162: DHCPv6 Topology 2

DHCPv6 Guard Policies Configuration

You can configure DHCPv6 Guard policies using CLI, SNMP and EDM. The following policies are supported for DHCPv6 Guard.

Port-based Filtering Using Device-role

Port-based filtering using device-role is an interface-level configuration. Only a DHCPv6 server or relay agent can send a DHCPv6 advertisement or reply. By configuring the device-role attached to the port (whether it is a client or server), the rogue server generating DHCPv6 advertisement or reply packets can be blocked if these packets are received on a port configured as a client. Device-role can be applied only on port, and not on MLT, SMLT, or VLAN. If you configure device-role on an MLT, SMLT, or VLAN, you must configure same device-role on all the MLT, SMLT, or VLAN member ports.

In DHCPv6 Guard Topology 1, only DHCPv6 server packets (that is, advertisement, reply) received on a port configured as a Server port accept the packets and process them for security validation and forwarding. The Client port drops the packets if it receives packets generated from a DHCPv6 rogue server.

Server or Relay Agent IPv6 Address Based Filtering

Server or relay agent IPv6 address-based filtering enables the verification of the advertised DHCPv6 server and relay address in messages with the configured authorized server access list. In DHCPv6 Guard Topology 1 and Topology 2, you can configure the access list to accept DHCPv6 server packets from a specific Source IPv6 address such as a DHCPv6 server or DHCPv6 relay IPv6 address.

Advertising IPv6 prefix-based filtering

Advertising IPv6 prefix-based filtering enables verification of the advertised prefixes in DHCPv6 reply messages with the configured authorized prefix list.

Server preference-based filtering

Server preference-based filtering enables verification by checking if the advertised preference (in preference option) is greater than or less than the specified limit.

RA Guard

Table 125: IPv6 Router Advertisement (RA) Guard product support

Feature	Product	Release introduced
IPv6 Router Advertisement (RA) Guard	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

IPv6 hosts can configure themselves automatically when connected to a routed IPv6 network through ICMPv6 router discovery messages. When the host is connected to the network for the first time, it sends a link-local router solicitation multicast request for its configuration parameters. If the host is configured correctly, routers respond to the request with a Router Advertisement (RA) packet. The RA packet contains network-layer configuration parameters.

In addition to filtering RAs, RA Guard introduces the concept of router authorization proxy. Instead of each node on the link analyzing RAs and making an individual decision, a legitimate node-in-the-middle performs the analysis on behalf of all other nodes on the link.

Stateless and statefull RA Guard functions are available. The switch supports only the stateless RA Guard function.

Stateless RA Guard examines incoming RAs and decides whether to forward or block them based on the information found in the message or in the Layer 2 device configuration. The following list identifies the typical information available in the received frames that are used for RA validation:

- Port on which the frame is received
- Source IPv6 address
- Prefix list which RA carries
- Link-Layer address of the sender

After the Layer 2 device successfully validates the RA packet content against the configuration, the RA is forwarded to its destination, whether unicast or multicast. If the validation fails, the RA is dropped at the Layer 2 device.

RA Guard policies description

This section describes the RA Guard policies. The following policies are supported for RA Guard:

- Port-based filtering using device role (host or router)
- Source IPv6 based filtering
- Advertised IPv6 prefix-based filtering
- Source MAC address-based filtering
- RA packet for managed address configuration flag validation
- RA packet for hop count limit validation
- RA packet for Router Preference validation

Port-based Filtering Using Device-role

This configuration is an interface-level configuration. According to Neighbor Discovery (ND) RFC 4861, only the IPv6 router can generate the RA packets. By configuring the device-role attached to the port whether it is a host or router, the rogue host which is generating RA packets can be blocked. Device-role can be applied only on a port, and not on an MLT, SMLT, or VLAN. If you configure device-role on an MLT, SMLT, or VLAN, you must configure the same device-role on all the MLT, SMLT, or VLAN member ports.

In the following topology, the switch is connected to a Layer 3 router and three hosts. Because the router is directly connected to port 1/2, the device-role of the port 1/2 is configured in Router mode. The other hosts are connected to ports 1/3, 1/4, and 1/5, and the device-role of ports 1/3, 1/4, and 1/5 are configured in Host Mode.

The host connected to the port 1/4 is a rogue host and if it is trying to send RA packets, then the switch drops those RA packets received on the interface 1/4 as the device-role of this port is Host Mode.

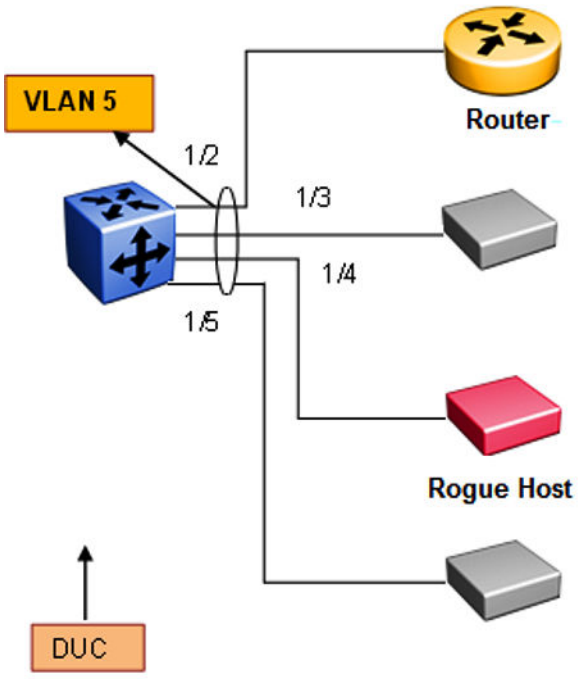

Figure 163: RA Guard Topology1

IPv6 Source Address Based Filtering

An IPv6 source address based filtering policy enables the source IPv6 address verification of the RA packets against the configured RA source IPv6 list.

The following figure shows the RA packet format. RA Guard policy verifies the IPv6 source address (SrcIP) in the IPv6 Header against the configured RA source IPv6 list.

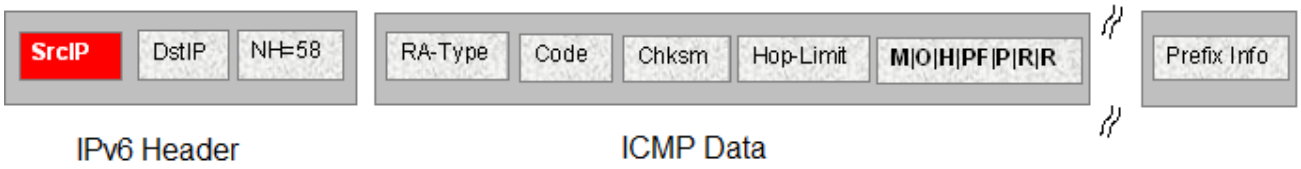

Figure 164: IPv6 ICMP RA Data Packet Online

Advertised IPv6 Prefix-based Filtering

Advertised IPv6 prefix-based filtering enables verification of the advertised prefixes in inspected messages against the configured RA prefix list.

The following figure illustrates the IPv6 ICMP RA data packet outline. This RA Guard policy verifies the RA (Prefix Information) in ICMPv6 data against the configured RA prefix list.

Figure 165: IPv6 ICMP RA Data Packet Outline

Source MAC Address-based Filtering

Source MAC address-based filtering enables the source MAC address of the RA packets verification against the configured authorized MAC list.

The following figure illustrates the IPv6 Ethernet packet. This RA Guard policy verifies the received RA packets source MAC address against the configured authorized MAC access list.

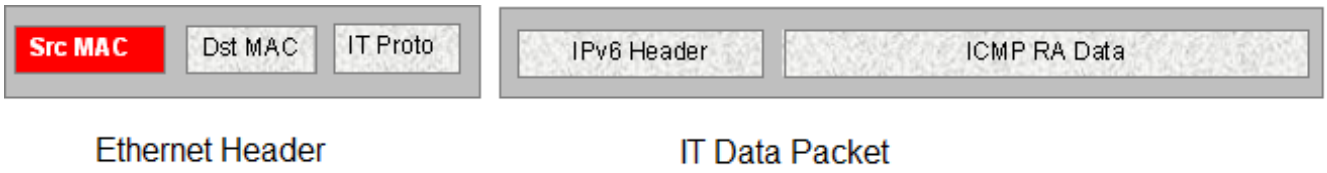

Figure 166: IPv6 Ethernet Packet

RA packet for managed address configuration flag validation

In the RA packets, there is an “M” flag (managed address configuration flag) that can be configured to indicate that the address assignments are available through DHCPv6. This means that DHCPv6 takes care of the interface address assignment in that LAN segment. If a filtering policy is enabled, then all the RA packets without an “M” flag are dropped. By default, this validation is not performed.

The following figure illustrates IPv6 ICMP RA data packet outline for managed address configuration.

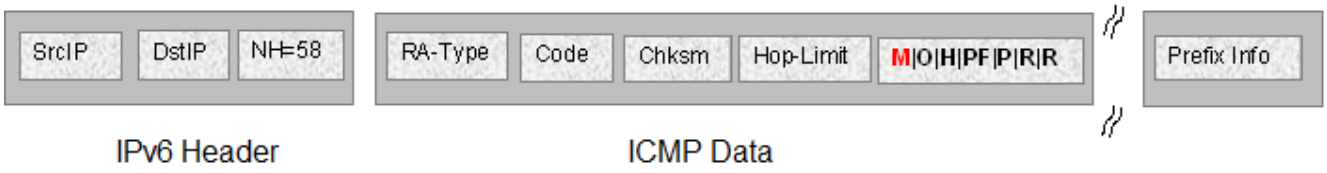

Figure 167: IPv6 ICMP RA data packet outline

RA packet for hop count limit validation

RA packet for hop count limit validation policy verifies the advertised RA message if the hop count limit is within the configured hop count limit. If the received hop count limit is not within the configured limit, then those RA packets are dropped.

The following figure illustrates IPv6 ICMP RA data packet outline for hop count limit validation.

Figure 168: IPv6 ICMP RA data packet outline

RA packet for router preference validation

The RA packet contains the Router Preference as part of the flags field. This can be high, medium, or low. This filtering policy option verifies if the advertised default router preference parameter value is lower than or equal to a specified limit.

The following figure illustrates IPv6 ICMP RA data packet outline for router preference validation.

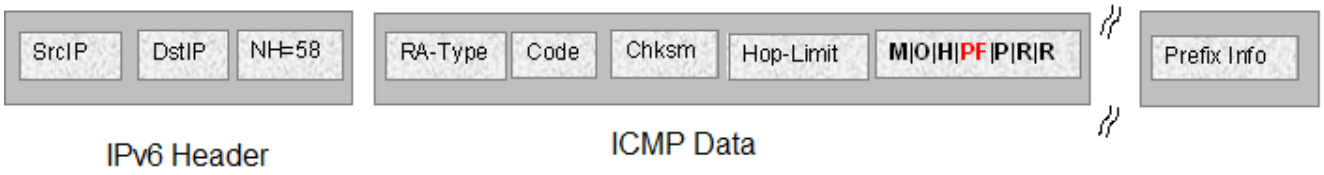

Figure 169: IPv6 ICMP RA data packet outline for router preference validation

Capturing and verifying FHS specific packets against the configured policies

First Hop Security filters can be installed only if FHS is enabled globally. The DHCPv6 Guard or RA Guard filters are created as a part of First Hop Security filter with port bit mask “0”.

The following list identifies the high-level tasks to capture DHCPv6 packets received on a physical port:

1. Enable FHS globally.
2. Enable DHCPv6 Guard or RA Guard globally.
3. Create a DHCPv6 Guard or an RA Guard policy.

4. Configure RA Guard or DHCPv6 Guard device role on the port.
5. Attach DHCPv6 Guard and/or RA Guard policy to a physical port if needed.

On configuring RA Guard or DHCPv6 Guard device role on the port, the appropriate port bitmask for that port will be updated in the data path filter.

The RA or DHCPv6 sever initiated packets received on trusted ports (router or server ports) will be sent to the local CPU for further validations. If these packets pass the RA Guard and DHCPv6 Guard validation, they will be forwarded towards the intended host or DHCPv6 client; if not, they will be dropped by the switch.

FHS limitations

The following limitations exist in First Hop Security:

- Fragmented RA and DHCPv6 server initiated packets are dropped on the FHS enabled switch.
- DHCPv6 Guard and RA Guard do not work on devices connected on shared media or on tunneled interfaces.
- DHCPv6 Guard or RA Guard policies are not VLAN or MLT based.
- FHS is not supported on the Out Of Band (OOB) port on the switch.
- Packets received on FHS ports with more than one extension header, and if they are destined to link-local unicast or link-scope multicast address, are dropped as they cannot be classified as RA or DHCPv6 reply packets.
- The FHS functionality can be bypassed at the first hop switch, if the malicious packets are destined to global address, and have more than one extension header.
- If the FHS rules and IPv6 filters match for a packet, the IPv6 filter has precedence.
- In a Layer 2 VSN, packets are not filtered based on FHS rules. Enable FHS on the required UNI ports to protect the connected devices from FHS attacks.

Guidelines for FHS configuration

Some of the FHS configurations need details on how they work and how they should be used. Following are the details:

1. FHS IPv6 Access lists are generic access/prefix lists which can be applied on IPv6 source address or the prefixes advertised in RA or DHCPv6 messages. If you filter on the basis of a particular IPv6 source address, you must configure the access list entry with complete source address with prefix-length value of 128. If you allow a group of source addresses within a prefix range, you must configure the IPv6 ACL entry with an appropriate prefix length and attach this IPv6 ACL to the appropriate match parameters in RA Guard or DHCPv6 Guard policies.

   If you filter a particular prefix, you must configure an IPv6 access list entry with appropriate prefix and prefix-lengths. To filter based on prefix, prefix-lengths should be less than 128. Following is an example of IPv6 access list entry:

ipv6 fhs ipv6-access-list match_src_allow fe80:0:0:0:0:ff:fe00:113/128 mode allow

Note

a. If no IPv6 ACL is attached to an RA Guard or DHCPv6 Guard policy as a source ACL, then IPv6 source address in the incoming RA packets or packets from DHCP server will not be validated, and such packets will not be dropped due to source address validations.
b. If no IPv6 ACL is attached to an RA Guard or DHCPv6 Guard policy as a prefix ACL, then prefix information in incoming RA packets or packets from DHCP server will not be validated and these packets will not be dropped due to prefix validations.
c. The FHS access or prefix lists are different from IPv6 prefix lists. For FHS, the switch maintains a separate list (cannot reuse IPv6 prefix lists) as IPv6 prefix lists do not have any action associated with them, whereas FHS has an action associated with each ACL entry.

2. When an IPv6 ACL is attached to an RA Guard or DHCPv6 Guard policy and the address or prefix in the incoming RA Guard or DHCPv6 server packets received on port to which this RA Guard or DHCPv6 Guard policy is attached does not match any of the entries in that IPv6 ACL, the packet will be dropped by default. If you want to change this behavior to default (allow, for IPv6 ACLs), you can add an entry that matches all the packets and set the action as allow. To do this, use the following command:

   ipv6 fhs ipv6-access-list no_match_src_def_allow 0:0:0:0:0:0:0:0/0 mode allow
3. IPv6 ACL entries with conflicting prefixes within an IPv6 ACLs are not allowed, and such configuration will fail with appropriate error message. Conflicting entries can be present in two or more different IPv6 ACLs.
4. The entries within an IPv6 ACL will be sorted in increasing order of IPv6 prefixes. If there are two entries with same prefix address within an ACL, then such entries will be ordered with increasing value of their prefix-lengths.
5. MAC ACL entries are ordered in the increasing order of MAC addresses within a MAC ACL. If none of the entries in the MAC ACL match the source MAC address of RA packet, then the packet will be dropped by default. If no MAC ACL is attached to an RA Guard policy, then the source MAC address of RA packets is not validated.
6. When matching for a prefix using IPv6 ACL entry, if you advertise a prefix with matching prefix but prefix-length lesser than configured prefix-length, then the packet has to be considered as no match and prefix matching process has to continue with remaining IPv6 ACL entries in that ACL.

   The rationale behind this functionality is to avoid wrong configuration of access side devices. This functionality safeguards the devices in an access network if a wrongly configured IPv6 prefix is advertised or a malicious user is sending invalid (wrong) prefixes. For example, consider the following scenario:

   Configure the prefix in ACL entry (without ge and le values): **ipv6 fhs ipv6-access-list ipv6_acl_entry_1 2000:0123:4567:89ab::/64 mode allow**

   Advertise the prefix in RA packet: **2001:0123:4567:89ab::/48**

This advertised prefix matches the configured IPv6 ACL entry and without this prefix-length check functionality, the packet is allowed to pass through. But, actually it is configuring all access devices in that network with wrong IPv6 configurations in different IPv6 network (**2001:0123:4567::/48**)

With prefix-length check functionality (explained above), this configuration is not allowed as advertised prefix length is not equal to configured prefix length. So, the wrong configurations of access devices is avoided.

7. Importance of “ge” and “le” parameters in an IPv6 ACL entry:

   A user can optionally configure “ge” (greater than or equal to) and “le” (lesser than or equal to) parameters while configuring an IPv6 ACL entry. If the prefix advertised in a packet matches the configured prefix in an IPv6 ACL entry, and “ge” and “le” values are configured (not default) for that IPv6 ACL entry:

   - The packet will be allowed to go through only if the prefix-length in the packet is within the range of configured “ge” and “le” values.
   - If prefix lengths in the packet are not within the configured range of “ge” and “le” values (non-default values), then the packets would be considered as no match for that IPv6 ACL entry and search for matching IPv6 ACL entry continues within that IPv6 ACL.
   - If no ge and le values are configured, those values by default are set to configured prefix length in that IPv6 ACL entry.
   - ge and le values are allowed only if they are greater than configured prefix.
   - When both are configured (not default values), ge value should always be smaller than le value.

   These configurations provide more control over the advertised prefixes in RA or DHCPv6 packets.

8. As “ge” and “le” values are valid only for advertised prefixes, they will not be applied to IPv6 addresses, which are not prefixes. For such addresses, prefix match is considered as match for that IPv6 ACL entry and the corresponding action of that ACL entry is applied on that packet. “ge” and “le” configurations are irrelevant for the following:

   - IPv6 source address in RA packet
   - IPv6 source address in packets from DHCPv6 server (like DHCPv6 advertise, DHCPv6 reply)
   - IPv6 address (temporary or non-temporary) advertised in packets from DHCPv6 server. For example, IPv6 addresses advertised in IANA option of DHCPv6 reply packets

9. Order of packet validations:

   In RA or DHCPv6 packets received at the CP for FHS processing, the following order of processing is carried out:

   a. Packet parsing
   b. Checking for presence of IPv6 fragment header
   c. Checking if packets are RA packets or DHCPv6 packets from server (Advertise, Reply, Reconfigure, Relay-Reply)
   d. Basic validations:
      - Non-Link-Local source IPv6 address (only for RA packets)
      - L4 length validations

- Checksum validations

e. If an RA Guard or DHCPv6 Guard policy is attached to a port:
   - MAC ACL validations (if configured) (Only for RA packets)
   - IPv6 source address ACL validation (if configured)
   - IPv6 prefix ACL validations (if configured)
   - Other packet parameter validations like:
     - Managed config flag (RA)
     - ICMP hop limit (RA)
     - Router preference (RA)
     - Server preference (DHCPv6)

   If any of these validations fail or if action associated with a match ACL entry indicates to DROP (or default drop if ACL is attached to corresponding policy but packet does not match any ACL entry in that ACL), then the packets are dropped and corresponding statistics are updated. If all these pass or actions related to all matched ACL entries are PERMIT, then the packet is allowed to go through.

10. Longest prefix match: If a packet matches multiple entries in an ACL, then the action associated with an entry with longest prefix match would be applied on the packet.
11. If a port is configured as untrusted ("host" as device role for RA Guard or "client" as device role for DHCPv6 Guard), all the FHS trusted traffic (RA packets for RA Guard or packets from DHCPv6 server for DHCPv6 Guard) are dropped in data path itself. Also for such drops, statistics are not incremented.

    If a port is neither configured as trusted nor untrusted, then the FHS traffic (RA packets or DHCPv6 packets from DHCPv6 server) is switched as if FHS is not present.
12. Creation of FHS port policy mappings:

    Until, and unless, any of the FHS parameters are configured on a port, port policy mappings are not created and thus with no port to policy mapping configured, the system does not display any entries while listing port policy mappings using the command **`show ipv6 fhs port-policy`**.
13. If a RA Guard or DHCPv6 Guard policy is attached to any of the ports, deletion of such policy is not allowed. In the contrary, to delete an RA Guard or DHCPv6 Guard policy, those policies need to be detached from all the ports in the switch. However, modification of an RA Guard or DHCPv6 Guard policy is allowed even if it is attached to ports.
14. If a MAC or IPv6 ACL is attached to an RA Guard or DHCPv6 Guard policy, you cannot delete the ACL itself. You can delete the entries from this policy even if it is attached to any policy. At least one entry needs to exist in a MAC or IPv6 ACL; you cannot delete the last entry in that ACL if that ACL is attached to any RA Guard or DHCPv6 Guard policy. You must detach that ACL from all the policies to delete that ACL. However, you can update the entries in that ACL even if it is attached to a policy.

    If a port is configured as trusted ("Server" port for DHCPv6 Guard and "Router" port for RA Guard), then only one can attach a DHCPv6 Guard or RA Guard policy to that port. In the contrary, if any policy is attached to a port, the port role cannot be changed from trusted ("Server" port for DHCPv6 Guard and "Router" port for RA Guard) to other role ("Client" port for DHCPv6 Guard, "Host" port for RA Guard or "None" for both) until that policy is not detached from port.

DHCP Snooping and Neighbor Discovery inspection

Table 126: Dynamic Host Configuration Protocol Snooping and Neighbor Discovery Inspection product support

Feature	Product	Release introduced
DHCP Snooping(IPv4)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
DHCP Snooping (IPv6)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Neighbor Discovery Inspection (IPv6)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

DHCP Snooping

DHCP Snooping is a Layer 2 security feature, that provides network security by filtering untrusted DHCP messages received from the external network causing traffic attacks within the network. DHCP Snooping is based on the concept of trusted versus untrusted switch ports. Switch ports configured as trusted can forward DHCP Replies, and the untrusted switch ports cannot. DHCP Snooping acts like a firewall between untrusted hosts and DHCP servers.

Note

The switch supports:

- DHCP Snooping for both IPv4 and IPv6.
- Neighbor Discovery (ND) inspection for IPv6.

Security is critically important in an access network because various devices can connect to an access network that may not be administratively controlled by a single administrator. Stateless Address Autoconfiguration (SLAAC) and Duplicate Address Detection (DAD) mechanisms used by IPv6 are more vulnerable to attacks from a malicious user. If any person, intentionally or unintentionally, configures an IP address on the device interface wrongly and advertises that IP address as one's own address during DAD mechanism initiated by other device, DAD initiated devices cannot assign this address. If a malicious user replies to all the DAD IP addresses as own address, none of the devices in the access network can assign any IP addresses to their interfaces. Thus, DoS attacks can be easily carried out by the malicious user making the entire network unfunctional. In another kind of attack, a malicious user can try to poison the neighbor cache of a host by sending ND packets with bogus MAC address which is learnt by other hosts into their neighbor table. Due to the infiltration of the bogus MAC

address in the host's neighbor table, the packets destined to its neighbor is sent to the bogus MAC address and is eventually dropped or received by an unintended host.

In general, these kinds of attacks are carried out by sending different Neighbor Discovery (ND) packets – either through solicited ND packet exchanges or as a result of unsolicited ND packet exchanges triggered due to an event like the expiry of ND timers. These packets carry interface IP address information and link-layer address information. Other devices use this information to build their neighbor table for forwarding traffic to or through the malicious device. As part of ND inspection mechanism, ND (specifically, NS, NA, and redirect) packets from only trusted hosts are allowed to pass through and the packets from un-trusted hosts are dropped in the switch itself. Other network devices can safely use ND mechanisms for correctly assigning IP address to their interfaces resulting in a smooth traffic flow.

For validating the ND packets, the switch must first learn the trusted information by various mechanisms and store the information in a DHCP binding table. If the switch receives ND packets on an untrusted port, the packets are validated against entries in the DHCP binding table. If the ND packets pass the validation, the packets are forwarded. If the packets fail the validation, they are dropped in the switch itself. This process avoids invalid NA packets from propagating beyond the access switch.

DHCP Snooping and ND inspection feature protects the network from the following types of attacks:

- User misconfigurations: Host assigns an address which should not be used by the recipient device. ND inspection blocks this address in the access switch because binding entry does not exist for that address for that host.
- DAD spoofing: Malicious user claims that the address is taken even if it is not.
- NUD spoofing: Malicious host responds to NUD NS packets indicating that the address is still reachable via that host even if that neighbor is actually not reachable.
- ND cache poisoning: Malicious user sends different (invalid) link-layer addresses for a target IP address causing other hosts in the network to program bogus MAC for a given IP neighbor, as a result of which, the traffic gets black-holed or misused by malicious host.

DHCP Binding Table

DHCP Snooping builds and maintains a binding table, this binding table contains the MAC address, IP address, lease time, binding type, VLAN number, and port information that correspond to the local untrusted ports of the switch. When the switch receives a DHCPRELEASE or DHCPDECLINE broadcast message, DHCP Snooping performs a lookup of the MAC address in the binding table to determine if the port information in the binding table matches the port on which the message was received. If the port information matches, the DHCP packet is forwarded, otherwise it is dropped.

Trust Bindings

A switch enabled with the Neighbor Discovery inspection feature allows NA packets through, if the packets are from a trusted host. To allow or deny Neighbor Advertisement (NA) packets, trust bindings must be established using following methods:

- Configuring the port connected to a device (or host) as trusted.
- Building a DHCP binding table which contains entries from trusted devices (or hosts) only. This DHCP binding table is used for validating NA packets.

  This method of trust binding involves 2 processes:

  - IP address learning (snooping) process

In this process an IP address is learnt through a trusted means and a DHCP binding table is built. The switch supports the DHCP binding table entry learning by:

- Statically configuring the entries
- Dynamically learning by DHCP Snooping packets

- NA packet validation (inspection) process

  This process uses the DHCP binding table entries which are populated as part of IP address learning process to validate the incoming NA packets.

After the DHCP binding tables are built, the information gathered using trust binding is used to validate the ND packets. If the ND packets cannot be validated using this information, they are considered as packets received from an un-trusted host and are dropped by the switch.

Restrictions

In addition to the FHS restrictions, DHCP Snooping and ND inspection have the following restrictions:

- Link-local address validation is not supported under ND inspection. Thus, an FHS enabled switch is vulnerable to attackers who try to attack with link-local addresses.
- As a 5-second timer is used to cleanup expired DHCP binding table entries, the expired DHCP binding table entries may remain in the DHCP binding table for up to 5 seconds after they expire.
- If a FHS-enabled switch gets rebooted, all the dynamically-learned binding entries get flushed and those entries need to be re-learned for ND inspection to pass. However, when the switch is rebooted, DHCP clients connected to it do not re-initiate DHCP learning, due to which, the switch cannot learn these assigned IP addresses. As a result, ND inspection fails for these addresses. To overcome this problem either DHCP client must learn the IP address again through DHCP mechanisms or the administrator must add static entries for these addresses.
- For IPv6, DHCP binding table entries learned through DHCP are not removed from the DHCP table on DHCP clients that release these addresses. The administrator must manually remove these entries once the addresses are released.
- A dynamic DHCP binding table entry is learned only using the DHCP mechanism. For other modes of address configuration on the host, a relevant DHCP binding table entry must be configured on the FHS switch so that ND packets from such host are not blocked due to ND inspection processing.
- DHCP Snooping is not supported on:
  - DHCP Relay
  - Etree
  - Private VLANs
  - Split Multi-Link Trunking (SMLT)

IP Source Guard

Table 127: IP Source Guard product support

Feature	Product	Release introduced
IP Source Guard (IPv4)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
IP Source Guard (IPv6)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

IP Source Guard (IPSG) is a Layer 2 port-to-port feature that works closely with DHCP Snooping. It prevents IP spoofing by allowing only IP addresses obtained using DHCP Snooping. When you enable IPSG on an untrusted port with DHCP Snooping enabled, an IP filter is automatically created or deleted for that port based on the information stored in the corresponding DHCP Snooping binding table entry. When a connecting client receives a valid IP address from the DHCP server, the filter installed on the port allows traffic only from that assigned IP address.

You can configure IPSG on a port using the command line interface (CLI), the Enterprise Device Manager (EDM), or SNMP.

Note

The switch supports configuration of IP Source Guard for both IPv4 and IPv6 addresses.

The following table shows how IPSG works with DHCP Snooping.

Table 128: IP Source Guard and DHCP snooping

IP Source Guard configuration state	DHCP snooping configuration state	DHCP snooping Binding Entry action (untrusted ports)	IP Source Guard action
change from disabled to enabled	enabled	creates a binding entry	creates a filter for the IP address using the IP address from the binding table entry
enabled	enabled	creates a binding entry	creates a filter for the IP address using the IP address from the binding table entry
enabled	enabled	deletes a binding entry	deletes the IP filter and installs a default filter to block all IP traffic on the port

Table 128: IP Source Guard and DHCP snooping (continued)

IP Source Guard configuration state	DHCP snooping configuration state	DHCP snooping Binding Entry action (untrusted ports)	IP Source Guard action
enabled	enabled	deletes binding entries when one of the following conditions occur: • a DHCP release packet is received • the port link is down • the lease time has expired • the port is removed from the VLAN • the VLAN is deleted • the port is set as trusted • the binding entries are manually deleted	deletes the corresponding IP filter and installs a default filter to block all IP traffic
change from enabled to disabled	enabled	not applicable	deletes the installed IP filter for the port
disabled	enabled	creates a binding entry	
disabled	enabled	deletes a binding entry	

IPSG Limitations

- You can enable IP Source Guard (IPSG) only on a port that is DHCP Snooping and Dynamic ARP Inspection untrusted.
- The port must be a member of a VLAN. DHCP Snooping must be enabled globally and on the VLAN. You must also enable Dynamic ARP Inspection on the same VLAN.
- You cannot enable IPSG on MLT, SMLT, DMLT or LAG ports.
- You cannot enable IPSG on a brouter port.
- You cannot enable IPSG on ports that are members of a private VLAN.
- You cannot remove a port that is IPSG enabled from a VLAN. Similarly, you cannot delete a VLAN that has at least one port that is IPSG enabled.
- A maximum of 10 IP addresses are allowed on each IPSG enabled port. Correspondingly, a maximum of 10 IP filters are automatically created for each of those ports. When this number is reached, no more filters are set up and all traffic is dropped.
- On the switch, the total number of IP filters must not exceed 256. This limit includes both IP filters that are automatically created on IPSG ports and the manually created ACLs.

Layer 2 Security Configuration Using the CLI

Use the following sections to help you configure Layer 2 security features and protect the network by mitigating various types of attacks, using the Command Line Interface (CLI).

For IPv4 deployments, configure:

- DHCP Snooping
- Dynamic ARP Inspection
- IP Source Guard for IPv4 addresses

For IPv6 deployments, configure:

- First Hop Security (FHS)

  Note

  FHS does not solve all cases of denial of services like blocking flooding of the IPv6 messages.

- DHCP Snooping and IPv6 Neighbor Discovery Inspection
- IP Source Guard for IPv6 addresses

DHCP Snooping Configuration Using CLI

The following section provides procedures to configure DHCP Snooping using the CLI.

Enable or Disable DHCP Snooping globally

Use the following procedure to enable DHCP Snooping globally. If DHCP Snooping is globally disabled, the switch forwards DHCP reply packets to all required ports, both trusted or untrusted.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable DHCP Snooping globally:

   ```
   ip dhcp-snooping enable
   ```

3. Disable DHCP Snooping globally:

   ```
   no ip dhcp-snooping enable
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip dhcp-snooping enable
```

Variable Definitions

The following table defines parameters for the **`ip dhcp-snooping`** command.

Variable	Value
`enable`	Enables or disables DHCP Snooping globally. By default, DHCP Snooping is disabled.

Enable or Disable DHCP Snooping on a VLAN

Use the following procedure to configure DHCP Snooping on a specific VLAN. If DHCP Snooping is globally disabled, the switch forwards DHCP reply packets (received on trusted or untrusted ports) to all ports.

If you enable DHCP Snooping globally, the agent determines whether to forward DHCP reply packets based on the DHCP Snooping mode of the VLAN and trusted state of the port.

Note
You cannot enable DHCP Snooping on Private VLANs (E-Tree) and SPBM B-VLANs.

Before You Begin

You must enable DHCP Snooping globally.

Procedure

1. Enter VLAN Interface Configuration mode:
   ```
   enable

   configure terminal

   interface vlan <1-4059>
   ```
2. Enable DHCP Snooping on the VLAN:
   ```
   ip dhcp-snooping enable
   ```
3. Disable DHCP Snooping on the VLAN:
   ```
   no ip dhcp-snooping enable
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 5
Switch:1(config-if)#ip dhcp-snooping enable
```

Variable Definitions

The following table defines parameters for the **`ip dhcp-snooping`** command.

Variable	Value
`enable`	Enables or disables DHCP Snooping on the specified VLAN.

Configure Trusted and Untrusted Ports

Use the following procedure to set the trust factor associated with a port for DHCP Snooping. By default, the trust factor is set to untrusted.

Note
For ports that are members of an MLT, DHCP Snooping must be configured using the MLT configuration mode.

Before You Begin

You must enable DHCP Snooping globally.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface mlt <1-512>
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Set the trust factor for the port:

   ```
   ip dhcp—snooping <trusted|untrusted>
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#ip dhcp-snooping trusted
```

Variable Definitions

The following table defines parameters for the **ip dhcp-snooping** command.

Variable	Value
<trusted|untrusted>	Specifies the trust factor of the port for DHCP Snooping.

Display DHCP Snooping Global Configuration

Use the following procedure to display the global status of DHCP Snooping configuration.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the global configuration:

   ```
   show ip dhcp-snooping
   ```

Example

```
Switch:1>show ip dhcp-snooping
================================================================================
                           Dhcp Snooping General Info
================================================================================
        Dhcp Snooping                  : Enabled

--------------------------------------------------------------------------------
```

Display DHCP Snooping Interface Information

Use the following procedure to view the DHCP Snooping interface information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display DHCP Snooping brouter port information:
   `show ip dhcp-snooping interface [gigabitEthernet [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} [vrf WORD<1-16> | vrfids WORD<0-512>] | <1-4059> [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} [vrf WORD<1-16> | vrfids WORD<0-512>] | vrf WORD<1-16> | vrfids WORD<0-512>] | vrf WORD<1-16> | vrfids WORD<0-512>]]`
3. Display DHCP Snooping VLAN information:
   `show ip dhcp-snooping vlan <1-4059>`
4. Display DHCP Snooping information for specific VRF name:
   `show ip dhcp-snooping vrf WORD<1-16>`
5. Display DHCP Snooping information for specific VRF ID:
   `show ip dhcp-snooping vrfids WORD<0-512>`

Example

```

Add Static Entries to DHCP Snooping Binding Table

Use the following procedure to add devices with a specified MAC address to the DHCP Snooping binding table.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Add the static entry to the DHCP Snooping binding table:

   ```
   ip dhcp-snooping binding <1-4059> 0x00:0x00:0x00:0x00:0x00:0x00 ip
   {A.B.C.D} port {slot/port[sub-port]} [expiry <0-2147483646>]
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)# ip dhcp-snooping binding 1 00-14-22-01-23-45 ip 10.10.10.01 port 1/2
expiry 2
```

Variable Definitions

The following table defines parameters for the **ip dhcp-snooping binding** command.

Variable	Value
<1-4059>	Specifies the VLAN ID.
0x00:0x00:0x00:0x00:0x00:0x00	Specifies the MAC address of the DHCP client.
ip {A.B.C.D}	Specifies the IP address of the DHCP client.
port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Specifies the switch port to which the DHCP client connects.
expiry <0-2147483646>	Specifies the expiry time (in seconds) for the DHCP client.

Clear Entries from DHCP Snooping Binding Table

Use the following procedure to clear entries (static or dynamic) from the DHCP Snooping binding table.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Enter:

   ```
   clear ip dhcp-snooping binding [dynamic|static]
   ```

Example

```
Switch:1>enable
Switch:1#clear ip dhcp-snooping binding static
```

Variable Definitions

The following table defines parameters for the **clear ip dhcp-snooping binding** command.

Variable	Value
static	Clears static entries from the DHCP Snooping binding table.
dynamic	Clears dynamic entries from the DHCP Snooping binding table.

Display DHCP Snooping Binding Table Information

Use the following procedure to display the DHCP Snooping binding table, you can filter the entries displayed based on the type, port, or VLAN.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all binding entries:

   ```
   show ip dhcp-snooping binding
   ```

3. Display binding entries based on the MAC address or IP address:

   ```
   show ip dhcp-snooping binding address [0x00:0x00:0x00:0x00:0x00:0x00|{A.B.C.D}]
   ```

4. Display binding entries configured on the ports:

   ```
   show ip dhcp-snooping binding interface [gigabitEthernet{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
   ```

5. Display binding entries configured on the VLANs:

   ```
   show ip dhcp-snooping binding vlan <1-4059>
   ```

6. Display binding entries configured on a specific VRF:

   ```
   show ip dhcp-snooping binding vrf WORD<1-16>
   ```

7. Display binding entries configured on a specific VRF ID:

   ```
   show ip dhcp-snooping binding vrfids WORD<0-512>
   ```

8. Display a summary of the DHCP Snooping binding table:

   ```
   show ip dhcp-snooping binding summary [<1-4059>] [vrf WORD<1-16>] [vrfids WORD<0-512>] [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
   ```

9. Display binding entries based on the type of entry:

   ```
   show ip dhcp-snooping binding type [dynamic|static]
   ```

Example

```
Switch:1>show ip dhcp-snooping binding
==========================================================================================================

```

Dynamic ARP Inspection Configuration Using CLI

The following section provides procedures to configure Dynamic ARP Inspection (DAI) using CLI.

Enable or disable Dynamic ARP Inspection on a VLAN

You must enable DAI separately for each VLAN. When you enable DAI on a specific VLAN, the ARP packets are captured and inspected on that VLAN. DAI is disabled by default.

Note

DAI cannot be enabled on Private VLANs (E-Tree) and SPBM B-VLANs.

Before You Begin

You must enable DHCP Snooping globally.

Procedure

1. Enter VLAN Interface Configuration mode:

   ```
   enable

   configure terminal

   interface vlan <1-4059>
   ```

2. Enable DAI on the VLAN:

   ```
   ip arp-inspection enable
   ```

3. Disable DAI on the VLAN:

   ```
   no ip arp-inspection enable
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 5
Switch:1(config-if)#ip arp-inspection enable
```

Variable Definitions

The following table defines parameters for the **`ip arp-inspection`** command.

Variable	Value
`enable`	Enables or disables DAI on the specified VLAN.

Configuring Trusted and Untrusted Ports

Use the following procedure to set the trust factor associated with a port for DAI. By default, the trust factor is set to untrusted.

Note

For ports that are part of an MLT, DAI must be configured using the MLT configuration mode.

Before You Begin

You must enable DHCP Snooping globally.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface mlt <1-512>
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Set the trust factor for the port:

   ```
   ip arp-inspection <trusted|untrusted>
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#ip arp-inspection trusted
```

Variable Definitions

The following table defines parameters for the **ip arp-inspection** command.

Variable	Value
<trusted|untrusted>	Specifies the trust factor of the port for DAI.

Display Dynamic ARP Inspection Interface Information

Use the following procedure to view the DAI interface information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display DAI brouter port information:

   ```
   show ip arp-inspection interface [ gigabitEthernet [ {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} [ vrf WORD<1-16> | vrfids WORD<0-512> ] | <1-4059> [ {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} [ vrf WORD<1-16> | vrfids WORD<0-512> ] | vrf WORD<1-16> | vrfids WORD<0-512> ] | vrf WORD<1-16> | vrfids WORD<0-512> ] ]
   ```

3. Display DAI VLAN information:

   ```
   show ip arp-inspection vlan <1-4059>
   ```

4. Display DAI information for specific VRF name:

   ```
   show ip arp-inspection vrf WORD<1-16>
   ```

5. Display DAI information for specific VRF ID:

   ```
   show ip arp-inspection vrfids WORD<0-512>
   ```

Example

```
Switch:1>show ip arp-inspection interface gigabitEthernet 1/2

FHS configuration

Configure IPv6 FHS features to enable IPv6 link security and management over the Layer 2 links.

Enable or Disable FHS Globally

About This Task

You must enable First Hop Security globally for RA Guard or DHCPv6 Guard to be operational.

Enabling FHS globally installs the required filters for FHS. Disabling FHS, uninstalls these filters. By default, FHS is disabled.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable First Hop Security globally:

   ```
   ipv6 fhs enable
   ```

3. Disable First Hop Security globally:

   ```
   no ipv6 fhs enable
   ```

   OR

   ```
   default ipv6 fhs enable
   ```

Managing the FHS IPv6 access list

About This Task

You can create an FHS IPv6 access list or add IPv6 prefixes to an existing IPv6 access list.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create an FHS IPv6 access list or add IPv6 prefixes to an existing IPv6 access list:

   ```
   ipv6 fhs ipv6-access-list [WORD<1-64>] [WORD<0-46>] [ge<0-128>] [le
   <0-128>] [mode <allow | deny>]
   ```

3. Delete an FHS IPv6 access list or delete a particular IPv6 prefix from the IPv6 access list:

   ```
   no ipv6 fhs ipv6-access-list [WORD<1-64>] [WORD<0-46>]
   ```

4. Set the ge/le values and mode of the FHS IPv6 access list to default value:

   ```
   default ipv6 fhs ipv6-access-list [WORD<1-64>] [WORD<0-46>] [ge|le|
   mode]
   ```

Example

```
Switch>enable
Switch#config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)#ipv6 fhs ipv6-access-list ipv6_acl_1 fe80::221:2fff:fe31:5376/64
Switch(config)#
```

Variable Definitions

The following table defines parameters for the **ipv6 fhs ipv6-access-list** command.

Variable	Description
WORD<1-64>	Specifies the IPv6 access list name.
WORD<0-46>	Specifies the IPv6 address or the prefix length to be added to the IPv6 access list.
ge <0 -128>	Specifies the minimum value of prefix length advertised in prefix information of RA or DHCPv6 packets. By default, the value is equal to the configured prefix length. Note: If you manually configure the value, ensure that it is greater than the configured prefix length. Also ensure, the ge value is always less than the le value.
le <0 -128>	Specifies the maximum value of prefix length advertised in prefix information of RA or DHCPv6 packets. By default, the value is equal to the configured prefix length. Note: If you manually configure the value, ensure that it is greater than the configured prefix length.
mode <allow | deny>	Specifies the access mode. By default, the value is allow.

Displaying FHS IPv6 access list information

About This Task

Displays the current FHS IPv6 access list information.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Display the current FHS IPv6 access list information:
   ```
   show ipv6 fhs ipv6-access-list [WORD<1-64>]
   ```

Example

```
Switch:1# show ipv6 fhs ipv6-access-list

================================================================================
                        IPv6 FHS Access List Table Info

--------------------------------------------------------------------------------

All 2 out of 2 Total Num of ipv6 access list entries displayed
```

Managing the FHS MAC access list

About This Task

You can create an FHS MAC access list or add MAC addresses to an existing MAC access list.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create an FHS MAC access list or add MAC addresses to an existing MAC access list:

   ```
   ipv6 fhs mac-access-list WORD<1-64> <0x00:0x00:0x00:0x00:0x00:0x00>
   [mode <allow | deny>]
   ```

3. Delete an FHS MAC access list or delete a particular MAC address from the MAC access list:

   ```
   no ipv6 fhs mac-access-list WORD<1-64> <0x00:0x00:0x00:0x00:0x00:0x00>
   ```

4. Set the MAC ACL mode to its default value:

   ```
   default ipv6 fhs mac-access-list WORD<1-64>
   <0x00:0x00:0x00:0x00:0x00:0x00> [mode]
   ```

Variable Definitions

The following table defines parameters for the **`ipv6 fhs mac-access-list`** command.

Variable	Description
WORD<1-64>	Specifies the MAC access list name.
< 0x00:0x00:0x00:0x00: 0x00:0x00>	Specifies the MAC address to be added or deleted.
mode <allow | deny>	Specifies the access mode. By default, the value is Allow

Displaying FHS MAC access list information

About This Task

Displays the current FHS MAC access list information.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display the current FHS MAC access list information:

   ```
   show ipv6 fhs mac-access-list [WORD<1-64>]
   ```

Example

```
Switch#show ipv6 fhs mac-access-list
================================================================
IPv6 FHS Mac Access List Table Info
================================================================
ACC-LIST-NAME      MAC-ADDRESS            ACL-MODE
```

                   00:11:22:33:44:55         Deny
-------------------------------------------------------------
All 1 out of 1 Total Num of MAC access list entries displayed
-------------------------------------------------------------
```

Displaying current FHS configuration

About This Task

Displays the current FHS configuration.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display the current FHS configuration:

   ```
   show ipv6 fhs port-policy {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

Example

```
Switch:1#show ipv6 fhs port-policy

================================================================================
                          IPv6 FHS Port Policy Info

```

DHCPv6 Guard Policy Configuration

DHCPv6 Guard policy blocks DHCPv6 reply and advertisement messages that originate from unauthorized DHCPv6 servers and relay agents that forward DHCPv6 packets from servers to clients.

Enable or Disable DHCPv6 Guard Globally

About This Task

Enabling DHCPv6 Guard globally installs filters on the configured interfaces. By default, DHCPv6 Guard is disabled.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable FHS globally:

   ```
   ipv6 fhs enable
   ```

3. Enable DHCPv6 Guard globally:
   ```
   ipv6 dhcp-guard enable
   ```
4. Disable DHCPv6 Guard globally:
   ```
   no ipv6 dhcp-guard enable
   ```
5. Set DHCPv6 Guard to its default value:
   ```
   default ipv6 dhcp-guard enable
   ```

Manage the DHCPv6 Guard Policy

About This Task

Configure or modify the DHCPv6 Guard policy.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Create a DHCPv6 Guard policy:
   ```
   ipv6 dhcp-guard policy WORD<1-64>
   ```
3. Delete a DHCPv6 Guard policy:
   ```
   no ipv6 dhcp-guard policy WORD<1-64>
   ```

   Note
   You cannot delete a policy that is already attached to a port.

Variable Definitions

The following table defines parameters for the **`ipv6 dhcp-guard policy`** command.

Variable	Description
WORD<1-64>	Specifies the created or deleted DHCPv6 Guard policy name.

Attach a DHCPv6 Guard Policy to a Port

About This Task

Applies a DHCPv6 Guard policy to a specific interface.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Apply a DHCPv6 Guard policy.

   ```
   ipv6 fhs dhcp-guard attach-policy WORD<1-64>
   ```

3. Detach a DHCPv6 Guard policy from an interface.

   ```
   no ipv6 fhs dhcp-guard attach-policy
   ```

   OR

   ```
   default ipv6 dhcp-guard attach-policy
   ```

4. Enable device role verification attached to the port. By default, router is selected.

   ```
   ipv6 fhs dhcp-guard device-role {client|server} attach-policy WORD<1-64>
   ```

   Note
   A DHCPv6 Guard policy can be attached to a port only if the device-role configured on that port is 'server'.

Variable Definitions

The following table defines parameters for the **ipv6 fhs dhcp-guard attach-policy** and **ipv6 fhs dhcp-guard device-role** command.

Variable	Description
WORD<1-64>	Specify the name of the DHCPv6 Guard policy to be attached or detached.
{client | server}	Sets the DHCPv6 Guard device role as client or server.

Configure DHCPv6 Guard in dhcp-guard Mode

About This Task

Configures DHCPv6 Guard under dhcp-guard mode.

Procedure

1. Enter DHCP-guard Configuration mode.

   ```
   enable

   configure terminal

   ipv6 fhs dhcp-guard policy WORD<1-64>
   ```

2. Specify IPv6 access list to verify IPv6 source address of DHCPv6 packets..

   ```
   match server access-list <ipv6-access-list-name>
   ```

3. Remove DHCPv6 Guard filtering for the sender's IPv6 addresses.

   ```
   no match server access-list
   ```

   OR

   ```
   default match server access-list
   ```

4. Specify IPv6 prefix list to verify advertised prefixes.

   ```
   match reply prefix-list <ipv6-prefix-list-name>
   ```

5. Remove DHCPv6 Guard filtering for advertised prefixes.

   ```
   no match reply prefix-list
   ```

   OR

   ```
   default match reply prefix-list
   ```

6. Specify the minimum limit for verification of the advertised preference.

   ```
   preference min-limit <0-255>
   ```

7. Set the minimum limit for verification of the advertised preference to its default value.

   ```
   default preference min-limit
   ```

8. Specify the maximum limit for verification of the advertised preference.

   ```
   preference max-limit <0-255>
   ```

9. Set the maximum limit for verification of the advertised preference to its default value.

   ```
   default preference max-limit
   ```

Variable Definitions

The following table defines parameters for the **dhcp-guard** configuration mode commands.

Variable	Description
match server access-list *<ipv6-access-list-name>*	Enables verification of the sender's IPv6 address in inspected messages from the configured authorized device source access list specified. Note: If the access-list is not attached, the IPv6 source address in DHCPv6 packet is not validated. If the list is attached and it does not match any entries in IPv6 access list, the switch drops the DHCPv6 packet. If you wish to change this behavior, add an entry with IPv6 prefix"0::0/0" with the Allow option, which changes the default drop to default Allow.
{ no | default } match server access-list	Removes the sender's IPv6 address based DHCPv6 Guard filtering.
match reply prefix-list *<ipv6-prefix-list-name>*	Enables verification of the advertised prefixes in DHCPv6 reply messages from the configured authorized prefix list. If prefix-list is not configured, this check is bypassed. Note: If the access-list is not attached, the inspection does not occur. If the list is attached and advertised IPv6 address does not match any IPv6 prefixes in the list, the switch drops the DHCPv6 packet. If you wish to change this behavior, add an IPv6 access list entry with prefix 0::0/0 with the Allow option, which changes the default drop to default Allow.
{ no | default } match reply prefix-list	Removes the advertised prefix-based DHCPv6 Guard filtering.
preference min-limit<0-255>	Enables validation of advertised preference (in preference option) to check if it is greater than the specified limit. If preference is not specified, this field in the packet is not validated. While changing the preference limit, ensure the maximum limit is greater than the minimum limit.
default preference min-limit	Sets the specified limit to its default value. By default, the value is 0.
preference max-limit<0-255>	Enables validation of advertised preference (in preference option) to check if it is less than the specified limit. If preference is not specified, this field in the packet is not validated. Note: The preference value in the packet is not validated if both minimum and maximum values are zero.
default preference max-limit	Sets the specified limit to its default value. By default, the value is 0.

Display the DHCPv6 Guard Policy

About This Task

Displays DHCPv6 Guard policy information for all the configured DHCPv6 Guard policies or a particular policy.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display DHCPv6 Guard policy information:

   `show ipv6 fhs dhcp-guard policy` *`WORD<1-64>`*

Example

```
Switch:1# show ipv6 fhs dhcp-guard policy

================================================================================================
========
                                    IPv6 DHCP Guard Policy Info
================================================================================================
========
POLICY-NAME          SERVER-ACC-LIST      REPLY-PREF-LIST     MIN-RTR-PREF MAX-RTR-PREF
------------------------------------------------------------------------------------------------
--------
dhcp_pol1            v6_acl1              v6_acl2             0            0
------------------------------------------------------------------------------------------------
--------

All 1 out of 1 Total Num of dhcp-guard stats entries displayed
```

Variable Definitions

The following table defines parameters for the `show ipv6 fhs dhcp-guard policy` command.

Variable	Description
`WORD<1-64>`	Displays DHCPv6 Guard policy information for all the configured DHCPv6 Guard policies. Policy name is an optional parameter. If policy name is provided, only the DHCPv6 Guard policy of the specified policy-name is displayed.

RA Guard Configuration

IPv6 RA Guard provides support to the administrator to block or reject unwanted RA Guard messages that arrive at the network switch platform. The routers use Router Advertisements (RAs) to announce themselves on the link. The RA Guard feature analyzes these RAs and filters out bogus RAs sent by unauthorized routers. The RA Guard feature compares configuration information on the Layer 2 device with the information found in the received RA frame. After the Layer 2 device validates the content of the RA packet against the configuration, it forwards the RA to its destination. If the RA packet validation fails, the RA is dropped.

Enable or Disable RA Guard Globally

About This Task

Enables RA Guard globally. By default, RA Guard is disabled.

Procedure

1. Enter Global Configuration mode:
   ```
   enable
   configure terminal
   ```
2. Enable FHS globally:
   ```
   ipv6 fhs enable
   ```
3. Enable RA Guard globally:
   ```
   ipv6 fhs ra-guard enable
   ```
4. Disable RA Guard globally:
   ```
   no ipv6 fhs ra-guard enable
   ```
5. Set the RA Guard to its default value:
   ```
   default ipv6 fhs ra-guard enable
   ```

Manage the RA Guard Policy

About This Task

Configure or modify RA Guard policy. This command also enables the RA Guard configuration mode.

Procedure

1. Enter Global Configuration mode:
   ```
   enable
   configure terminal
   ```
2. Create the RA Guard policy:
   ```
   ipv6 fhs ra-guard policy WORD<1-64>
   ```
3. Delete the RA Guard policy:
   ```
   no ipv6 fhs ra-guard policy WORD<1-64>
   ```

Note
You cannot delete a policy that is attached to a port.

Variable Definitions

The following table defines parameters for the **`ipv6 fhs ra-guard policy`** command.

Variable	Description
WORD<1-64>	Specifies the name of the RA Guard policy to be created or deleted. This is a mandatory parameter in this command.

Configure RA Guard on an Interface

About This Task

Attaches or detaches a RA Guard policy on the specific interface.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:
   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Apply a RA Guard policy.
   ```
   ipv6 fhs ra-guard attach-policy WORD<1-64>
   ```

   Note
   RA Guard device-role on the port has to be configured as 'router' before attaching any RA Guard policy to the port. If device-role on the port is not 'router', this command will fail with an appropriate error message.

3. Detach a RA Guard policy from an interface.
   ```
   no ipv6 fhs ra-guard attach-policy
   ```

   OR

   ```
   default ipv6 fhs ra-guard attach-policy
   ```

4. Enable device role verification attached to the port.
   ```
   ipv6 fhs ra-guard device-role {router|host} attach-policy WORD<1-64>
   ```

   Note
   A DHCPv6 Guard policy can be attached to a port only if the device-role configured on that port is 'server'.

Variable Definitions

The following table defines parameters for the **ipv6 fhs ra-guard attach-policy** and **ipv6 fhs ra-guard device-role** command.

Variable	Description
WORD<1-64>	Specifies the name of the RA Guard policy to be attached or detached.
{host | router}	Sets the RA Guard device role as host or router.

Configure RA Guard in RA Guard Mode

About This Task

Configures RA Guard in the RA Guard configuration mode.

Procedure

1. Enter RA Guard Configuration mode.

   ```
   enable

   configure terminal

   ipv6 fhs ra-guard policy WORD<1-64>
   ```

2. Configure the filter to match the IPv6 prefixes advertised in RA packets.

   ```
   match ra-prefix-list WORD<1-64>
   ```

3. Remove RA Guard filtering for the advertised prefixes.

   ```
   no match ra-prefix-list
   ```

   OR

   ```
   default match ra-prefix-list
   ```

4. Configure the filter to match the source MAC address of RA packets.

   ```
   match ra-macaddr-list WORD<1-64>
   ```

5. Remove the source MAC address-based RA Guard filtering.

   ```
   no match ra-macaddr-list
   ```

   OR

   ```
   default match ra-macaddr-list
   ```

6. Configure the filter to match source IPv6 address of RA packets.

   ```
   match ra-srcaddr-list WORD<1-64>
   ```

7. Remove the source IPv6 address based RA Guard filtering.

   ```
   no match ra-srcaddr-list
   ```

   OR

   ```
   default match ra-srcaddr-list
   ```

8. Enable managed address configuration flag verification in the advertised RA packet.

   ```
   managed-config-flag <none |on | off>
   ```

9. Enable advertised hop count limit verification.

   ```
   hop-limit {maximum | minimum} <0-255>
   ```

10. Enable the advertised default router-preference parameter value verification.

    ```
    router-preference maximum {none | high | low | medium}
    ```

Variable Definitions

The following table defines parameters to configure RA Guard policy.

Variable	Description
match ra-prefix-list *WORD<1–64>*	Verifies the advertised prefixes in RA packets against the configured authorized prefix list. Note: RA packet's sender IPv6 address is not validated if no IPv6 source access list is attached to the RA Guard policy. If the list is attached and if RA packet's sender IPv6 address does not match any entry in that IPv6 prefix list, then the RA packet is dropped. To change this behavior, add a entry with ipv6 prefix“0::0/0” with Allow option. The default value changes from Drop to Allow.
{no | default} match ra-prefix-list	Removes the advertised prefix-based RA Guard filtering
match ra-macaddr-list *WORD<1–64>*	Verifies sender’s source MAC address against the configured mac-access-list. Note: Advertised prefixes in RA packet are not validated if no IPv6 prefix list is attached to the RA Guard policy. If the list is attached and if it does not match any MAC in the list, then the RA packet is dropped.
{no | default} match ra-macaddr-list	Removes the source MAC address-based RA Guard filtering for the specified MAC address access list names.
match ra-srcaddr-list *WORD<1–64>*	Verifies sender’s source IPV6 address against the configured list. Note: Inspection is not done if the access-list is not attached. If the list is attached and if it does not match any IPv6 in the list, then the RA packet is dropped. To change the behavior, add a dummy IPv6 “0:0:0:0:0:0” to the list with Allow option. The default value changes from Drop to Allow.
{no | default} match ra-srcaddr-list	Removes the source IPv6 address-based RA Guard filtering for the specified IPv6 address access list names.
managed-config-flag <*none | on | off*>	Verifies managed address configuration flag in the advertised RA packet. By default, the value is none and check is bypassed.
hop-limit {maximum | minimum} <*0–255*>	Verifies the advertised hop count limit. The limit value range is from 0 to 255. While changing the minimum or maximum value, ensure the maximum value is greater than the minimum value. By default, the minimum and maximum limit are 0. In this case, the hop-limit check is bypassed.
router-preference maximum {none | high | low | medium}	Verifies if the advertised default router-preference parameter value is lower than or equal to a specified limit. By default, the value is none and the check is bypassed.

Display RA Guard Configuration

About This Task

Display configured RA Guard policy information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display configured RA Guard policy information:

   `show ipv6 fhs ra-guard policy WORD<1-64>`

Example

```
Switch:1# show ipv6 fhs ra-guard policy
================================================================================================================
                                          IPv6 Ra Guard Policy Info
================================================================================================================
                                                                                  MIN-HOP MAX-HOP MANAGED
POLICY-NAME    RA-SRC-ADDR-LIST  RA-MAC-ADDR-LIST  RA-PREFIX-LIST   LIMIT    LIMIT   CON-FLAG PREF
----------------------------------------------------------------------------------------------------------------
 Ra_guard_pol1    None              None              acl1           0        0         None            None
----------------------------------------------------------------------------------------------------------------

All 1 out of 1 Total Num of ra-guard policy entries displayed
```

Variable Definitions

The following table defines parameters for the **`show ipv6 fhs ra-guard policy`** command.

Variable	Description
WORD<1-64>	Displays the RA Guard policy for the specified policy-name. By default, all the configured RA Guard policies are displayed.

IPv6 Neighbor Discovery inspection configuration

This section describes how to configure ND inspection on the switch and protect the network by mitigating the various types of attacks.

Important

Enable FHS globally before enabling ND inspection.

Enabling ND inspection globally

Before You Begin

Enable FHS globally for ND inspection to work.

About This Task

Use this procedure to enable Neighbor Discovery (ND) inspection globally.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable ND inspection globally:

   ```
   ipv6 fhs nd-inspection enable
   ```

Clear Neighbor Discovery Inspection Statistics

About This Task

Use this procedure to clear the Neighbor Discovery inspection statistics.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Clear the Neighbor Discovery inspection statistics:

   ```
   clear ipv6 fhs statistics nd-inspection [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
   ```

   Note

   Alternatively, you can use the command `clear ipv6 fhs statistics all` to clear the ND inspection statistics along with RA guard statistics and DHCPv6 Guard statistics.

Variable Definitions

The following table defines parameters for the **`clear ipv6 fhs statistics nd-inspection`** command.

Variable	Value
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Enabling Neighbor Discovery inspection on a VLAN

Before You Begin

Enable FHS globally for ND inspection to work.

About This Task

Use this procedure to enable Neighbor Discovery inspection on a VLAN.

Procedure

1. Enter VLAN Interface Configuration mode:

   ```
   enable

   configure terminal

   interface vlan <1-4059>
   ```

2. Enable Neighbor Discovery inspection on the VLAN:

   ```
   ipv6 fhs nd-inspection enable
   ```

Enabling Neighbor Discovery inspection on a port

Before You Begin

Enable FHS globally for ND inspection to work.

About This Task

Use this procedure to enable Neighbor Discovery inspection on a port

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Neighbor Discovery inspection on the port:

   ```
   ipv6 fhs nd-inspection enable
   ```

Viewing Neighbor Discovery inspection status globally

About This Task

Use this procedure to view the Neighbor Discovery inspection status globally

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display the ND inspection status globally:

   ```
   show ipv6 fhs status
   ```

Viewing Neighbor Discovery inspection status on a port

About This Task

Use this procedure to view Neighbor Discovery inspection status on a port.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Display port-wise ND inspection status:
   ```
   show ipv6 fhs port-policy
   ```

Viewing Neighbor Discovery inspection statistics on a port

About This Task

Use this procedure to view the Neighbor Discovery inspection statistics on a port or set of ports.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Display ND inspection statistics on a port or a set of ports:
   ```
   show ipv6 fhs statistics nd-inspection {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
   ```

Variable Definitions

The following table defines parameters for the **`show ipv6 fhs statistics nd-inspection`** command.

Variable	Value
`{slot/port[/sub-port][-slot/port[/sub-port]][,...]}`	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

IPv6 DHCP Snooping Configuration

This section describes how to configure IPv6 DHCP snooping on the switch and protect the network by mitigating the various types of attacks.

Important

Configure DHCPv6 Guard before enabling IPv6 DHCP snooping. DHCPv6 Guard classifies the ports as trusted or untrusted and extracts DHCPv6 reply packets received on trusted ports to the control path. For more information on how to configure DHCPv6 Guard, see DHCPv6 Guard Policy Configuration on page 1830.

Creating a static Security Binding Table entry

Use this procedure to enable learning Security Binding Table (SBT) entries on all the VLANs where IPv6 DHCP snooping is configured.

About This Task

Use this procedure to create a static SBT entry.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Add a static SBT entry:
   ```
   ipv6 fhs snooping static-binding ipv6-address WORD<0-46> vlan <1-4059>
   mac-address 0x00:0x00:0x00 port {slot/port[/sub-port]}
   ```

   Note
   To delete an SBT entry, use the command `no ipv6 fhs snooping static-binding`.

Example

Add a static SBT entry.

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)#ipv6 fhs snooping static-binding ipv6-address
2001:DB8:89ab:cdef:0123:4567:89ab:cdef vlan 1000 mac-address 00:11:22:33:44:55 port 1/2
```

Variable Definitions

The following table defines parameters for the **`ipv6 fhs snooping static-binding ipv6-address`** command.

Variable	Value
mac-address 0x00:0x00:0x00	Specifies the MAC address of the binding entry.
port {slot/port[/sub-port]}	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
vlan <1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
WORD<0-46>	Specifies the IPv6 address for the binding entry.

Clearing a dynamic SBT entry

About This Task

Use this procedure to clear all or a particular dynamic SBT entry.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Clear a dynamic SBT entry:
   ```
   clear ipv6 fhs snooping [vlan <1-4059>][ipv6-address WORD<0-46>]
   ```

Example

Clear a dynamic SBT entry on a VLAN.

```
Switch:1> enable
Switch:1>clear ipv6 fhs snooping vlan 1000 ipv6-address
2001:DB8:89ab:cdef:0123:4567:89ab:cdef
```

Variable Definitions

The following table defines parameters for the **`clear ipv6 fhs snooping`** command.

Variable	Value
`ipv6-address WORD<0-46>`	Specifies the IPv6 address for the binding entry to clear. You cannot specify an address without first specifying the VLAN.
`vlan <1-4059>`	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *`vrf-scaling`* and *`spbm-config-mode`* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. If you do not specify a VLAN, the command clears all entries.

Enable IPv6 DHCP Snooping on a VLAN

Before You Begin

Enable IPv6 DHCPv6 Guard for IPv6 DHCP snooping to work.

About This Task

Use this procedure to configure IPv6 DHCP snooping on a VLAN.

Procedure

1. Enter VLAN Interface Configuration mode:
   ```
   enable

   configure terminal

   interface vlan <1-4059>
   ```
2. Configure IPv6 DHCP snooping on the VLAN:
   ```
   ipv6 fhs snooping dhcp enable
   ```

Viewing IPv6 DHCP snooping and ND inspection status on a VLAN

About This Task

Use this procedure to view IPv6 DHCP snooping and ND inspection status on a VLAN.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. View the IPv6 DHCP snooping and ND inspection status on a VLAN:
   ```
   show ipv6 fhs status vlan [<1-4059>]
   ```

Example

View the status for all VLANs.

```
Switch:1#show ipv6 fhs status vlan

================================================================================================
                            IPv6 FHS VLAN Information

================================================================================================
VLAN-ID              DHCP-SNOOPING-STATUS           ND-INSPECTION-STATUS
------------------------------------------------------------------------------------------------
1                    Disabled                       Disabled
3                    Disabled                       Disabled
4                    Disabled                       Disabled
22                   Disabled                       Disabled
------------------------------------------------------------------------------------------------

All 4 out of 4 Total Num of FHS VLAN entries displayed
```

Variable Definitions

The following table defines parameters for the **`show ipv6 fhs status vlan`** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *`vrf-scaling`* and *`spbm-config-mode`* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. If you do not specify a VLAN ID, the command output includes all VLANs.

Viewing SBT entries

About This Task

Use this procedure to view SBT entries.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```

2. View all SBT entries:

   ```
   show ipv6 fhs snooping binding
   ```

3. View the SBT entries by type:

   ```
   show ipv6 fhs snooping binding type {dynamic | static}
   ```

4. View the SBT entries by VLAN:

   ```
   show ipv6 fhs snooping binding vlan <1-4059>[ipv6-address WORD<0-46>]
   ```

Variable Definitions

The following table defines parameters for the **`show ipv6 fhs snooping binding`** command.

Variable	Value
`ipv6-address WORD<0-46>`	Specifies the IPv6 address for the binding entry.
`type {dynamic | static}`	Shows only dynamic binding entries or static binding entries.
`vlan <1-4059>`	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *`vrf-scaling`* and *`spbm-config-mode`* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

IP Source Guard Configuration

The following sections provide procedural information you can use to configure IP Source Guard (IPSG) using the Command Line Interface (CLI).

Note

The switch supports configuration of IP Source Guard for both IPv4 and IPv6 addresses.

Enable IP Source Guard on a Port for IPv4 Addresses

About This Task

Enable IP Source Guard (IPSG) on a port to add a higher level of security to the port by preventing IP spoofing. When you enable IPSG on the interface, filters are automatically installed for the IPv4 addresses that are already learned on that interface.

Important

Do not enable IPSG on MLT, DMLT, SMLT, LAG, trunk ports or ports that are a part of private VLANs.

Before You Begin

Ensure that the following conditions are all satisfied, before you enable IPSG on a port. Otherwise, the system displays error messages.

- DHCP Snooping is enabled globally.
- The port is a member of a VLAN that is configured with both DHCP Snooping and Dynamic ARP Inspection.
- The port is an untrusted port enabled with both DHCP Snooping and Dynamic ARP Inspection.
- The port has enough resources allocated, to support the maximum number of 10 IP addresses allowed for IPSG.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable IPSG on the port:

   ```
   ip source verify enable
   ```

3. Verify IPSG configuration:

   ```
   show ip source verify interface gigabitethernet [{slot/port[/sub-port]
   [-slot/port[/sub-port]] [,...]}]
   ```

Example

Configure IPSG on port 4/1.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 4/1
Switch:1(config-if)#ip source verify enable
```

Verify the configuration.

```
Switch:1(config-if)#show ip source verify interface gigabitEthernet

Variable Definitions

The following table defines parameters for the **`ip source verify`** command.

Variable	Value
enable	Enables IP Source Guard on the port.

Disable IP Source Guard for IPv4 Addresses

About This Task

Disable IP Source Guard (IPSG) on a port to allow traffic from all IPv4 addresses to go through the port without being filtered.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Disable IPSG for IPv4 addresses:

   ```
   no ip source verify
   ```

3. Verify IPSG configuration:

   ```
   show ip source verify interface gigabitethernet [{slot/port[/sub-port]
   [-slot/port[/sub-port]] [,...]}]
   ```

Example

Disable IPSG on port 4/1.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 4/1
Switch:1(config-if)#no ip source verify
```

Verify the configuration.

```
Switch:1(config-if)#show ip source verify interface gigabitEthernet 4/1

```

View IP Source Guard Configuration on a Port

About This Task

View IP Source Guard (IPSG) configuration on a port, with filters for IPv4 addresses.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View IPSG configuration:

   `show ip source verify interface gigabitEthernet [{`*`slot/port[/sub-port] [-slot/port[/sub-port]] [,...]`*`}]`

Example

```
Switch:1>show ip source verify interface gigabitEthernet 4/1

================================================================================
                            Source Guard Port Info
================================================================================
PORT                    IPSC
NUM        ENABLE       ORIGIN
--------------------------------------------------------------------------------
4/1        true         RADIUS
--------------------------------------------------------------------------------

All 1 out of 1 Total Num of Ip Source Guard entries displayed
```

Variable Definitions

The following table defines parameters for the **show ip source verify interface gigabitEthernet** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

View IPv4 Address Bindings

About This Task

View the IPv4 address bindings that IP Source Guard (IPSG) allows.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the allowed IPv4 address bindings for a specific interface:
   `show ip source binding [interface gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]|[vlan <1-4059>]|[vrf WORD<1-16>]|[vrfids WORD<0-512>]`
3. View the allowed IPv4 address bindings for a specific IP address:
   `show ip source binding {A.B.C.D}`

Example

View the allowed IPv4 address bindings for the port 4/1.

```
Switch:1>show ip source binding interface gigabitEthernet 4/1

================================================================================================
                                                    IPSG Source Table
================================================================================================
PORT       IP              VLAN    VRF
NUM        ADDRESS         ID      NAME
------------------------------------------------------------------------------------------------
4/1        192.0.2.1       200     GlobalRouter
------------------------------------------------------------------------------------------------

All 1 out of 1 Total IP Source Guard entries displayed
```

View the IPv4 address bindings for a specific IP address.

```
Switch:1>show ip source binding 192.0.2.1

================================================================================================
                                                    IPSG Source Table
================================================================================================
PORT       IP              VLAN    VRF
NUM        ADDRESS         ID      NAME
------------------------------------------------------------------------------------------------
4/1        192.0.2.1       200     GlobalRouter
------------------------------------------------------------------------------------------------
```

```
All 1 out of 1 Total IP Source Guard entries displayed
```

Variable Definitions

The following table defines parameters for the **show ip source binding** command.

Variable	Value
{A.B.C.D}	Identifies the IPv4 address.
interface gigabitEthernet *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
vlan *<1-4059>*	Specifies the VLAN ID of the VLAN for which to view IPv4 address bindings.
vrf *WORD<1-16>*	Specifies the VRF name of the VRF for which to view the IPv4 address bindings.
vrfids *WORD<0-512>*	Specifies the VRF ID of the VRF for which to view IPv4 address bindings.

Enable IP Source Guard on a Port for IPv6 Addresses

About This Task

Enable IP Source Guard (IPSG) on a port, to add a higher level of security to the port by preventing IP spoofing. When you enable IPSG on the interface, filters are installed for IPv6 addresses that are already learned on that interface.

Important

Do not enable IPSG on MLT, DMLT, SMLT, LAG, trunk ports or ports that are a part of private VLANs.

Before You Begin

Ensure that the following conditions are all satisfied, before you enable IPSG on a port. Otherwise, the system displays error messages.

- DHCP Snooping is enabled globally.
- The port is a member of a VLAN that is configured with both DHCP Snooping and IPv6 Neighbor Discovery inspection.
- The port is an untrusted port enabled with both DHCP Snooping and IPv6 Neighbor Discovery inspection.
- The port has enough resources allocated, to support the maximum number of 10 IP addresses allowed for IPSG.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the maximum number of allowed IPv6 addresses on a port:

   ```
   ipv6 source-guard [max-allowed-addr <2-10>]
   ```

   Note

   Ensure that you configure the maximum number of allowed IPv6 addresses on a port, before you enable IPSG on that port.

3. Enable IPSG on the port:

   ```
   ipv6 source-guard enable
   ```

4. Verify IPSG configuration information on the port:

   ```
   show ipv6 source-guard interface gigabitEthernet [{slot/port[/sub-
   port] [-slot/port[/sub-port]] [,...]}]
   ```

Example

Enable IPSG on a port.

Configure the maximum allowed IPv6 addresses on port 4/1 as 10 and enable IPSG on that port.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 4/1
Switch:1(config-if)#ipv6 source-guard max-allowed-addr 10
Switch:1(config-if)#ipv6 source-guard enable
```

Verify the configuration.

```
Switch:1(config-if)#show ipv6 source-guard interface gigabitEthernet 4/1
Slot/Port  Source Guard  Number of  IPv6  Address
             Mode        address allowed  overflow count
=========================================================
4/1          Enabled           10          0
```

Optionally view all interfaces with IPSG enabled.

```
Switch:1(config-if)#show ipv6 source-guard interface enabled
Slot/Port  Source Guard  Number of  IPv6  Address
             Mode        address allowed  overflow count
=========================================================
4/1          Enabled            4           0
3/1          Enabled            9           0
```

Variable Definitions

The following table defines parameters for the **ipv6 source-guard** command.

Variable	Value
enable	Enables IP Source Guard on a port.
max-allowed-addr <2-10>	Specifies the maximum number of IPv6 addresses allowed to transmit data through the port. The default value is 4. Note: To reset the value to default, IPSG must be disabled on the interface.

Disable IP Source Guard for IPv6 Addresses

About This Task

Disable IP Source Guard (IPSG) on a port to allow traffic from all IPv6 addresses to go through the port without being filtered.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:
   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Disable IPSG for IPv6 addresses on a port:
   ```
   no ipv6 source-guard enable
   ```
3. Verify IPSG configuration on the port:
   ```
   show ipv6 source-guard interface gigabitEthernet [{slot/port[/sub-
   port] [-slot/port[/sub-port]] [,...]}]
   ```

Example

Disable IPSG on port 4/1.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 4/1
Switch:1(config-if)no ipv6 source-guard enable
```

Verify the configuration.

```
Switch:1(config-if)#show ipv6 source-guard interface gigabitEthernet 4/1
Slot/Port  Source Guard  Number of  IPv6  Address
```

```
             Mode        address allowed  overflow count
=============================================================
4/1          Disabled          10          0
```

Clear IP Source Guard Overflow Counters

About This Task

Overflow counters consist of IPv6 addresses that are not added to IP Source Guard (IPSG) due to lack of filter resources. Use this procedure to clear the overflow counters for an IPSG port.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:
   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Clear the overflow counters:
   ```
   ipv6 source-guard overflow-count clear
   ```
3. Verify the configuration on the port:
   ```
   show ipv6 source-guard interface gigabitEthernet [{slot/port[/sub-
   port] [-slot/port[/sub-port]] [,...]}]
   ```
4. (Optional) View the overflow counters on all IPSG enabled ports:
   ```
   show ipv6 source-guard interface enabled
   ```

Example

Clear overflow counters on the IPSG port 4/1.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 4/1
Switch:1(config-if)#ipv6 source-guard overflow-count clear
```

Verify the configuration on port 4/1.

```
Switch:1(config-if)#show ipv6 source-guard interface gigabitEthernet 4/1
Slot/Port  Source Guard  Number of  IPv6  Address
             Mode        address allowed  overflow count
=============================================================
4/1          Enabled           10          0
```

Optionally view the overflow counters on all IPSG enabled ports.

```
Switch:1(config-if)#show ipv6 source-guard interface enabled
Slot/Port  Source Guard  Number of  IPv6  Address
             Mode        address allowed  overflow count
=============================================================
```

```
4/1          Enabled            4           0
3/1          Enabled            9           0
```

View IP Source Guard Configuration for IPv6 Addresses

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View IPSG configuration on a specified interface:

   `show ipv6 source-guard interface gigabitEthernet [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]`
3. View IPSG configuration on all IPSG enabled interfaces:

   `show ipv6 source-guard interface enabled`

Example

```
Switch:1#show ipv6 source-guard interface gigabitEthernet 4/1

Slot/Port  Source Guard  Number of  IPv6  Address
             Mode        address allowed  overflow count
============================================================
4/1          Enabled           4           0

Switch:1#show ipv6 source-guard interface enabled

Slot/Port  Source Guard  Number of  IPv6  Address
             Mode        address allowed  overflow count
============================================================
4/1          Enabled           4           0
4/2          Enabled           9           0
```

Variable Definitions

The following table defines parameters for the **`show ipv6 source-guard interface gigabitEthernet`** command.

Variable	Value
enabled	Displays IPSG configuration on all IPSG enabled interfaces.
gigabitEthernet *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*	Displays IPSG configuration on the specified interface. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

View IPv6 Address Bindings

About This Task

View the IPv6 address bindings that IP Source Guard (IPSG) allows.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. View the allowed IPv6 address bindings:

   `show ipv6 source-guard binding [WORD<0-46>] [interface gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]`

Example

View the IPv6 address bindings for port 1/3.

```
Switch:1>show ipv6 source-guard binding interface gigabitEthernet 1/3
Slot/Port    IPv6  Address
============================================================
1/3          2001::10:10:0:1
1/3          fe80::210:94ff:fe00:550b
------------------------------------------------------------
```

View the IPv6 address bindings for a specific IPv6 address.

```
Switch:1>show ipv6 source-guard binding fe80::210:94ff:fe00:550b
Slot/Port    IPv6  Address
============================================================
1/3          fe80::210:94ff:fe00:550b
------------------------------------------------------------
```

Variable Definitions

The following table defines parameters for the **`show ipv6 source-guard binding`** command.

Variable	Value
WORD<0-46>	Identifies the IPv6 address.
interface gigabitEthernet *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Layer 2 Security Configuration using EDM

Use the following sections to help you configure Layer 2 security features and protect the network by mitigating various types of attacks, using Enterprise Device Manager (EDM).

For IPv4 deployments, configure:

- DHCP Snooping
- Dynamic ARP Inspection
- IP Source Guard for IPv4 addresses

For IPv6 deployments, configure:

- First Hop Security (FHS)

  Note
  FHS does not solve all cases of denial of services like blocking flooding of the IPv6 messages.

- DHCP Snooping and IPv6 Neighbor Discovery Inspection
- IP Source Guard for IPv6 addresses

Dynamic ARP Inspection Configuration Using EDM

The following section provides procedures to configure Dynamic ARP Inspection (DAI) using EDM.

Configure Dynamic ARP Inspection on VLANs

Use the following procedure to enable or disable DAI on one or more VLANs.

Note
DAI cannot be enabled on Private VLANs (E-Tree) and SPBM B-VLANs.

Before You Begin

You must enable DHCP Snooping globally.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Click **ARP Inspection**.
3. Click the **ARP Inspection-VLAN** tab.
4. In the row for the VLAN, double-click the **Enabled** field, and select **true** to enable DAI.
5. Click **Apply**.

ARP Inspection-VLAN Field Descriptions

Use the data in the following table to use the **ARP Inspection-VLAN** tab.

Name	Description
VlanId	Specifies the VLAN ID.
Enabled	Specifies if DAI is enabled or disabled for the particular VLAN. By default, DAI is disabled.
Origin	Specifies the origin of Address Resolution Protocol (ARP) Inspection configuration on the VLAN. The supported values are: • config - Set by the user. • radius - Set by the Remote Authentication Dail-In User Service (RADIUS) attribute.

Configure Dynamic ARP Inspection on Ports

Use the following procedure to set the trust factor associated with a port for DAI . By default, the trust factor is set to untrusted.

Note

For ports that are part of an MLT, DAI must be configured using the MLT configuration mode.

Before You Begin

You must enable DHCP Snooping globally.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Click **ARP Inspection**.
3. Click the **ARP Inspection-port** tab.
4. In the row for the port, double-click the **IfTrusted** field, and select **trusted** or **untrusted** to set DAI.
5. Click **Apply**.

ARP Inspection-port Field Descriptions

Use the data in the following table to use the **ARP Inspection-port** tab.

Name	Description
Port	Specifies the port on the switch.
IfTrusted	Specifies the trust factor for DAI on the specific port. By default, it is set as untrusted.

Configure FHS Globals

About This Task

Use this procedure to enable FHS to enable DHCPv6 Guard, RA Guard, and ND-inspection globally, and to configure the lifetime for these policies.

Procedure

1. From the navigation pane, expand **Configuration** > **IPv6**.
2. Click **FHS**.
3. Click the **Globals** tab.
4. Select FHS global options.
5. Click **Apply** to save the changes.
6. (Optional) Click **Refresh** to update the results.

Globals *Field Descriptions*

Use the data in the following table to use the **Globals** tab.

Name	Description
Admin	Enables or disables the FHS policy.
RAGuardAdmin	Enables or disables the RA Guard policy.
DHCPv6GuardAdmin	Enables or disables the DHCPv6 Guard policy.
NdInspectAdmin	Enables or disables Neighbor Discovery inspection.

IPv6 access list configuration

An IPv6 access list is created to verify the sender's IPv6 address in the inspected messages. You can create, view, or delete an IPv6 access list.

Creating IPv6 access list

About This Task

Use this procedure to create an FHS IPv6 access list or add IPv6 prefixes to the existing IPv6 access list.

Procedure

1. In the navigation pane, expand **Configuration**—> **IPv6**.
2. Click **FHS**.
3. Click the **IPv6 Access List** tab.
4. Click **Insert**.
5. Configure the parameters for the IPv6 access list.
6. Click **Insert**.

IPv6 Access List field descriptions

Use the data in the following table to use the **IPv6 Access List** tab.

Name	Description
Name	Specify the IPv6 access list name to create the IPv6 access list.
Prefix	Specify the IPv6 prefix for adding it to the IPv6 access list.
PrefixMaskLen	Specify the prefix length for adding it to the IPv6 access list. The value range is from 0 to 128. By default, the value is 0.
MaskLenFrom	Specify the start mask length for providing the IPv6 range. The value range is from 0 to 128. By default, the value is set to the configured prefix length of the IPv6 access list entry.

Name	Description
MaskLenTo	Specify the end mask length for providing the IPv6 range. The value range is from 0 to 128. By default, the value is set to the configured prefix length of the IPv6 access list entry.
AccessType	Select the access type to allow or deny the entry. By default, the access type is allow.

Note

- **MaskLenFrom** and **MaskLenTo** must always be greater than or equal to the configured **PrefixMaskLen** for this IPv6 access list entry
- The **MaskLenFrom** value must always be less than or equal to the **MaskLenTo** value.

View IPv6 access List

About This Task

Use this procedure to display the IPv6 access list.

Procedure

1. In the navigation pane, expand **Configuration**—> **IPv6**.
2. Click **FHS**.
3. Click the **IPv6 Access List** tab.

IPv6 Access List field descriptions

Use the data in the following table to use the **IPv6 Access List** tab.

Name	Description
Name	Specify the IPv6 access list name to create the IPv6 access list.
Prefix	Specify the IPv6 prefix for adding it to the IPv6 access list.
PrefixMaskLen	Specify the prefix length for adding it to the IPv6 access list. The value range is from 0 to 128. By default, the value is 0.
MaskLenFrom	Specify the start mask length for providing the IPv6 range. The value range is from 0 to 128. By default, the value is set to the configured prefix length of the IPv6 access list entry.

Name	Description
MaskLenTo	Specify the end mask length for providing the IPv6 range. The value range is from 0 to 128. By default, the value is set to the configured prefix length of the IPv6 access list entry.
AccessType	Select the access type to allow or deny the entry. By default, the access type is allow.

Note

- **MaskLenFrom** and **MaskLenTo** must always be greater than or equal to the configured **PrefixMaskLen** for this IPv6 access list entry
- The **MaskLenFrom** value must always be less than or equal to the **MaskLenTo** value.

Delete the IPv6 Access List

About This Task

Use this procedure to delete the created IPv6 access list.

Procedure

1. In the navigation pane, expand **Configuration**—> **IPv6**.
2. Click **FHS**.
3. Click the **IPv6 Access List** tab.
4. Select a row from the IPv6 access list to delete.
5. Click **Delete**.

MAC access list configuration

A MAC access list is created to verify the sender's MAC address in the RA packet. You can view, create or delete a MAC access list.

Create MAC Access List

About This Task

Use this procedure to create a MAC access list or add a MAC address to the existing MAC access list.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **FHS**.
3. Click the **MAC Access List** tab.
4. Click **Insert**.
5. Configure the parameters for the MAC access list.
6. Click **Insert**.

MAC Access List field descriptions

Use the data in the following table to use the **MAC Access List** tab.

Name	Description
Name	Specify a name to create a MAC access list.
Mac	Specify the MAC address to add to the MAC access list, in (xx:xx:xx:xx:xx:xx) format.
AccessType	Specify allow or deny. By default, the access type is allow.

View a MAC Access List

About This Task

Use this procedure to display a configured MAC access list.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **FHS**.
3. Click the **MAC Access List** tab.

MAC Access List field descriptions

Use the data in the following table to use the **MAC Access List** tab.

Name	Description
Name	Specify a name to create a MAC access list.
Mac	Specify the MAC address to add to the MAC access list, in (xx:xx:xx:xx:xx:xx) format.
AccessType	Specify allow or deny. By default, the access type is allow.

Delete a MAC Access List

About This Task

Use this procedure to delete the created MAC access list.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **FHS**.
3. Click the **MAC Access List** tab.
4. Select a row from the MAC access list to delete.
5. Click **Delete**.

DHCPv6 Guard Policy Configuration

Configure the DHCPv6 Guard policy to block DHCPv6 reply and advertisement messages that originate from unauthorized DHCPv6 servers and relay agents that forward DHCPv6 packets from servers to clients. You can view, create or delete a DHCPv6 Guard policy.

Create DHCPv6 Guard Policy

About This Task

Use this procedure to create the DHCPv6 Guard policy to block DHCPv6 reply and advertisement messages that originate from unauthorized DHCPv6 servers and relay agents.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **FHS**.
3. Click the **DHCPv6 Guard Policy** tab.
4. Click **Insert**.
5. Configure the parameters for the DHCPv6 Guard policy.
6. Click **Insert**.
7. (Optional) Click **Refresh** to update the results.

DHCPv6 Guard Policy Field Descriptions

Use the data in the following table to use the **DHCPv6 Guard Policy** tab.

Name	Description
PolicyName	Specifies the policy name to create or modify DHCPv6 Guard policy.
ServerAccessListName	Enables verification of the sender IPv6 address in the DHCPv6 reply or advertisement packets against attached IPv6 server access list. Note: If the access-list is not attached, the source IPv6 address is not validated. If the list is attached and it does not match with any entries in attached IPv6 access list, the switch drops the DHCPv6 packet. To change this behavior, add an entry in the IPv6 access list with prefix 0::0/0 with access type as allow, which changes the drop by default to allow by default.

Name	Description
ReplyPrefixListName	Enables verification of the advertised prefixes in DHCPv6 reply messages against the attached prefix list. If not configured, this check is bypassed. Note: If the access-list is not attached, the advertised address/prefix is not validated. If the list is attached and it does not match with any entries in attached IPv6 access list, the switch drops the DHCPv6 packet. To change this behavior, an entry in the IPv6 access list with prefix 0::0/0 with access type as allow, which changes the drop by default to allow by default.
PrefLimitMin	Enables verification if the advertised preference (in reference option) is greater than the specified limit. If not specified, this check does not occur. The value range is from 0 to 255.
PrefixLimitMax	Enables verification if the advertised preference (in preference option) is less than the specified limit. If not specified, this check does not occur. The value range is from 0 to 255. Note: If both the maximum and minimum limit is 0, this preference check is ignored.

View a DHCPv6 Guard Policy

About This Task

Use this procedure to display configured DHCPv6 Guard policies.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **FHS**.
3. Click the **DHCPv6 Guard Policy** tab.

DHCPv6 Guard Policy Field Descriptions

Use the data in the following table to use the **DHCPv6 Guard Policy** tab.

Name	Description
PolicyName	Specifies the policy name to create or modify DHCPv6 Guard policy.
ServerAccessListName	Enables verification of the sender IPv6 address in the DHCPv6 reply or advertisement packets against attached IPv6 server access list. Note: If the access-list is not attached, the source IPv6 address is not validated. If the list is attached and it does not match with any entries in attached IPv6 access list, the switch drops the DHCPv6 packet. To change this behavior, add an entry in the IPv6 access list with prefix 0::0/0 with access type as allow, which changes the drop by default to allow by default.
ReplyPrefixListName	Enables verification of the advertised prefixes in DHCPv6 reply messages against the attached prefix list. If not configured, this check is bypassed. Note: If the access-list is not attached, the advertised address/prefix is not validated. If the list is attached and it does not match with any entries in attached IPv6 access list, the switch drops the DHCPv6 packet. To change this behavior, an entry in the IPv6 access list with prefix 0::0/0 with access type as allow, which changes the drop by default to allow by default.
PrefLimitMin	Enables verification if the advertised preference (in reference option) is greater than the specified limit. If not specified, this check does not occur. The value range is from 0 to 255.
PrefixLimitMax	Enables verification if the advertised preference (in preference option) is less than the specified limit. If not specified, this check does not occur. The value range is from 0 to 255. Note: If both the maximum and minimum limit is 0, this preference check is ignored.

Delete a DHCPv6 Guard Policy

About This Task

Use this procedure to delete the created DHCPv6 Guard policy.

Note

If this policy is already attached to an interface, then this policy cannot be deleted.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **FHS**.
3. Click the **DHCPv6 Guard Policy** tab.
4. Select a row from DHCPv6 Guard policies to delete.
5. Click **Delete**.

RA Guard Policy Configuration

Configure RA Guard to block or reject unwanted or rogue RA messages that arrive at the network device platform. You can view, create or delete RA Guard policy.

Create RA Guard Policy

About This Task

Use this procedure to create a RA Guard policy to block or reject unwanted or rogue RA messages that arrive at the network device platform.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **FHS**.
3. Click the **RA Guard Policy** tab.
4. Click **Insert**.
5. Configure the parameters for the RA Guard policy.
6. Click **Insert**.
7. (Optional) Click **Refresh** to update the results.

RA Guard Policy Field Descriptions

Use the data in the following table to use the **RA Guard Policy** tab.

Name	Description
PolicyName	Specifies the name of the RA Guard policy to be created or modified.
SrcAddrList	Specify the IPv6 access list name to verify the sender IPv6 address in the RA packets against the attached IPv6 access list. Note: The source address in the RA packet is not validated if the access-list is not attached. If the list is attached and the IPv6 source address in RA packet does not match any IPv6-prefix in the list, then the RA packet is dropped. To change this behavior, add an entry in the IPv6 access list with prefix 0::0/0 with access type as allow. The default value changes from drop to allow.

Name	Description
PrefixList	Specify the IPv6 prefix list name to verify the advertised prefixes in the RA packet against the attached IPv6 prefix list. Note: Advertised prefixes are not validated if the access-list is not attached. If the list is attached and the advertised prefix in the RA packet does not match any IPv6-prefix in the list, then the RA packet is dropped. To change this behavior, add an entry in the IPv6 access list with prefix 0::0/0 with access type as allow. The default value changes from drop to allow.
MacAddrList	Specify the MAC list name to verify the sender source MAC address against the attached MAC access list. Note: The source MAC address in the RA packet is not validated if the access-list is not attached. If the list is attached and the source MAC address in the RA packet does not match any MAC address in the list, then the RA packet is dropped.
ManagedConfigFlag	Select the managed configuration flag to verify managed address configuration in the advertised RA packet. By default, none is selected and managed configuration flag validation is skipped.
RouterPrefMax	Select the router preference maximum to verify the if the advertised default router preference parameter value is lower than or equal to a specified limit. By default, none is selected and router preference validation is skipped.
HopLimitMin	Specify the minimum hop limit to verify the advertised hop count limit. The value range is from 0 to 255 By default, minimum hop limit is 0.
HopLimitMax	Specify the maximum hop limit to verify the advertised hop count limit. The value range is from 0 to 255 By default, the maximum hop limit is 0 and If both HopLimitMin and HopLimitMax are set to 0, then the hop limit parameter in the RA packet is not validated.

View RA Guard Policy

About This Task

Use this procedure to display configured RA Guard policies.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **FHS**.
3. Click the **RA Guard Policy** tab.

RA Guard Policy Field Descriptions

Use the data in the following table to use the **RA Guard Policy** tab.

Name	Description
PolicyName	Specifies the name of the RA Guard policy to be created or modified.
SrcAddrList	Specify the IPv6 access list name to verify the sender IPv6 address in the RA packets against the attached IPv6 access list. Note: The source address in the RA packet is not validated if the access-list is not attached. If the list is attached and the IPv6 source address in RA packet does not match any IPv6-prefix in the list, then the RA packet is dropped. To change this behavior, add an entry in the IPv6 access list with prefix 0::0/0 with access type as allow. The default value changes from drop to allow.
PrefixList	Specify the IPv6 prefix list name to verify the advertised prefixes in the RA packet against the attached IPv6 prefix list. Note: Advertised prefixes are not validated if the access-list is not attached. If the list is attached and the advertised prefix in the RA packet does not match any IPv6-prefix in the list, then the RA packet is dropped. To change this behavior, add an entry in the IPv6 access list with prefix 0::0/0 with access type as allow. The default value changes from drop to allow.
MacAddrList	Specify the MAC list name to verify the sender source MAC address against the attached MAC access list. Note: The source MAC address in the RA packet is not validated if the access-list is not attached. If the list is attached and the source MAC address in the RA packet does not match any MAC address in the list, then the RA packet is dropped.

Name	Description
ManagedConfigFlag	Select the managed configuration flag to verify managed address configuration in the advertised RA packet. By default, none is selected and managed configuration flag validation is skipped.
RouterPrefMax	Select the router preference maximum to verify the if the advertised default router preference parameter value is lower than or equal to a specified limit. By default, none is selected and router preference validation is skipped.
HopLimitMin	Specify the minimum hop limit to verify the advertised hop count limit. The value range is from 0 to 255 By default, minimum hop limit is 0.
HopLimitMax	Specify the maximum hop limit to verify the advertised hop count limit. The value range is from 0 to 255 By default, the maximum hop limit is 0 and If both HopLimitMin and HopLimitMax are set to 0, then the hop limit parameter in the RA packet is not validated.

Delete an RA Guard Policy

About This Task

Use this procedure to delete the created RA Guard policy.

Note

If this policy is already attached to an interface, then you cannot delete this policy.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **FHS**.
3. Click the **RA Guard Policy** tab.
4. Select a row from the RA Guard policies to delete.
5. Click **Delete**.

Port Policy Mapping Configuration

This configuration allows you to map the port with DHCPv6 Guard or RA Guard policy. You can view, create or delete the mappings.

Create Port to Policy Mapping

About This Task

Use this procedure to map a port to a RA Guard or DHCPv6 Guard policy, DHCPv6 Guard or RA Guard statistics.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **FHS**.
3. Click the **Port Policy Mapping** tab.
4. Click **Insert**.
5. Configure the parameters for the port policy mapping.
6. Click **Insert**.
7. (Optional) Click **Refresh** to update the results.

Port Policy Mapping Field Descriptions

Use the data in the following table to use the **Insert Port Policy Mapping** dialog box.

Name	Description
IfIndex	Specify the port.
DHCPv6GuardPolicyName	Enter an already-created DHCPv6 Guard policy name to map it with the port.
RAGuardPolicyName	Enter an already-created RA Guard policy name to map it with the port.
Dhcpv6gDeviceRole	Select server or client configuration. The default is server.
RagDeviceRole	Select host or router configuration. The default is router.

View Port Policy Mapping

About This Task

Use this procedure to display port policy mapping information.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **FHS**.
3. Click the **Port Policy Mapping** tab.

Port Policy Mapping Field Descriptions

Use the data in the following table to use the **Port Policy Mapping** tab.

Name	Description
IfIndex	Identifies the port.
Dhcpv6gDeviceRole	Specifies the DHCPv6 Guard device-role of the received port. If the device role is client and if it receives DHCPv6 reply then those packets should be dropped.
DHCPv6GuardPolicyName	Specifies the DHCPv6 Guard policy name associated with the port.
TotalDHCPv6PktRcv	Shows the total number of DHCPv6 packets received on the DHCPv6 Guard enabled interface.
TotalDHCPv6PktDropped	Shows the total number of DHCPv6 packets dropped due to DHCPv6 Guard filtering.
RagDeviceRole	Specifies the RA Guard device-role.
RAGuardPolicyName	Specifies the RA Guard policy name associated with the port.
TotalRAPktRcv	Shows the total number of RA packets received on the RA Guard enabled interface.
TotalRAPktDropped	Shows the total number of RA packets dropped due to RA Guard filtering.
NDInspection	Enables or disables Neighbor Discovery (ND) inspection. The default is disabled.
TotNdPktRcv	Shows the total number of ND packets received on the RA Guard enabled interface.
TotNdPktDropped	Shows the total number of ND packets dropped due to RA Guard filtering.
ClearDHCPGuardStats	Clears, if true, the DHCPv6 Guard statistics for the port.
ClearRAGuardStats	Clears, if true, the RA Guard statistics for the port.
ClearNDInspectStats	Clears, if true, the ND-inspection statistics for the port.

Delete Port Policy Mapping

About This Task

Use this procedure to delete the created port policy mapping.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **FHS**.
3. Click the **Port Policy Mapping** tab.
4. Select a row from Port Policy Mapping to delete.
5. Click **Delete**.
6. Click **Apply**.

DHCP Snooping Configuration Using EDM

The following section provides procedures to configure DHCP Snooping using EDM.

Enable DHCP Snooping Globally

Use the following procedure to enable DHCP Snooping globally. If DHCP Snooping is globally disabled, the switch forwards DHCP reply packets (received on trusted or untrusted ports) to all ports.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Click **DHCP Snooping**.
3. Click the **DHCP Snooping Globals** tab.
4. Select **Enabled**.
5. Click **Apply**.

DHCP Snooping Globals Field Descriptions

Use data in the following table to use the **DHCP Snooping Globals** tab.

Name	Description
Enabled	Enables DHCP Snooping globally. By default, DHCP Snooping is disabled.

Configure DHCP Snooping on VLANs

Use the following procedure to configure DHCP Snooping on a specific VLAN. If DHCP Snooping is globally disabled, the switch forwards DHCP reply packets (received on trusted or untrusted ports) to all ports.

If you enable DHCP Snooping globally, the agent determines whether to forward DHCP reply packets based on the DHCP Snooping mode of the VLAN and trusted state of the port.

Note

You cannot enable DHCP Snooping on Private VLANs (E-Tree) and SPBM B-VLANs.

Before You Begin

You must enable DHCP Snooping globally.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Click **DHCP Snooping**.
3. Click the **DHCP Snooping-VLAN** tab.
4. In the row for the VLAN, double-click the **DhcpSnoopingEnabled** field, and select **true** to enable DHCP Snooping.
5. Click **Apply**.

DHCP Snooping-VLAN Field Descriptions

Use the data in the following table to use the **DHCP Snooping-VLAN** tab.

Name	Description
VlanId	Specifies the VLAN ID.
DhcpSnoopingEnabled	Specifies if DHCP Snooping is enabled or disabled for the particular VLAN. By default, DHCP Snooping is disabled.
Origin	Specifies the origin of DHCP Snooping configuration on the VLAN. The supported values are: • config - Set by the user. • radius - Set by the Remote Authentication Dail-In User Service (RADIUS) attribute.

Configure Trusted and Untrusted Ports

Use the following procedure to set the trust factor associated with a port for DHCP Snooping. By default, the trust factor is set to untrusted on all ports.

Note

For ports that are members of an MLT, DHCP Snooping must be configured using the MLT configuration mode.

Before You Begin

To enable DHCP Snooping on a port, you must enable DHCP Snooping globally.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Click **DHCP Snooping**.
3. Click the **DHCP Snooping-port** tab.
4. In the row for the port, double-click the **DhcpSnoopingIfTrusted** field, and select **trusted** or **untrusted** to set DHCP Snooping.
5. Click **Apply**.

DHCP Snooping-port Field Descriptions

Use data in the following table to use the **DHCP Snooping-port** tab.

Name	Description
Port	Specifies the port on the switch.
DhcpSnoopingIfTrusted	Specifies if the switch ports are trusted for DHCP Snooping. By default, it is set as untrusted.

DHCP binding configuration

The following section provides procedures to configure the DHCP binding table using EDM.

Create DHCP Binding Table Entries

Use the following procedure to add entries for devices with static IP addresses to the DHCP binding table.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Click **DHCP Snooping**.
3. Click the **DHCP Bindings** tab.
4. Click **Insert**.
5. In the **VlanId** field, enter the VLAN ID.
6. In the **MacAddress** field, enter the MAC address of the DHCP client.
7. In the **AddressType** field, select a value.
8. In the **Address** field, enter the IP address of the DHCP client.
9. In the **Interface** field, select a port.
10. In the **LeaseTime(sec)** field, enter the time in seconds.
11. Click **Insert**.
12. Click **Apply**.

DHCP Bindings field descriptions

Use data in the following table to use the **DHCP Bindings** tab.

Name	Description
VlanId	Specifies the VLAN to which the DHCP client belongs.
MacAddress	Specifies the MAC address of the DHCP client.
AddressType	Specifies the type of address. The default address type is IPv4.
Address	Specifies the IP address assigned to the DHCP client.
Interface	Specifies the interface to which the DHCP client connects.
LeaseTime(sec)	Specifies the lease time (in seconds) of the particular DHCP binding entry. The time range is 0 to 2147483646 seconds.
TimeToExpiry(sec)	Species the time of expiry (in seconds) of the DHCP binding entry.
EntryType	Specifies the type of the DHCP binding entry. • If the entry was created through DHCP snooping, the type is learned(1). • If the entry was created through a management operation, the type is static(2).

Viewing DHCP Binding Information

Use the following procedure to view all entries in the DHCP binding table.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Click **DHCP Snooping**.

3. Click the **DHCP Bindings** tab.

DHCP Bindings field descriptions

Use data in the following table to use the **DHCP Bindings** tab.

Name	Description
VlanId	Specifies the VLAN to which the DHCP client belongs.
MacAddress	Specifies the MAC address of the DHCP client.
AddressType	Specifies the type of address. The default address type is IPv4.
Address	Specifies the IP address assigned to the DHCP client.
Interface	Specifies the interface to which the DHCP client connects.
LeaseTime(sec)	Specifies the lease time (in seconds) of the particular DHCP binding entry. The time range is 0 to 2147483646 seconds.
TimeToExpiry(sec)	Species the time of expiry (in seconds) of the DHCP binding entry.
EntryType	Specifies the type of the DHCP binding entry. • If the entry was created through DHCP snooping, the type is learned(1). • If the entry was created through a management operation, the type is static(2).

SBT configuration

This configuration allows you to build a snooping binding table (SBT) which contains entries from only trusted devices or hosts. This SBT table is used to validate Neighbor Discovery (ND) packets. You can view, create, or delete the entries in the SBT.

Create an SBT Entry

About This Task

Use this procedure to create an SBT entry.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **FHS**.
3. Click the **Snoop Binding** tab.
4. Click **Insert**.
5. Configure the parameters for the snoop binding.
6. Click **Insert**.
7. (Optional) Click **Refresh** to update the results.

Snoop Binding field descriptions

Use the data in the following table to use the **Snoop Binding** tab. The system displays a subset of these fields if click **Insert**.

Name	Description
VlanId	Specify the VLAN to which the snooped entry belongs.
Ipv6Address	Enter the IPv6 address assigned to the IPv6 host.
MacAddress	Enter the MAC address of the snooped entry.
InterfaceIndex	Specify the interface on which the entry is learnt.
EntryType	Indicates the type of entry - static (1) or dynamic (2).
EntrySource	Indicates the method entry was learnt from - static (1) or dhcp (2).
ValidTime	Indicates the valid time for the snooped entry.
TimeToExpiry	Indicates the time to expiry of the snooped entry.

View SBT Entries

About This Task

Use this procedure to display a configured SBT table.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **FHS**.
3. Click the **Snoop Binding** tab.

Snoop Binding field descriptions

Use the data in the following table to use the **Snoop Binding** tab. The system displays a subset of these fields if click **Insert**.

Name	Description
VlanId	Specify the VLAN to which the snooped entry belongs.
Ipv6Address	Enter the IPv6 address assigned to the IPv6 host.
MacAddress	Enter the MAC address of the snooped entry.
InterfaceIndex	Specify the interface on which the entry is learnt.
EntryType	Indicates the type of entry - static (1) or dynamic (2).
EntrySource	Indicates the method entry was learnt from - static (1) or dhcp (2).
ValidTime	Indicates the valid time for the snooped entry.
TimeToExpiry	Indicates the time to expiry of the snooped entry.

Delete an SBT Entry

About This Task

Use this procedure to delete an entry from the SBT table.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **FHS**.
3. Click the **Snoop Binding** tab.
4. Select a row from the list to delete.
5. Click **Delete**.

IP Source Guard Configuration using EDM

Note

The switch supports configuration of IP Source Guard for both IPv4 and IPv6 addresses.

Enable IP Source Guard on a Port for IPv4 Addresses

About This Task

Enable IP Source Guard (IPSG) to add a higher level of security to a desired port by preventing IP spoofing. When you enable IPSG on the interface, filters are installed for IPv4 addresses that are already learned on that interface.

Before You Begin

Ensure that the following conditions are all satisfied, before you enable IPSG on a port. Otherwise, the system displays error messages.

- DHCP Snooping is enabled globally.
- The port on which you want to enable IPSG is a member of a VLAN that is configured with both DHCP Snooping and Dynamic ARP Inspection.
- The port is an untrusted port enabled with both DHCP Snooping and Dynamic ARP Inspection.
- The port has enough resources allocated to support the maximum number of 10 IP addresses allowed for IPSG.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Click **Source Guard**.
3. Click the **IP Source Guard-port** tab.
4. Double-click the **Mode** field
5. Select **ip** from the list, to enable IPSG.
6. Repeat the steps above to configure IPSG on additional ports.
7. Click **Apply** to save your changes.
8. Click **Refresh** to update the **IP Source Guard-port** tab.

IP Source Guard-port field descriptions

Use the data in the following table to use the **IP Source Guard-port** tab.

Name	Description
Port	Identifies the port on which to enable IPSG.
Mode	Displays whether IPSG is enabled on the port. The default is disabled.
Origin	Specifies the origin of Source Guard configuration on the port. The supported values are: • config - Set by the user. • radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.

View IPv4 Address Bindings

View the IPv4 address bindings that IPSG allows.

Procedure

1. In the navigation pane, expand **Configuration** > **IP**.
2. Select **Source Guard**.
3. Select the **IP Source Guard-addresses** tab.

IP Source Guard-addresses field descriptions

Use the data in the following table to use the **IP Source Guard-addresses** tab.

Field	Description
Port	Indicates the port on which IPSG is configured.
Type	Indicates the address type.
Address	Indicates the IPv4 address that is allowed by IPSG on the port.
Source	Indicates the source of the IPv4 address, which is DHCP Snooping.

Configure IP Source Guard on a Port for IPv6 Addresses

About This Task

Enable IPSG to add a higher level of security to a desired port, by preventing IP spoofing. When you enable IPSG on an interface, filters are automatically installed for the IPv6 addresses that are already learned on that interface.

Before You Begin

Ensure that the following conditions are all satisfied, before you enable IPSG on a port. Otherwise, the system displays error messages.

- DHCP Snooping is enabled globally.
- The port is a member of a VLAN that is configured with both DHCP Snooping and IPv6 Neighbor Discovery inspection.
- The port is an untrusted port enabled with both DHCP Snooping and IPv6 Neighbor Discovery inspection.
- The port has enough resources allocated to support the maximum number of 10 IP addresses allowed for IPSG.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **IPv6**.
3. Click the **Source Guard** tab.
4. Double-click the **InterfaceState** field.
5. Select a value from the list: **true** or **false**.
6. Double-click the **MaxAddr** field.
7. Enter the maximum number of IPv6 addresses that are allowed to transmit data on the port.
8. (Optional) To clear the overflow counters, double-click **ClearOverflowCount** and select **true**.
9. Click **Apply** to save your changes.
10. Click **Refresh** to update the **Source Guard** tab.

Source Guard field descriptions

Use the data in the following table to use the **Source Guard** tab.

Name	Description
IfIndex	Specifies a value that uniquely identifies the port.
InterfaceState	Specifies the state of the interface. The default value is false.
MaxAddr	Specifies the maximum number of IPv6 addresses allowed to transmit data through the port. The default value is 4. Note: To reset the value to default, IPSG must first be disabled on the interface.
OverflowCount	Specifies the number of IPv6 addresses for which filters are not added on the IPSG port, due to a lack of filter resources. The default value is 0.
ClearOverflowCount	Specifies whether the overflow counter must be cleared. By default, the value is false.

View IPv6 Address Bindings

View the IPv6 address bindings that IPSG allows.

Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Click **IPv6**.
3. Click the **Source Guard Binding** tab.

Source Guard Binding field descriptions

Use the data in the following table to use the **Source Guard Binding** tab.

Field	Description
IfIndex	Specifies a value that uniquely identifies the port.
IPv6Addr	Specifies the binding entry for the IPv6 address.

Layer 2 security example scenarios

The following sections describe configuration examples to configure Layer 2 security features for IPv4 and IPv6 deployments.

FHS Deployment Scenario

In the following example, the Layer 2 switch “SW-1” is connected to another Layer 2 switch “SW-2”, two hosts and a DHCP server. Switch “SW-2” is connected to two other hosts and a router. Out of the two hosts connected to SW-2, one is a malicious host, which can generate bogus RA packets to advertise route prefix, and can also generate bogus DHCP reply packets to configure wrong IPv6 address or wrong default gateway. By doing this, it tries denial-of-service or Man-in-the-Middle attacks. These attacks must be prevented as it affects all the nodes present in the Layer 2 network and FHS can be effective in preventing these attacks.

These attacks can spread over the entire Layer 2 network and thus can affect the hosts connected to SW-2 as well as the hosts connected to SW-1. If you enable FHS only on SW-2, then it could only save the nodes which are directly connected to it. To prevent the good node connected to SW-1 from these attacks, the SW-1 switch also should be FHS enabled.

The following figure shows the FHS deployment scenario topology.

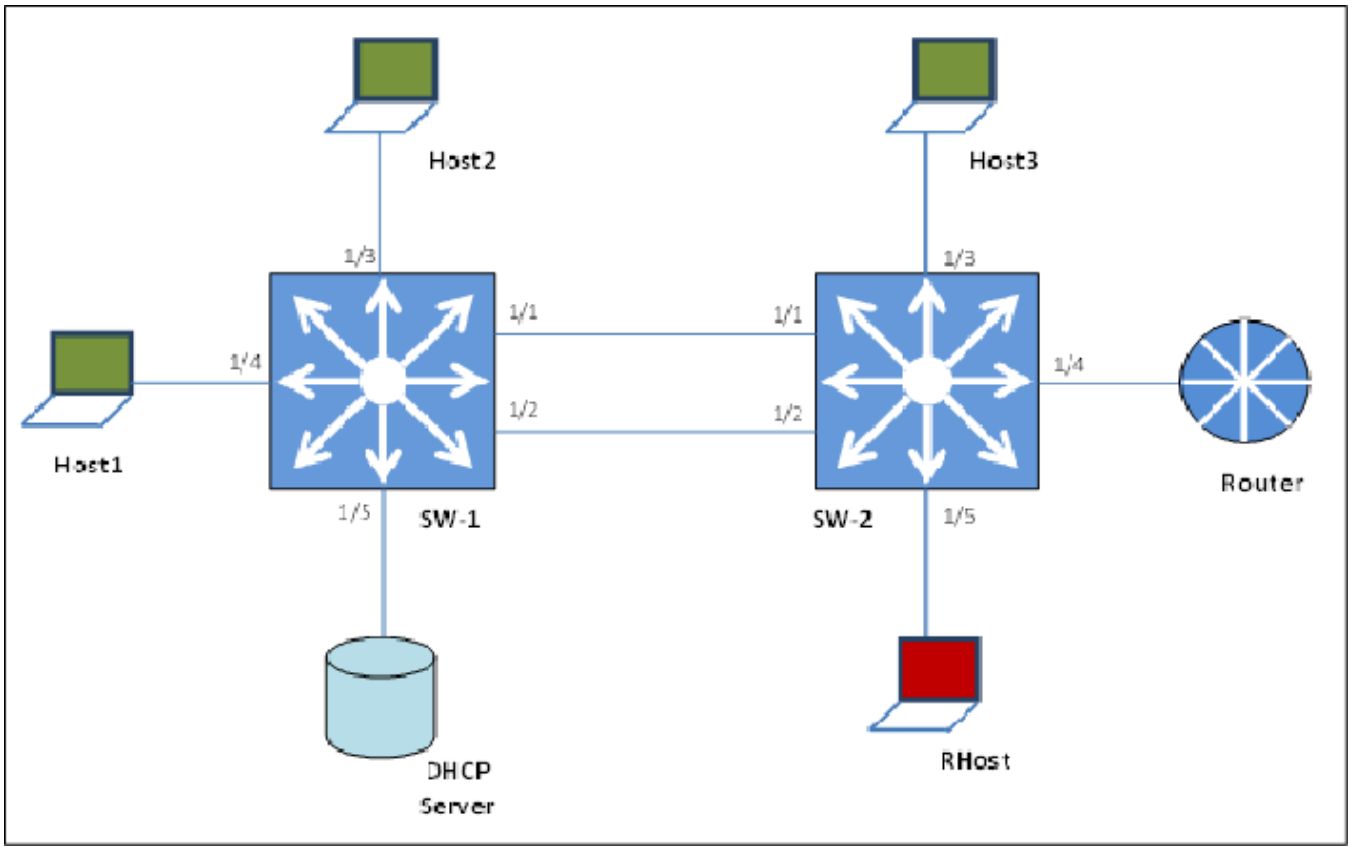

Figure 170: FHS deployment topology

By default, all the ports are trusted, until you configure DHCPv6 Guard or RA Guard policies.

See the following procedures to configure FHS RA Guard and DHCPv6 Guard for the preceding topology.

Creating FHS IPv6 ACL

About This Task

Filter IPv6 traffic by creating IPv6 Access Control Lists (ACLs) and applying them to the interfaces similar to the way that you create and apply IPv4 named ACLs.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create an IP ACL name (ipv6_acl_1) to match the source IPv6 address of the router connected to the interface.

   ```
   ipv6 fhs ipv6-access-list ipv6_acl_1
   fe80:0:0:0:cef9:54ff:feb4:9481/128 mode allow
   ```

3. Create an IP ACL name (ipv6_acl_1) to match the source IPv6 address of the DHCPv6-server connected to the interface.

   ```
   ipv6 fhs ipv6-access-list ipv6_acl_1
   fe80:0:0:0:cef9:54ff:feb4:9481/128 mode allow
   ```

What to Do Next

Create a First Hop Security MAC ACL.

Creating an FHS MAC ACL

About This Task

Filter the IPv6 traffic by creating a MAC access list with the ACL mode.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create a MAC ACL name (rtr_smac) to match the source MAC of the router connected to the interface 1/2.

   ```
   ipv6 fhs mac-access-list mac_acl_1 00:11:22:33:44:66 mode allow
   ```

Create a DHCPv6 Guard Policy for the Router

About This Task

Create a DHCPv6 Guard policy to provide Layer 2 security to DHCPv6 clients by protecting them against rogue DHCPv6 servers.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enter DHCP Guard mode with the DHCPv6 Guard policy name (dhcpv6g_pol_1). The DHCPv6 Guard policy for the interface is connected to a router.

   ```
   ipv6 fhs dhcp-guard policy dhcpv6g_pol_1
   ```

3. Configure the source IPv6 access list to allow only a DHCPv6 server replies that originate from the IPv6 address fe80:0:0:0:cef9:54ff:feb4:9481/128 and check the preceding IPv6 ACL configuration for ipv6_acl_1 list.

   ```
   match server access-list ipv6_acl_1
   ```

4. Verify the prefixes sent in the DHCPv6 server reply message so that the ipv6_acl_2 IPv6 ACL configuration allows only the prefix 1000::1/64.

   ```
   match reply prefix-list ipv6_acl_1
   ```

Create an RA Guard Policy for the Router

About This Task

Create a rag_pol_1 RA Guard policy for the router and configure the source IPv6 access list to allow only the RA packets that originate from the source IPv6 address fe80:0:0:0:cef9:54ff:feb4:9481/128. This configuration verifies the prefixes sent in the RA packets.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Enter the RA Guard mode and configure RA Guard policy (rag_pol_1) for the interface connected to a router.
   ```
   ipv6 fhs ra-guard policy rag_pol_1
   ```
3. Configure the source IPv6 access list to allow only RA packets originating from the source IPv6 address fe80:0:0:0:cef9:54ff:feb4:9481/128.
   ```
   match ipv6 ra-srcaddr-list ipv6_acl_1
   ```
4. Verify the prefixes sent in the RA packets so that the rtr_pip IPv6 ACL configuration allows only the prefix 60::0/64.
   ```
   match reply ra-prefix-list ipv6_acl_1
   ```

Attach FHS policies to the Interfaces

About This Task

Attach the FHS policies to the interfaces.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Configure DHCPv6 Guard and RA Guard policies on the interface (1/2) that connects to the router.
   ```
   interface ethernet 1/2

   ipv6 dhcp-guard attach-policy dhcpv6g_pol_1

   ipv6 ra-guard attach-policy rag_pol_1
   ```

IPv6 DHCP Snooping and ND Inspection Configuration Example

This section shows examples of IPv6 DHCP snooping and ND inspection configuration.

Enable DHCPv6 Guard, ND inspection, and First Hop Security.

```
ipv6 fhs dhcp-guard enable
ipv6 fhs nd-inspection enable
ipv6 fhs enable
```

Create VLAN 1000 and add port members.

```
vlan create 1000 type port-mstprstp 0
vlan members add 1000 1/1-1/10
```

Enable DHCPv6 snooping and ND inspection on VLAN 1000.

```
interface vlan 1000
ipv6 fhs snooping dhcp enable
ipv6 fhs nd-inspection enable
exit
```

Add static SBT entry.

```
ipv6 fhs snooping static-binding ipv6-address 2001:DB8:0:0:0001:02ff:fe03:0405 vlan 1000
mac-address 00:01:02:03:04:05 port 1/5
```

Set the DHCPv6 Guard device-role on port 1/1 of the device on which DHCPv6 Guard is configured.

```
interface gigabitEthernet 1/1
ipv6 fhs dhcp-guard device-role server
exit
```

Enable ND inspection on ports 1/2 through 1/10.

```
interface gigabitEthernet 1/2-1/10
ipv6 fhs nd-inspection enable
exit
```

View the status.

```
show ipv6 fhs port-policy
show ipv6 fhs status
show ipv6 fhs status vlan
show ipv6 fhs snooping binding
```

Configure IP Source Guard

The following section describes a simple configuration example to configure IP Source Guard (IPSG) on a port.

When you enable IPSG on a port, filters are installed for the IPv4 or IPv6 addresses that are already learned on that port.

Procedure

Enable DHCP Snooping globally on the switch and verify the configuration.

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable DHCP Snooping globally.

   ```
   ip dhcp-snooping enable
   ```

3. Verify the configuration.

   ```
   show ip dhcp-snooping
   ```

Enable DHCP Snooping and Dynamic ARP Inspection on the VLAN that the port is a member of.

4. Enter VLAN Interface Configuration mode:

   ```
   enable

   configure terminal

   interface vlan <1-4059>
   ```

5. Enable DHCP Snooping on the VLAN.

   ```
   ip dhcp-snooping enable
   ```

6. Verify the configuration.

   ```
   show ip dhcp-snooping vlan <1-4059>
   ```

7. Enable Dynamic ARP Inspection on the VLAN.

   ```
   ip arp-inspection enable
   ```

8. Verify the configuration.

   ```
   show ip arp-inspection vlan <1-4059>
   ```

9. Verify that the port on which you want to configure IPSG is a DHCP Snooping and a Dynamic ARP Inspection untrusted port.

   ```
   show ip dhcp-snooping interface gigabitEthernet [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]

   show ip arp-inspection interface gigabitEthernet [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
   ```

Configure IPSG on a port and verify the configuration.

10. Perform one of the following steps to configure IPSG on a port, for IPv4 or IPv6 addresses.

    - Enable and verify IPSG on a port for IPv4 addresses:

      a. `ip source verify enable`

      b. `show ip source verify interface gigabitethernet [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]`

    - Enable and verify IPSG on a port for IPv6 addresses:

      a. `ipv6 source-guard enable`

      b. `ipv6 source-guard [max-allowed-addr <2-10>]`

      > **Note**
      > The default value is 4. To reset the value to default, IPSG must first be disabled on the interface.

      c. `show ipv6 source-guard interface gigabitEthernet [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]`

Examples

The following example describes how to enable IPSG on port 4/5 which is a member of VLAN 10, for IPv4 or IPv6 addresses.

```
Switch:1>en
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#
```

Enable DHCP Snooping globally and verify the configuration.

```
Switch:1(config)#ip dhcp-snooping enable
Switch:1(config)#show ip dhcp-snooping

Licensing

Table 129: Licensing product support

Feature	Product	Release introduced
Universal Hardware licenses	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
License files signed using Extreme Networks signature	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Subscription-based licenses	5320 Series	Not Supported
	5420 Series	Not Supported
	5520 Series	Not Supported
	5720 Series	Not Supported
Ability to extend the Factory Default Premier Trial License	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.4
	5720 Series	Fabric Engine 8.7

Licensing Fundamentals

This section provides conceptual information about licensing. Subsequent sections discuss how to acquire, install, and enable licenses.

Factory Default Premier Trial License

New hardware switches include a Factory Default Premier Trial License to use all features (excluding MACsec). You can run the **extend-time-period** command up to three times to extend the trial license. You can configure all features, except MACsec, without restrictions and save the configuration.

Note

On 5320 Series, the four highest SFP+ ports are available at 10 Gbps with Trial Licenses. After expiration, behavior is the same as with other licensed features.

You cannot configure new features after the trial period, but the switch continues to run with the existing configured features. If you reboot the switch after the trial period, and a valid software license is not present, licensed features in the configuration are not loaded. You must install a valid license to enable licensed features.

Table 130: Factory Default Premier Trial License

Platform	Initial trial period in days
5320 Series, 5420 Series, 5520 Series, and 5720 Series	30

Note

The evaluation period is based on the switch System Up Time.

If a Premier license was installed and then revoked, the trial period cannot be extended.

To extend the factory default trial license, see Extend the Factory Default Premier Trial License on page 1895.

License Types

The topics in this section explain licensing for the following products:

- 5320 Series
- 5420 Series
- 5520 Series
- 5720 Series

License File Requirements

The license file name must meet the following requirements:

- Maximum of 63 alphanumeric characters
- No spaces or special characters allowed
- Underscore (_) is allowed
- The file extension is `.lic`.

Feature Licensing for Universal Hardware

Extreme Networks offers universal hardware products that support more than one Network Operating System (NOS) personality. The universal hardware products share a unified license, which is NOS agnostic.

The Base License, which is included with the purchase of the switch, enables the basic networking capabilities of the device. You can purchase additional licenses separately to enable advanced features on the switch.

Licenses are tied to the switch serial number. After you generate the license through the Extreme Networks Support Portal at https://extremeportal.force.com/ExtrLicenseLanding, you can install the license on the switch manually. You can also use ExtremeCloud IQ to obtain licenses for universal hardware switches.

The following sections detail the different categories of licenses.

Base License

A Base license gives customers the right to use Base software features on the switch.

Licenses for Advanced Features

Licenses enable advanced features not available in the Base License. The following table provides information on the features enabled by each license, if the hardware supports the feature. For information on supported features, see *Fabric Engine Feature Support Matrix*.

License type	Supported features
MACsec License	IEEE 802.1AE MACsec
Premier License	• DvR Controller (5520 Series and 5720 Series only) • Fabric Connect Layer 3 Virtual Services Networks (VSNs) • Extreme Integrated Application Hosting, including Fabric IPsec Gateway (5720 Series only) • Greater than four OSPF active Interfaces • Greater than two BGP peers

10 Gbps Port License

By default, the SFP+ ports on the 5320 Series switches operate at 1 Gbps. To use the ports at full 10 Gbps, you must purchase a 10 Gbps Port License. You can purchase one of two port license types:

- For all 5320 Series models — Use only the highest four SFP+ ports at 10 Gbps.
- For the 24- and 48-port 5320 Series models — Use all eight SFP+ ports at 10 Gbps.

Note

By default, the Advanced Feature Bandwidth Reservation boot configuration flag is enabled, which means the first three ports are reserved for internal loopback.

You can have a 4-port and an 8-port 10 Gbps license on the same switch simultaneously. To move from one license to another without a loss in connectivity, apply both licenses on the switch before you revoke your original license.

License Types and Part Numbers

The following table lists the license types and the associated part numbers.

License Type	Part Number / Order Code
10 Gbps Port License for the highest four SFP + ports on the 5320 Series	5320-10GUPG-4X-LIC-P
10 Gbps Port License for all eight SFP+ ports on the 24- and 48-port models of the 5320 Series	5320-10GUPG-8X-LIC-P
MACsec License	5000-PRMR-LIC
Premier License	5000-PRMR-LIC

ExtremeCloud™ IQ Pilot License

ExtremeSwitching 5320 Series, 5420 Series, 5520 Series, and 5720 Series switches include a one-year subscription to an ExtremeCloud™ IQ Pilot license.

Note

The entitlement period starts the day the switch ships from Extreme Networks or an Extreme Networks distribution partner.

ExtremeCloud IQ enables end-to-end network management and operations, delivering a fully integrated, extensible platform that simplifies the design, deployment, and security of networks from the edge to the data center, while simultaneously unlocking valuable IT and business insights. To activate these premium Pilot level capabilities, go to https://www.extremenetworks.com/universal-switch-xiq-pilot/.

Install and Uninstall Licenses on Universal Switches

This topic explains how to obtain, activate, and transfer licenses on universal hardware switches.

Obtain and Install a License

For universal hardware switches, you can activate a license on the switch using either of the following methods:

- Manual activation by obtaining the license activation file from the Extreme Networks Support portal.
- Automated activation using ExtremeCloud IQ. For information about using ExtremeCloud IQ for bulk automated license activation, go to https://www.extremenetworks.com/support/documentation/extremecloud-iq.

To obtain and install a license, follow these steps:

Note

You should have received by email a license voucher after your purchase of a switch. You will need the voucher ID number on this email to generate a license.

For manual license generation and installation:

1. Upgrade the switch so that it is running the most recent GA version of the software.

To download the latest GA software, visit the Extreme Networks Support portal.

2. Follow manual activation instructions for license generation available on the Extreme Networks Support portal: **Products** > **ExtremeSwitching** > **Universal** > **Fabric Engine (VOSS) (for your switch)** > **Activation Instructions**.
3. Download the license file onto the switch.
4. Install the license, using the command **load-license** *license_filename*.

The software verifies the license and activates the features that correspond to the license category.

For more information, see either of the following:

- License Installation using CLI on page 1893
- License Installation using EDM on page 1897

Transfer a License

You can permanently remove a license, which allows you to transfer the license to another switch. This should only be done when preparing to return a defective switch for a replacement switch (RMA).

For more information, see either of the following:

- Revoke a License on page 1894 (using CLI)
- Revoke a License on page 1900 (using EDM)

To transfer a license from a defective switch to a replacement switch (RMA), follow these steps.

1. Go to the Extreme Networks Support portal.
2. Select **Assets** > **Licenses Home**.
3. Select **License Transfer**.
4. Enter the serial number of the defective unit, replacement unit serial number, and the RMA/case number.
5. Generate the new license, following the process in step 2 in Obtain and Install a License on page 1892.
6. Download the license file onto the switch.
7. Install the license, using the command **load-license** *license_filename*.

License Installation using CLI

Install and manage a license file for the switch by using the Command Line Interface (CLI).

Note

This section applies to multiple platforms. The command syntax and example outputs may not be identical on all hardware platforms.

Install a License File

Install a license file on the switch to enable licensed features.

Before You Begin

- File Transfer Protocol (FTP) and Trivial File Transfer Protocol (TFTP) support both IPv4 and IPv6 addresses, with no difference in functionality or configuration.
- You must enable File Transfer Protocol (FTP) or Trivial File Transfer Protocol (TFTP) in the boot configuration flags depending on which protocol you use to download the license file to the device.
- Ensure that you have the correct license file with the base MAC address of the switch on which you need to install the license. Otherwise, the system does not unblock the licensed features.

Procedure

1. From a remote station or PC, use FTP or TFTP to download the license file to the device and store the license file in the /intflash directory.
2. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```
3. Load the license:

   ```
   load-license WORD<1-64>
   ```

Examples

Log in to the device and load the license. The following example shows a successful operation.

```
Switch:1(config)#load-license license_5320-48T-8XE_8P_1
Switch:1(config)#2021-09-01T13:48:27.275Z 5320-48T-8XE-VOSS CP1 - 0x000006ef - 00000000
GlobalRouter SW INFO License key successfully loaded from <license_5320-48T-8XE_8P_1>.
```

Variable Definitions

The following table defines parameters for the **copy** command.

Variable	Value
<a.b.c.d>	Specifies the IPv4 and IPv6 address of the TFTP server from which to copy the license file.
<file>	Specifies the name of the license file when copied to the flash.
<srcfile>	Specifies the name of the license file on the TFTP server.

The following table defines parameters for the **load-license** command.

Variable	Value
WORD<1-64>	Specifies the name of the license file in the `/intflash` directory.

Revoke a License

Revoke a license on the switch if you need to transfer the license to a different switch.

You can permanently remove a license, which allows you to transfer the license to another switch. This should only be done when preparing to return a defective switch for a replacement switch (RMA).

About This Task

The **no license** command invalidates the feature license and generates a revocation certificate, which is the first step to releasing the license entitlement back to the license entitlement manager (LEM). The revocation certificate is contained in a file where the first part of the file name is the switch serial number and the file extension is .rvk.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Revoke a license:

   ```
   no license <10G WORD<1-64> | macsec | premier>
   ```

Example

Revoke the Premier license.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#no license premier
Successfully revoked license of type <PRD-5000-PRMR>, revocation certificate available at
"/intflash/2011G-00165-PRD-5000-PRMR.rvk"
```

Variable Definitions

The following table defines parameters for the **no license 10G** command.

Variable	Value
WORD<1-64> Note: Exception: only supported on the 5320 Series.	Specifies the type of port license to revoke: 4-Port or 8-Port.

Extend the Factory Default Premier Trial License

Use the following procedure to extend the Factory Default Premier Trial License on your switch.

You can run the **extend-time-period** command up to three times to extend the evaluation license in 30-day increments for an additional 90 days.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Extend the trial software license on your device:
   `extend-time-period`

   Note
   You must reboot your switch after each license extension.

Example

Extend the trial license period for 30-days:

```
Switch:1>enable
Switch:1#extend-time-period
Are you sure you want to reset the box to apply changes? (y/n) y
```

Show a License File

Display the existing software licenses on your device. If the switch uses a Factory Default Premier Trial License, the output shows the time remaining in the trial period.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the existing software licenses on your device:
   `show license`

Examples

Note
Example outputs might not be identical on all hardware platforms.

The following output shows time remaining on a Trial License for a universal hardware platform when the trial period is extended:

```
Switch:1>show license

BASE License   : Available, Perpetual
PREMIER License: Factory Default Evaluation
                 Evaluation, 120 days
                 Remaining Days: 117
MACSEC License:  Available, Perpetual
                 Date and Time of Generation: 2020/09/17 00:00:00

*********************************************************************
Features requiring a Premier license:
- Layer 3 VSNs
- MACsec
- Distributed Virtual Routing(DvR) Controller
- >16 BGP Peers
```

The following **`show license`** command output is from a universal hardware platform that supports Base, Premier, MACsec and Port licenses.

```
Switch:1>show license
        BASE License: Available, Perpetual
        PREMIER License: Factory Default Evaluation
                         Evaluation, 30 days
```

```
                        Remaining Days: 28
        MACSEC License: Not Available
        10G License: Available, Perpetual
                      Type: 8-Port 10G
                      Date and Time of Generation: 2021/05/25 00:00:00
*******************************************************************************
```

License Installation using EDM

Install and manage a license file for the switch by using Enterprise Device Manager (EDM).

Note

This section applies to multiple platforms. The fields may not be identical on all hardware platforms.

Install a License File

Install a license file on the switch to enable licensed features.

Before You Begin

- You must store the license file on a file server.
- Ensure that you have the correct license file with the base MAC address of the switch on which you need to install the license. Otherwise, the system does not unblock the licensed features.

About This Task

IPv4 and IPv6 addresses are supported.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **File System**.
3. Select the **Copy File** tab.
4. In the **Source** box, type the IP address of the file server where the license file is located and the name of the license file.
5. In the **Destination** box, type the flash device and the name of the license file.

   The license file name must have a file extension of .xml.
6. Select **start**.
7. Select **Apply**.

   The license file is copied to the flash of the device. The system displays the status of the file copy in the Result field.
8. In the navigation pane, expand **Configuration** > **Edit**.
9. Select **Chassis**.
10. Select the **System** tab.
11. In **ActionGroup1**, select **loadLicense**.
12. In **LicenseFileName** box, type the name of the license file.

13. Select **Apply**.

Important

If the loading fails, the switch cannot unlock the licensed features and reverts to base functionality.

14. On the **System** tab, in **ActionGroup1**, select **saveRuntimeConfig**.
15. Select **Apply**.

Copy File *Field Descriptions*

Use the data in the following table to use the **Copy File** tab.

Name	Description
Source	Identifies the device and file name to copy. You must specify the full path and filename, for example, `<deviceip-ftp server>:/<filename>` Note: For certain switches in enhanced secure mode, sensitive files and paths are protected.
Destination	Identifies the location to which to copy the source file with the filename, for example, `/intflash/<filename>`. Note: For certain switches in enhanced secure mode, sensitive files and paths are protected.
Action	Starts or stops the copy process.
Result	Specifies the result of the copy process: • none • inProgress • success • fail • invalidSource • invalidDestination • outOfMemory • outOfSpace • fileNotFound

System *Field Descriptions*

Use the data in the following table to use the **System** tab.

Name	Description
sysDescr	Shows the system assigned name and the software version.
sysUpTime	Shows the elapsed time since the system last started.

Name	Description
sysContact	Configures the contact information.
sysName	Configures the name of this device.
sysLocation	Configures the physical location of this device.
VirtualIpAddr	Configures the virtual IP address that the primary CPU advertises and stores in the switch configuration file.
VirtualNetMask	Configures the net mask of the virtual management IP address.
VirtualIpv6Addr	Specifies the virtual IPv6 address.
VirtualIpv6PrefixLength	Specifies the length of the virtual IPv6 address prefix (in bits).
DnsDomainName	Configures the default domain for querying the DNS server.
LastChange	Displays the time since the last configuration change.
LastVlanChange	Displays the time since the last VLAN change.
LastStatisticsReset	Displays the time since the statistics counters were last reset.
LastRunTimeConfigSave	Displays the last run-time configuration saved.
DefaultRuntimeConfigFileName	Displays the default Run-time configuration file directory name.
ConfigFileName	Specifies the name of a new configuration file.
ActionGroup1	Performs one of the following actions: • **resetCounters**— Resets all statistic counters. • **saveRuntimeConfig**— Saves the current run-time configuration. • **loadLicense**— Loads a software license file to enable features. • **revokeLicensePremier**— Revokes the Premier license and generates a revocation certificate in XML format. • **revokeLicenseMacsec**—Revokes the MACsec license and generates a revocation certificate in XML format. • **revokeLicense10G4P**— Revokes the 4-port 10 Gbps Port License on 5320 Series and generates a revocation certificate in XML format. • **revokeLicense10G8P**— Revokes the 8-port 10 Gbps Port License on 5320 Series and generates a revocation certificate in XML format.
LicenseFileName	Specifies the name of the license file in the `/intflash` directory.

Name	Description
ActionGroup2	Specifies the following action: **resetIstStatCounters**—Resets the IST statistic counters
ActionGroup3	Can be the following action: • **flushIpRouteTbl**—flushes IP routes from the routing table
ActionGroup4	Can be the following action: • **softReset**—resets the device without running power-on tests • **cpuSwitchOver**—switches over to the other CPU • **softResetCoreDump** —reset with coredump
Result	Displays a message after you select **Apply**.
LocatorLED	Configures the system Locator LED on or off. The default is off.

Revoke a License

Revoke a license on the switch if you need to transfer the license to a different switch.

You can permanently remove a license, which allows you to transfer the license to another switch. This should only be done when preparing to return a defective switch for a replacement switch (RMA).

About This Task

The revocation parameters invalidate the feature license and generate a revocation certificate, which is the first step to releasing the license entitlement back to the license entitlement manager (LEM). The revocation certificate is contained in a file where the first part of the file name is the switch serial number and the file extension is .rvk.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Chassis**.
3. Select the **System** tab.
4. In **ActionGroup1**, select one of the following:
   - **revokeLicense10G4P**
   - **revokeLicense10G8P**
   - **revokeLicenseMacsec**
   - **revokeLicensePremier**
5. Select **Apply**.
6. In **ActionGroup1**, select **saveRuntimeConfig**.
7. Select **Apply**.

System *Field Descriptions*

Use the data in the following table to use the **System** tab.

Name	Description
sysDescr	Shows the system assigned name and the software version.
sysUpTime	Shows the elapsed time since the system last started.
sysContact	Configures the contact information.
sysName	Configures the name of this device.
sysLocation	Configures the physical location of this device.
VirtualIpAddr	Configures the virtual IP address that the primary CPU advertises and stores in the switch configuration file.
VirtualNetMask	Configures the net mask of the virtual management IP address.
VirtualIpv6Addr	Specifies the virtual IPv6 address.
VirtualIpv6PrefixLength	Specifies the length of the virtual IPv6 address prefix (in bits).
DnsDomainName	Configures the default domain for querying the DNS server.
LastChange	Displays the time since the last configuration change.
LastVlanChange	Displays the time since the last VLAN change.
LastStatisticsReset	Displays the time since the statistics counters were last reset.
LastRunTimeConfigSave	Displays the last run-time configuration saved.
DefaultRuntimeConfigFileName	Displays the default Run-time configuration file directory name.
ConfigFileName	Specifies the name of a new configuration file.

Name	Description
ActionGroup1	Performs one of the following actions: • **resetCounters**— Resets all statistic counters. • **saveRuntimeConfig**— Saves the current run-time configuration. • **loadLicense**— Loads a software license file to enable features. • **revokeLicensePremier**— Revokes the Premier license and generates a revocation certificate in XML format. • **revokeLicenseMacsec**—Revokes the MACsec license and generates a revocation certificate in XML format. • **revokeLicense10G4P**— Revokes the 4-port 10 Gbps Port License on 5320 Series and generates a revocation certificate in XML format. • **revokeLicense10G8P**— Revokes the 8-port 10 Gbps Port License on 5320 Series and generates a revocation certificate in XML format.
LicenseFileName	Specifies the name of the license file in the `/intflash` directory.
ActionGroup2	Specifies the following action: **resetIstStatCounters**—Resets the IST statistic counters
ActionGroup3	Can be the following action: • **flushIpRouteTbl**—flushes IP routes from the routing table
ActionGroup4	Can be the following action: • **softReset**—resets the device without running power-on tests • **cpuSwitchOver**—switches over to the other CPU • **softResetCoreDump** —reset with coredump
Result	Displays a message after you select **Apply**.
LocatorLED	Configures the system Locator LED on or off. The default is off.

View License File Information

About This Task

View information about the license file for the switch.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.

2. Click **Chassis**.
3. Click the **License** tab.

License *field descriptions*

Use the data in the following table to use the **License** tab.

Name	Description
FileName	Indicates the file name of the current license. Note: If this field is empty it indicates that there is no license installed on the switch.
LicenseType	Indicates the level type of the current license.
DurationType	Indicates the duration type of the current license.
RemainingDays	Indicates the days left before the factory default trial period or subscription license expires. Note: For other license types, the field displays 0.
GenerationTime	Indicates the date on which the license file was generated. Note: If there is no license installed on the system, this field displays 0000000000000000 H.
ExpirationTime	Indicates the date on which the license file expired. Note: If there is no license installed on the system, this field displays 0000000000000000 H.

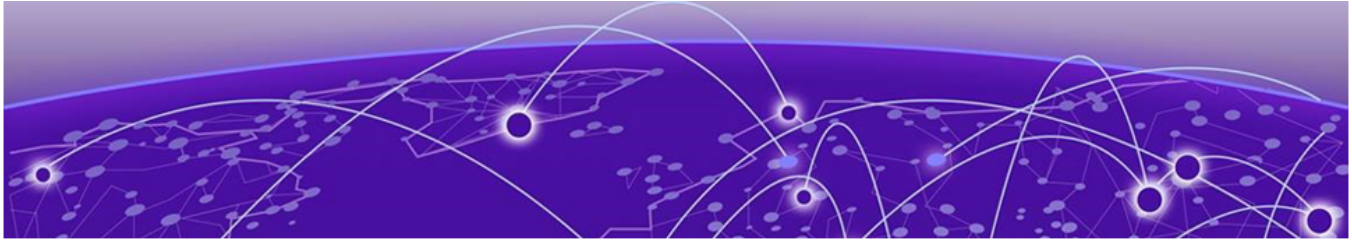
System *Field Descriptions*

Use the data in the following table to use the **System** tab.

Name	Description
sysDescr	Shows the system assigned name and the software version.
sysUpTime	Shows the elapsed time since the system last started.
sysContact	Configures the contact information.
sysName	Configures the name of this device.
sysLocation	Configures the physical location of this device.

Name	Description
VirtualIpAddr	Configures the virtual IP address that the primary CPU advertises and stores in the switch configuration file.
VirtualNetMask	Configures the net mask of the virtual management IP address.
VirtualIpv6Addr	Specifies the virtual IPv6 address.
VirtualIpv6PrefixLength	Specifies the length of the virtual IPv6 address prefix (in bits).
DnsDomainName	Configures the default domain for querying the DNS server.
LastChange	Displays the time since the last configuration change.
LastVlanChange	Displays the time since the last VLAN change.
LastStatisticsReset	Displays the time since the statistics counters were last reset.
LastRunTimeConfigSave	Displays the last run-time configuration saved.
DefaultRuntimeConfigFileName	Displays the default Run-time configuration file directory name.
ConfigFileName	Specifies the name of a new configuration file.
ActionGroup1	Performs one of the following actions: • **resetCounters**— Resets all statistic counters. • **saveRuntimeConfig**— Saves the current run-time configuration. • **loadLicense**— Loads a software license file to enable features. • **revokeLicensePremier**— Revokes the Premier license and generates a revocation certificate in XML format. • **revokeLicenseMacsec**—Revokes the MACsec license and generates a revocation certificate in XML format. • **revokeLicense10G4P**— Revokes the 4-port 10 Gbps Port License on 5320 Series and generates a revocation certificate in XML format. • **revokeLicense10G8P**— Revokes the 8-port 10 Gbps Port License on 5320 Series and generates a revocation certificate in XML format.
LicenseFileName	Specifies the name of the license file in the `/intflash` directory.
ActionGroup2	Specifies the following action: **resetIstStatCounters**—Resets the IST statistic counters

Name	Description
ActionGroup3	Can be the following action: • **flushIpRouteTbl**—flushes IP routes from the routing table
ActionGroup4	Can be the following action: • **softReset**—resets the device without running power-on tests • **cpuSwitchOver**—switches over to the other CPU • **softResetCoreDump** —reset with coredump
Result	Displays a message after you select **Apply**.
LocatorLED	Configures the system Locator LED on or off. The default is off.



Link Aggregation Control Protocol

The following sections provide the concepts and procedures you need to configure the Link Aggregation Control Protocol (LACP) to dynamically aggregate links as they become available to a trunk group.

Link Aggregation Overview

Link aggregation provides link level redundancy and increases load sharing. Use Link aggregation to bundle the ports into a port group, which is represented as one logical interface to the Media Access Control (MAC) layer.

The switch supports the following types of link aggregation:

- MultiLink Trunking (MLT)—a statically configured link bundling method. MLT is not standards based, but it interoperates with static link methods of other vendors.
- IEEE 802.3ad based link aggregation, through the Link Aggregation Control Protocol (LACP), dynamically aggregates links as they become available to a trunk group. Link Aggregation Control Protocol dynamically detects whether links can be aggregated into a link aggregation group (LAG) and does so after links become available. Link Aggregation Control Protocol also provides link integrity checking at Layer 2 for all links within the LAG.

Both MLT and IEEE 802.3ad based link aggregation are point-to-point functions.

The switch software offers LACP functionality layered with MLT. This document uses the term MLT with LACP to refer to this functionality.

Split MultiLink Trunking (SMLT)

Split MultiLink Trunking (SMLT) is an option that improves Layer 2 (bridged) resiliency by providing for the addition of failure redundancy with subsecond failover, on top of all standard MLT link failure protection and flexible bandwidth scaling functionality. Use SMLT to connect a device that supports some form of link aggregation, be it a switch or a server, to two distinct separate SMLT endpoints or switches. These SMLT devices form a virtualized Switch Cluster through the SPBM cloud and are referred to as a Virtual Inter-Switch Trunk (vIST) Core Switch pair.

For more information, see the following sections:

- Virtual Inter-Switch Trunk (vIST) on page 2090
- Simplified Virtual-IST on page 2092
- Split MultiLink Trunking on page 2095

LACP with SMLT

You can use LACP on SMLT configurations. The switch provides modifications to the LACP in SMLT configurations. LACP-capable devices can connect to an SMLT aggregation pair.

Note

Virtual IST is not supported on LACP-enabled MLTs.

VLACP with SMLT

You can also configure Virtual LACP (VLACP) with an SMLT configuration. VLACP is a modification that provides end-to-end failure detection. VLACP is not a link aggregation protocol.

VLACP implements link status control protocol at the port level. This mechanism periodically checks the end-to-end health of a point-to-point or end-to-end connection. You can run VLACP on single ports or on ports that are part of an MLT.

Note

Do not configure VLACP on LACP-enabled ports. VLACP does not operate properly with LACP.

MultiLink Trunking with LACP

MultiLink Trunking (MLT) with Link Aggregation Control Protocol (LACP) manages ports and port memberships to form a link aggregation group (LAG). Use Link Aggregation Control Protocol to gather one or more links to form a LAG, which a Media Access Control (MAC) client treats as a single link. Link Aggregation Control Protocol can dynamically add or remove LAG ports, depending on availability and state.

IEEE 802.3ad overview

The IEEE 802.3ad standard comprises service interfaces, the LACP, the Marker Protocol, link aggregation selection logic, a parser or multiplexer, frame distribution, and frame collection functions.

The following illustration shows the major functions of IEEE 802.3ad defined as multiple link aggregation.

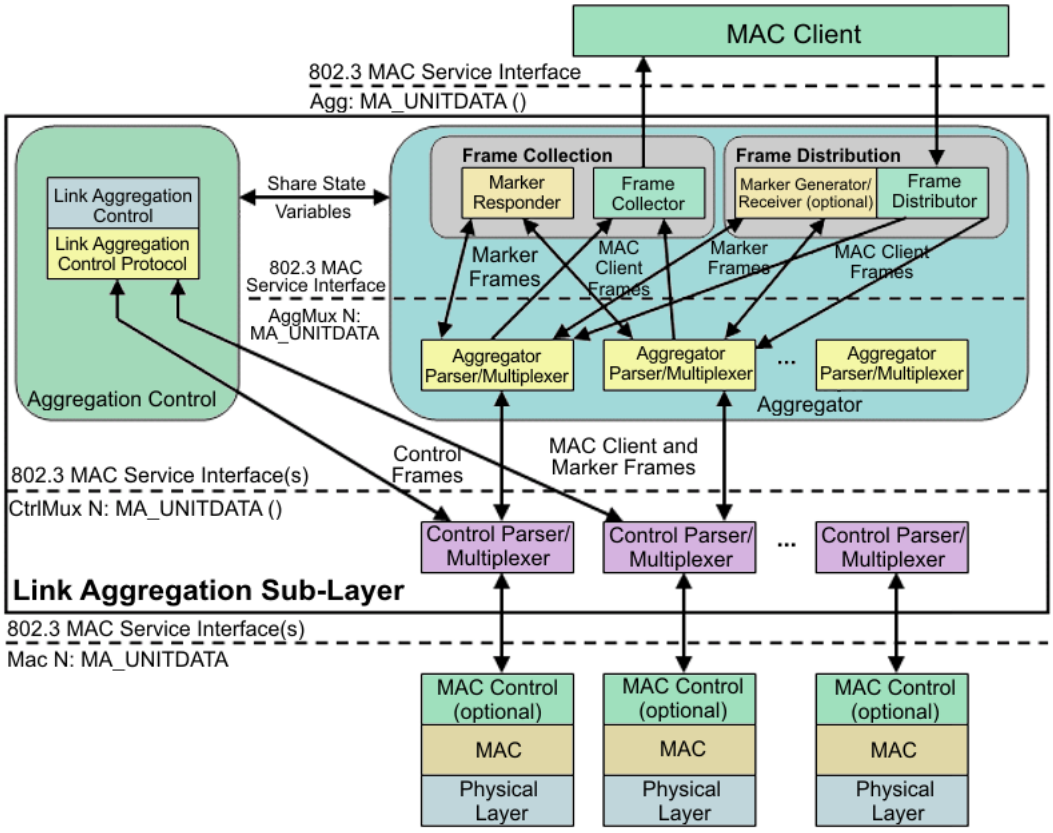


Figure 171: Link aggregation sublayer (according to IEEE 802.3ad)

The link aggregation sublayer comprises the following functions:

- frame distribution

  This block takes frames submitted by the MAC client and sends them for transmission on the appropriate port based on a frame distribution algorithm employed by the Frame Distributor.

  Frame distribution also includes an optional Marker Generator/Receiver used for the Marker Protocol. The switch only implements the Marker Receiver function. For more information about the frame distribution algorithm, see MLT Traffic Distribution Algorithm on page 2093.

- frame collection

  This block passes frames received from the various ports to the MAC client. Frame collection also includes a Marker Responder used for the Marker Protocol.

- aggregator parser or multiplexers

  During transmission operations, these blocks pass frame transmission requests from the Distributor, Marker Generator, and Marker Responder to the appropriate port.

  During receive operations, these blocks distinguish among Marker Request, Marker Response, MAC Client Protocol Data Units (PDU), and pass the blocks to the appropriate entity (Marker Responder, Marker Receiver, and Collector, respectively).

- aggregator

The combination of frame distribution and collection, and aggregator parser or multiplexers.

- aggregation control

  This block configures and controls link aggregation. It incorporates LACP for the automatic communication of aggregation capabilities between systems and automatic configuration of link aggregation.

- control parser/multiplexers

  During transmission operations, these blocks pass frame transmission requests from the aggregator and Control entities to the appropriate port.

  During receive operations, these blocks distinguish Link Aggregation Control Protocol Data Units (LACPDUs) from other frames. The blocks pass, passing the LACPDUs to the appropriate sublayer entity and all other frames to the aggregator.

802.3ad link aggregation principles

Use link aggregation to group ports together to form a link group to another device. Link groups increase aggregate throughput between devices and provide link redundancy.

Link aggregation employs the following principles and concepts:

- A MAC client communicates with a set of ports through an aggregator, which presents a standard IEEE 802.3 service interface to the MAC client. The aggregator binds to one or more ports within a system.
- The aggregator distributes frame transmissions from the MAC client to various ports, collects received frames from the ports, and transparently passes the frames to the MAC client.
- A system can contain multiple aggregators serving multiple MAC clients. A port binds to a single aggregator at a time. A MAC client is served by a single aggregator at a time.
- The Link Aggregation Control function binds ports to aggregators within a system. The control function aggregates links, binds the system ports to an appropriate aggregator, and monitors conditions to determine if a change in aggregation is needed. Network managers can manually provide link aggregation control by manipulating the link aggregation state variables (for example, keys). You can also use LACP to automatically determine, configure, bind, and monitor link aggregation.
- LACP uses peer exchanges across links to continually determine the aggregation capability of the links and provide the maximum level of aggregation capability between a pair of systems.
- Frame ordering is maintained for certain sequences of frame exchanges between MAC Clients. The distributor ensures that all frames of a conversation pass to a single port. The collector passes frames to the MAC client in the order they are received from the port. The collector can select frames received from the aggregated ports. Because the frames are not ordered on a single link, this guarantees that frame ordering is maintained for all conversations.
- Conversations move among ports within an aggregation for load balancing and for maintaining availability if a link fails.
- Each port is assigned a unique, globally administered MAC address.

After entities initiate frame exchanges within the link aggregation sublayer, the source address is the MAC address. An example of an entity that initiates frame exchanges is LACP and Marker Protocol exchanges.

- Each aggregator is assigned a unique, globally administered MAC address that is used from the perspective of the MAC client, both as a source address for transmitted frames and as the destination address for received frames. You can use one of the port MAC addresses in the associated LAG as the MAC address of the aggregator.

Input/output port redundancy

You can use the MLT link aggregation mechanism to protect I/O ports. MLT is compatible with 802.3ad static, and provides a load sharing and failover mechanism to protect against module, port, fiber, or complete link failures.

You can use MLT with Link Access Control Protocol (LACP) disabled or use LACP enabled by itself.

LACP configuration considerations

You can configure priorities, keys, modes, and timers for the LACP.

LACP priority

You can configure LACP priority at the system and port level as follows:

- Port priority—determines which ports are aggregated into a LAG that has more than eight ports configured to it.
- System priority—generates the switch ID after communicating with other systems. As a best practice, use the default value. If you need to change it, first disable the LACP, and then enable it again after you change the value.

LACP keys

You must use the LACP keys to determine which ports are eligible for link aggregation. The LACP keys are defined by the ports after you configure the multilink trunk. You can aggregate the ports key that match the MLT key into that multilink trunk.

- Keys do not have to match between two LACP peers.

LACP timers

You can customize failover times by changing the LACP timer attributes (fast periodic time, slow periodic time, and aggregate wait time). Values are set by default to match the IEEE 802.3ad values. If you change the values, they must match on the ports participating in aggregation between two devices.

Changes to LACP timer values at the global level are reflected on all ports. However, you can change the LACP timer values for each port level. After you change an LACP timer globally, this value is set on all ports. The global timer value overwrites the local port value irrespective of the LACP state. You must configure port values that differ from the global values.

The switch software uses the following LACP timers:

- fast periodic timer—200 to 20 000 milliseconds (ms); default 1000 ms
- slow periodic timer—10 000 to 30 000 ms; default 30000 ms
- aggregation-wait timer—200 to 2000; default 2000

You cannot aggregate a link if it does not receive an LACPDU for a period of timeout x slow periodic time = 3 x 30 seconds = 90 seconds. If you use the fast periodic time, the timeout period is 3 x 1000 ms = 3 seconds. You must make timer changes to all ports participating in link aggregation and to the ports on the partnering node.

Configuration changes to the LACP timers are not reflected immediately. Link Aggregation Control Protocol timers do not reset until the next time you restart LACP globally or on a port. This ensures consistency with peer switches.

After you enable LACP on a port, the timer values are set at the port level. You must toggle the LACP status after timer values change. This does not impact existing ports unless you toggle the LACP status on the port.

LACP modes

LACP uses two active and passive modes.

- Active mode—ports initiate the aggregation process. Active mode ports aggregate with other active mode ports or passive mode ports.
- Passive mode—ports participate in LACP but do not initiate the aggregation process. You must partner passive mode ports with active mode ports for aggregation to occur.

LACP and private VLANs

- When using LACP, configure the private-vlan at the interface level.

Link aggregation scaling

For the latest applicable scaling information, see *Fabric Engine Release Notes* for the version of the software running on the switch.

Important Information and Restrictions

Before you use the switch, review the following important information and restrictions.

LACP with Simplified vIST/SPB NNI links

You should not use LACP on SPB NNI MLT links or on the Simplified Virtual IST.

vIST VLAN IP addresses

Do not configure a Rendezvous Point (RP) or Bootstrap Router (BSR) on the vIST VLAN because you cannot ping them outside of the vIST VLAN subnet. When you enter the **ip pim enable** command on the vIST VLAN, the following message displays:

```
WARNING: Please do not use virtual IST VLAN IP address for BSR and RP
related configurations, as unicast packets to virtual IST vlan IP
address from outside of  virtual IST vlan subnet will be dropped. Use
Loopback or CLIP interface IP address for BSR and RP related
configurations.
```

Simplified vIST and egress port-based filters

On Simplified vIST nodes, egress port-based filters may not work for IP multicast routed traffic because vIST internal filter rules (to prevent duplicate traffic) have higher precedence than user-created filters.

Note

- This issue is specific to IP multicast routed traffic only.
- Egress port-based filters work for Layer 2 multicast, broadcast and unicast traffic.

LACP configuration using CLI

This section describes how to configure and manage link aggregation using the Command Line Interface (CLI), including Link Aggregation Control Protocol (LACP), to increase the link speed and redundancy for higher availability.

MultiLink Trunking (MLT) with LACP manages switch ports and port memberships to form a link aggregation group (LAG). Configure LACP to allow dynamic bundling of physical ports to form a single logical channel.

You can describe the LACP in terms of link aggregation operations within a single system. You can configure a single piece of equipment so it contains more than one system (from the point of view of the link aggregation operation).

Before You Begin

- Changes to LACP made at the global level overrides and resets all port level settings.

Important

After you globally configure the LACP system priority, it applies to all LACP-enabled aggregators and ports. After you enable the LACP on an aggregator or port, it uses the global system priority value.

- After you make a timer change, restart the LACP (globally or on the port) so the changes are consistent across the link.

  

  Important

  Configuration changes to LACP timers are not reflected immediately. LACP timers are not reset until the next time LACP is restarted globally or on a port. This action ensures consistency with peer switches.

- The switch does not support standby ports for LACP aggregation groups.

Configuring global LACP parameters

Configure LACP parameters globally. After you configure the LACP system priority globally, it applies to all LACP-enabled aggregators and ports. After you enable the LACP on an aggregator or a port, it uses the global system priority value.

A change to the global parameter configuration takes effect after you restart the LACP globally or on each port.

About This Task

Important

Changes made at the global level override and reset all port level settings.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Change the system priority:

   ```
   lacp system-priority <0-65535>
   ```

3. Configure additional LACP parameters as required:

   ```
   lacp enable [aggr-wait-time <200-2000>] [fast-periodic-time
   <200-20000>] [slow-periodic-time <10000-30000>] [smlt-sys-id
   <0x00:0x00:0x00:0x00:0x00:0x00> ] [system-priority <0-65535> ]
   [timeout—scale <2-10>]
   ```

   If you do not configure the optional parameters, the system uses the default values.

Example

```
Switch:1(config)#lacp fast-periodic-time 2000
Switch:1(config)#lacp enable
```

Variable Definitions

The following table defines parameters for the **lacp** command.

Variable	Value
aggr-wait-time <200–2000>	Configures the aggregation wait time (in milliseconds) globally. The default value is 2000.
enable	Enables LACP globally. The default value is disabled.
fast-periodic-time <200–20000>	Configures the fast periodic time (in milliseconds) globally. The default value is 1000.
slow-periodic-time <10000–30000>	Configures the slow periodic time globally. The default value is 30000.
smlt-sys-id <0x00:0x00:0x00:0x00:0x00:0x00> Note: Exception: not supported on 5320 Series.	Configures the LACP system ID globally. Enter a MAC address in the following format: 0x00:0x00:0x00:0x00:0x00:0x00.
system-priority <0–65535>	Configures the LACP system priority globally. The default value is 32768.
timeout-scale <2–10>	Configures the timeout scale globally. The default value is 3.

Configure LACP on a Port

Important

Changes made at the global level override and reset the port-level configuration.

Configure LACP on a port to enable or disable LACP on the selected ports.

You must use the LACP keys to determine which ports are eligible for link aggregation. The LACP keys are defined by the ports after you configure the multilink trunk. You can aggregate the ports key that match the MLT key into that multilink trunk.

Before You Begin

When enabling or disabling LACP on a port, as a best practice, disable the port first and re-enable the port after the configuration is complete.

About This Task

The minimum LACP configuration is as follows:

- Assign a given key to a set of ports. In the following procedure steps, you must assign the key before you enable LACP on the port.
- Assign the same key to an MLT with no members. The ports will automatically become MLT members.

Keys do not need to match between two LACP peers.

A port can operate in active or passive mode. You can configure a port to be an individual link or an aggregated link.

Note
When using LACP with private VLANs, configure the private VLAN at the interface level.

Procedure

1. Enter Interface Configuration mode:
   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Assign an LACP key:
   ```
   lacp key <1-512|defVal>
   ```
3. Change the LACP mode:
   ```
   lacp mode <active|passive>
   ```
4. Change the port priority:
   ```
   lacp priority <0-65535>
   ```
5. (Optional) Change the system priority:
   ```
   lacp system-priority <0-65535>
   ```
6. Configure aggregation for the port:
   ```
   lacp aggr-wait-time <200-2000>[aggregation enable]
   ```

   If you do not configure the optional parameter, the system uses the default values.
7. Configure parameters for the partner device at the opposite end of the link:

   Note
   All parameters beginning with **partner** are for debug purposes only. If you configure these commands locally and there is a mismatch with what is learned from the partner, there will be trace or log messages.

   ```
   lacp partner-key <0-65535|defVal>

   lacp partner-port <0-65535>

   lacp partner-port-priority <0-65535>

   lacp partner-state <0-255 | 0x0-0xff>

   lacp partner-system-id 0x00:0x00:0x00:0x00:0x00:0x00

   lacp partner-system-priority <0-65535>
   ```

8. Configure additional LACP parameters as required:

   ```
   lacp enable [fast-periodic-time <200-20000>] [slow-periodic-time
   <10000-30000>] [timeout-time <long|short>] [timeout-scale <2-10>]
   ```

   If you do not configure the optional parameters, the system uses the default values.
9. Enable LACP aggregation:

   ```
   lacp aggregation enable
   ```

Examples

Configure LACP on ports 1/2 and 1/3:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/2-1/3
Switch:1(config-if)#lacp key 100
Switch:1(config-if)#lacp aggregation enable
Switch:1(config-if)#lacp enable
```

Return the key to the default value:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/2-1/3
Switch:1(config-if)#no lacp aggregation enable
Switch:1(config-if)#default lacp key
Switch:1(config-if)#lacp aggregation enable
```

Variable Definitions

The following table defines parameters for the **lacp** command.

Note

All parameters beginning with **partner** are for debug purposes only. If you configure these commands locally and there is a mismatch with what is learned from the partner, there will be trace or log messages.

Variable	Value
aggr-wait-time <200-2000>	Configures the aggregation wait time (in milliseconds) for this port. The default is 2000.
aggregation enable	Enables aggregation on the port, which makes it an aggregated link.
enable	Enables LACP for this port. The default is disabled.
fast-periodic-time <200-20000>	Configures the fast periodic time (in milliseconds) for this port. The default is 1000 ms.
key <1-512|defVal>	Configures the aggregation key for this port. Enter the aggregation key value or defVal (1024 + IfIndex) To return a configured key to the default value, you must first disable LACP aggregation on the port.
mode {active | passive}	Configures the LACP mode to be active or passive.

Variable	Value
partner-key <0-65535>	Configures the partner administrative key.
partner-port <0-65535>	Configures the partner administrative port value.
partner-port-priority <0-65535>	Configures the partner administrative port priority value.
partner-state <0-255 | 0x0-0xff>	Configures the partner administrative state bitmask. Specify the partner administrative state bitmap in the range 0x0–0xff. The bit to state mapping is Exp, Def, Dis, Col, Syn, Agg, Time, and Act. For example, to set the two partner-state parameters • Act = true • Agg = true specify a value of 0x05 (bitmap = 00000101).
partner-system-id <0x00:0x00:0x00:0x00:0x00:0x00>	Configures the partner administrative system ID. Specify a MAC address in the format 0x00:0x00:0x00:0x00:0x00:0x00.
partner-system-priority <0-65535>	Configures the partner administrative system priority value.
priority <0-65535>	Configures the port priority. The default value is 32768. To set this option to the default value, use the **default** operator with the command.
slow-periodic-time <10000-30000>	Configures the slow periodic time for this port. The default is 30000 ms. To set this option to the default value, use the **default** operator with the command.
system-priority <0-65535>	Configures the system priority for this port. The default is 32768.
timeout-scale <2-10>	Configures a timeout scale for this port. The default value is 3. The LACP timeout is equal to the slow periodic time or fast periodic time multiplied by the timeout-scale, depending how you configure the timeout-time variable.
timeout-time {long|short}	Configures the timeout to either long or short.

Configure LACP on an MLT

Configure an MLT with LACP to use the dynamic link aggregation function.

About This Task

Important

Attach ports to an aggregator only if their system priorities are the same; otherwise, they are considered to be operating in two different switches. You can attach ports to an aggregator only if their keys are the same.

When you add a VLAN to a dynamic MLT, only the active ports of the MLT are added as port members of the VLAN. Ports configured with the same aggregation key, but not active, are not added to the

VLAN. If these inactive ports become active later, the system does not automatically add them to the VLAN port member list.

You must add all inactive ports to the VLAN. If you do not add the inactive ports to the VLAN, when they become active later, hashing can result in choosing a newly active port for traffic forwarding. Because the port is not a port member of the VLAN, traffic will be dropped. When you add the VLAN to the MLT, also add the inactive aggregation ports to the VLAN. You may need to disable LACP on the inactive ports before you can add them to the VLAN. Because the ports are inactive, disabling LACP does not cause a traffic interruption.

Similarly when you remove a VLAN from a dynamic MLT, all active ports of the MLT are removed from the VLAN port member list but the inactive members are not removed. You must remove the inactive aggregation members from the VLAN.

If you later configure a port for the same aggregation, you must add this port to all VLANs that are members of the MLT.

Procedure

1. Enter MLT Interface Configuration mode:

   ```
   enable

   configure terminal

   interface mlt <1-512>
   ```

2. Configure LACP on an MLT:

   ```
   lacp enable [key <0-512>] [system-priority <0-65535>]
   ```

Example

Enable LACP and configure the LACP key on MLT 3:

```
Switch:1(config)# interface mlt 3
Switch:1(config-mlt)# lacp enable key 1281
```

Variable definitions

Use the data in the following table to use the **lacp** command.

Variable	Value
enable	Enables LACP on the MLT interface.
key <0-512>	Configures the LACP aggregator key for a specific MLT. • *0–512* is the LACP actor admin key.
system-priority <0-65535>	Configures the LACP system priority for a specific MLT. • *0–65535* is the system priority.

Configuring LACP and Private VLANs

About This Task

Use the following procedure to configure Link Aggregation Control Protocol (LACP) on a private VLAN.

Procedure

1. Enter Interface Configuration mode:

   ```
   enable
   ```

   ```
   configure terminal
   ```

   ```
   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]} or interface vlan <1-4059>
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable trunking:

   ```
   encapsulation dot1q
   ```

3. Set private VLAN port type:

   ```
   private-vlan [isolated|promiscuous|trunk]
   ```

Example

```
Switch:1(config)#interface GigabitEthernet 1/6
Switch:1(config-if)#encapsulation dot1q
Switch:1(config-if)#private-vlan promiscuous
Switch:1(config-if)#exit

Switch:1(config)#interface GigabitEthernet 1/37
Switch:1(config-if)#encapsulation dot1q
Switch:1(config-if)#private-vlan promiscuous
```

Viewing LACP configuration information

View LACP configuration information to determine the LACP parameters and to ensure your configuration is correct.

Procedure

1. View the global configuration:

   ```
   show lacp
   ```

2. View LACP administrative information for the local device:

   ```
   show lacp actor-admin interface [gigabitethernet]
   ```

   OR

   ```
   show lacp actor-admin interface gigabitethernet [vid <1-4059>] [{slot/port[/sub-port][-slot/port[/sub-port]][,...]}]
   ```

3. View LACP operational information for the actor device:

   ```
   show lacp actor-oper interface [gigabitethernet]
   ```

   OR

   ```
   show lacp actor-oper interface gigabitethernet [vid <1-4059>] [{slot/
   port[/sub-port][-slot/port[/sub-port]][,...]}]
   ```

4. View LACP timer information:

   ```
   show lacp extension interface [gigabitethernet]
   ```

5. View LACP interface configuration information

   ```
   show lacp interface
   ```

   OR

   ```
   show lacp interface gigabitethernet [vid <1-4059>] [{slot/port[/sub-
   port][-slot/port[/sub-port]][,...]}]
   ```

   OR

   ```
   show lacp interface mlt [<64-6399>]
   ```

   OR

   ```
   show lacp interface mlt [id<1-512>]
   ```

6. View LACP administrative information for the partner device:

   ```
   show lacp partner-admin interface [gigabitethernet]
   ```

   OR

   ```
   show lacp partner-admin interface gigabitethernet [vid <1-4059>]
   [{slot/port[/sub-port][-slot/port[/sub-port]][,...]}]
   ```

7. View LACP operational information for the partner device:

   ```
   show lacp partner-oper interface [gigabitethernet]
   ```

   OR

   ```
   show lacp partner-oper interface gigabitethernet [vid <1-4059>]
   [{slot/port[/sub-port][-slot/port[/sub-port]][,...]}]
   ```

Example

```
Switch:1# show lacp

================================================================================
                            Lacp Global Information
================================================================================
               SystemId: 00:24:7f:a1:70:00
           SmltSystemId: 00:00:00:00:00:00
               Lacp: enable
        system-priority: 32768
                 timeout-admin: 3
     fast-periodic-time-admin: 1000
     slow-periodic-time-admin: 30000
         aggr-wait-time-admin: 2000
                 timeout-oper: 3
```

```
     fast-periodic-time-oper: 2000
     slow-periodic-time-oper: 30000
         aggr-wait-time-oper: 2000
```

In the following example output, `aggr` indicates the port has become part of an aggregation. `indi` indicates individual.

```
Switch:1(config-if)# show lacp actor-admin interface gigabitethernet 1/1
================================================================================
                                Actor Admin
================================================================================
INDEX SYS   SYS               KEY   PORT  PORT  STATE
      PRIO  ID                            PRIO
--------------------------------------------------------------------------------
1/1  32768 00:24:7f:9f:c0:00 1     0x114   32768 act short aggr

Switch:1(config-if)# show lacp partner-admin interface gigabitethernet 1/1
================================================================================
                               Partner Admin
================================================================================
INDEX SYS   SYS               KEY   PORT  PORT  STATE
      PRIO  ID                            PRIO
--------------------------------------------------------------------------------
1/1  0     00:00:00:00:00:00 0     0x0     0     pas               long indi
```

Variable definitions

Use the data in the following table to use the **show lacp** command.

Variable	Value
actor-admin interface gigabitethernet [vid *<1-4059> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*	Shows LACP actor (or local) administrative information for all interfaces or the specified interface. • Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. • *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}* is the port or port list.
actor-oper interface gigabitethernet [vid *<1-4059>*[*{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*]	Shows LACP actor operational information for all interfaces or the specified interface. • Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. • *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}* is the port or port list.
extension interface gigabitethernet [vid *<1-4059>*[*{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*]	Shows LACP timer information for all interfaces or the specified interface. • Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. • *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}* is the port or port list.

Variable	Value
interface [gigabitethernet [vid *<1-4059>*[*{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*] [mlt <64-6399>}] [mlt id <1-128>}]	Shows all LACP port configuration information for all interfaces or the interface you specify. • Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. • *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}* is the port or port list. • *<64-6399>* is the interface index of the mlt. • *<1-128>* is the MLT ID.
partner-admin interface[gigabitethernet] [vid *<1-4059>*[*{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*]	Shows LACP partner administrative information for all interfaces or the specified interface. • Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. • *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}* is the port or port list.
partner-oper interface [gigabitethernet] [vid *<1-4059>*[*{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*]	Shows LACP partner operational information for all interfaces or the specified interface. • Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. • *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}* is the port or port list.

Displaying LACP Statistics for Specific Ports

Display individual LACP statistics for specific ports to manage network performance.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. View statistics for specific ports:

   ```
   show interfaces GigabitEthernet statistics lacp [{slot/port[/sub-port]
   [-slot/port[/sub-port]][,...]}]
   ```

Example

View LACP statistics:

```
Switch:1>enable
Switch:1#show interfaces gigabitethernet statistics lacp

================================================================================
                                Port Stats Lacp
================================================================================

--------------------------------------------------------------------------------
1/39  0        0        0         0         0              0       0       0
1/40  0        0        0         0         0              0       0       0
2/37  0        0        0         0         0              0       0       0
2/38  0        0        0         0         0              0       0       0
```

Variable Definitions

Use the data in the following table to use the **`show interfaces GigabitEthernet statistics lacp`** command.

Variable	Value
`{slot/port[/sub-port][-slot/port[/sub-port]][,...]}`	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

LACP configuration using EDM

MultiLink Trunking (MLT) with Link Aggregation Control Protocol (LACP) manages switch ports and port memberships to form a link aggregation group (LAG). Configure LACP to allow dynamic bundling of physical ports to form a single logical channel.

Note

The switch does not support standby ports for LACP aggregation groups.

Configuring global LACP parameters

Use LACP parameters to manage switch ports and their port memberships to form link aggregation groups (LAG). Link Aggregation Control Protocol (LACP) can dynamically add or remove LAG ports, depending on their availability and states.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **VLAN**.
2. Click **MLT/LACP**.
3. Click the **LACP Global** tab.
4. To enable LACP globally, select the **Enable** check box.
5. Configure the remaining parameters as required.

Important

Configuration changes to the LACP timers are not effective immediately. Link Aggregation Control Protocol timers are not reset until the next time LACP is restarted globally or on a port. This ensures consistency with peer switches.

6. Click **Apply**.

LACP Global *Field Descriptions*

Use the data in the following table to use the **LACP Global** tab.

Name	Description
Enable	Enables or disables LACP globally.
SystemPriority	Configures the system priority for all LACP enabled aggregators and ports. The default value is 32768.
FastPeriodicTime	Configures the number of milliseconds between periodic transmissions that use short timeouts. Sets this value to all LACP-enabled ports. The range is 200–20000. The default value is 1000.
FastPeriodicTimeOper	Displays the operating value of the fast periodic timer on the port. The default value is 1000.
SlowPeriodicTime	Configures the number of milliseconds between periodic transmissions that use long timeouts. All LACP enabled ports get the same value from this setting. The range is 10000–30000. The default value is 30000.
SlowPeriodicTimeOper	Displays the operating value of the slow periodic timer on the port. The default value is 30000.
AggrWaitTime	Configures the number of milliseconds to delay aggregation to allow multiple links to aggregate simultaneously. The range is 200–2000. The default value is 2000.

Name	Description
AggrWaitTimeOper	Displays the operating value of the aggregate wait timer on the port. The default value is 2000.
TimeoutScale	Configures the value used to calculate timeout time from the periodic time. All LACP-enabled ports get the same value from this setting. The range is 2–10. The default value is 3.
TimeoutScaleOper	Displays the operating value of the timeout scale on the port. The default value is 3.
SysId	Specifies the LACP system ID. The default value is f8:73:a2:00:90:00.
SmltSysId Note: Exception: not supported on 5320 Series.	Specifies the LACP system ID for Split MultiLink Trunking (SMLT).

Configuring LACP parameters

Configure LACP parameters to manage LACP information.

About This Task

Important

The switch does not support standby ports for LACP aggregation groups.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **VLAN**.
2. Click **MLT/LACP**.
3. Click the **LACP** tab.
4. Double-click a field to change the value.

   You cannot edit grey-shaded fields in the table.
5. Click **Apply**.

LACP *field descriptions*

Use the data in the following table to use the **LACP** tab.

Name	Description
Index	The unique identifier the local system allocates to this aggregator. This attribute identifies an aggregator instance among the subordinate managed objects of the containing object. This value is read-only.
MACAddress	The six octet read-only value carrying the individual MAC address assigned to the aggregator.

Name	Description
ActorSystemPriority	The two octet read-write value indicating the priority value associated with the actor system ID. The default value is 32768.
ActorSystemID	The six octet read-write MAC address value used as a unique identifier for the system that contains this aggregator. From the perspective of the link aggregation mechanisms, only a single combination of actor system ID and system priority are considered. No distinction is made between the values of these parameters for an aggregator and the ports that are associated with it. The protocol is described in terms of the operation of aggregation within a single system. However, the managed objects provided for the both the aggregator and the port allow management of these parameters. The result permits a single piece of equipment to be configured by management to contain more than one system from the point of view of the operation of link aggregation, which is useful in the configuration of equipment that has limited aggregation capability.
AggregateOrIndividual	Indicates whether the aggregator represents an aggregate (true) or an individual link (false).
ActorAdminKey	Specifies the current administrative value of the key for the aggregator, which is a 16-bit read-write value. The administrative key value can differ from the operational key value. This key needs to match the LAG key. The default value is 0.
ActorOperKey	Displays the current read-only operational value of the key for the aggregator. The operational key value can differ from the administrative key value. The meaning of particular key values is of local significance.
PartnerSystemID	The six octet read-only MAC address value consisting of the unique identifier for the current protocol partner of this aggregator. A value of zero indicates that there is no known partner. If the aggregation is manually configured, the value is assigned by the local system.
PartnerSystemPriority	The two octet read-only value that indicates the priority value associated with the partner system ID. If the aggregation is manually configured, this system priority value is a value assigned by the local system.
PartnerOperKey	The current operational value of the key for the aggregator current protocol partner, which is a 16-bit read-only value. If the aggregation is manually configured, the value is assigned by the local system.

Configure LACP on a Port

Important

Changes made at the global level override and reset the port-level configuration.

Configure LACP on a port to enable LACP.

You must use the LACP keys to determine which ports are eligible for link aggregation. The LACP keys are defined by the ports after you configure the multilink trunk. You can aggregate the ports key that match the MLT key into that multilink trunk.

Before You Begin

When enabling or disabling LACP on a port, as a best practice, disable the port first and re-enable the port after the configuration is complete.

About This Task

The minimum LACP configuration is as follows:

- Assign a given key to a set of ports. In the following procedure steps, you must assign the key before you enable LACP on the port.
- Assign the same key to an MLT with no members. The ports will automatically become MLT members.

Keys do not need to match between two LACP peers.

A port can operate in active or passive mode. You can configure a port to be an individual link or an aggregated link.

Note

When using LACP with private VLANs, configure the private VLAN at the interface level.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
3. Select **General**.
4. Select the **LACP** tab.
5. To assign an LACP key, configure **ActorAdminKey**.
6. Select **Apply**.
7. To enable LACP on the port, select **AdminEnable**.
8. Configure the remaining parameters as required.
9. Select **Apply**.

LACP *Field Descriptions*

Use the data in the following table to use the **LACP** tab.

All parameters beginning with **Partner** are for debug purposes only. If you configure these commands locally and there is a mismatch with what is learned from the partner, there will be trace or log messages.

Name	Description
AdminEnable	Enables LACP status for the port. The default value is false.
OperEnable	Displays the operational status of LACP for the port. The default value is false.
FastPeriodicTime	Specifies the number of milliseconds between periodic transmissions using short timeouts for all LACP enabled ports. The default value is 1000.
FastPeriodicTimeOper	Displays the operating value of the fast periodic timer on the port. The default value is 1000.
SlowPeriodicTime	Specifies the number of milliseconds between periodic transmissions using long timeouts for all LACP enabled ports. The default value is 30000.
SlowPeriodicTimeOper	Displays the operating value of the slow periodic timer on the port. The default value is 30000.
AggrWaitTime	Specifies the number of milliseconds to delay aggregation so multiple links can aggregate simultaneously. The default value is 2000.
AggrWaitTimeOper	Displays the operating value of the aggregate wait timer on the port. The default value is 2000.
TimeoutScale	Assigns the value used to calculate timeout time from the periodic time. Configure this value for all LACP-enabled ports. The default value is 3.
TimeoutScaleOper	Displays the operating value of the timeout scale on the port. The default value is 3.
ActorSystemPriority	Specifies the two octet read-write value indicating the priority value associated with the actor system ID. The default value is 32768.

Name	Description
ActorSystemID	Displays the six octet read-write MAC address value used as a unique identifier for the system that contains this aggregator. From the perspective of the link aggregation mechanisms, only a single combination of actor system ID and system priority are considered, and no distinction is made between the values of these parameters for an aggregator and the ports that are associated with it; that is, the protocol is described in terms of the operation of aggregation within a single system. However, the managed objects provided for the aggregator and the port both enable management of these parameters. The result of this is to permit a single piece of equipment to be configured by management to contain more than one system from the point of view of the operation of link aggregation. This can be of particular use in the configuration of equipment that has limited aggregation capability.
ActorAdminKey	Configures the aggregation key for this port. The administrative key value can differ from the operational key value. This key must match the LAG key. To return a configured key to the default value, you must first disable LACP aggregation on the port.
ActorOperKey	Displays the current operational value of the key for the aggregator. The operational key value can differ from the administrative key value. The meaning of particular key values is of local significance.
SelectedAggID	Displays the identifier value of the aggregator that this aggregation port has currently selected. Zero indicates that the aggregation port has not selected an aggregator, either because it is in the process of detaching from an aggregator or because there is no suitable aggregator available for it to select.
AttachedAggID	Displays the identifier value of the aggregator to which this aggregation port is currently attached. Zero indicates that the aggregation port is not currently attached to an aggregator.
ActorPort	Displays the port number locally assigned to the aggregation port. The port number is communicated in LACPDUs as the Actor_Port.
ActorPortPriority	Specifies the priority value assigned to this aggregation port. The default value is 32768.

Name	Description
ActorAdminState	Configures one or more of the following: • **lacpActive** - Configures the LACP mode to be active. • **lacpShortTimeout** - Configures the timeout to short. • **aggregation** - Enables aggregation on the port, which makes it an aggregated link. By default, only lacpActive is enabled. These values enable administrative control over the values of LACP_Activity, LACP_Timeout, and aggregation.
ActorOperState	Displays a string of eight bits, corresponding to the current operational values of Actor_State as transmitted by the actor in LACPDUs. The default value is lacpActive.
PartnerAdminSystemPriority	Specifies the current administrative value of the port number for the protocol partner. The assigned value is used, along with the value of PartnerAdminSystemPriority, PartnerAdminSystemID, PartnerAdminKey, and PartnerAdminPortPriority, to achieve manually configured aggregation. The default value is 0.
PartnerOperSystemPriority	Displays a two octet value indicating the operational value of priority associated with the partner system ID. The value of this attribute can contain the manually configured value carried in PartnerAdminSystemPriority if there is no protocol partner. The default value is 0.
PartnerAdminSystemID	Specifies a six octet MAC address value that represents the administrative value of the aggregation port protocol partners system ID. The assigned value is used with the values of PartnerAdminSystemPriority, PartnerAdminKey, PartnerAdminPort, and PartnerAdminPortPriority to achieve manually configured aggregation. The default value is 00:00:00:00:00:00.
PartnerOperSystemID	Displays a six octet MAC address value that indicates representing the current value of the aggregation port protocol partner system ID. A value of zero indicates that there is no known protocol partner. The value of this attribute can contain the manually configured value carried in PartnerAdminSystemID if there is no protocol partner. The default value is 00:00:00:00:00:00.

Name	Description
PartnerAdminKey	Specifies the current administrative value of the key for the protocol partner. The assigned value is used with the value of PartnerAdminSystemPriority, PartnerAdminSystemID, PartnerAdminPort, and PartnerAdminPortPriority to achieve manually configured aggregation. The default value is 0.
PartnerOperKey	Displays the current operational value of the key for the aggregator current protocol partner. If the aggregation is manually configured, this value is assigned by the local system. The default value is 0.
PartnerAdminPort	Specifies the current administrative value of the port number for the protocol partner. The assigned value is used, along with the value of PartnerAdminSystemPriority, PartnerAdminSystemID, PartnerAdminKey, and PartnerAdminPortPriority, to achieve manually configured aggregation. The default value is 0.
PartnerOperPort	Displays the operational port number assigned to this aggregation port by the aggregation port protocol partner. The value of this attribute can contain the manually configured value carried in AggPortPartnerAdminPort if there is no protocol partner. The default value is 0.
PartnerAdminPortPriority	Specifies the current administrative value of the port priority for the protocol partner. The assigned value is used with the values of PartnerAdminSystemPriority, PartnerAdminSystemID, PartnerAdminKey, and PartnerAdminPort to achieve manually configured aggregation. The default value is 0.
PartnerOperPortPriority	Displays the priority value assigned to this aggregation port by the partner. The value of this attribute can contain the manually configured value carried in PartnerAdminPortPriority if there is no protocol partner. The default value is 0.

Name	Description
PartnerAdminState	Specifies a string of eight bits, corresponding to the current administrative value of Actor_State for the protocol partner, by selecting check boxes. The assigned value is used to achieve manually configured aggregation. The default value is none.
PartnerOperState	Displays a string of eight bits, corresponding to the current values of Actor_State in the most recently received LACPDU transmitted by the protocol partner. In the absence of an active protocol partner, this value can reflect the manually configured value PartnerAdminState. The default value is none.

Configuring LACP on an Extreme Integrated Application Hosting Port

Note

This procedure only applies to 5720 Series only.

About This Task

Perform this procedure to configure Link Aggregation Control Protocol (LACP) on an Extreme Integrated Application Hosting (IAH) port. You must use the LACP keys to determine which IAH ports are eligible for link aggregation. The LACP keys are defined by the IAH ports after you configure the multilink trunk (MLT). You can aggregate the IAH port key that matches the MLT key into that multilink trunk.

The minimum LACP configuration is as follows:

- Assign a given key to a set of IAH ports.
- Assign the same key to an MLT with no members. The IAH ports automatically become MLT members.

The keys do not have to match between two LACP peers.

Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **Edit** > **Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **LACP** tab.
4. Select **AdminEnable**.
5. In the **ActorAdminKey** field, enter a value.
6. Configure the other parameters as required.
7. Select **Apply**.

LACP *Field Descriptions*

Use data in the following table to use the **LACP** tab.

Note

The **Partner** fields in the **LACP** tab are for debug purpose only. If you configure them locally and there is a mismatch with what is learned from the partner, trace or log messages are generated.

Name	Description
AdminEnable	Enables LACP status for the Extreme Integrated Application Hosting port. The default value is false.
OperEnable	Specifies the LACP operational status for the Extreme Integrated Application Hosting port. The default value is false.
FastPeriodicTime	Specifies the number of milliseconds between periodic transmissions using short timeouts for all LACP enabled Extreme Integrated Application Hosting ports. The default value is 1000.
FastPeriodicTimeOper	Specifies the operating value of the fast periodic timer on the Extreme Integrated Application Hosting port. The default value is 1000.
SlowPeriodicTime	Specifies the number of milliseconds between periodic transmissions using long timeouts for all LACP enabled Extreme Integrated Application Hosting ports. The default value is 30000.
SlowPeriodicTimeOper	Specifies the operating value of the slow periodic timer on the Extreme Integrated Application Hosting port. The default value is 30000.
AggrWaitTime	Specifies the number of milliseconds to delay aggregation to enable multiple links to aggregate simultaneously. The default value is 2000.
AggrWaitTimeOper	Specifies the operating value of the aggregate wait timer on the Extreme Integrated Application Hosting port. The default value is 2000.
TimeoutScale	Specifies the value used to calculate timeout duration from the periodic time. Set the same value for all LACP enabled Extreme Integrated Application Hosting ports. The default value is 3.

Name	Description
TimeoutScaleOper	Specifies the operating value of the timeout scale on the Extreme Integrated Application Hosting port. The default value is 3.
ActorSystemPriority	Specifies the two octet read-write value indicating the priority value associated with the actor system ID. The default value is 32768.
ActorSystemID	Specifies the six octet read-write MAC address value used as a unique identifier for the system that contains this aggregator. From the perspective of the link aggregation mechanisms, only a single combination of actor system ID and system priority are considered, and no distinction is made between the values of these parameters for an aggregator and the Extreme Integrated Application Hosting ports that are associated with it; that is, the protocol is described in terms of the operation of aggregation within a single system. However, the managed objects provided for the aggregator and the Extreme Integrated Application Hosting port both allow management of these parameters. The result of this is to permit a single piece of equipment to be configured by management to contain more than one system from the point of view of the operation of link aggregation. This can be of particular use in the configuration of equipment that has limited aggregation capability.
ActorAdminKey	Specifies the current read-write administrative value of the key for the aggregator, which is a 16-bit value. The administrative key value can differ from the operational key value. This key must match the LAG key.
ActorOperKey	Specifies the current read-only operational value of the key for the aggregator. The operational key value can differ from the administrative key value. The meaning of particular key values is of local significance.
SelectedAggID	Specifes the identifier value of the aggregator that this aggregation port has currently selected. Zero indicates that the aggregation port has not selected an aggregator, either because it is in the process of detaching from an aggregator or because there is no suitable aggregator available for it to select. This value is read-only.
AttachedAggID	Specifies the identifier value of the aggregator to which this aggregation port is currently attached. Zero indicates that the aggregation port is not currently attached to an aggregator. This value is read-only.

Name	Description
ActorPort	Specifies the port number locally assigned to the aggregation port. The port number is communicated in LACPDUs as the Actor_Port. This value is read-only.
ActorPortPriority	Specifies the priority value assigned to this aggregation port. This 16-bit value is read-write. The default value is 32768.
ActorAdminState	Specifies a string of eight bits, corresponding to the administrative values as transmitted by the actor in LACPDUs. The values are: • the first bit corresponds to bit 0 of Actor_State (LACP_Activity) (the default value) • the second bit corresponds to bit 1 (LACP_Timeout) • the third bit corresponds to bit 2 (Aggregation) • the fourth bit corresponds to bit 3 (Synchronization) • the fifth bit corresponds to bit 4 (Collecting) • the sixth bit corresponds to bit 5 (Distributing) • the seventh bit corresponds to bit 6 (Defaulted) • the eighth bit corresponds to bit 7 (Expired) These values enable administrative control over the values of LACP_Activity, LACP_Timeout, and aggregation. This attribute value is read-write.
ActorOperState	Specifies a string of eight bits, corresponding to the current operational values of Actor_State as transmitted by the actor in LACPDUs. This attribute value is read-only. The default value is lacpActive.
PartnerAdminSystemPriority	Specifies the current administrative value of the Extreme Integrated Application Hosting port number for the protocol partner. It is a 16-bit read-write value. The assigned value is used, along with the value of PartnerAdminSystemPriority, PartnerAdminSystemID, PartnerAdminKey, and PartnerAdminPortPriority, to achieve manually configured aggregation. The default value is 0.
PartnerOperSystemPriority	Displays a two octet read-only value indicating the operational value of priority associated with the partner system ID. The value of this attribute can contain the manually configured value carried in PartnerAdminSystemPriority if there is no protocol partner. The default value is 0.

Name	Description
PartnerAdminSystemID	Specifies a six octet read-write MAC address value that represents the administrative value of the aggregation port protocol partners system ID. The assigned value is used with the values of PartnerAdminSystemPriority, PartnerAdminKey, PartnerAdminPort, and PartnerAdminPortPriority to achieve manually configured aggregation. The default value is 00:00:00:00:00:00.
PartnerOperSystemID	Displays a six octet read-only MAC address value that indicates representing the current value of the aggregation port protocol partner system ID. A value of zero indicates that there is no known protocol partner. The value of this attribute can contain the manually configured value carried in PartnerAdminSystemID if there is no protocol partner. The default value is 00:00:00:00:00:00.
PartnerAdminKey	Specifies the current administrative value of the key for the protocol partner. It is a 16–bit read-write value. The assigned value is used with the value of PartnerAdminSystemPriority, PartnerAdminSystemID, PartnerAdminPort, and PartnerAdminPortPriority to achieve manually configured aggregation. The default value is 0.
PartnerOperKey	Specifies the current operational value of the key for the aggregator current protocol partner. It is a 16-bit read-only value. If the aggregation is manually configured, this value is assigned by the local system. The default value is 0.
PartnerAdminPort	Specifies the current administrative value of the port number for the protocol partner. It is a 16–bit read-write value. The assigned value is used, along with the value of PartnerAdminSystemPriority, PartnerAdminSystemID, PartnerAdminKey, and PartnerAdminPortPriority, to achieve manually configured aggregation. The default value is 0.
PartnerOperPort	Specifies the operational Extreme Integrated Application Hosting port number assigned to this aggregation port by the aggregation port protocol partner. The value of this attribute can contain the manually configured value carried in AggPortPartnerAdminPort if there is no protocol partner. This 16-bit value is read-only. The default value is 0.

Name	Description
PartnerAdminPortPriority	Specifies the current administrative value of the port priority for the protocol partner. It is a 16-bit read-write value. The assigned value is used with the values of PartnerAdminSystemPriority, PartnerAdminSystemID, PartnerAdminKey, and PartnerAdminPort to achieve manually configured aggregation. The default value is 0.
PartnerOperPortPriority	Specifies the priority value assigned to this aggregation port by the partner. The value of this attribute can contain the manually configured value carried in PartnerAdminPortPriority if there is no protocol partner. This 16 bit value is read-only. The default value is 0.
PartnerAdminState	Specifies a string of eight bits, corresponding to the current administrative value of Actor_State for the protocol partner, by selecting check boxes. This attribute value is read-write. The assigned value is used to achieve manually configured aggregation. The default value is none.
PartnerOperState	Specifies a string of eight bits, corresponding to the current values of Actor_State in the most recently received LACPDU transmitted by the protocol partner. In the absence of an active protocol partner, this value can reflect the manually configured value PartnerAdminState. This attribute value is read-only. The default value is none.

Viewing LACP Port Statistics

View LACP port statistics to monitor the performance of the port.

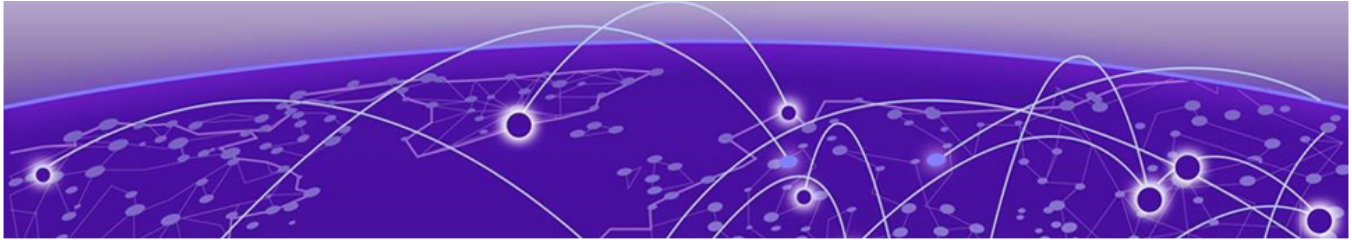
Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration** > **Graph** folders.
3. Click **Port**.
4. Click the **LACP** tab.
5. To change the poll interval, in the toolbar click the **Poll Interval** box, and then select a new interval.

LACP Field Descriptions

Use the data in the following table to view the LACP statistics.

Name	Description
LACPDUsRx	The number of valid LACPDU received on this aggregation port.
MarkerPDUsRx	The number of valid marker PDUs received on this aggregation port.
MarkerResponsePDUsRx	The number of valid marker response PDUs received on this aggregation port.
UnknownRx	The number of frames received that either: • carry Slow Protocols Ethernet type values, but contain an unknown PDU. • are addressed to the Slow Protocols group MAC Address, but do not carry the Slow Protocols Ethernet Type.
IllegalRx	The number of frames received that carry the Slow Protocols Ethernet Type value (43B.4), but contain a badly formed PDU or an illegal value of Protocol Subtype (43B.4).
LACPDUsTx	The number of LACPDUs transmitted on this aggregation port.
MarkerPDUsTx	The number of marker PDUs transmitted on this aggregation port.
MarkerResponsePDUsTx	The number of marker response PDUs transmitted on this aggregation port.



Link Layer Discovery Protocol

Table 131: Link Layer Discovery Protocol product support

Feature	Product	Release introduced
Industry Standard Discovery Protocol (ISDP) (CDP compatible)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Link Layer Discovery Protocol (LLDP)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
Link Layer Discovery Protocol-Media Endpoint Discovery (LLDP-MED)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

The following sections describe how to use Link Layer Discovery Protocol (LLDP) and Industry Standard Discovery Protocol (ISDP).

Link Layer Discovery Protocol (802.1AB) Fundamentals

With Link Layer Discovery Protocol (LLDP) you can obtain node and topology information to help detect and correct network and configuration errors.

LLDP

802.1AB is the IEEE standard called Station and Media Access Control Connectivity Discovery. This standard defines the Link Layer Discovery Protocol.

LLDP stations connected to a local area network (LAN) can advertise station capabilities to each other, allowing the discovery of physical topology information for network management.

LLDP-compatible stations can comprise any interconnection device, including PCs, IP Phones, switches, and routers.

Each LLDP station stores LLDP information in a standard Management Information Base (MIB), making it possible for a network management system (NMS) or application to access the information.

The functions of an LLDP station include:

- Advertising connectivity and management information about the local station to adjacent stations
- Receiving network management information from adjacent stations
- Enabling the discovery of certain configuration inconsistencies or malfunctions that can result in impaired communications at higher layers

  For example, you can use LLDP to discover duplex mismatches between an IP Phone and the connected switch.

LLDP is compatible with IETF PROTO MIB (IETF RFC 2922).

The following figure shows an example of a LAN using LLDP.

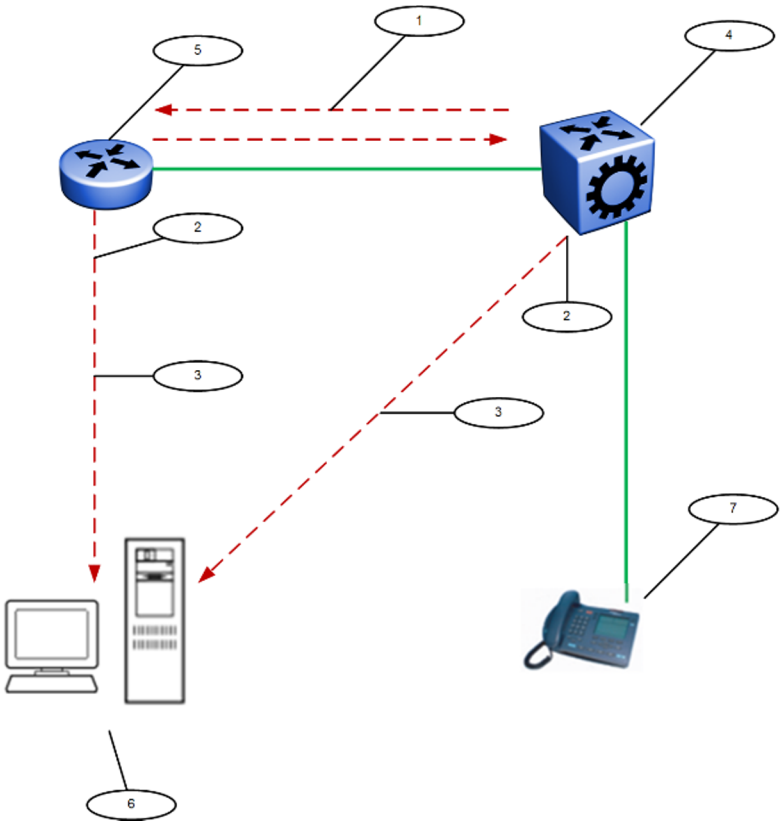


Figure 172: LLDP in a LAN

Legend:

1. The switch and an LLDP-enabled router advertise chassis and port IDs and system descriptions to each other
2. The devices store the information about each other in local MIB databases, accessible with SNMP
3. A network management system retrieves the data stored by each device and builds a network topology map
4. Switch
5. Router
6. Management work station
7. IP Phone

LLDP modes

LLDP is a one-way protocol.

An LLDP agent can transmit information about the capabilities and current status of the system associated with its MAC service access point (MSAP) identifier.

The LLDP agent also can receive information about the capabilities and current status of the system associated with a remote MSAP identifier.

However, LLDP agents cannot solicit information from each other.

You can configure the local LLDP agent to transmit and receive.

Connectivity and management information

The information parameters in each LLDP frame are in a Link Layer Discovery Protocol Data Unit (LLDP PDU) as a sequence of short, variable length information elements known as TLVs (type, length, value).

Each LLDP PDU includes the following mandatory TLVs:

- Chassis ID
- Port ID
- Time To Live
- Port Description
- System Name
- System Description
- System Capabilities (indicates both the system supported capabilities and enabled capabilities, such as end station, bridge, or router)
- Management Address

The chassis ID and the port ID values are concatenated to form a logical MSAP identifier that the recipient uses to identify the sending LLDP agent and port.

A non-zero value in the Time to Live (TTL) field of the TTL TLV indicates to the receiving LLDP agent how long the LLDP PDU information from the MSAP identifier remains valid.

The receiving LLDP agent automatically discards all LLDP PDU information, if the sender fails to update it in a timely manner.

A zero value in TTL field of Time To Live TLV tells the receiving LLDP agent to discard the information associated with the LLDP PDU MSAP identifier.

LLDP for the Segmented Management Instance

LLDP and SONMP both advertise the same topology IP address for the Segmented Management Instance management interface. LLDP supports IPv4 and IPv6 advertisement. If all three management interfaces are configured, the advertised default topology IP priority is management CLIP, then management VLAN, then management OOB. You can change the default topology IP using CLI or EDM. If multiple IPv4 addresses are configured on an OOB or VLAN management interface, the advertised IP priority is static IP address, then DHCP IP address, then link-local IP address.

Transmitting LLDP PDUs

When a transmit cycle is initiated, the LLDP manager extracts the managed objects from the LLDP local system MIB and formats this information into TLVs. TLVs are inserted into the LLDP PDU.

LLDP PDUs are regularly transmitted at a user-configurable transmit interval (tx-interval) or when any of the variables in the LLPDU is modified on the local system; for example, system name or management address.

Transmission delay (tx-delay) is the minimum delay between successive LLDP frame transmissions.

TLV system MIBs

The LLDP local system MIB stores the information to construct the various TLVs for transmission.

The LLDP remote systems MIB stores the information received from remote LLDP agents.

LLDP PDU and TLV error handling

The system discards LLDP PDUs and TLVs that contain detectable errors.

The system assumes that TLVs that contain no basic format errors, but that it does not recognize, are valid and stores them for retrieval by network management.

LLDP and MultiLink Trunking

You must apply TLVs on a per-port basis.

Because LLDP manages trunked ports individually, TLVs configured on one port in a trunk do not propagate automatically to other ports in the trunk.

And the system sends advertisements to each port in a trunk, not on a per-trunk basis.

LLDP and Fabric Attach

Fabric Attach uses LLDP to signal a desire to join the SPB network. When a switch is enabled as an FA Server, it receives IEEE 802.1AB LLDP messages from FA Client and FA Proxy devices requesting the creation of Switched UNI service identifiers (I-SIDs). All of the discovery handshakes and I-SID mapping requests are using LLDP TLV fields. Based on the LLDP standard, FA information is transmitted using organizational TLVs within LLDP PDUs.

FA also leverages LLDP to discover directly connected FA peers and to exchange information associated with FA between those peers.

Link Layer Discovery Protocol-Media Endpoint Discovery

Link Layer Discovery Protocol-Media Endpoint Discovery (LLDP-MED) defined in ANSI/TIA-1057, is an extension to the LLDP standard protocol as defined in IEEE 802.1AB. LLDP-MED provides support to deploy Voice over Internet Protocol (VoIP) telephones into the LAN environment. LLDP-MED provides additional TLVs for basic configuration, network policy configuration, location identification, and inventory management.

Following are the types of LLDP-MED devices:

- Network connectivity devices: provide access to the IEEE 802 based LAN infrastructure for LLDP-MED endpoint devices. The LLDP-MED Network Connectivity device is a LAN access device based on:
  - LAN Switch or Router
  - IEEE 802.1 Bridge

- IEEE 802.3 Repeater
- IEEE 802.11 Wireless Access Point
- Any device that supports the IEEE 802.1AB, LLDP-MED, and can relay IEEE 802 frames.

- Endpoint devices: located at the IEEE 802 LAN network edge, participating in the IP communication service using the LLDP-MED framework. The endpoint devices are divided into three classes:
  - Class 1 - LLDP-MED Generic Endpoint devices, for example, IP communication controllers.
  - Class 2 - LLDP-MED Media Endpoint devices, for example, media servers, conference bridges.
  - Class 3 - LLDP-MED Communication Endpoint devices, for example, IP telephones.

Organizational-specific TLVs for LLDP-MED

The organizational-specific TLVs for use by LLDP-MED network connectivity and endpoint devices are:

- Capabilities TLV — enables a network element to determine whether particular connected devices support LLDP-MED, and also discover the TLVs supported by specific network connectivity or endpoint devices.
- Network Policy Discovery TLV — enables both network connectivity and endpoint devices to advertise VLAN information, Layer 2, and Layer 3 priorities associated with a specific set of applications on a port. In addition, an LLDP-MED endpoint advertises this TLV for supported application types to enable the discovery of specific policy information and the diagnosis of network policy configuration mismatch issues.
- Location Identification Discovery TLV — allows network connectivity devices to advertise the appropriate location information for communication endpoint devices, including emergency call service location, to use in the context of location-based applications.
- Extended Power-via-MDI Discovery TLV — enables advanced power management between an LLDP-MED network connectivity and endpoint devices. The Extended Power-via-MDI TLV enables the advertisement of fine grained power requirement details, endpoint power priority, and power status for network connectivity and endpoint devices.
- Inventory Management Discovery TLV — enables tracking and identification of inventory-related attributes for endpoint devices. For example, manufacturer, model name, and software version.

Link Layer Discovery Protocol configuration using CLI

This section describes how to configure Link Layer Discovery Protocol using the Command Line Interface (CLI).

IPv4 management IP addresses are supported by LLDP, including the management virtual IP address, and they are advertised in the Management address TLV.

Configuring global LLDP transmission parameters

Before You Begin

- In the GigabitEthernet Interface Configuration mode, specify the LLDP port status as transmit only or transmit and receive.

About This Task

Use this procedure to configure global LLDP transmission parameters on the switch. If required, you can also restore these parameters to their default values.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. To configure the LLDP transmission parameters, enter:

   ```
   lldp [tx-interval|tx-hold-multiplier]
   ```

3. (Optional) To restore specific LLDP transmission parameters to their default values, enter:

   ```
   default lldp [tx-interval|tx-hold-multiplier]
   ```

4. (Optional) To restore all LLDP transmission parameters to their default values, enter:

   ```
   default lldp
   ```

Example

Configure the LLDP transmission interval. The LLDP port status is set to transmit and receive prior to the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 4/4
Switch:1(config-if)#lldp status txAndRx
Switch:1(config-if)#exit
Switch:1(config)#lldp tx-interval 31
```

Optionally, restore the LLDP transmission interval to its default value:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#default lldp tx-interval
```

Variable Definitions

The following table defines parameters for the **lldp** command.

Variable	Value
tx-interval<5-32768>	Specifies the global LLDP transmit interval in seconds, that is, the interval in which LLDP frames are transmitted. The default is 30 seconds.
tx-hold-multiplier <2-10>	Configures the multiplier for the transmit interval used to compute the Time To Live (TTL) value in LLDP frames. The default is 4 seconds.

Configuring LLDP status on ports

About This Task

Use this procedure to configure LLDP and configure the status to transmit and receive on a port, or ports, on your switch.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. To configure LLDP and configure the status for transmit and receive on a port or ports, enter:

   `lldp port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} status <txAndRx>`

3. To configure LLDP to the default setting for a port or ports, enter:

   `default lldp port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} status <txAndRx>`

Example

Configure LLDP on your switch and set the status for transmit and receive on a port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 4/4
Switch:1(config-if)#lldp status txAndRx
```

Restore LLDP port status to the default value. The default status is disabled.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 4/4
Switch:1(config-if)#default lldp status
```

Disable LLDP on your switch:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 4/4
Switch:1(config-if)#no lldp status
```

Variable Definitions

The following table defines parameters for the **lldp port** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
status <txAndRx>	Configures the LLDP Data Unit (LLDP PDU) transmit and receive status on the port(s). • default—restores LLDP port parameters to default values • txAndrx—enables LLDP PDU transmit and receive

Enable CDP Mode on a Port

To configure the switch as CDP-compatible, you must enable the Industry Standard Discovery Protocol (ISDP) on a port, or ports, on the switch. To enable ISDP, you use the **lldp cdp** command.

If CDP is enabled, the interface accepts only CDP packets. Similarly, if CDP is disabled but LLDP is enabled, the interface accepts only LLDP packets.

To switch a port from CDP mode to LLDP mode, the LLDP status on that port must be txAndrx.

About This Task

Do not enable CDP mode if you plan to use the port with Fabric Attach.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. To enable CDP, enter the following command:

   ```
   lldp cdp enable
   ```

3. (Optional) To disable CDP, enter the following command:

   ```
   no lldp cdp enable
   ```

Example

To enable CDP on a port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 4/4
Switch:1(config-if)#lldp cdp enable
```

Note

To switch a port from CDP mode to LLDP mode, LLDP status on that port must be txAndrx.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 4/4
Switch:1(config-if)#no lldp cdp enable
```

To shutdown LLDP or CDP on a port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 4/4
Switch:1>(config-if)#no lldp status
```

Configure LLDP Tx-TLVs

About This Task

Use this procedure to configure optional management Link Layer Discovery Protocol (LLDP) TLVs for transmission.

LLDP TLVs for transmission are enabled by default.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. To disable LLDP TLVs for transmission, enter:

   ```
   no lldp tx-tlv {local-mgmt-addr | port-desc | sys-cap | sys-desc |sys-
   name}
   ```

3. To restore LLDP TLVs to their default value, enter:

   ```
   default lldp tx-tlv {local-mgmt-addr | port-desc | sys-cap | sys-desc
   |sys-name}
   ```

4. Verify the configuration:

   `show lldp tx-tlv port` **{slot/port[/sub-port][-slot/port[/sub-port]] [,...]}**

Example

Disable the port description LLDP transmission TLV:

```
Switch:1>enable
Switch:1#config
Configuring from terminal or network [terminal]? t
Enter configuration commands, one per line.  End with CNTL/Z.

-------------------------------------------------------
1/2        enabled    enabled   enabled   enabled   enabled
```

Variable Definitions

The following table defines parameters for the **`lldp tx-tlv`** command.

Variable	Value
local-mgmt-addr	Specifies the local management address TLV. The default is enabled.
port-desc	Specifies the port description transmission TLV. The default is enabled.
sys-cap	Specifies the system capabilities transmission TLV. The default is enabled.

Variable	Value
sys-desc	Specifies the system description transmission TLV. The default is enabled.
sys-name	Specifies the system name transmission TLV. The default is enabled.

Enable Dot3 LLDP TLVs

About This Task

Use this procedure to enable transmission of dot3 MAC/PHY configuration/status Link Layer Discovery Protocol (LLDP) TLV.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable LLDP TLVs for transmission on a specific port:

   ```
   lldp tx-tlv dot3 {mac-phy-config-status}
   ```

3. Verify the configuration:

   ```
   show lldp tx-tlv dot 3
   ```

Example

Enable LLDP TLVs for transmission on a specific port:

```
Switch:1>enable
Switch:1#config
Configuring from terminal or network [terminal]? t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/2
Switch:1(config-if)#lldp tx-tlv dot3 mac-phy-config-status
Switch:1(config-if)#show lldp tx-tlv dot3
================================================================================
                              LLDP port dot3 tlvs
================================================================================
--------------------------------------------------------------------------------
Port       MAC Physical
           Config Status
--------------------------------------------------------------------------------
1/1        disabled
1/2        enabled
1/3        enabled
```

```
1/4         disabled
1/5         disabled
```

Variable Definitions

The following table defines parameters for the **`lldp tx-tlv dot3`** command.

Variable	Value
mac-phy-config-status	Specifies the status of the MAC Physical Config Status TLV. The default is disabled.

Configure LLDP MED TLVs for Transmission on Ports

About This Task

Use this procedure to configure organizational-specific TLVs for Link Layer Discovery Protocol (LLDP) Media Endpoint Devices (MED). LLDP MED TLVs are enabled by default.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Disable LLDP MED TLVs for transmission:

   ```
   no lldp tx-tlv med {extendedPSE | inventory | location | med-
   capabilities | network-policy}
   ```

3. Restore LLDP MED TLVs for transmission to their default value:

   ```
   default lldp tx-tlv med {extendedPSE | inventory | location | med-
   capabilities | network-policy}
   ```

4. Verify the configuration:

   ```
   show lldp tx-tlv med
   ```

Example

Disable LLDP MED TLVs

```
Switch:1>enable
Switch:1#config
Configuring from terminal or network [terminal]? t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/2
```

```
Switch:1(config-if)#no lldp tx-tlv med inventory
Switch:1(config-if)#no lldp tx-tlv med location

witch:1#show lldp tx-tlv med

================================================================================
                              LLDP port med tlvs
================================================================================
--------------------------------------------------------------------------------
Port          Med        Network   Location  ExtendedPower Inventory
           Capabilities   Policy               ViaMDI
--------------------------------------------------------------------------------
1/2        disabled      enabled   enabled   enabled      disabled
```

Restore LLDP MED TLVs for transmission to their default value:

```
Switch:1>enable
Switch:1#config
Configuring from terminal or network [terminal]? t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/2
Switch:1(config-if)#default lldp tx-tlv med inventory
Switch:1(config-if)#default lldp tx-tlv med med-capabilities

Switch:1#show lldp tx-tlv med

================================================================================
                              LLDP port med tlvs
================================================================================
--------------------------------------------------------------------------------
Port          Med        Network   Location  ExtendedPower Inventory
           Capabilities   Policy               ViaMDI
--------------------------------------------------------------------------------
1/1        enabled       enabled   enabled   enabled       enabled
1/2        enabled       enabled   enabled   enabled       enabled
```

Variable Definitions

The following table defines parameters for the **`lldp tx-tlv med`** command.

Variable	Value
extendedPSE	Specifies the extended power-via-MDI Media Endpoint Device (MED) transmission TLV. This TLV is applilcable for POE-capable switches only. The default is enabled on POE-capable switches only.
inventory	Specifies the system capabilities MED transmission TLV. The default is enabled.
location	Specifies the system description MED transmission TLV. The default is enabled.
med-capabilities	Specifies the system name MED transmission TLV. The default is enabled.
network-policy	Specifies the network policy MED transmission TLV. The default is enabled.

View Global LLDP Information

About This Task

Use this procedure to view global LLDP information, to know which LLDP settings and parameters are configured.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display LLDP local system data:

   ```
   show lldp local-sys-data [med]
   ```

3. Display the LLDP neighbor system information:

   ```
   show lldp neighbor [summary] [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
   ```

4. Display the list of ports:

   ```
   show lldp port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
   ```

5. Display the LLDP reception statistics:

   ```
   show lldp rx-stats [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
   ```

6. Display the LLDP statistics:

   ```
   show lldp stats
   ```

7. Display the LLDP transmission statistics:

   ```
   show lldp tx-stats [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]
   ```

Examples

View global LLDP information:

```
Switch:1#show lldp
802.1ab Configuration:
-------------------------------------
             TxInterval: 30
       TxHoldMultiplier: 4
            ReinitDelay: 1
                TxDelay: 1
   NotificationInterval: 5
```

View the LLDP local system data on the switch:

```
Switch:1#show lldp local-sys-data

Variable Definitions

The following table defines parameters for the **show lldp** command.

Variable	Value
local-sys-data	Displays the LLDP local system data.
neighbor [summary] [port *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*]	Displays the LLDP neighbor system information. You can also view this on a specific port. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Variable	Value
port[*{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*]	Displays the LLDP administrative status of a port or all ports on the switch. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
rx-stats [port *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*]	Displays the LLDP reception statistics on all ports on the switch, or on a specific port. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
stats	Displays the LLDP statistics.
tx-stats [port *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*]	Displays the LLDP transmission statistics on all ports on the switch or on a specific port. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

View LLDP Neighbor Information

Display information about LLDP neighbors to help you configure LLDP for maximum benefit.

About This Task

Use this procedure to display LLDP neighbor information.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. To view LLDP neighbor information, enter:

   ```
   show lldp neighbor {[port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}] | [summary {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}] [med]}
   ```

Examples

The following example shows how two switches—an FA Server and an FA Proxy discover each other as LLDP neighbors.

Switch A, which is the FA Server is a 5320 Series switch (model 5320-48T-8XE) and switch B which is the proxy device is an ERS 4826GTS switch.

The following examples show neighbor discovery on non-channelized ports.

On the non-channelized port 1/1 on the FA Server, verify neighbor discovery of the proxy switch.

On the proxy switch, verify discovery of the FA Server switch.

```
Switch:1>enable
Switch:1#show lldp neighbor
--------------------------------------------------------------------------------
                            LLDP neighbor

```

Variable Definitions

The following table defines parameters for the **`show lldp neighbor`** command.

Variable	Value
port *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*	Displays LLDP neighbor information on the specified port. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
med	Displays LLDP neighbors learned based on LLDP-MED TLV information.
summary *{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}*	Displays the summary of LLDP neighbors of a port or all ports on the switch. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Viewing global LLDP statistics

Use this procedure to view and verify global LLDP statistics.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. To view LLDP statistics, enter:
   `show lldp stats`
3. To view LLDP reception statistics, enter:
   `show lldp rx-stats`
4. To view LLDP transmission statistics, enter:
   `show lldp tx-stats`
5. (Optional) Clear global LLDP statistics:
   `clear lldp stats summary`

Example

View LLDP statistics:

```
Switch:1>enable
Switch:1#show lldp stats

=================================================================
                                LLDP Stats
=================================================================
Inserts    Deletes    Drops      Ageouts
-----------------------------------------------------------------
0          0          0          0
-----------------------------------------------------------------
```

View LLDP transmission statistics:

```
Switch:1#show lldp tx-stats
=================================================================
                                LLDP Tx-Stats
=================================================================

PORT NUM                FRAMES
-----------------------------------------------------------------
1/2                     100
```

View LLDP reception statistics:

```
Switch:1#show lldp rx-stats

=================================================================
                                LLDP Rx-Stats
=================================================================

Port  Frames      Frames   Frames   TLVs        TLVs         AgeOuts
Num   Discarded   Errors   Total    Discarded   Unrecognized
-----------------------------------------------------------------
1/2   0           0        46       0           0            0
```

Viewing Port-based LLDP Statistics

Use this procedure to verify port-based LLDP statistics.

About This Task

LLDP operates at the interface level. Enabling FA on a port automatically enables LLDP transmission and reception on the port. It also enables traffic tagging and disables spanning tree on that port.

Enabling FA on an MLT enables LLDP transmission and reception on all ports in the MLT.

Note

When FA is enabled on ports in an MLT or LACP MLT, tagging is enabled and spanning tree is disabled on those ports.

When a port is removed from an MLT, LLDP transmission on that port stops and spanning tree is enabled. Any I-SID-to-VLAN mappings on that port are removed, if not already learned on any other port in the MLT. This also causes the Switched UNI I-SID to be deleted from the MLT. If however, the mappings are learned on another port on the MLT, then the Switched UNI I-SID continues to exist for that MLT.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. To verify successful LLDP transmission on a port, enter:

   ```
   show lldp tx-stats port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
   ```

3. To verify that a port receives LLDP PDUs successfully, enter:

   ```
   show lldp rx-stats port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
   ```

4. (Optional) To clear LLDP statistics on a port, or ports, enter:

   ```
   clear lldp stats {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
   ```

Example

Verify LLDP transmission statistics on a port:

```
Switch:1>en
Switch:1#show lldp tx-stats port 1/2
================================================================
                                LLDP Tx-Stats
================================================================

PORT NUM                FRAMES
----------------------------------------------------------------
1/2                     100
```

Verify that the port is receiving LLDP PDUs:

```
Switch:1#show lldp rx-stats port 1/2

================================================================================
                                LLDP Rx-Stats
================================================================================

Port      Frames      Frames   Frames   TLVs        TLVs           AgeOuts
Num       Discarded   Errors   Total    Discarded   Unsupported
                                        (Non FA)    (Non FA)
--------------------------------------------------------------------------------
1/2       0           0        46       0           0              0
```

LLDP-MED Configuration Using CLI

Configure LLDP-MED information for local and remote systems on specific ports. LLDP-MED is enabled by default and all its TLVs are enabled for transmission.

To configure LLDP-MED TLVs in the LLDP PDUs on an interface:

- Configure LLDP-MED.
- Configure LLDP-MED network policy and location information.
- The switch automatically configures LLDP-MED capabilities, power, and inventory information.

Configure LLDP-MED Network Policies on Ports

About This Task

Perform this procedure to configure network policies on specific ports.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure a network policy:

   ```
   lldp med-network-policies {guest-voice | guest-voice-signaling |
   softphone-voice | streaming-video | video-conferencing | video-
   signaling | voice | voice-signaling} [dscp <0-63>] [priority <0-7>]
   [tagging {tagged|untagged}] [vlan-id <0-4059>]
   ```

Example

Configuring guest voice network policy on port 1/2:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#lldp med-network-policies guest-voice dscp 1 priority 5 tagging
tagged vlan-id 5
```

Variable Definitions

The following table defines parameters for the **`lldp med-network-policies`** command.

Variable	Value
{guest-voice | guest-voice-signaling | softphone-voice | streaming-video | video-conferencing | video-signaling | voice | voice-signaling}	Specifies the type of network policy.
dscp <0-63>	Specifies the Layer 3 DiffServ Code Point (DSCP) value, as defined in IETF RFC 2474 and RFC 2475. The default is 0.
priority <0-7>	Specifies the priority level, as defined in IEEE 802.1D. The default is 0.
tagging {tagged | untagged}	Specifies the type of VLAN tagging to apply on the selected ports. The default is untagged.
vlan-id <0-4059>	Specifies the VLAN ID for the port, as defined in IEEE 802.1Q. If you configure priority tagged frames, the system recognizes only the 802.1D priority level and uses a value of 0 for the VLAN ID of the ingress port. The default is 0.

Configure LLDP-MED Civic Address Location Information

About This Task

Perform the following procedure to configure civic address location information of local LLDP-MED on specific ports.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the civic address location by configuring the country-code and at least one other location parameter:

   ```
   lldp location-identification civic-address country-code WORD<2-2>
   (additional-code additional-information apartment block building city
   city-district county floor house-number house-number-suffix landmark
   leading-street-direction name place-type pobox postal-community-name
   postal-zip-code room-number state street street-suffix trailing-
   street-suffix) WORD<0-255>
   ```

   Note

   If you try to configure a civic-address with a large number of arguments, 26 or more, the command fails and a software message informs you to split the command into multiple smaller commands.

Example

Configuring civic address location on port 2/12:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 2/12
Switch:1(config-if)#lldp location-identification civic-address country-code US city New
York
```

Variable Definitions

The following table defines parameters for the **`lldp location-identification civic-address`** command.

Variable	Value
additional-code WORD<0–255>	Specifies the location information parameters.
additional-information WORD<0–255>	Example: South Wing
apartment WORD<0–255>	Example: Apt 42
block WORD<0–255>	Specifies a block, e.g. 3
building WORD<0–255>	Example: Low Library
city WORD<0–255>	Specifies a city, e.g. Sunnyvale
city-district WORD<0–255>	Specifies a city district, e.g. Santa Clara
country-code WORD<2–2>	Specifies a country using a 2 character string, example US (United States), CA (Canada).
county WORD<0–255>	Specifies a county, e.g. Alameda
floor WORD<0–255>	Example: 8
house-number WORD<0–255>	Specifies a house number, e.g. 123
house-number-suffix WORD<0–255>	Specifies a house number suffix, e.g. A, 1/2
landmark WORD<0–255>	Specifies a landmark, e.g. Columbia University
leading-street-direction WORD<0–255>	Specifies a leading street direction, e.g. N

Variable	Value
name WORD<0–255>	Example: Joe's Barbershop
place-type WORD<0–255>	Example: office
pobox WORD<0–255>	Example: 12345
postal-community-name WORD<0–255>	Example: Leonia
postal-zip-code WORD<0–255>	Specifies a postal or zip code, e.g. 95054
room-number WORD<0–255>	Example: 450F
state WORD<0–255>	Specifies a state, e.g. NJ, FL
street WORD<0–255>	Specifies a street, e.g. Great America Parkway
street-suffix WORD<0–255>	Specifies a street suffix, e.g. Ave, Blvd
trailing-street-suffix WORD<0–255>	Specifies a trailing street suffix, e.g. SW

Configure LLDP-MED Coordinate Based Location Information

About This Task

Perform the following procedure to configure coordinate based location information of local LLDP-MED on specific ports.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure coordinate based location:

   ```
   lldp location-identification coordinate (altitude WORD<1-13> {floors |
   meters} datum {NAD83/MLLW | NAD83/NAVD88 | WGS84} latitude WORD<1-14>
   {NORTH | SOUTH} longitude WORD<1-14> {EAST | WEST})
   ```

Example

Configuring coordinate based location on port 1/2:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#lldp location-identification coordinate-base altitude 3 floors
```

Variable Definitions

The following table defines parameters for the **lldp location-identification coordinate** command.

Variable	Value
altitude WORD<1-13>	Specifies the value for altitude. The units of measurement are: • *floors* • *meters*
datum	Specifies the reference datum. The formats are: • NAD83/MLLW • NAD83/NAVD88 • WGS84
latitude WORD<1-14>	Specifies the latitude in degrees, and its relation to the equator from North or South.
longitude WORD<1-14>	Specifies the longitude in degrees, and its relation to the prime meridian from East or West.

Configure LLDP-MED Emergency Call Service Location

Perform the following procedure to configure emergency call service location of local LLDP-MED on specific ports.

About This Task

Procedure

1. Enter GigabitEthernet Interface Configuration mode:
   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure emergency call service location:
   ```
   lldp location-identification ecs-elin WORD<10-25>
   ```

Example

Configuring emergency call service location on port 2/1-2/10:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 2/1-2/10
Switch:1(config-if)#lldp location-identification ecs-elin 123456789
```

Variable Definitions

The following table defines parameters for the **lldp location-identification ecs-elin** command.

Variable	Value
WORD<10–25>	Specifies the emergency line information number for emergency call service.

Display Local LLDP-MEDLocation Information

About This Task

Perform this procedure to display location information of the LLDP-MED configured locally.

Procedure

1. Enter Privileged EXEC mode:
   `enable`
2. Display location information for local LLDP-MED:
   `show lldp [port {slot/port[/sub-port][-slot/port[/sub-port]][,...]}] location-identification`

Example

```
Switch:1>enable
Switch:1#show lldp port 1/1-1/3 location-identification
================================================================================
                              LLDP-MED Location Information

Display LLDP-MED Local Network Policies Configuration

About This Task

Perform this procedure to display LLDP-MED network policies locally configured on specific ports.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display LLDP-MED network policies configured:

   ```
   show lldp [port {slot/port[/sub-port][-slot/port[/sub-port]][,...]}]
   med-network-policies [guest-voice | guest-voice-signaling | softphone-
   voice | streaming-video | video-conferencing | video-signaling | voice
   | voice-signaling]
   ```

Example

```
Switch:1>enable
Switch:1#show lldp med-network-policies

Link Layer Discovery Protocol configuration using EDM

This section describes how to configure LLDP on your switch using EDM.

Configure LLDP Global Information

Use this procedure to configure or view LLDP global information.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Click **LLDP**.
3. Click the **Globals** tab.
4. After you make the required configuration changes, click **Apply** to save changes.

***Globals** field descriptions*

Use the data in the following table to use the **Globals** tab.

Field	Description
lldpMessageTxInterval	Specifies the interval at which LLDP messages are transmitted. The default is 30 seconds.
lldpMessageTxHoldMultiplier	Specifies the multiplier used to calculate the time-to-live (TTL) value of an LLDP message. The default value is 4 seconds.
lldpReinitDelay	Specifies the delay in seconds between the time a port is disabled and the time it is re-initialized. The default is 1 second.
lldpTxDelay	Specifies the delay in seconds between successive LLDP transmissions. The default is 1 second. The value is as follows: 1 < **lldpTxDelay** < (0.25 x **lldpMessageTxInterval**)
lldpNotificationInterval	Specifies the time interval between successive LLDP notifications. It controls the transmission of notifications. The default is 5 seconds.
Stats	
RemTablesLastChangeTime	Specifies the timestamp of LLDP missed notification events on a port, for example, due to transmission loss.
RemTablesInserts	Specifies the number of times the information advertised by a MAC Service Access Point (MSAP) is inserted into the respective tables.
RemTablesDeletes	Specifies the number of times the information advertised by an MSAP is deleted from the respective tables.
RemTablesDrops	Specifies the number of times the information advertised by an MSAP was not entered into the respective tables.
RemTablesAgeouts	Specifies the number of times the information advertised by an MSAP was deleted from the respective tables.

View the LLDP Port Information

Use this procedure to view the LLDP port information.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Click **LLDP**.
3. Click the **Port** tab.
4. View the administrative status of the port in the **AdminStatus** field. To modify, double-click on a cell and select a value from the drop-down list.
5. View whether the port is enabled for notifications in the **NotificationEnable** field. To modify, double-click on a cell and select a value from the drop-down list.
6. View the set of TLVs whose transmission using LLDP is always allowed by network management in the **TLVsTxEnable** field.

7. (Optional) Modify the TLVs as follows:
   a. To enable a TLV, select the appropriate check box, and click **Ok**. You can select more than one check box.
   b. To enable all TLVs, click **Select All**, and click **Ok**.
   c. To disable all TLVs, click **Disable All**, and click **Ok**.
8. View the CDP administrative status in the **CdpAdminState** field. To modify, double-click on a cell and select a value from the drop-down list.
9. Click **Apply** to save any configuration changes.
10. Click **Refresh** to verify the configuration.

Port *Field Descriptions*

Use the data in the following table to use the **Port** tab.

Name	Description
PortNum	Specifies the port number. This is a read-only cell.
AdminStatus	Specifies the administrative status of the port. The options are: • txOnly: LLDP frames are only transmitted on this port. • rxOnly: LLDP frames are only received on this port. • txAndRx: LLDP frames are transmitted and received on this port. • disabled: LLDP frames are neither transmitted or received on this port. Any information received on this port from remote systems before this is disabled, ages out. The default is disabled.
NotificationEnable	Specifies whether the port is enabled or disabled for notifications. • true: indicates that the notifications are enabled. • false: indicates that the notifications are disabled. The default is false.
TLVsTxEnable	Specifies the set of TLVs whose transmission using LLDP is always allowed by network management. The following list describes the TLV types: • portDesc — indicates that the Port Description TLV is transmitted. • sysName — indicates that the System Name TLV. is transmitted. • sysDesc — indicates that the System Description TLV. is transmitted. • sysCap — indicates that the System Capabilities TLV. is transmitted. The default is an empty set of TLVs.

Name	Description
CdpAdminState	Specifies the CDP administrative status of the port. Configure this field to true to enable the Industry Standard Discovery Protocol (ISDP) on a port. ISDP is CDP-compatible. • true: indicates CDP is enabled. • false: indicates CDP is disabled. The default is false. If CDP is enabled, the interface accepts only CDP packets. Similarly, if CDP is disabled but LLDP is enabled, the interface accepts only LLDP packets. To switch a port from CDP mode to LLDP mode, the LLDP status on that port must be txAndRx.
CapSupported(med)	Specifies the LLDP-MED capabilities supported. The default is enabled.

View LLDP Transmission Statistics

Use this procedure to view the LLDP transmission statistics. You can also view the statistics graphically.

About This Task

LLDP operates at the port interface level. Enabling FA on a port automatically enables LLDP transmission and reception on that port. It also enables traffic tagging and disables spanning tree on that port.

Enabling FA on an MLT enables LLDP transmission and reception on all ports in that MLT.

Note

When a port is removed from an MLT, LLDP transmission on that port stops and spanning tree is enabled. Any I-SID-to-VLAN mappings on that port are removed, if not already learned on any other port in the MLT. This also causes the Switched UNI I-SID to be deleted from the MLT. If however, the mappings are learned on another port on the MLT, then the Switched UNI I-SID continues to exist for that MLT.

For ports in an LACP MLT, when FA is enabled, tagging is enabled on all ports in the LACP MLT. The consistency check for FA is based on key membership. If all ports with the same key do not support FA, FA is not successfully enabled on those ports.

Note

If a slot is removed from the switch chassis, the statistics are not displayed on the slot ports. When the slot is inserted back again, the statistics counters are reset.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Click **LLDP**.
3. Click the **TX Stats** tab.

   The transmission statistics are displayed.

4. To view the transmission statistics graphically for a port:
   a. In the content pane (on the right-hand-side), select a row and click the **Graph** button.

      The **TX Stats-Graph,<port-number>** tab displays.

      You can view a graphical representation of the LLDP frames transmitted (**FramesTotal**), for the following parameters:

      - AbsoluteValue
      - Cumulative
      - Average/sec
      - Minimum/sec
      - Maximum/sec
      - LastVal/sec

   b. To view the graph, select one of the above parameters and click the appropriate icon on the top left-hand-side of the menu bar to draw a line chart, area chart, bar chart or a pie chart.
   c. Click **Clear Counters** to clear the existing counters, and fix a reference point in time to restart the counters.
   d. Click **Export**, to export the statistical data to a file.
   e. To fix a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

TX Stats *Field Descriptions*

Use the data in the following table to use the **TX Stats** tab.

Name	Description
PortNum	Specifies the port number.
FramesTotal	Specifies the total number of LLDP frames transmitted.

View LLDP Reception Statistics

Use this procedure to view the LLDP reception statistics. You can also view these statistics graphically.

About This Task

LLDP operates at the port interface level. Enabling FA on a port automatically enables LLDP transmission and reception on that port. It also enables traffic tagging and disables spanning tree on that port.

Enabling FA on an MLT enables LLDP transmission and reception on all ports in that MLT.

Note

When a port is removed from an MLT, LLDP transmission on that port stops and spanning tree is enabled. Any I-SID-to-VLAN mappings on that port are removed, if not already learned on any other port in the MLT. This also causes the Switched UNI I-SID to be deleted from the MLT. If however, the mappings are learned on another port on the MLT, then the Switched UNI I-SID continues to exist for that MLT.

For ports in an LACP MLT, when FA is enabled, tagging is enabled on all ports in the LACP MLT. The consistency check for FA is based on key membership. If all ports with the same key do not support FA, FA is not successfully enabled on those ports.

Note

If a slot is removed from the switch chassis, the statistics are not displayed on the slot ports. When the slot is inserted back again, the statistics counters are reset.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Click **LLDP**.
3. Click the **RX Stats** tab.
4. To view the reception statistics graphically for a port:
   a. Select a row and click **Graph**.

      The **RX Stats-Graph,<port-number>** tab displays.

      You can view a graphical representation of the following data:

      - **FramesDiscardedTotal** — Total number of LLDP received frames that were discarded.
      - **FramesErrors** — Total number of erroneous LLDP frames received.
      - **FramesTotal** — Total number of frames received.
      - **TLVsDiscardedTotal** — Total number of received TLVs that were discarded.
      - **TLVsUnrecognizedTotal** — Total number of unrecognized TLVs received.

   b. Select one of the above parameters and click the appropriate icon on the top left-hand-side corner of the menu bar to draw a line chart, area chart, bar chart or a pie chart.
   c. Click **Clear Counters** to clear the existing counters, and fix a reference point in time to restart the counters.
   d. Click **Export**, to export the statistical data to a file.
   e. To fix a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

RX Stats *Field Descriptions*

Use the data in the following table to use the **RX Stats** tab.

Name	Description
PortNum	Specifies the port number.
FramesDiscardedTotal	Specifies the number of LLDP frames received on the port, but discarded, for any reason. This counter provides an indication of possible LLDP header formatting problems in the sending system, or LLDP PDU validation problems in the receiving system.
FramesErrors	Specifies the number of invalid LLDP frames received on the port.
FramesTotal	Specifies the total number of LLDP frames received on the port.
TLVsDiscardedTotal	Specifies the number of LLDP TLVs discarded on the port, for any reason.
TLVsUnrecognizedTotal	Specifies the number of LLDP TLVs on the port, that are unrecognized on that port. An unrecognized TLV is referred to as the TLV whose type value is in the range of reserved TLV types (000 1001–111 1110). An unrecognized TLV could be, for example, a basic management TLV from a later LLDP version.
AgeoutsTotal	Specifies the number of LLDP age-outs that occur on a specific port. An age-out is the number of times the complete set of information advertised by a particular MSAP is deleted, because the information timeliness interval has expired.

View LLDP Local System Information

Use this procedure to view the LLDP local system information.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Click **LLDP**.
3. Click the **Local System** tab.

Local System *field descriptions*

Use the data in the following table to use the **Local System** tab.

Name	Description
ChassisIdSubType	Indicates the encoding used to identify the local system chassis. • chassisComponent • interfaceAlias • portComponent • macAddress • networkAddress • interfaceName • local
ChassisId	Indicates the chassis ID of the local system.
SysName	Indicates local system name.

Name	Description
SysDesc	Indicates local system description.
SysCapSupported	Indicates the system capabilities supported on the local system.
SysCapEnabled	Indicates the system capabilities that are enabled on the local system.

View LLDP Local Port Information

Use this procedure to view the LLDP local port information.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Click **LLDP**.
3. Click the **Local Port** tab.

Local port *field descriptions*

Use the data in the following table to use the **Local Port** tab.

Name	Description
PortNum	Indicates the port number.
PortIdSubType	Indicates the type of port identifier. • interfaceAlias • portComponent • macAddress • networkAddress • interfaceName • agentCircuitId • local
PortId	Indicates the identifier associated with the port, on the local system.
PortDesc	Indicates the description of the port, on the local system.

View LLDP CDP Remote Information

Use this procedure to view the remote device information received through the Industry Standard Discovery Protocol (ISDP) (CDP-compatible) messages on the local interface.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Select **LLDP**.
3. Select the **CDP Remote** tab.

CDP Remote *Field Descriptions*

Use the data in the following table to use the **CDP Remote** tab.

Name	Description
PortNum	Indicates the port number on which the remote system information is received.
CallServers	Indicates the remote call server IP addresses that are received on this port.
FileServers	Indicates remote file server IP addresses that are received on this port.

View LLDP Neighbor Information

Use this procedure to view the LLDP neighbor information.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Click **LLDP**.
3. Click the **Neighbor** tab.

Neighbor *Field Descriptions*

Use the data in the following table to use the **Neighbor** tab.

Name	Description
TimeMark	Indicates the time filter. For more information about TimeFilter, see the TimeFilter textual convention in IETF RFC 2021.
LocalPortNum	Identifies the port on which the remote system information is received.
Index	Indicates a particular connection instance that is unique to the remote system.
ProtocolType	Indicates whether the entry protocol is CDP or LLDP.
SysName	Indicates the name of the remote system.
IpAddress	Indicates the neighbor's IP address.
PortIdSubType	Indicates the type of encoding used to identify the remote port.
PortId	Indicates the remote port ID.
PortDesc	Indicates the remote port description.
ChassisIdSubtype	Indicates the type of encoding used to identify the remote system chassis. • chassisComponent • interfaceAlias • portComponent • macAddress • networkAddress • interfaceName • local

Name	Description
ChassisId	Indicates the chassis ID of the remote system.
SysCapSupported	Identifies the system capabilities supported on the remote system.
SysCapEnabled	Identifies the system capabilities enabled on the remote system.
SysDesc	Indicates the description of the remote system.

LLDP-MED Configuration Using EDM

Configure LLDP-MED information for local and remote systems on specific ports. LLDP-MED is enabled by default and all its TLVs are enabled for transmission.

To configure LLDP-MED TLVs in the LLDP PDUs on an interface:

- Configure LLDP-MED.
- Configure LLDP-MED location information.
- The switch automatically configures LLDP-MED capabilities, power, and inventory information.

View LLDP-MED Local Policy Information

About This Task

Perform this procedure to view policy information for local LLDP-MED on specific ports.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Click **Port MED**.
3. Click the **Local Policy** tab.

Local Policy *Field Descriptions*

Name	Description
PortNum	Specifies the port.
PolicyAppType	Specifies the application type.
PolicyVlanId	Specifies the VLAN ID for the port, as defined in IEEE 802.1Q-2003. The value 0 is used if the device is using priority tagged frames, which means only the 802.1D priority level is significant, and the default VLAN ID of the ingress port is used instead.
PolicyPriority	Specifies the Layer 2 priority used for the specified application type, as defined in IEEE 802.1D-2004. The default is 0.

Name	Description
PolicyDscp	Specifies the value of the Differentiated Service Code Point (DSCP) associated with a specific port on the local LLDP-MED, as defined in IETF RFC 2474 and RFC 2475. The default is 0.
PolicyTagged	Specifies whether the application uses a tagged or untagged VLAN, as defined by IEEE 802.1Q-2003. • true — uses tagged VLAN • false — uses untagged VLAN or does not support a port-based VLAN

Add LLDP-MED Local Location Information

About This Task

Perform this procedure to add location information of local LLDP-MED configured on specific ports.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Click **Port MED**.
3. Click the **Local Location** tab.
4. In **LocationInfo** column, double-click on the cell, and type the information.

Local Location *Field Descriptions*

Name	Description
PortNum	Specifies the port number.
LocationSubtype	Specifies the location subtype of the local LLDP-MED: • coordinateBased • civicAddress • elin
LocationInfo	Specifies the location information of local LLDP-MED. The parsing of this information depends on the location subtype.

View LLDP-MED Local PoE PSE Information

About This Task

Perform this procedure to view PoE Power Sourcing Entity (PSE) information for local LLDP-MED on specific ports.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Click **Port MED**.

3. Click the **Local PoE PSE** tab.

***Local PoE PSE** Field Descriptions*

Name	Description
PortNum	Specifies the port.
PSEPortPowerAvailable	Specifies the value of the power available (in units of 0.1 watts) from the PSE through the specific port.
PSEPortPDPriority	Specifies the Power Device (PD) power priority for the PSE port (see RFC 3621): • unknown — priority is not configured or known by the PD • critical • high • low

View LLDP-MED Neighbor Capabilities Information

About This Task

Perform this procedure to view capabilities information for remote LLDP-MED on specific ports based on the information advertised by the remote device and received on each port in the capabilities TLV.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Click **Port MED**.
3. Click the **Neighbor Capabilities** tab.

***Neighbor Capabilities** Field Descriptions*

Name	Description
TimeMark	Specifies the time filter. For more information about TimeFilter, see the TimeFilter textual convention in IETF RFC 2021.
LocalPortNum	Specifies the port on which the remote LLDP-MED information is received.
Index	Specifies the connection instance unique to the remote LLDP-MED.
CapSupported	Specifies the LLDP-MED capabilities supported on the remote system.
CapCurrent	Specifies the LLDP-MED capabilities that are enabled on the remote system.
DeviceClass	Specifies the remote LLDP-MED device class.

View LLDP-MED Neighbor Policy Information

About This Task

Perform this procedure to view policy information of remote LLDP-MED on specific ports.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Click **Port MED**.
3. Click the **Neighbor Policy** tab.

Neighbor Policy *Field Descriptions*

Name	Description
TimeMark	Specifies the time filter. For more information about TimeFilter, see the TimeFilter textual convention in IETF RFC 2021.
LocalPortNum	Specifies the port on which the remote LLDP-MED information is received.
Index	Specifies the particular connection instance that is unique to the remote LLDP-MED.
PolicyAppType	Specifies the policy application type.
PolicyVlanId	Specifies the VLAN ID for the port, as defined in IEEE 802.1Q-2003. The value 0 is used if the device is using priority tagged frames, which means only the 802.1D priority level is significant, and the default VLAN ID of the ingress port is used instead.
PolicyPriority	Specifies the Layer 2 priority used for the specified application type, as defined in IEEE 802.1D-2004. The default value is 0.
PolicyDscp	Specifies the value of the Differentiated Service Code Point (DSCP) associated with a specific port on the remote LLDP-MED, as defined in IETF RFC 2474 and RFC 2475. The default value is 0.
PolicyUnknown	Specifies the network policy for the remote LLDP-MED is currently unknown.
PolicyTagged	Specifies whether the application uses a tagged or untagged VLAN, as defined by IEEE 802.1Q-2003. • true — uses tagged VLAN • false — uses untagged VLAN or does not support a port based VLAN

View LLDP-MED Neighbor Location Information

About This Task

Perform this procedure to view location information of remote LLDP-MED on specific ports.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Click **Port MED**.
3. Click the **Neighbor Location** tab.

Neighbor Location *Field Descriptions*

Name	Description
TimeMark	Specifies the time filter. For more information about TimeFilter, see the TimeFilter textual convention in IETF RFC 2021.
LocalPortNum	Specifies the port on which the remote LLDP-MED information is received.
Index	Specifies the particular connection instance that is unique to the remote LLDP-MED.
LocationSubType	Specifies the subtype of the remote LLDP-MED location: • coordinateBased • civicAddress • elin
LocationInfo	Specifies the location information of the remote LLDP-MED.

View LLDP-MED Neighbor PoE Information

About This Task

Perform this procedure to view PoE information of remote LLDP-MED on specific ports.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Click **Port MED**.
3. Click the **Neighbor PoE** tab.

Neighbor PoE *Field Descriptions*

Name	Description
TimeMark	Specifies the time filter. For more information about TimeFilter, see the TimeFilter textual convention in IETF RFC 2021.
LocalPortNum	Specifies the port on which the remote LLDP-MED information is received.

Name	Description
Index	Specifies the particular connection instance that is unique to the remote LLDP-MED.
PoEDeviceType	Specifies the type of PoE LLDP-MED. • PseDevice: specifies the device as a Power Sourcing Entity (PSE). • pdDevice: specifies the device as a Power Device (PD). • none: specifies that the device does not support PoE.

View LLDP-MED Neighbor PoE PSE Information

About This Task

Perform this procedure to view PoE Power Sourcing Entity (PSE) information for remote LLDP-MED on specific ports.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Click **Port MED**.
3. Click the **Neighbor PoE PSE** tab.

Neighbor PoE PSE *Field Descriptions*

Name	Description
TimeMark	Specifies the time filter. For more information about TimeFilter, see the TimeFilter textual convention in IETF RFC 2021.
LocalPortNum	Specifies the port on which the remote LLDP-MED information is received.
Index	Specifies the particular connection instance that is unique to the remote LLDP-MED.
PSEPowerAvailable	Specifies the power available from the PSE connected remotely to the specific port.

Name	Description
PSEPowerSource	Specifies the type of PSE Power Source for the remote LLDP-MED. • unknown • primary • backup
PSEPowerPriority	Specifies the power priority associated with the PSE LLDP-MED, for more information, see RFC 3621. • unknown • critical • high • low

View LLDP-MED Neighbor PoE PD Information

About This Task

Perform this procedure to view PoE Powered Device (PD) information for remote LLDP-MED on specific ports.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Click **Port MED**.
3. Click the **Neighbor PoE PD** tab.

Neighbor PoE PD *Field Descriptions*

Name	Description
TimeMark	Specifies the time filter. For more information about TimeFilter, see the TimeFilter textual convention in IETF RFC 2021.
LocalPortNum	Specifies the port on which the remote LLDP-MED information is received.
Index	Specifies the particular connection instance that is unique to the remote LLDP-MED.
PDPowerReq	Specifies the value of the power required by a PD LLDP-MED connected remotely to the port.

Name	Description
PDPowerSource	Specifies the power source being utilized by the PD LLDP-MED. • from PSE: specifies that the device advertises its power source as received from a PSE. • local: specifies that the device advertises its power source as local. • local and PSE: specifies that the device advertises its power source as using both local and PSE power.
PDPowerPriority	Specifies the priority of the PD LLDP-MED connected remotely to the port, for more information, see RFC 3621. • unknown — priority is not configured for the PD LLDP-MED • critical • high • low

View LLDP-MED Neighbor Inventory Information

About This Task

Perform this procedure to view inventory attributes for LLDP-MED on specific ports.

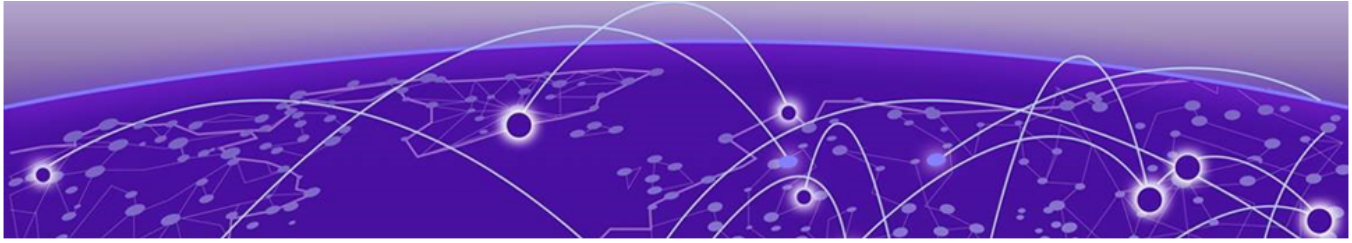
Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics** > **802_1ab**.
2. Click **Port MED**.
3. Click the **Neighbor Inventory** tab.

Neighbor Inventory *Field Descriptions*

Name	Description
TimeMark	Specifies the time filter. For more information about TimeFilter, see the TimeFilter textual convention in IETF RFC 2021.
LocalPortNum	Specifies the port on which the remote LLDP-MED information is received.
Index	Specifies the particular connection instance that is unique to the remote LLDP-MED.
HardwareRev	Specifies the current hardware revision of the LLDP-MED.
FirmwareRev	Specifies the current firmware revision of the LLDP-MED.
SoftwareRev	Specifies the current software revision of the LLDP-MED.

Name	Description
SerialNum	Specifies the current serial number of the LLDP-MED.
MfgName	Specifies the manufacturer of the LLDP-MED.
ModelName	Specifies the model name of the LLDP-MED.
AssetID	Specifies the asset tracking identifier for the LLDP-MED.



Link State Change Control

Rapid fluctuation in a port link state is called link flapping.

Link flapping is detrimental to network stability because it can trigger recalculation in spanning tree and the routing table.

If the number of port down events exceeds a configured limit during a specified interval, the system forces the port out of service.

You can configure link flap detection to control link state changes on a physical port. You can set thresholds for the number and frequency of changes allowed.

You can configure the system to take one of the following actions if changes exceed the thresholds:

- send a trap
- bring down the port

If changes exceed the link state change thresholds, the system generates a log entry.

Link Debounce

Table 132: Link Debounce for WAN Links

Feature	Product	Release introduced
Link Debounce	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.5
	5520 Series	VOSS 8.5
	5720 Series	Fabric Engine 8.7

In a WAN environment, when a carrier-side link failure occurs, switchover on the carrier side can take a few hundred milliseconds. During that time, a lag in the sending and receiving of packets can occur. Use Link Debounce to hold the connection path until the switchover is complete. You can configure Link Debounce on each port.

Link Debounce protects the upper layers from unnecessary state changes by delaying the change of a port link state when the following situations occur:

- There are frequent flaps in a short interval at the physical layer in the case of Fiber WAN services.
- There is a delay in switching from the working path to the protected path in the case of Carrier Wave WAN services.

Link Debounce works only on Layer 1 protocol applications. Layer 2 / Layer 3 protocols make decisions based on how they receive packets. For example, STP makes the decision according to the lack of traffic and port up condition; OSPF and IS-IS can still fail adjacencies.

Link State Change Control Using CLI

Detect and control link flapping to bring more stability to your network.

Controlling Link State Changes

Configure link flap detection to control state changes on a physical port.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the interval for link state changes:

   ```
   link-flap-detect interval <2-600>
   ```

3. Configure the number of changes allowed during the interval:

   ```
   link-flap-detect frequency <1-9999>
   ```

4. Enable automatic port disabling:

   ```
   link-flap-detect auto-port-down
   ```

5. Enable sending a trap:

   ```
   link-flap-detect send-trap
   ```

Example

Enable automatic disabling of the port:

```
Switch:1(config)#link-flap-detect auto-port-down
```

Configure the link-flap-detect interval:

```
Switch:1(config)#link-flap-detect interval 20
```

Enable sending traps:

```
Switch:1(config)#link-flap-detect send-trap
```

Variable Definitions

Use the data in the following table to use the **link-flap-detect** command.

Variable	Value
<auto-port-down>	Automatically disables the port if state changes exceed the link-flap threshold. By default, auto-port-down is enabled. Use the **no** operator to remove this configuration. To set this option to the default value, use the **default** operator with the command.
frequency <1-9999>	Configures the number of changes that are permitted during the time specified by the *interval* command. The default is 20. To set this option to the default value, use the **default** operator with the command.
interval <2-600>	Configures the link-flap-detect interval in seconds. The default value is 60. To set this option to the default value, use the **default** operator with the command.
send-trap	Activates traps transmission. The default setting is activated. Use the **no** operator to remove this configuration. To set this option to the default value, use the **default** operator with the command.

Displaying Link State Changes

Displays link flap detection state changes on a physical port.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. Display link state changes:

   ```
   show link-flap-detect
   ```

Example

```
Switch:1>enable
Switch:1#show link-flap-detect

 Auto Port Down : enable
 Send Trap      : enable
 Interval       : 60
 Frequency      : 20
```

Configure Link Debounce

About This Task

Configure Link Debounce for ports to hold the connection path until the carrier side switchover is complete.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Link Debounce:

   ```
   link-debounce <0-300000>
   ```

3. Verify the configuration:

   ```
   show interfaces gigabitEthernet link-debounce [{slot/port[/sub-port][-
   slot/port[/sub-port]][,...]}]
   ```

Examples

Configure the Link Debounce timer on port 1/2 to 300000 milliseconds.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#link-debounce 300000
```

Display the Link Debounce configuration for ports 1/1 through 1/4.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#show interfaces gigabitEthernet link-debounce 1/1-1/4
================================================================================
                              Port link debounce
================================================================================
--------------------------------------------------------------------------------
PORT     LINK-DEBOUNCE     LINK-DEBOUNCE         DEBOUNCE    DEBOUNCE
NUM      STATUS            TIMER MILLISECONDS    COUNT       SUCCEEDED
--------------------------------------------------------------------------------
1/1      Enable            1500                   0           0
1/2      Enable            300000                  0           0
1/3      Disable           --                     0           0
1/4      Enable            4000                   0           0
```

Variable Definitions

The following table defines parameters for the **link-debounce** command.

Variable	Value
<0–300000>	Link debounce configures time for ports in milliseconds. The default status is disabled for all ports when not initially configured. If you run the **default link-debounce** command, the default configuration is enabled with a value of 1,000 milliseconds. To return to the initial disabled state, you must run the **no link-debounce** command or set the Link Debounce timer to 0.

Link State Change Control Using EDM

Detect and control link flapping to bring more stability to your network.

Controlling Link State Changes

About This Task

Configure link flap detection to control link state changes on a physical port.

Procedure

1. In the navigation pane, expand the **Configuration** > **Serviceability** > **Diagnostics** folders.
2. Click **General**.
3. Click the **Link Flap** tab.
4. Configure the parameters as required.
5. Click **Apply**.

Link Flap *Field Descriptions*

Use the data in the following table to use the **Link Flap** tab.

Name	Description
AutoPortDownEnable	Enables or disables Link Flap Detect. If you enable Link Flap Detect, the system monitors the number of times a port goes down during a designated interval. If the number of drops exceeds a specified limit, the system forces the port out-of-service. The default is enabled.
SendTrap	Specifies that a trap is sent if the port is forced out-of-service.
Frequency	Specifies the number of times the port can go down. The default is 20.
Interval	Specifies the interval (in seconds) between port failures. The default is 60.

Configure Link Debounce

About This Task

Configure Link Debounce for ports to hold the connection path until the carrier side switchover is complete.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
3. Select **General**.
4. Select **Interface** tab.
5. In **LinkDebounce**, type the value in milliseconds to configure the timer.
6. Select **Apply**.

Interface *Field Descriptions*

Use the data in the following table to use the **Interface** tab.

Name	Description
Index	Displays the index of the port, written in the slot/port[/sub-port] format.
Name	Configures the name of the port.
Descr	Displays the description of the port. A textual string containing information about the interface.
Type	Displays the type of connector plugged in the port.
Mtu	Displays the Maximum Transmission Unit (MTU) for the port. The size of the largest datagram which can be sent or received on the interface, specified in octets. For interfaces that are used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface.
PhysAddress	Displays the physical address of the port. The address of the interface at the protocol layer immediately `below' the network layer in the protocol stack. For interfaces which do not have such an address, for example, a serial line, this object should contain an octet string of zero length.
VendorDescr	Displays the vendor of the connector plugged in the port.
DisplayFormat	Identifies the slot and port numbers (slot/port). If the port is channelized, the format also includes the sub-port in the format slot/port/sub-port
AdminStatus	Configures the port as enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.

Name	Description
OperStatus	Displays the current status of the port. The status includes enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.
LicenseControlStatus Note: Exception: only supported on 5320 Series.	Shows the port license status.
ShutdownReason	Indicates the reason for a port state change.
LastChange	Displays the timestamp of the last change.
LinkTrap	Enable or disable link trapping.
AutoNegotiate	Enables or disables Auto-Negotiation for this port. The default Auto-Negotiation behavior depends on the switch model and transceiver type.
AutoNegAd	Specifies the port speed and duplex abilities to advertise during link negotiation. Supported speeds and duplex modes vary, depending on your hardware. The abilities specified in this object are only used when auto-negotiation is enabled on the port. If all bits in this object are disabled, and auto-negotiation is enabled on the port, then the physical link process on the port will be disabled (if hardware supports this ability). Any change to this configuration restarts the auto-negotiation process, which has the same effect as physically unplugging and reattaching the cable attached to the port. If you select **default**, all capabilities supported by the hardware are advertised.
AdminDuplex	Configures the administrative duplex setting for the port.
OperDuplex	Indicates the operational duplex setting for the port.
AdminSpeed	Configures the administrative speed for the port.
OperSpeed	Indicates the operational speed for the port.
QoSLevel	Selects the Quality of Service (QoS) level for this port. The default is level1.
DiffServ	Enables the Differentiated Service feature for this port. The default is disabled.
Layer3Trust	Configures if the system should trust Layer 3 packets coming from access links or core links only. The default is core.
Layer2Override8021p	Specifies whether Layer 2 802.1p override is enabled (selected) or disabled (cleared) on the port. The default is disabled (clear).

Name	Description
MltId	Shows the MLT ID associated with this port. The default is 0.
Locked	Shows if the port is locked. The default is unlocked.
UnknownMacDiscard	Discards packets that have an unknown source MAC address, and prevents other ports from sending packets with that same MAC address as the destination MAC address. The default is disabled.
DirectBroadcastEnable	Specifies if this interface forwards direct broadcast traffic.
OperRouting	Shows the routing status of the port.
HighSecureEnable	Enables or disables the high secure feature for this port.
RmonEnable	Enables or disables Remote Monitoring (RMON) on the interface. The default is disabled.
FlexUniEnable	Enables Flex UNI on the port. The default is disabled.
EgressRateLimitState	Enables or disables egress port-based shaping to bind the maximum rate at which traffic leaves the port. The default is disabled.
EgressRateLimit	Specifies the egress rate limit in Kbps. Different hardware platforms support different egress rate limits, depending on the port with the highest speed available on the platform. You cannot configure the egress shaper rate to exceed the port capability. If you configure this value to 0, shaping is disabled on the port.
TxFlowControl	Configures if the port sends pause frames. By default, an interface does not send pause frames. You must also enable the flow control feature globally before an interface can send pause frames.
TxFlowControlOperState	Shows the operational state of flow control.
BpduGuardTimerCount	Shows the time, starting at 0, since the port became disabled. When the BpduGuardTimerCount reaches the BpduGuardTimeout value, the port is enabled. Displays in 1/100 seconds.
BpduGuardTimeout	Specifies the value to use for port-state recovery. After a BPDU guard disables a port, the port remains in the disabled state until this timer expires. You can configure a value of 0 or to 65535. The default is 120 seconds. If you configure the value to 0, the expiry is infinity.

Name	Description
BpduGuardAdminEnabled	Enables BPDU Guard on the port. The default is disabled.
ForwardErrorCorrection	Configures one of the following options for Forward Error Correction (FEC) on the port: • CL 91 • CL 108 • CL 74 • disable • auto The disable option disables this configuration on the port.
ForwardErrorCorrectionApplicability	Displays whether FEC is applicable on the interface.
OperAutoNegotiate	Shows the operational state of Auto-Negotiation.
OperForwardErrorCorrection	Shows the negotiated operational FEC clause. If the value is off, the port supports FEC and is up but not configured for FEC. If the value is notApplicable, the port does not support FEC. If the value is unknown, the port supports FEC but is down.
Action	Performs one of the following actions on the port • none - none of the following actions • flushMacFdb - flush the MAC forwarding table • flushArp - flush the ARP table • flushIp - flush the IP route table • flushAll - flush all tables • triggerRipUpdate — manually triggers a RIP update The default is none.
Result	Displays the result of the selected action. The default is none.
AutoSense	Enables or disables Auto-sense on the specific port. The default value is disabled for existing configurations but enabled for new Zero Touch Fabric Configuration deployments.
AutoSenseKeepAutoConfig	Retains the Auto-sense configuration if you disable Auto-sense on the port. The dynamic configuration becomes a manual configuration and is visible in the **`show running-config`** output.
CustomAutoNegAdOrigin	Specifies the origin of Custom Auto Negotiation Advertisements (CANA) configuration on the port. The supported values are: • config - Set by the user. • radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.

Name	Description
BpduGuardOrigin	Specifies the origin of BPDU Guard configuration on the port. The supported values are: • config - Set by the user. • radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.
AutoSenseState	Displays the Auto-sense port state.
LinkDebounce	Specifies the extended debounce timer on the port. The range is 0 to 300000 milliseconds. The value 0 milliseconds disables debounce time. The default value is 1000.
AutoSenseDataIsid	Specifies the Auto-sense data I-SID per port. The range is 0 to 15999999.

Link-state tracking (LST)

Table 133: Link-state tracking (LST) product support

Feature	Product	Release introduced
Link-state tracking (LST)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

Link-state tracking (LST) Overview

Link-state tracking (LST) binds the link state of multiple interfaces, creating LST groups with upstream (to-be-followed) and downstream (to-follow) interfaces. LST monitors the state of upstream interfaces and automatically transfers the upstream state to the downstream interfaces. If all the upstream interfaces in a LST group are down, the downstream interfaces are administratively configured as down after approximately five seconds. If any upstream interface in a LST group is up, the downstream interfaces are not affected. The role of the LST group is to keep the downstream interfaces in the same state as the upstream interface.

An interface can be an aggregation of ports, multi-link trunks (MLT) or link aggregation groups (LAG). Interfaces can only belong to one LST group. You can configure LST using CLI or EDM. LST receives updates from Port Manager, MLT, and VLACP regarding the upstream state of ports and trunks in the group.

LST can detect a link failure of upstream interfaces and shutdown downstream interfaces, eliminating loss of traffic and allowing the source to reroute traffic. When a LST group disables a downstream interface, the interface can only be enabled by the LST group. You can recover the downstream interfaces that LST disabled by removing the interfaces from the LST group or by disabling the LST group. You can administratively enable or disable LST group downstream interfaces with shutdown commands. A LST group cannot enable ports that you administratively disabled.

Note

If you administratively enable an interface which LST disabled, only the administrative status of the interface changes. The interface remains disabled until the LST group enables the interface, or until you remove the interface from the LST group.

MLT interactions

For MLTs, a last-link-down event triggers a down operational state and a first-link-up event triggers an up operational state. You cannot delete an MLT that is a member of a LST group.

LAG and LACP interactions

For LAGs, a static LAG trunk ID associated with a LACP administrative key can be a member of a LST group. You can add LAGs to a LST group by specifying the LAG trunk ID. You cannot break the association between trunk ID, LACP key, and ports while the LAG trunk is in a LST group. For LACP, you cannot add ports with link-aggregation enabled to a LST group, or enable link-aggregation on interfaces already in a LST group.

VLACP interactions

You can add LST group interfaces configured with VLACP. For upstream interfaces with VLACP enabled, when the physical link is up with a VLACP partner, the operational state is up. Otherwise the operational state is down. If VLACP is enabled, the value of the VLACP have partner field and the link status correspond to the operational state of upstream interfaces. For upstream interfaces with VLACP disabled, the up and down operational states correspond directly with the physical link.

SLPP Guard interactions

You can add LST group interfaces configured with SLPP Guard. When LST disables a port that is already disabled by SLPP Guard, the interface is unblocked by SLPP Guard and the blocking timer clears.

BPDU Guard and MACsec interactions

You can add LST group interfaces configured with BPDU Guard or MACsec. BPDU Guard and MACsec can enable or disable ports administratively. An interface is enabled if both LST and BPDU Guard or MACsec consider the port enabled. If BPDU Guard or MACsec disables the port, the port remains down and does not link up.

LST configuration using CLI

Configure Link-state tracking (LST) groups composed of upstream and downstream interfaces. Valid LST group members are switch ports, multi-link trunks (MLT), or link aggregation groups (LAG).

Configuring LST

Use this procedure to configure LST groups.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the LST group upstream and downstream interface members:

   ```
   link-state group <1–48> <upstream | downstream> interface
   gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
   ```

3. Configure the LST group upstream and downstream mlt members:

   ```
   link-state group <1–48> <upstream | downstream> mlt <1–512>
   ```

4. Enable the group:

   ```
   link-state group <1–48> enable
   ```

5. Display the status of the groups:

   ```
   show link-state group <1–48> [detail]
   ```

Example

The following example shows a LST group created with ports 1–4 and mlt 1 as upstream members and ports 11–14 and mlt 2 as downstream members. The LST group is enabled. Because port 1 is up, the LST group receives an up operational state and the downstream interfaces are enabled. Upstream ports 2, 4 and mlt 1 have VLACP admin enabled and are listed in the VLACP Upstream State section.

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# link-state group 1 upstream interface gigabitEthernet 1/1-1/4
Switch:1(config)# link-state group 1 upstream mlt 1
Switch:1(config)# link-state group 1 downstream interface gigabitEthernet 1/11-1/14
Switch:1(config)# link-state group 1 downstream mlt 2
Switch:1(config)# link-state group 1 enable
Switch:1(config)# show link-state group 1

Variable definitions

Use the data in the following table to use the **link-state** command.

Variable	Value
enable	Activates the action specified for the LST group or specified interfaces.
group <1–48>	Specifies a LST group ID.
interface gigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Adds ports to the specified upstream or downstream LST group. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
mlt <1–512>	Adds an MLT to the specified upstream or downstream LSTgroup.
<upstream | downstream>	Specifies the upstream or downstream interfaces in the LST group.

Use the data in the following table to use the **show link-state** command.

Variable	Value
detail	Displays the specified LST group status as enabled or disabled and if the operational status is up or down. Detail displays LST group additional information.

LST configuration using EDM

Configure Link-state tracking (LST) groups composed of upstream and downstream interfaces. Valid LST group members are switch ports, multi-link trunks (MLT), or link aggregation groups (LAG).

Configuring LST

Use this procedure to configure LST groups.

Procedure

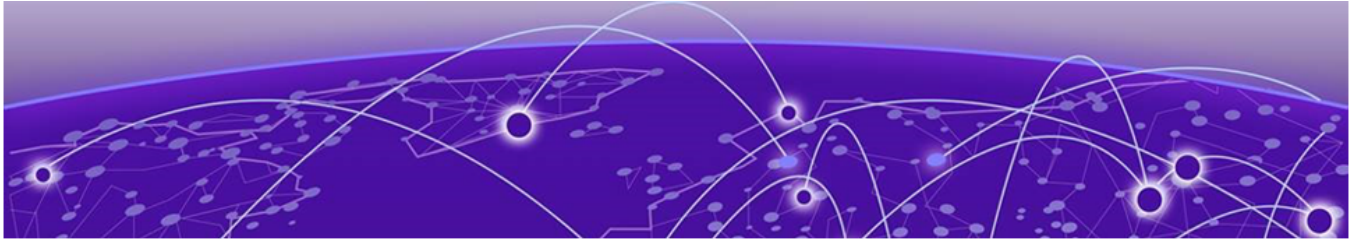
1. In the navigation pane, expand the **Configuration** > **Edit** folders.
2. Click **Link State Tracking**
3. Click the **Link State Tracking** tab.
4. Choose a **GroupId** row to configure.
5. To add upstream ports to the LST group, double click the **UpstreamPortList** field, select the upstream ports to add, then click **OK**.

6. To add downstream ports to the LST group, double click the **DownstreamPortList** field, select the upstream ports to add, then click **OK**.
7. To add an upstream MLT to the LST group, double click the **UpstreamMltList** field and enter an upstream MLT ID.
8. To add a downstream MLT to the LST group, double click the **DownstreamMltList** field and enter an upstream MLT ID.
9. To enable a LST group, double click the **Enabled** field and select **true**.
10. To activate the LST group configuration, click **Apply.**
11. View the **OperState** field of the LST groups to verify the current operating state.

Link State Tracking *field descriptions*

Use the data in the following table to use the **Link State Tracking** tab.

Name	Description
GroupId	Specifies the LST group number between 1 and 48.
Enabled	Specifies if the LST group is enabled. Values are true or false. Default is false.
UpstreamPortList	Specifies upstream interface ports in the LST group.
DownstreamPortList	Specifies downstream interface ports in the LST group.
UpstreamMltList	Specifies an upstream multi-link trunk in the LST group.
DownstreamMltList	Specifies a downstream multi-link trunk in the LST group.
OperState	Displays the current operating status of the LST group. Values are up, down, or notConfigured.



Logs and Traps

Table 134: Logs and traps product support

Feature	Product	Release introduced

Logs and Traps Fundamentals

This section details SNMP traps and log files, available as part of the switch System Messaging Platform.

Overview of Traps and Logs

System Log Messaging

On a UNIX-based management platform, you can use system log (syslog) messaging to manage event messages. The switch syslog software communicates with a server software component named syslogd on the management workstation.

The UNIX daemon syslogd is a software component that receives and locally logs, displays, prints, and forwards messages that originate from sources internal and external to the workstation. For example, syslogd on a UNIX workstation concurrently handles messages received from applications that run on the workstation, as well as messages received from the switch that runs in a network accessible to the workstation.

The remote UNIX management workstation performs the following actions:

- Receives system log messages from the switch.
- Examines the severity code in each message.
- Uses the severity code to determine appropriate system handling for each message.

Log Consolidation

The switch generates a system log file and can forward that file to a syslog server for remote viewing, storage, and analyzing.

The system log captures messages for the following components:

- Extensible Authentication Protocol (EAP)
- Remote Authentication Dial-in User Service (RADIUS)
- Remote Monitoring (RMON)
- web
- hardware (HW)
- MultiLink Trunking (MLT)
- filter
- Quality of Service (QoS)
- Command line interface (CLI) log
- software (SW)
- Central Processing Unit (CPU)
- Internet Protocol (IP)
- Virtual Local Area Network (VLAN)
- policy
- Simple Network Management Protocol (SNMP) log

The switch can send information in the system log file, including CLI command log and the SNMP operation log, to a syslog server.

View logs for CLILOG module to track all CLI commands executed and for fault management purposes. The CLI commands are logged to the system log file as CLILOG module.

View logs for SNMPLOG module to track SNMP logs. The SNMP operation log is logged to the system log file as SNMPLOG module.

The platform logs CLILOG and SNMPLOG as INFO. Normally, if you configure the logging level to WARNING, the system skips all INFO messages. However, if you enable CLILOG and SNMPLOG the system logs CLI Log and SNMP Log information regardless of the logging level you configure. This is not the case for other INFO messages.

System Log Client over IPv6 Transport

You can log system log messages to external system log hosts with both IPv4 and IPv6 addresses with no difference in functionality or configuration except in the following case. When you configure the system log table in EDM, under the **System Log Table** tab, you must select either IPv4 or IPv6.

Log Files with Enhanced Secure Mode

Enhanced secure mode allows the system to provide role-based access levels to log file commands. If you enable enhanced secure mode, the system encrypts the entire log file.

Log files are generated to `/inflash/shared`.

The current log file is protected against wiping for Telnet, SSH, FTP, SFTP, TFTP, and SCP applications for the following commands:

- Telnet and SSH:
  - mv
  - rename
  - delete
  - copy
  - cp
- FTP:
  - delete
  - mput
  - put
- TFTP:
  - put
- SCP:
  - destination file only

Log Commands Accessible for Various Users

The following table summarizes log file command access based on role-based access levels.

Access level role	Commands
No user at any access level.	The following commands: • **more** • **edit** • **rename** • **copy** • **remove** • **delete**
Administrator and auditor	All show commands for log files.
All users (Administrator, auditor, security, privilege, operator)	All show commands for log configurations.

With enhanced secure mode enabled, authorized users can use Telnet, SSH, FTP, SFTP, TFTP, SCP to transfer files to a remote server with the content encrypted.

SNMP Traps

The SNMP trap is an industry-standard method used to manage events. You can set SNMP traps for specific types of log message (for example, warning or fatal), from specific applications, and send them to a trap server for further processing. For example, you can configure the switch to send SNMP traps to a server after a port is unplugged or if a power supply fails.

This section only describes SNMP commands related to traps. For more information about how to configure SNMP community strings and related topics, see Simple Network Management Protocol (SNMP) on page 2784.

Secure Syslog

Syslog is a standard used to send event log messages to devices within a network. The switch sends event messages to a logging server called syslog server. The syslog server stores the log messages and displays them for event reporting. Syslog messages are used for monitoring system activities and troubleshooting.

The secure syslog feature adds security and authenticated access to the plain text event log messages that are communicated between a remote syslog server and a syslog client. The secure syslog feature helps prevent unauthorized access to confidential data transmitted on an unsecured communication channel between a remote syslog server and client.

To implement the security, this feature employs port forwarding using the Transport Layer Security (TLS) to provide encrypted communication between a syslog server and client.

After starting the syslog server, to ensure authentication, you must setup a remote port forwarding connection to connect the switch with a remote TLS Server.

TLS client for secure syslog

The syslog server is installed on a host that serves as a TLS Server. The switch plays the role of a TLS client for secure syslog. A TLS handshake is initiated between the syslog server and the switch. The syslog server transmits a certificate which has a subject common name and an optional subject alternative name (SAN). The subject common name is always present in the certificate but the SAN is optional. The server-cert-name must match the SAN name, if present in the certificate. If the SAN name is not present, it must match the subject common name. Otherwise, TLS negotiation fails and the connection to the server is closed. If the server-cert-name part is not configured, this check is not done.

Once the TLS handshake is successful, the log messages sent from the switch to the syslog server are encrypted. The syslog server decrypts these messages using a private key. The server then stores the messages or forwards them to other servers.

This feature supports the Rsyslog, which is a Linux based open source syslog server for TLS tunneling.

Simple Network Management Protocol

The Simple Network Management Protocol (SNMP) provides facilities to manage and monitor network resources. SNMP consists of:

- Agents—An agent is software that runs on a device that maintains information about device configuration and current state in a database.
- Managers—An SNMP manager is an application that contacts an SNMP agent to query or modify the agent database.
- The SNMP protocol—SNMP is the application-layer protocol SNMP agents and managers use to send and receive data.
- Management Information Bases (MIB)—The MIB is a text file that specifies the managed objects by an object identifier (OID).

Important

The switch does not reply to SNMP requests sent to the Virtual Router Redundancy Protocol (VRRP) virtual interface address; it does, however, reply to SNMP requests sent to the physical IP address.

An SNMP manager and agent communicate through the SNMP protocol. A manager sends queries and an agent responds; however, an agent initiates traps. Several types of packets transmit between SNMP managers and agents:

- Get request—This message requests the values of one or more objects.
- Get next request—This message requests the value of the next object.
- Set request—This message requests to modify the value of one or more objects.
- Get response—An SNMP agent sends this message in response to a get request, get next request, or set request message.
- Trap—SNMP trap is a notification triggered by events at the agent.

Log Message Format

The log messages for the switch have a standardized format. All system messages are tagged with the following information, except that alarm type and alarm status apply to alarm messages only:

- CPU slot number—Indicates the CP slot where the command is logged.
- timestamp—Records the date and time at which the event occurred. The format is MM/DD/YY hh:mm:ss.uuu, where uuu is milliseconds. Example: [11/01/10 11:41:21.376].
- hostname—The Hostname from which the message is generated.
- event code—Precisely identifies the event reported.
- alarm code—Specifies the alarm code.
- alarm type—Identifies the alarm type (Dynamic or Persistent) for alarm messages.
- alarm status—Identifies the alarm status (set or clear) for alarm messages.
- VRF name—Identifies the Virtual Routing and Forwarding (VRF) instance, if applicable.
- module name—Identifies the software module or hardware from which the log is generated.
- severity level—Identifies the severity of the message.
- sequence number—Identifies a specific CLI command.
- context—Specifies the type of the session used to connect to the switch. If the session is a remote session, the remote IP address is identified.
- user name—Specifies the user name used to login to the switch.
- CLI command—Specifies the commands typed during the CLI session. The system logs anything type during the CLI session as soon as the user presses the `Enter` key.

The following messages are examples of an informational message for CLILOG:

```
CP1  [07/18/14 13:23:11.253] 0x002c0600 00000000 GlobalRouter CLILOG INFO    13
TELNET:192.0.2.200 rwa show log file name-of-file log.40300001.1806

CP1  [07/18/14 13:24:19.739] 0x002c0600 00000000 GlobalRouter CLILOG INFO    15
TELNET:192.0.2.200 rwa term more en

 CP1  [07/18/14 13:24:22.577] 0x002c0600 00000000 GlobalRouter CLILOG INFO    16
TELNET:192.0.2.200 rwa show log

CP1  [01/12/70 15:13:59.056] 0x002c0600 00000000 GlobalRouter CLILOG INFO     5
TELNET:198.51.100.108 rwa syslog host 4

TELNET:198.51.100.108 rwa syslog host enable

CP1  [01/12/70 15:13:14.576] 0x002c0600 00000000 GlobalRouter CLILOG INFO     3
TELNET:198.51.100.108 rwa show syslog

CP1  [01/12/70 15:12:44.640] 0x002c0600 00000000 GlobalRouter CLILOG INFO     2
TELNET:198.51.100.108 rwa show logging file tail
```

The following messages are examples of an informational message for SNMPLOG:

```
CP1  [05/07/14 10:24:05.468] 0x002c4600 00000000 GlobalRouter SNMPLOG INFO     1
ver=v2c  public  rcVlanPortMembers.2 =

CP1  [05/07/14 10:29:58.133] 0x002c4600 00000000 GlobalRouter SNMPLOG INFO     2
ver=v2c  public  rcVlanPortMembers.2 =
```

```
CP1  [05/07/14 10:30:20.466] 0x002c4600 00000000 GlobalRouter SNMPLOG INFO    3  ver=v2c
public  rcVlanPortMembers.1 =
```

The following messages are examples of an informational message for system logs:

```
CP1  [07/24/14 18:04:08.304] 0x00000670 00000000 GlobalRouter SW INFO Basic license
supports all features on this device
CP1  [07/24/14 18:04:10.651] 0x00034594 00000000 GlobalRouter SW INFO System boot
```

The system encrypts AP information before writing it to the log file.

The encrypted information in a log file is for debugging purposes. Only a Customer Service engineer can decrypt the encrypted information in a log file. CLI commands display the logs without the encrypted information. Do not edit the log file.

The following table describes the system message severity levels.

Table 135: Severity levels

Severity level	Definition
EMERGENCY	A panic condition that occurs when the system becomes unusable. A severity level of emergency is usually a condition where multiple applications or servers are affected. You must correct a severity level of emergency immediately.
ALERT	Any condition requiring immediate attention and correction. You must correct a severity level of alert immediately, but this level usually indicates failure of a secondary system, such as an Internet Service Provider connection.
CRITICAL	Any critical conditions, such as a hard drive error.
ERROR	A nonfatal condition occurred. You can be required to take appropriate action. For example, the system generates an error message if it is unable to lock onto the semaphore required to initialize the IP addresses used to transfer the log file to a remote host.
WARNING	A nonfatal condition occurred. No immediate action is needed. An indication that an error can occur if action is not taken within a given amount of time.
NOTIFICATION	Significant event of a normal nature. An indication that unusual, but not error, conditions have occurred. No immediate action is required.
INFO	Information only. No action is required.
DEBUG	Message containing information useful for debugging.
FATAL	A fatal condition occurred. The system cannot recover without restarting. For example, a fatal message is generated after the configuration database is corrupted.

Based on the severity code in each message, the platform dispatches each message to one or more of the following destinations:

- workstation display
- local log file
- one or more remote hosts

You can log system log messages to external system log hosts with both IPv4 and IPv6 addresses with no difference in functionality or configuration except in the following case. When you configure the system log table in EDM, under the **System Log Table** tab, you must select either IPv4 or IPv6.

Internally, the switch has four severity levels for log messages: INFO, WARNING, ERROR, and FATAL. The system log supports eight different severity levels:

- Debug
- Info
- Notice
- Warning
- Critical
- Error
- Alert
- Emergency

The following table shows the default mapping of internal severity levels to syslog severity levels.

Table 136: Default and Ssystem log severity level mapping

UNIX system error codes	System log severity level	Internal severity level
0	Emergency	Fatal
1	Alert	
2	Critical	
3	Error	Error
4	Warning	Warning
5	Notice	
6	Info	Info
7	Debug	

Log Files

The log file captures hardware and software log messages, and alarm messages. The switch logs to internal flash.

The system saves internal log messages in a circular list in memory, which overwrite older log messages as the log fills. Unlike the log messages in a log file, the internal log messages in memory do not contain encrypted information, which can limit the information available during troubleshooting. Free up the disk space on the flash if the system generates the disk space 75% full alarm. After the disk space utilization returns below 75%, the system clears the alarm, and then starts logging to a file again.

Log file naming conventions

The following list provides the naming conventions for the log file:

- The log file is named as log.xxxxxxxx.sss format. The prefix of the log file name is log. The six characters after the log file prefix contain the last three bytes of the chassis base MAC address. The

next two characters are 01. The last three characters (sss) denote the sequence number of the log file.

- The sequence number of the log file is incremented for each new log file created after the existing log file reaches the maximum configured size.
- At initial system start up when no log file exists, a new log file with the sequence number 000 is created. After a restart, the system finds the newest log file from internal flash based on file timestamps. If the newest log file is on the flash that is used for logging, the system continues to use the newest log file. And once the maximum configured size is reached, system continues to create a new log file with incremental sequence number on the internal flash for logging.

Log File Transfer

The system logs contain important information for debugging and maintaining the switch. After the current log file reaches the configured maximum size, the system creates a new log file for logging. The system transfers old log files to a remote host. You can configure up to 10 remote hosts, which creates long-term backup storage of your system log files.

Of the 10 configured remote hosts, 1 is the primary host and the other 9 are redundant. Upon initiating a transfer, system messaging attempts to use host 1 first. If host 1 is not reachable, system messaging tries hosts 2 to 10.

If log file transfer is unsuccessful, the system keeps the old log files on internal flash. The system attempts to transfer old log files after the new log file reaches the configured maximum size. The system also attempts to transfer old log files periodically (once in one hundred log writes) if the disk space on the flash is more than 75% full.

You can log system log messages to external system log hosts with both IPv4 and IPv6 addresses with no difference in functionality or configuration.

With enhanced secure mode enabled, authorized users can use SFTP to transfer files to a remote server with the content encrypted.

You can specify the following information to configure the transfer criteria:

- The maximum size of the log file.
- The IP address of the remote host.
- The name prefix of the log file to store on the remote host.

  The system appends a suffix of .xxxxxxxx.sss to the file name. The first six characters of the suffix contain the last three bytes of the chassis base MAC address. The next two characters are 01. The last three characters (sss) denote the sequence number of the log file. For example, if you configure the name prefix as mylog, a possible file name is mylog.90000001.001.
- The user name and password, if using File Transfer Protocol (FTP) for file transfer. Use the following commands to configure the user name and password:

  ```
  boot config host user WORD<0-16>

  boot config host password WORD<0-16>
  ```

Be aware of the following restrictions to transfer log files to a remote host:

- The remote host IP address must be reachable.
- If you transfer a log file from a host to the system, (for example, to display it with a show command), rename the log file. Failure to rename the log file can cause the system to use the recently transferred file as the current log, if the sequence number in the extension is higher than the current log file. For example, if bf860005.002 is the current log file and you transfer bf860005.007 to the system, the system logs future messages to the bf860005.007 file. You can avoid this if you rename the log file to something other than the format used by system messaging.
- If your TFTP server is a UNIX-based machine, files written to the server must already exist. For example, you must create dummy files with the same names as your system logs. This action is commonly performed by using the touch command (for example, **`touch bf860005.001`**).

Three parameters exist to configure the log file:

- the minimum acceptable free space available for logging
- the maximum size of the log file
- the percentage of free disk space the system can use for logging

Although these three parameters exist, you can only configure the maximum size of the log file. The switch does not support the minimum size and percentage of free disk space parameters. The internal flash must be less than 75% full for the system to log a file. If the internal flash is more than 75% full, logging to a file stops to prevent exhausting disk space.

Log file transfer using a wildcard filename

File transfers using SFTP require file permissions.

Use the command **`attribute WORD<1-99> [+/-] R`** to change the permissions of a file.

To change permissions for all log files, use the wildcard filename **`log.*`**. Using the command in the wildcard form **`attribute log.* [+/-]R`** changes permissions for log files with names that begin with the characters “log.”.

Important

You cannot use a wildcard pattern other than **`log.*`** for this command.

Email Notification

The switch can send email notification for failed components or other critical log-event conditions. The switch can also send periodic health status notifications.

Enable and configure a Simple Mail Transfer Protocol (SMTP) client on the switch for one SMTP server by specifying the server hostname or IPv4 address. To use a hostname, you must also configure a Domain Name System (DNS) client on the switch.

You must configure at least one email recipient and can create a maximum of five email recipients.

The switch can periodically send general health status notifications. Status email messages include information about the following items:

- General switch
- Chassis
- Card
- Temperature
- Power supplies
- Fans
- LEDs
- System errors
- Port lock
- Message control
- Operational configuration changes
- Current Uboot
- Port interfaces
- Port statistics

The switch maintains a default list of event IDs for which it generates an email notification. You can add specific event IDs to this list. To see the default list of event IDs, run the **show smtp event-id** command.

The following example shows an email that the switch sends for log events.

```
Subject: Logs from LabSwitch - 50712100008
From: <LabSwitch@default.com>
To: <test1@default.com>
CP1  [08/04/15 21:48:04.527:UTC] 0x00004603 00400003.67108870 DYNAMIC CLEAR GlobalRouter

CP1  [08/04/15 21:50:03.511:UTC] 0x00088524 00000000 GlobalRouter SW INFO Boot sequence
successful
```

If you enable the SMTP client but the switch cannot reach the SMTP server, the switch generates an alarm. The switch holds log and status information in a queue until the connection with the SMTP server is restored. The message queue holds a maximum of 2,000 messages. If the queue fills, the switch drops new messages.

The following text is an example of the alarm that the switch generates when it cannot connect to the SMTP server.

```
CP1  [06/10/15 19:27:07.901:EST] 0x00398600 0e600000 DYNAMIC SET GlobalRouter SMTP
WARNING SMTP: Unable to establish connection with server: mailhost.usae.company.com,
port:25
```

If the switch cannot establish a connection to the SMTP server, verify that the server IP address or hostname, and the TCP port are correct. If you specify the server hostname, confirm that the IP address for the DNS server is correct. Check for network issues such as unplugged cables.

If the SMTP server rejects the email message, the switch generates a log message.

Log Configuration Using CLI

Use log files and messages to perform diagnostic and fault management functions.

Configure a UNIX System Log and Syslog Host

Configure the syslog to control a facility in UNIX machines that logs SNMP messages and assigns each message a severity level based on importance.

About This Task

You can log system log messages to external system log hosts with both IPv4 and IPv6 addresses with no difference in functionality or configuration.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable the system log:

   ```
   syslog enable
   ```

3. Configure the maximum number of syslog hosts:

   ```
   syslog max-hosts <1-10>
   ```

4. Create the syslog host:

   ```
   syslog host <1-10>
   ```

5. Configure the IP address for the syslog host:

   ```
   syslog host <1-10> address WORD <0-46>
   ```

6. Enable the syslog host:

   ```
   syslog host <1-10> enable
   ```

   Configure optional syslog host parameters by using the variables in the following variable definition tables.

7. View the configuration to ensure it is correct:

   ```
   show syslog [host <1-10>]
   ```

Examples

```
Switch:1(config)#syslog enable
Switch:1(config)#syslog host 7 address 192.0.2.1
Switch:1(config)#syslog host 7 enable
Switch:1(config)#show syslog host 7

                Id : 7
            IpAddr : 192.0.2.1
           UdpPort : 514
          Facility : local7
          Severity : info|warning|error|fatal
   MapInfoSeverity : info
```

```
 MapWarningSeverity : warning
   MapErrorSeverity : error
     MapMfgSeverity : notice
   MapFatalSeverity : emergency
             Enable : true
SecureForwardingMode: none
           Tcp Port : 1025

Switch:1(config)#show syslog

 Enable    : true
 Max Hosts : 5
 OperState : active
 header : default
 Total number of configured hosts : 3
 Total number of enabled hosts : 1
 Configured host : 7  8  9
 Enabled host : 7

 TLS-minimum-version           : tlsv11
 Ciphers-Tls                   : TLS_DHE_RSA_WITH_AES_256_CBC_SHA
TLS_DHE_RSA_WITH_AES_128_CBC_SHA
                                TLS_RSA_WITH_AES_256_CBC_SHA TLS_RSA_WITH_AES_128_CBC_SHA
```

Variable Definitions

The following table defines parameters for the **syslog** command.

Variable	Value
enable	Enables the sending of syslog messages on the device. Use the *no* operator before this parameter, *no syslog enable*, to disable the sending of syslog messages on the device. The default is enabled.
max-hosts <1-10>	Specifies the maximum number of syslog hosts supported, from 1–10. The default is 5.

The following table defines parameters for the **syslog host** command.

Variable	Value
1–10	Creates and configures a host instance. Use the *no* operator before this parameter, *no syslog host*, to delete a host instance.
address WORD <0–46>	Configures a host location for the syslog host. *WORD <0–46>* is the IPv4 or IPv6 address of the UNIX system syslog host in the format A.B.C.D or x:x:x:x:x:x:x:x. You can log system log messages to external system log hosts with both IPv4 and IPv6 addresses with no difference in functionality or configuration.
enable	Enables the syslog host. Use the *no* operator before this parameter, *no syslog host enable*, to disable syslog host. The default is disabled.

Variable	Value
facility {local0|local1|local2|local3|local4|local5|local6|local7}	Specifies the UNIX facility in messages to the syslog host. *{local0|local1|local2|local3|local4|local5|local6|local7}* is the UNIX system syslog host facility. The default is local7.
maperror {emergency|alert|critical|error|warning|notice|info|debug}	Specifies the syslog severity to use for error messages. The default is error.
mapfatal {emergency|alert|critical|error|warning|notice|info|debug}	Specifies the syslog severity to use for fatal messages. The default is *emergency*.
mapinfo {emergency|alert|critical|error|warning|notice|info|debug}	Specifies the syslog severity level to use for information messages. The default is info.
mapwarning {emergency|alert|critical|error|warning|notice|info|debug}	Specifies the syslog severity to use for warning messages. The default is *warning*.
severity <info|warning|error|fatal> [<info|warning|error|fatal>] [<info|warning|error|fatal>] [<info|warning|error|fatal>]	Specifies the severity levels for which to send syslog messages. You can specify up to four severity levels in the same command string. The default is *info*.
udp-port <514-530>	Specifies the User Datagram Protocol port number on which to send syslog messages to the syslog host. This value is the UNIX system syslog host port number from 514–530. The default is 514.

Configuring Secure Forwarding

Configuring secure forwarding includes setting the mode for the particular syslog host and setting the TCP port through which the logs are sent to the syslog server.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create the syslog host:

   ```
   syslog host <1–10>
   ```

   Use the no operator before this parameter, that is, `no syslog host` to delete a host instance.

3. Configure an IP address for the syslog host:

   ```
   syslog host <1–10> address WORD<0–46>
   ```

4. Enable the syslog host:

   ```
   syslog host <1–10> enable
   ```

5. Enable syslog globally:

   ```
   syslog enable
   ```

6. Set the mode for secure forwarding on the host:

   ```
   syslog host <1–10> secure-forwarding mode <none | tls [server-cert-name WORD<1-64>]>
   ```

7. Set the TCP port:

   ```
   syslog host <1–10> secure-forwarding tcp-port <1025–49151>
   ```

8. Display the secure forwarding configured values:

   ```
   show syslog host <1–10>
   ```

9. (Optional) Remove the server certificate name:

   ```
   no syslog host <1–10> secure-forwarding mode tls server-cert-name
   ```

10. (Optional) Set secure-forwarding mode to none for a particular host:

    ```
    default syslog host <1–10> secure-forwarding mode
    ```

What to Do Next

After configuring secure forwarding on the switch, set the syslog server to be able to see the log messages on the interactive syslog viewer.

- For TLS secure syslog, on the rsyslog server, configure the server to use TLS method and install the root certificate on the server in the switch.

Variable Definitions

The following table defines parameters for the **`syslog host`** command.

Variable	Value
host *<1–10>*	Specifies the ID for the syslog host. The range is 1–10.
address *WORD<0–46>*	Configures a host location for the syslog host. WORD <0–46> is the IPv4 or IPv6 address of the UNIX system syslog host in the format A.B.C.D or x:x:x:x:x:x:x:x. You can log system log messages to external system log hosts with both IPv4 and IPv6 addresses with no difference in functionality or configuration using CLI.
enable	Enables the syslog host. Use the no operator before this parameter, no syslog host enable to disable syslog host. The default is disabled.
secure-forwarding	Adds protected syslog using remote port forwarding for host.

The following table defines parameters for the **syslog host secure-forwarding** command.

Variable	Value
host <1-10>	Creates and configures a host instance. Use the no operator before this parameter, no syslog host to delete a host instance.
mode <none | tls [server-cert-name WORD<1-64>]>	Specifies the mode of secure forwarding of syslog on the host. The default mode is none, that is, tls mode is disabled by default. Note: Certificate validation is done only if the server-cert-name is configured.
tcp-port <1025-49151>	Set tcp-port for secure forwarding of syslog for host. The default tcp-port is 1025. To set the TCP port to default value, use command **default syslog host <1-10> secure-forwarding tcp-port**. Important: The tcp-port 6000 cannot be used, as it is used as an internal port for Internal Spanning Tree (IST).

Installing Root Certificate for Syslog Client

Use the following procedure to install a root certificate for a syslog client.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Install a root certificate on the store:

   ```
   syslog root-cert install-filename <file-name>
   ```

   The certificate is installed in folder: `/intflash/.cert/.syslogrootinstalledcert/`.

   Note

   The offline root certificate for TLS syslog must be kept in folder: `/intflash/.cert/..syslogofflinerootcert/`.

3. **Uninstall a root certificate from the store:**

   ```
   no syslog root-cert install-filename <file-name>
   ```

4. To display the installed syslog server root certificate file:

   ```
   show syslog root-cert-file
   ```

Variable Definition

The following table defines parameters for the **syslog root-cert** command.

Variable	Value
install-filename WORD<1-128>	Specifies the name of the root certificate to be installed on the store.

Configuring Logging

Configure logging to determine the types of messages to log and where to store the messages.

About This Task

Note

The platform logs CLILOG and SNMPLOG as INFO. Normally, if you configure the logging level to WARNING, the system skips all INFO messages. However, if you enable CLILOG and SNMPLOG the system logs CLI Log and SNMP Log information regardless of the logging level you configure. This is not the case for other INFO messages.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Define which messages to log:

   ```
   logging level <0-4>
   ```

3. Write the log file from memory to a file:

   ```
   logging write WORD<1-1536>
   ```

4. Show logging on the screen:

   ```
   logging screen
   ```

Example

```
Switch:1(config)#logging level 0
Switch:1(config)#logging write log2
Switch:1(config)#logging screen
```

Variable Definitions

The following table defines parameters for the **logging** command.

Variable	Value
level <0-4>	Shows and configures the logging level. The level is one of the following values: • 0: Information — all messages are recorded • 1: Warning — only warning and more serious messages are recorded • 2: Error — only error and more serious messages are recorded • 3: Manufacturing — this parameter is not available for customer use • 4: Fatal — only fatal messages are recorded
screen	Configures the log display on the screen to on. Use the no form of the command to stop the log display on the screen: **no logging screen**
transferFile <1-10> address {A.B.C.D} filename-prefix WORD<0-200	Transfers the syslog file to a remote FTP or TFTP server. *<1-10>* specifies the file ID. The *address {A.B.C.D}* option specifies the IP address. The *filename-prefix WORD<0-200>* option sets the filename prefix for the log file at the remote host.
write WORD<1-1536>	Writes the log file with the designated string. *WORD<1-1536>* is the string or command that you append to the log file. If the string contains spaces, you must enclose the string in quotation marks (").

Configuring the Remote Host Address for Log Transfer

Configure the remote host address for log transfer. The system transfers the current log file to a remote host after the log file size reaches the maximum size.

Before You Begin

- The IP address you configure for the remote host must be reachable at the time of configuration.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the remote host address for log transfer:

   ```
   logging transferFile {1-10} address {A.B.C.D} [filename—prefix WORD<0-200>]
   ```

Example

```
Switch:1(config)# logging transferFile 1 address 192.0.2.10
```

Variable Definitions

The following table defines parameters for the **logging transferFile** command.

Variable	Value
1–10	Specifies the file ID to transfer.
address {A.B.C.D}	Specifies the IP address of the host to which to transfer the log file. The remote host must be reachable or the configuration fails.
filename-prefix WORD<0–200>	Specifies the name of the file on the remote host. If you do not configure a name, the current log file name is the default.

Configuring System Logging

System logs are a valuable diagnostic tool. You can send log messages to flash files for later retrieval.

About This Task

You can change log file parameters at anytime without restarting the system. Changes made to these parameters take effect immediately.

Configure logging to a flash file at all times as a best practice.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable system logging to a PC card file:

   ```
   boot config flags logging
   ```

3. Configure the logfile parameters:

   ```
   boot config logfile <64-500> <500-16384> <10-90>
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config logfile 64 600 10
```

Variable Definitions

The following table defines parameters for the **boot config** command.

Variable	Value
flags logging	Enables or disables logging to a flash file. The log file is named using the format log.xxxxxxxx.sss. The first six characters after the prefix of the file name log contain the last three bytes of the chassis base MAC address. The next two characters specify the slot number. The last three characters denote the sequence number of the log file.
logfile <64-500> <500-16384> <10-90>	Configures the following logfile parameters: • *<64-500>* specifies the minimum free memory space on the external storage device from 64–500 KB. The switch does not support this parameter. • *<500-16384>* specifies the maximum size of the log file from 500–16384 KB. • *<10-90>* specifies the maximum percentage, ranging from 10–90 percent, of space on the external storage device the logfile can use. The switch does not support this parameter.

Configuring System Message Control

Configure system message control to suppress duplicate error messages on the console, and to determine the action to take if they occur.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure system message control action:

   ```
   sys msg-control action <both|send-trap|suppress-msg>
   ```

3. Configure the maximum number of messages:

   ```
   sys msg-control max-msg-num <2-500>
   ```

4. Configure the interval:

   ```
   sys msg-control control-interval <1-30>
   ```

5. Enable message control:

   ```
   sys msg-control
   ```

Example

```
Switch:1(config)#sys msg-control action suppress-msg
Switch:1(config)#sys msg-control max-msg-num 10
Switch:1(config)#sys msg-control control-interval 15
Switch:1(config)#sys msg-control
```

Variable Definitions

The following table defines parameters for the **sys msg-control** command.

Variable	Value
action <both|send-trap|suppress-msg>	Configures the message control action. You can either suppress the message or send a trap notification, or both. The default is suppress.
control-interval <1-30>	Configures the message control interval in minutes. The valid options are 1–30. The default is 5.
max-msg-num <2-500>	Configures the number of occurrences of a message after which the control action occurs. To configure the maximum number of occurrences, enter a value from 2–500. The default is 5.

Extending System Message Control

Use the force message control option to extend the message control feature functionality to the software and hardware log messages.

About This Task

To enable the message control feature, you must specify an action, control interval, and maximum message number. After you enable the feature, the log messages that get repeated and cross the maximum message number in the control interval, trigger the force message feature. You can either suppress the message or send a trap notification, or both.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the force message control option:

   ```
   sys force-msg WORD<4-4>
   ```

Example

Add a force message control pattern. If you use a wildcard pattern (****), all messages undergo message control.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys force-msg ****
```

Variable Definitions

The following table defines parameters for the **sys force-msg** command.

Variable	Value
WORD<4-4>	Adds a forced message control pattern, where *WORD<4-4>* is a string of 4 characters. You can add a four-byte pattern into the force-msg table. The software and the hardware log messages that use the first four bytes that match one of the patterns in the force-msg table undergo the configured message control action. You can specify up to 32 different patterns in the force-msg table, including a wildcard pattern (****) as well. If you specify the wildcard pattern, all messages undergo message control.

Viewing Logs

View log files by file name, category, or severity to identify possible problems.

About This Task

View CLI command and SNMP trap logs, which are logged as normal log messages and logged to the system log file.

Procedure

1. Enter Privileged EXEC mode:
   ```
   enable
   ```
2. Show log information:
   ```
   show logging file [alarm] [CPU WORD<0-100>] [detail] [event-code
   WORD<0-10>] [module WORD<0-100>] [name-of-file WORD<1-99>] [save-to-
   file WORD<1-99>] [severity WORD<0-25>] [tail] [vrf WORD<0-32>]
   ```

Example

Display log file information:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#show logging file

Variable Definitions

The following table defines parameters for the **show logging file** command.

Variable	Value
alarm	Displays alarm log entries.
CPU WORD <0-100>	Filters and lists the logs according to the CPU that generated the message. Specify a string length of 0-25 characters. To specify multiple filters, separate each CPU by the vertical bar (|), for example, CPU1|CPU2.
detail	Displays CLI and SNMP logging information.
event-code WORD<0-10>	Specifies a number that precisely identifies the event reported.

Variable	Value
module WORD<0-100>	Filters and lists the logs according to module. Specifies a string length of 0–100 characters. Categories include SNMP, EAP, RADIUS, RMON, WEB, HW, MLT, FILTER, QOS, CLILOG, SW, CPU, IP, VLAN, IPMC, and SNMPLOG. To specify multiple filters, separate each category by the vertical bar (|), for example, *|FILTER|QOS*.
name-of-file WORD<1-99>	Displays the valid logs from this file. For example, /intflash/logcopy.txt. You cannot use this command on the current log file, the file into which the messages are currently logged. Specify a string length of 1 to 99 characters. If you enable enhanced secure mode, the system encrypts the entire log file. After you use the **show log file name-of-file WORD<1-99>** command, the system takes the encrypted log file name as input, then decrypts it, and prints the output to the screen. You can then redirect the decrypted output to a file that you can store onto the flash. If enhanced secure mode is disabled, the system only encrypts the proprietary portion of the log file.
save-to-file WORD<1-99>	Redirects the output to the specified file and removes all encrypted information. You cannot use the *tail* option with the *save-to-file* option. Specify a string length of 1–99 characters.
severity WORD<0-25>	Filters and lists the logs according to severity. Choices include INFO, ERROR, WARNING, and FATAL. To specify multiple filters, separate each severity by the vertical bar (|), for example, *ERROR|WARNING|FATAL*.
tail	Shows the last results first.
vrf WORD<0-32>	Specifies the name of a VRF instance to show log messages that only pertain to that VRF.

Configuring CLI Logging

Use CLI logging to track all CLI commands executed and for fault management purposes. The CLI commands are logged to the system log file as CLILOG module.

About This Task

Note

The platform logs CLILOG and SNMPLOG as INFO. Normally, if you configure the logging level to WARNING, the system skips all INFO messages. However, if you enable CLILOG and SNMPLOG the system logs CLI Log and SNMP Log information regardless of the logging level you configure. This is not the case for other INFO messages.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Enable CLI logging:
   ```
   clilog enable
   ```

3. (Optional) Disable CLI logging:

   ```
   no clilog enable
   ```

4. Ensure that the configuration is correct:

   ```
   show clilog
   ```

5. View the CLI log:

   ```
   show logging file module clilog
   ```

Example

Enable CLI logging, and view the CLI log:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#clilog enable
Switch:1(config)#show logging file module clilog

Variable Definitions

The following table defines parameters for the **clilog** command.

Variable	Value
enable	Activates CLI logging. To disable, use the **no clilog enable** command.

Configure Email Notification

Configure the SMTP feature to generate email notifications for component failures, critical conditions, or general system health status.

About This Task

The SMTP feature is disabled by default.

Before You Begin

- To identify the SMTP server by hostname, you must first configure a DNS client on the switch.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the TCP port the client uses to open a connection with the SMTP server:

   ```
   smtp port <1-65535>
   ```

   Note
   The port you specify must match the port that the SMTP server uses.

3. Configure email recipients:

   ```
   smtp receiver-email add WORD<3-1274>

   smtp receiver-email remove WORD<3-1274>
   ```

   Note
   You must configure at least one recipient.

4. Configure the SMTP server hostname or IPv4 address:

   ```
   smtp server WORD<1-256>
   ```

5. (Optional) Configure a sender email address:

   ```
   smtp sender-email WORD<3-254>
   ```

6. (Optional) Add or remove log events to the default list that generate email notification:

   ```
   smtp event-id add WORD<1-1100>
   ```

   ```
   smtp event-id remove WORD<1-1100>
   ```

7. (Optional) Configure the status update interval:

   ```
   smtp status-send-timer <0 | 30-43200>
   ```

8. Enable the SMTP client:

   ```
   smtp enable
   ```

9. Configure an SMTP domain name:

   ```
   smtp domain-name WORD<1-254>
   ```

10. Verify the configuration:

    ```
    show smtp [event-id]
    ```

Examples

Configure the SMTP client to use TCP port 26 to communicate with an SMTP server that is using port 26. Add two receiver email addresses, configure the server information using an IPv4 address, and enable the SMTP feature. Finally, configure an SMTP domain name, and then verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#smtp port 26
Switch:1(config)#smtp receiver-email add test1@default.com,test2@default.com
Switch:1(config)#smtp server 192.0.2.1
Switch:1(config)#smtp enable
Switch:1(config)#smtp domain-name test mailer
Switch:1(config)#show smtp
================================================================================
                                SMTP Information
================================================================================
        SMTP Status:  Enabled
     Server Address:  192.0.2.1
        Server Port:  26
  Status send Timer:  30 (seconds)
       Sender Email:  LabSwitch@default.com
        Domain Name:  test mailer
    Receiver Emails:  test1@default.com
                      test2@default.com
```

Add an event ID to the list for which the switch sends email notification on a log event. Verify the configuration.

```
Switch:1(config)#smtp event-id add 0x0000c5ec
Switch:1(config)#show smtp event-id

Variable Definitions

The following table defines parameters for the **`smtp port`** command.

Variable	Value
<1–65535>	Specifies the TCP port on the switch that the SMTP client uses to communicate with the SMTP server. The default value is 25. Note: You must disable the SMTP feature before you can change an existing SMTP port configuration. The port you specify must match the port that the SMTP server uses.

The following table defines parameters for the **`smtp receiver-email`** command.

Variable	Value
add WORD<3–1274>	Adds an email address to the recipient list. The recipients receive the email notification generated by the switch. You must configure at least one email recipient and can create a maximum of five email recipients. You can specify multiple addresses in a single command by separating them with a comma. You cannot use quotation marks (“) or commas (,) in email addresses. Other restrictions for the format of the email address follow RFC 5321. The maximum length for the address is 254 characters.
remove WORD<3–1274>	Removes an email address from the recipient list. The recipients receive the email notification generated by the switch. You can specify multiple addresses in a single command by separating them with a comma. You cannot use quotation marks (“) or commas (,) in email addresses. Other restrictions for the format of the email address follow RFC 5321. The maximum length for the address is 254 characters.

The following table defines parameters for the **smtp server** command.

Variable	Value
WORD<1-256>	Specifies the SMTP server address. You can use either a hostname or IPv4 address. If you use a hostname, you must configure the DNS client on the switch.

The following table defines parameters for the **smtp sender-email** command.

Variable	Value
WORD<3-254>	Specifies the email address that the system displays it in the From field of the message that the switch generates. By default, the switch uses *<SystemName>*@default.com.

The following table defines parameters for the **smtp event-id** command.

Variable	Value
add WORD<1-1100>	Adds a log event to the list of events that generate email notification. You can specify multiple event IDs in a single command by separating them with a comma. The event ID can be up to 10 digits in hexadecimal format.
remove WORD<1-1100>	Removes a log event from the list of events that generate email notification. You can specify multiple event IDs in a single command by separating them with a comma. The event ID can be up to 10 digits in hexadecimal format.

The following table defines parameters for the **smtp status-send-timer** command.

Variable	Value
<0 | 30-43200>	Specifies the interval, in seconds, at which the switch sends status information. The default is 30 seconds. A value of 0 means the switch does not send status information.

The following table defines parameters for the **smtp domain-name** command.

Variable	Value
WORD<1-254>	Specifies the SMTP host name or IPv4 address (string length 1–254).

The following table defines parameters for the **show smtp** command.

Variable	Value
event-id	Shows a list of active event IDs for which the switch generates email notification. The command output includes the default list of IDs and IDs you specifically add or remove.

Configure Certificate Authority Trustpoint for Syslog

Before You Begin

Configure and install the digital certificate.

About This Task

Use this procedure to configure the certificate authority for the syslog.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the Certificate Authority trustpoint:

   ```
   syslog certificate ca-common-name WORD<1-45>
   ```

Variable Definitions

The following table defines parameters for the **`syslog certificate`** command.

Variable	Value
`ca-common-name WORD<1-45>`	Specifies the Certificate Authority common name.

Configure the Minimum Version of TLS for Syslog

About This Task

Use this procedure to configure the minimum version of TLS protocol supported by the syslog client.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure the TLS protocol version for the syslog client:

   ```
   syslog tls-min-verion {tlsv11 | tlsv12}
   ```

Variable Definitions

The following table defines parameters for the **`syslog tlv-min-ver`** command.

Variable	Value
`tlsv11` | *`tlsv12`*	Specifies the minimum version of the TLS protocol supported by the syslog client. • tlsv11 - configures version 1.1 • tlsv12 - configures version 1.2 The default is tlsv11.

Log Configuration Using EDM

Use log files and messages to perform diagnostic and fault management functions. This section provides procedures to configure and use the logging system in Enterprise Device Manager (EDM).

Configure the System Log

About This Task

Configure the system log to track all user activity on the device. The system log can send messages of up to ten syslog hosts.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics**.
2. Select **System Log**.
3. In the **System Log** tab, select **Enable**.
4. Configure the maximum number of syslog hosts.
5. Configure the minimum version of TLS protocol.
6. Select **Apply**.

System Log *Field Descriptions*

Use the data in the following table to use the **System Log** tab.

Name	Description
Enable	Enables or disables the syslog feature. If you select this variable, this feature sends a message to a server on a network that is configured to receive and store diagnostic messages from this device. You can configure the type of messages sent. The default is enabled.
MaxHosts	Specifies the maximum number of remote hosts considered active and can receive messages from the syslog service. The range is 0–10 and the default is 5.
OperState	Specifies the operational state of the syslog service. The default is active.
TlsMinimumVersion	Specifies the minimum version of TLS protocol supported by the syslog client. • tlsv11 - configures TLS version 1.1 • tlsv12 - configures TLS version 1.2 The default is tlsv11.
EncryptionType	Specifies the ciphers for preset version of TLS for the syslog.

Configure the System Log Table

About This Task

Use the system log table to customize the mappings between the severity levels and the type of alarms.

You can log system log messages to external system log hosts with both IPv4 and IPv6 addresses with no difference in functionality or configuration except in the following case. When you configure the system log table, under the **System Log Table** tab, you must select **ipv4** or **ipv6**, in the **AddressType** box. The **Address** box supports both IPv4 and IPv6 addresses.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics**.
2. Click **System Log**.
3. Click the **System Log Table** tab.
4. Click **Insert**.
5. Configure the parameters as required.
6. Click **Insert**.
7. To modify mappings, double-click a parameter to view a list of options.
8. Click **Apply**.

System Log Table *Field Descriptions*

Use the data in the following table to use the **System Log Table** tab.

Name	Description
Id	Specifies the ID for the syslog host. The range is 1–10.
AddressType	Specifies if the address is an IPv4 or IPv6 address.
Address	Specifies the IP address of the syslog host. You can log system log messages to external system log hosts with both IPv4 and IPv6 addresses.
UdpPort	Specifies the UDP port to use to send messages to the syslog host (514–530). The default is 514.
Enable	Enables or disables the sending of messages to the syslog host. The default is disabled.
HostFacility	Specifies the syslog host facility used to identify messages (local0 to local7). The default is local7.
Severity	Specifies the message severity for which syslog messages are sent. The default is info|warning|error|fatal.
MapInfoSeverity	Specifies the syslog severity to use for INFO messages. The default is info.
MapWarningSeverity	Specifies the syslog severity to use for WARNING messages. The default is warning.
MapErrorSeverity	Specifies the syslog severity to use for ERROR messages. The default is error.
MapFatalSeverity	Specifies the syslog severity to use for FATAL messages. The default is emergency.
MapMfgSeverity	Specifies the syslog severity to use for Accelar manufacturing messages. The default is notice.
SecureForwardingTcpPort	Specifies the TCP port to use for secure forwarding for a particular host. The default is 1025.

Name	Description
SecureForwardingMode	Enables or disables secure forwarding of syslog over remote port forwarding. The supported values are tls and none. The default is none, which means that secure forwarding is disabled.
SecureForwardingServerCertName	Specifies the server certificate name. Certificate validation is done only if the server certificate name is configured.

Configure the Syslog Certificate Authority Common Name

Use the following procedure to add the common name of the Certificate Authority.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics**.
2. Select **System Log**.
3. Select **Certificate Table** tab.
4. Select **Insert**.
5. In the **CaCommonName** field, enter the common name of the Certificate Authority.
6. Select **Insert**.

Certificate Table *Field Definitions*

Use the data in the following table to use the **Certificate Table** tab.

Name	Description
CaCommonName	Specifies the Certificate Authority common name of a syslog server.

Configure Email Notification

Configure the SMTP feature to generate email notifications for component failures, critical conditions, or general system health status.

About This Task

The SMTP feature is disabled by default.

Before You Begin

- To identify the SMTP server by hostname, you must first configure a DNS client on the switch.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **SMTP**.
3. Select the **Globals** tab.
4. In the **ServerAddress** field, configure the SMTP server address.

5. In the **ReceiverEmailsList** field, add email recipients.

   Note

   You must configure at least one recipient.

6. (Optional) In the **SenderEmail** field, configure a sender email address to use an address other than the default.
7. In the **DomainName** field, configure an SMTP domain name.
8. In the **Port** field, configure the TCP port that the client uses to open a connection with the SMTP server.
9. (Optional) In the **SystemStatusSendTimer** field, configure the status update interval.
10. Select **enable** to enable the SMTP client.
11. (Optional) In the **LogEventIds** field, add or remove log events to the default list that generates an email notification.
12. Select **Apply**.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
ServerAddressType	Specifies the type of server address as either an IPv4 address or a hostname. If you use a hostname, you must configure the DNS client on the switch.
ServerAddress	Specifies the SMTP server address. You can use either a hostname or an IPv4 address. If you use a hostname, you must configure the DNS client on the switch.
ReceiverEmailsList	Specifies the recipient list. The recipients receive the email notification generated by the switch. You must configure at least one email recipient and can create a maximum of five email recipients. You can specify multiple addresses in a single command by separating them with a comma. You cannot use quotation marks (“) or commas (,) in email addresses. Other restrictions for the format of the email address follow RFC5321. The maximum length for the address is 254 characters.
NumOfEmails	Shows the total number of addresses in **ReceiverEmailsList**.
SenderEmail	Specifies the email address that the system displays it in the From field of the message that the switch generates. By default, the switch uses *SystemName*@default.com.
DomainName	Specifies the SMTP domain name. The maximum length is 254 characters.

Name	Description
Port	Specifies the TCP port on the switch that the SMTP client uses to communicate with the SMTP server. The default value is 25. Note: You must disable the SMTP feature before you can change an existing SMTP port configuration. The port you specify must match the port that the SMTP server uses.
SystemStatusSendTimer	Specifies the interval, in seconds, at which the switch sends status information. The default is 30 seconds. A value of 0 means the switch does not send status information.
Enable	Enables or disables the SMTP feature. By default, SMTP is disabled.
LogEventIds	Specifies the list of events that generate email notification. You can specify multiple event IDs in a single command by separating them with a comma. The event ID can be up to 10 digits in hexadecimal format.
NumOfEventIds	Shows the total number of IDs in **LogEventIds**.
DefaultLogEventIds	Shows the default list of event IDs that generate email notification.
NumOfDefaultEventIds	Shows the total number of IDs in **DefaultLogEventIds**.

SNMP Trap Configuration Using CLI

Configuring an SNMP Host

Configure an SNMP host so that the system can forward SNMP traps to a host for monitoring. You can use SNMPv1, SNMPv2c, or SNMPv3. You configure the target table parameters (security name and model) as part of the host configuration.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure an SNMPv1 host:

   ```
   snmp-server host WORD<1-256> [port <1-65535>] v1 WORD<1-32> [filter WORD<1-32>]
   ```

3. Configure an SNMPv2c host:

   ```
   snmp-server host WORD<1-256> [port <1-65535>] v2c WORD<1-32> [inform
   [timeout <1-2147483647>] [retries <0-255>] [mms <0-2147483647>]]
   [filter WORD<1-32>]
   ```

4. Configure an SNMPv3 host:

   ```
   snmp-server host WORD<1-256> [port <1-65535>] v3 {noAuthNoPriv|
   authNoPriv|AuthPriv} WORD<1-32> [inform [timeout <1-2147483647>]
   [retries <0-255>]] [filter WORD<1-32>]
   ```

5. Ensure that the configuration is correct:

   ```
   show snmp-server host
   ```

Example

Configure the target table entry. Configure an SNMPv3 host.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmp-server host 192.0.2.207 port 162 v2c ReadView inform timeout 1500
retries 3 mms 484
Switch:1(config)#snmp-server host 192.0.2.207 port 163 v3 authPriv Lab3 inform timeout
1500 retries 3
```

Variable Definitions

The following table defines parameters for the **`snmp-server host`** command.

Variable	Value
`inform [timeout <1-2147483647>] [retries <0-255>] [mms <0-2147483647>]`	Sends SNMP notifications as inform (rather than trap). To use all three options in one command, you must use them in the following order: 1. *`timeout <1-2147483647>`* specifies the timeout value in seconds with a range of 1–214748364. 2. *`retries <0-255>`* specifies the retry count value with a range of 0–255. 3. *`mms <0-2147483647>`* specifies the maximum message size as an integer with a range of 0–2147483647.
`filter WORD<1-32>`	Specifies the filter profile to use.
`noAuthNoPriv|authNoPriv|AuthPriv`	Specifies the security level.
`port <1-65535>`	Specifies the host server port number.
`WORD<1-32>`	Specifies the security name, which identifies the principal that generates SNMP messages.
`WORD<1-256>`	Specifies either an IPv4 or IPv6 address.

Configuring an SNMP Notify Filter Table

Configure the notify table to select management targets to receive notifications, as well as the type of notification to send to each management target.

Before You Begin

- For more information about the notify filter table, see RFC3413.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Create a new notify filter table:

   ```
   snmp-server notify-filter WORD<1-32> WORD<1-32>
   ```

3. Ensure that the configuration is correct:

   ```
   show snmp-server notify-filter
   ```

Example

```
Switch:1(config)#snmp-server notify-filter profile3 99.3.6.1.6.3.1.1.4.1
Switch:1(config)#show snmp-server notify-filter

================================================================================
                        Notify Filter Configuration
================================================================================
Profile Name                    Subtree                         Mask
--------------------------------------------------------------------------------
profile1                        +99.3.6.1.6.3.1.1.4.1           0x7f
profile2                        +99.3.6.1.6.3.1.1.4.1           0x7f
profile3                        +99.3.6.1.6.3.1.1.4.1           0x7f
```

Variable Definitions

The following table defines parameters for the **`snmp-server notify-filter`** command.

Variable	Value
WORD<1-32> WORD<1-32>	Creates a notify filter table. The first instance of *WORD<1-32>* specifies the name of the filter profile with a string length of 1–32. The second instance of *WORD<1-32>* identifies the filter subtree OID with a string length of 1–32. If the subtree OID parameter uses a plus sign (+) prefix (or no prefix), this indicates include. If the subtree OID uses the minus sign (–) prefix, it indicates exclude. You do not calculate the mask because it is automatically calculated. You can use the wildcard character, the asterisk (*), to specify the mask within the OID. You do not need to specify the OID in the dotted decimal format; you can alternatively specify that the MIB parameter names and the OIDs are automatically calculated.

Enabling SNMP Trap Logging

Use SNMP trap logging to send a copy of all traps to the syslog server.

Before You Begin

- You must configure and enable the syslog server.

About This Task

Note

The platform logs CLILOG and SNMPLOG as INFO. Normally, if you configure the logging level to WARNING, the system skips all INFO messages. However, if you enable CLILOG and SNMPLOG the system logs CLI Log and SNMP Log information regardless of the logging level you set. This is not the case for other INFO messages.

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Enable SNMP trap logging:

   ```
   snmplog enable
   ```

3. (Optional) Disable SNMP trap logging:

   ```
   no snmplog enable
   ```

4. View the contents of the SNMP log:

   ```
   show logging file module snmplog
   ```

Example

Enable SNMP trap logging and view the contents of the SNMP log:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmplog enable
Switch:1(config-app)#show logging file module snmp
CP1  [02/06/15 22:39:58.530:UTC] 0x00004595 00000000 GlobalRouter SNMP INFO Boot
ed with file
CP1  [02/06/15 22:39:59.547:UTC] 0x00004603 00400003.67108870 DYNAMIC CLEAR Glob
alRouter SNMP INFO 2k card up(CardNum=1 AdminStatus=1 OperStatus=1)
CP1  [02/06/15 22:39:59.547:UTC] 0x00004603 00400003.67108870 DYNAMIC CLEAR Glob
alRouter SNMP INFO 2k card up(CardNum=2 AdminStatus=1 OperStatus=1)
CP1  [02/06/15 22:39:59.547:UTC] 0x00004603 00400003.67108870 DYNAMIC CLEAR Glob
alRouter SNMP INFO 2k card up(CardNum=3 AdminStatus=1 OperStatus=1)
CP1  [02/06/15 22:40:45.839:UTC] 0x000045e5 00400005 DYNAMIC SET GlobalRouter SN
MP INFO Sending Cold-Start Trap
```

Variable Definitions

The following table defines parameters for the **`snmplog`** command.

Variable	Value
`enable`	Enables the logging of traps. Use the command `no snmplog enable` to disable the logging of traps.

SNMP Trap Configuration Using EDM

Configure an SNMP Host Target Address

Configure a target table to specify the list of transport addresses to use in the generation of SNMP messages.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit** > **SnmpV3**.
2. Click **Target Table**.
3. In the **Target Table** tab, click **Insert**.
4. In the **Name** box, type a unique identifier.
5. In the **TDomain** box, select the transport type of the address. Select either **ipv4Tdomain** or **ipv6Tdomain**.
6. In the **TAddress** box, type the transport address and User Datagram Protocol (UDP) port.
7. In the **Timeout** box, type the maximum round trip time.
8. In the **RetryCount** box, type the number of retries to be attempted.
9. In the **TagList** box, type the list of tag values.
10. In the **Params** box, type the SnmpAdminString.
11. In the **TMask** box, type the mask.
12. In the **MMS** box, type the maximum message size.
13. Click **Insert**.

Target Table *Field Descriptions*

Use the data in the following table to use the **Target Table** tab.

Name	Description
Name	Specifies a unique identifier for this table. The name is a community string.
TDomain	Specifies the transport type of the address. **ipv4Tdomain** specifies the transport type of address is an IPv4 address. **ipv6Tdomain** specifies the transport type of address is IPv6. The default is ipv4Tdomain.
TAddress	Specifies the transport address in xx.xx.xx.xx:port format, for example: 192.1.2.12:162, where 162 is the trap listening port on the system 192.1.2.12.
Timeout	Specifies the maximum round trip time required to communicate with the transport address. The value is in 1/100 seconds from 0–2147483647. The default is 1500. After the system sends a message to this address, if a response (if one is expected) is not received within this time period, you can assume that the response is not delivered.
RetryCount	Specifies the maximum number of retries if a response is not received for a generated message. The count can be in the range of 0–255. The default is 3.

Name	Description
TagList	Contains a list of tag values used to select target addresses for a particular operation. A tag refers to a class of targets to which the messages can be sent.
Params	Contains SNMP parameters used to generate messages to send to this transport address. For example, to receive SNMPv2C traps, use TparamV2.
TMask	Specifies the mask. The value can be empty or in six-byte hex string format. Tmask is an optional parameter that permits an entry in the TargetAddrTable to specify multiple addresses.
MMS	Specifies the maximum message size. The size can be zero, or 484–2147483647. The default is 484. Although the maximum message size is 2147483647, the device supports the maximum SNMP packet size of 8192.

Configure Target Table Parameters

About This Task

Configure the target table to configure the security parameters for SNMP. Configure the target table to configure parameters such as SNMP version and security levels.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit** > **SnmpV3**.
2. Click **Target Table**.
3. Click the **Target Params Table** tab.
4. Click **Insert**.
5. In the **Name** box, type a target table name.
6. From the **MPModel** options, select an SNMP version.
7. From the **Security Model** options, select the security model.
8. In the **SecurityName** box, type `readview` or `writeview`.
9. From the **SecurityLevel** options, select the security level for the table.
10. Click **Insert**.

Target Params Table *Field Descriptions*

Use the data in the following table to use the **Target Params Table** tab.

Name	Description
Name	Identifies the target table.
MPModel	Specifies the message processing model to use to generate messages: SNMPv1, SNMPv2c, or SNMPv3/USM.
SecurityModel	Specifies the security model to use to generate messages: SNMPv1, SNMPv2c, or USM. You can receive an inconsistentValue error if you try to configure this variable to a value for a security model that the implementation does not support.

Name	Description
SecurityName	Identifies the principal on whose behalf SNMP messages are generated.
SecurityLevel	Specifies the security level used to generate SNMP messages: noAuthNoPriv, authNoPriv, or authPriv.

Configure SNMP Notify Filter Profiles

About This Task

Configure the SNMP table of filter profiles to determine whether particular management targets receive particular notifications.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit** > **SnmpV3**.
2. Click **Notify Table**.
3. Click the **Notify Filter Table** tab.
4. Click **Insert**.
5. In the **NotifyFilterProfileName** box, type a name for the notify filter profile.
6. In the **Subtree** box, type subtree location information in x.x.x.x.x.x.x.x.x. format.
7. In the **Mask** box, type the mask location in hex string format.
8. From the **Type** options, select **included** or **excluded**.
9. Click **Insert**.

Notify Filter Table *Field Descriptions*

Use the data in the following table to use the **Notify Filter Table** tab.

Name	Description
NotifyFilterProfileName	Specifies the name of the filter profile used to generate notifications.
Subtree	Specifies the MIB subtree that, if you combine it with the mask, defines a family of subtrees, which are included in or excluded from the filter profile. For more information, see RFC 2573.
Mask	Specifies the bit mask (in hexadecimal format) that, in combination with the subtree, defines a family of subtrees, which are included in or excluded from the filter profile.
Type	Indicates whether the family of filter subtrees are included in or excluded from a filter. The default is included.

Configure SNMP Notify Filter Profile Table Parameters

Before You Begin

- The notify filter profile exists.

About This Task

Configure the profile table to associate a notification filter profile with a particular set of target parameters.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit** > **SnmpV3**.
2. Click **Notify Table**.
3. Click the **Notify Filter Profile Table** tab.
4. Click **Insert**.
5. In the **TargetParamsName** box, type a name for the target parameters.
6. In the **NotifyFilterProfileName** box, type a name for the notify filter profile.
7. Click **Insert**.

Notify Filter Profile Table *Field Descriptions*

Use the data in the following table to use the **Notify Filter Profile Table** tab.

Name	Description
TargetParamsName	Specifies the unique identifier associated with this entry.
NotifyFilterProfileName	Specifies the name of the filter profile to use to generate notifications.

Enable Authentication Traps

About This Task

Enable the SNMP agent process to generate authentication-failure traps.

Procedure

1. In the navigation pane, expand **Configuration** > **Serviceability** > **Diagnostics**.
2. Click **General**.
3. Click the **Error** tab.
4. Select **AuthenticationTraps**.
5. Click **Apply**.

Error *Field Descriptions*

Use the data in the following table to use the **Error** tab.

Name	Description
AuthenticationTraps	Enables or disables the sending of traps after an error occurs. The default is disabled.
LastErrorCode	Specifies the last reported error code.
LastErrorSeverity	Specifies the last reported error severity: 0= Informative Information 1= Warning Condition 2= Error Condition 3= Manufacturing Information 4= Fatal Condition

MACsec

Table 137: MACsec product support

Feature	Product	Release introduced

MACsec Fundamentals

MAC Security (MACsec) is based on the IEEE 802.1ae standard that allows authorized systems in a network to transmit data confidentially and to protect against data transmitted or modified by unauthorized devices.

You can use MACsec for core and enterprise edge switches to do the following:

- Secure site-to-site connectivity between data centers.
- Provide data security on links that run over public ground.
- Provide data security on links that run outside the physically secure boundaries of a site.

You can use MACsec on access switches to secure host-to-switch connectivity, and host-to-switch connectivity in an environment where both trusted and untrusted hosts coexist.

In addition to host level authentication, MACsec capable LANs provide data origin authentication, data confidentiality, and data integrity between authenticated hosts or systems. MACsec protects data from external hacking while the data passes through the public network to reach a receiver host.

MACsec enabled hosts encrypt and decrypt every frame exchanged between them using a MACsec key. The source MACsec host encrypts data frames, and the destination MACsec host decrypts the frames, ensuring delivery of the frame in its original condition to the recipient host. This ensures secure data communication.

Note

Before you enable MACsec on the 5320 Series or 5420 Series you must configure the macsec boot flag.

You can configure MACsec encryption over any type of point-to-point Ethernet or emulated Ethernet connection, which includes:

- Dark fiber
- Conventional wavelength-division multiplexing/dense wavelength-division multiplexing (CWDM/DWDM) service
- Multiprotocol label switching (MPLS) point-to-point (ELINE)
- Provider Backbone Bridge Traffic Engineering (PBB-TE)

You can configure MACsec on physical ports only. However, the physical ports can belong to an MLT trunk group that includes: Split MultiLink Trunking (SMLT), distributed MultiLink Trunking (DMLT), or Link aggregate group (LAG).

You configure a pre-shared key on either end of the MACsec link. The pre-shared key is an interface parameter, not a switch-wide parameter.

MACsec encrypts all packets. If you configure MACsec on one or more MultiLink Trunking (MLT) port members on one side, you must configure MACsec on the same port members on the other side. If you do not do this, the port can physically be enabled, but any overlying protocols can be disabled. You do not have to provision MACsec on all MLT port members, but if you configure MACsec on an MLT port member on one side, you must also provision MACsec on the corresponding MLT port on the other side.

One way to detect a mismatch of MACsec configuration is to use Virtual Link Aggregation Control Protocol (VLACP) on the links. If VLACP is enabled on an MKA-enabled link, it takes approximately 30 seconds for the VLACP session to begin.

MACsec provides security at the data link layer or the physical layer. It provides enhancements at the MAC service sub layer for its operation and services to the upper layer.

MACsec is an interface-level feature and is disabled by default.

Note

On 5320 Series and 5420 Series, Fabric Extend is not available if you boot the switch when the MACsec boot flag is enabled.

MACsec keys

MACsec provides industry-standard security through secure point-to-point Ethernet links. The point-to-point links are secured after matching security keys.

Security keys are of two types:

- Connectivity Association Key (CAK), which is a configured pre-shared key.

  

  Important

  The switch supports the configuration of a pre-shared key to enable MACsec using the static connectivity association key (CAK) security mode.

  The CAK must be identical across both ends of MACsec links.

- Secure Association Key (SAK):
  - Static SAKs: SAKs are static short-lived keys derived from the CAK or pre-configured for a particular secure channel (SC). MACsec uses a timer to refresh these keys so that the key and the session are secure.
  - Dynamic SAKs: MACsec Key Agreement (MKA) protocol generates SAKs. The MKA protocol determines which switch on the point-to-point link becomes the key server. The key server then generates SAKs and distributes them to the switch at the other end of the point-to-point link.

MACsec uses derived keys to encrypt or decrypt data at each end of the MACsec links.

Integrity Check Verification (ICV)

MACsec ensures data integrity using Integrity Check Verification (ICV). MACsec introduces an 8-byte or 16-byte SecTag after the Ethernet header, and an 8-byte or 16-byte calculated ICV after the Encrypted Payload. MACsec computes the ICV for the entire frame, starting from the Ethernet header, SecTag until the Checksum. The receiving side recalculates the ICV after data decryption, and verifies if the received ICV and computed ICV match. If the ICVs do not match, it indicates that data is modified, and MACsec drops the frame.

MACsec Security Modes

The static Connectivity Association Key (CAK) security mode is the only supported MACsec security mode on the platform, and is also the most common mode to enable MACsec.

When you use the static CAK security mode to enable MACsec, you configure a connectivity association on both ends of the link. Secure Association Keys (SAK) establish the MACsec relationship between the switches on each end of the Ethernet link. The SAKs include a connectivity association key name (CKN) and its own CAK. The MACsec CKN and CAK are configured in a connectivity association, and the CAK must match on both ends of the link to initially enable MACsec.

To ensure link security, the system periodically refreshes keys based on traffic volume and link speed.

To enable MACsec at the port level, you must first associate the port to the connectivity association. You complete the configuration within the connectivity association, but outside of the secure channel.

Note

If you use MKA, you must apply MKA profile to a port before you associate it with a Connectivity Association (CA). After you associate the port with a CA, you cannot enable MKA on the port.

When you use the static CAK security mode, the system automatically creates two secure channels, one for inbound traffic and another for outbound traffic. You cannot configure any parameters in the automatically created secure channels.

The CAK security mode ensures security by frequently refreshing to a new random security key, and by only sharing the security key between the two devices on the MACsec-secured point-to-point link.

MACsec provides options to encrypt all data, or configure a confidentiality offset, which specifies the number of unencrypted bytes in a frame that precede MACsec encryption.

You can configure the following optional features:

- Data encryption — If you disable encryption, MACsec forwards traffic in clear text. You can view that data that is not encrypted in the Ethernet frame that travels across the link. Even if you disable encryption the MACsec header applies to the frame and integrity checks make sure that traffic has not been tampered with.
- Confidentiality offset — If encryption is enabled, and an offset is not configured, all traffic in the connectivity is encrypted. The confidentiality offset specifies the bytes after the Ethernet header from which data encryption begins. Valid values are 30 bytes and 50 bytes. The confidentiality offset facilitates traffic flow inspection and classification on intermediate devices by not encrypting the Network Layer header for IPv4 or IPv6. For instance, if you configure the offset to 30, the IPv4 header and the TCP/UDP header are not encrypted. If you configure the offset to 50, the IPv6 header and the TCP/UDP header are not encrypted.

Connectivity Associations and Secure Channels

You configure MACsec in connectivity associations (CA). You can enable MACsec after you associate a connectivity association with an interface. To use the static Connectivity Association Key (CAK) security mode to enable MACsec, you must create, and configure connectivity associations on both ends of the link.

A CA is a logical representation of a MACsec domain within a network. Each connectivity association is associated with a CAK. MACsec links are associated with a CA to establish end-to-end MACsec communication. Every MACsec enabled interface is a member of one CA. Switch ports are members of a CA, and can only be a member of one CA.

A secure channel (SC) is a unidirectional channel that connects two endpoints of MACsec. A secure channel is a long-term relationship that persists through the sequence of secure associations.

A secure association (SA) is a short-lived relationship within an SC. MACsec identifies each SA by AN, and supported secure association key (SAK), which is derived from the CAK or generated by the MKA key server. Both ends of the MACsec link use the SAK to encrypt and decrypt the frames. SAKs are frequently refreshed for security reasons. Periodically changing SAs allows the use of fresh keys without terminating the SC relationship.

For static MACsec, you configure CAs. SCs and SAs are internally created in the hardware.

For MKA MACsec, you configure CAs. SCs and SAs are internally created in the hardware based on the information provided by the MKA key server.

MACsec 2AN and 4AN mode

MACsec 2AN mode implementations use two security associations (SA) for each secure channel (SC) and symmetric keys on both MACsec endpoints. The keys are symmetric because they are both derived from the same connectivity association key (CAK).

MACsec 4AN mode generates four Secure Associations Keys (SAK) per secure channel. It uses enhanced hashing algorithm to derive eight SAKs, and uses asymmetric keys on both ends. You can use the **`macsec connectivity-association`** command to configure different (asymmetric) transmit keys for each endpoint by using the *`key-parity`* keyword. If you do not specify a value for *`key-parity`*, the connectivity association is created in 2AN mode. For more information about configuring MACsec transmit keys, see Configuring a connectivity association.

MACsec components

MACsec has three major components:

- Security entity (SecY)

  SecY is the entity that operates the MACsec protocol within the system. You configure a secure connectivity association (CA) to meet the requirements of MACsec for connectivity between stations that attach to an individual LAN. Unidirectional secure channels (SC) support each CA. Each SC supports secure transmission of frames by use of symmetric key cryptography from one of the systems to all others in the CA.

  Each SecY transmits frames conveying secure MACsec service requests on a single SC, and receives frames conveying secure service indications on separate SCs, one for each of the other SecYs that participate in the secure CA.

  A connectivity association (CA) is a logical representation of a MACsec domain within a network. Each connectivity association is associated with a connectivity association key (CAK). MACsec links are associated with a CA to establish end-to-end MACsec communication. Every MACsec enabled interface is a member of one connectivity association. Switch ports are members of a connectivity association, and can only be a member of one connectivity association.

A secure channel (SC) is a unidirectional channel that connects two endpoints of MACsec. A secure channel is a long-term relationship that persists through the sequence of secure associations. An SC is a unidirectional point-to-multipoint communication, and can persist through Secure Association Key (SAK) changes. A sequence of Secure Associations (SAs) support each SC and allow for the periodic use of fresh keys without terminating the relationship. A single secret key or a set of keys support each SA, where the cryptographic operations used to protect one frame require more than one key. A Secure Channel Identifier (SCI) identifies each SC. An SCI is comprised of a unique 48-bit universally administered MAC address, identifying the system to which the transmitting SecY belongs, concatenated with a 16-bit port number, identifying the SecY within that system.

The SCI concatenated with a two-bit AN identifies each SA. The Secure Association Identifier (SAI) that is created allows the receiving SecY to identify the SA. It also allows the SAK used to decrypt and authenticate the received frame. The AN, and hence the SAI, are unique only for the SAs that can be used or recorded by participating SecYs at any instant.

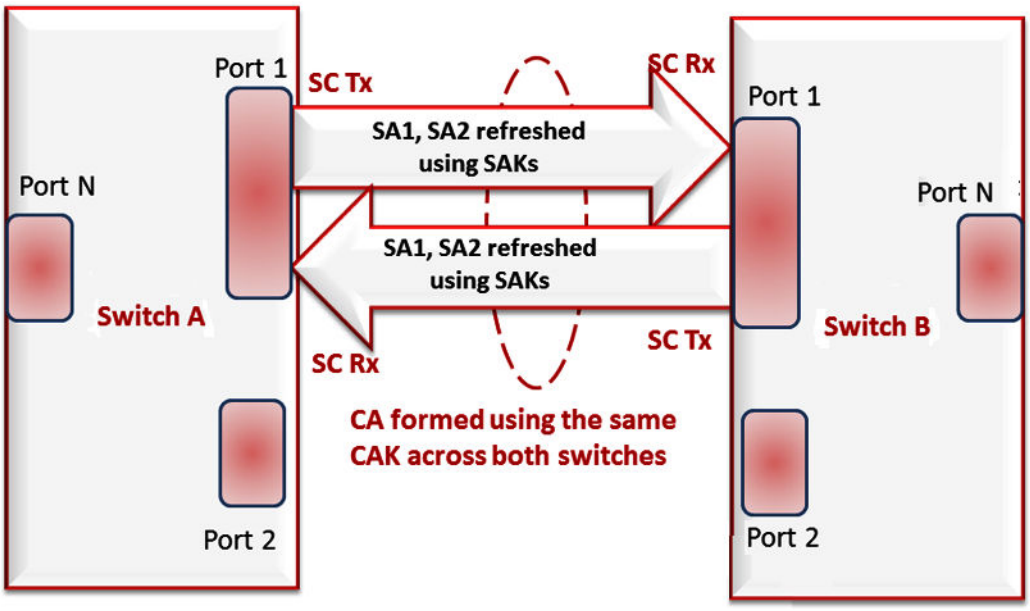

Figure 173: MACsec relationship

- Key agreement entity (KaY)

  The KaY in MACsec is responsible for CAK and SAK computations, distributions and maintenance. CAK is a global key that is persistent until the CA exists. When you configure the CAK, ensure that it is identical across MACsec links.

  In static SAK mode, SAKs are short-lived keys derived from the CAK, or pre-configured for a particular SC. MACsec uses a timer to refresh SAKs so that the key, as well the session, is secure.

  In dynamic SAK mode, the MKA key server generates SAKs. The key server maintains the ethernet link by periodically generating and distributing SAKs across the point-to-point link as long as MACsec is enabled.

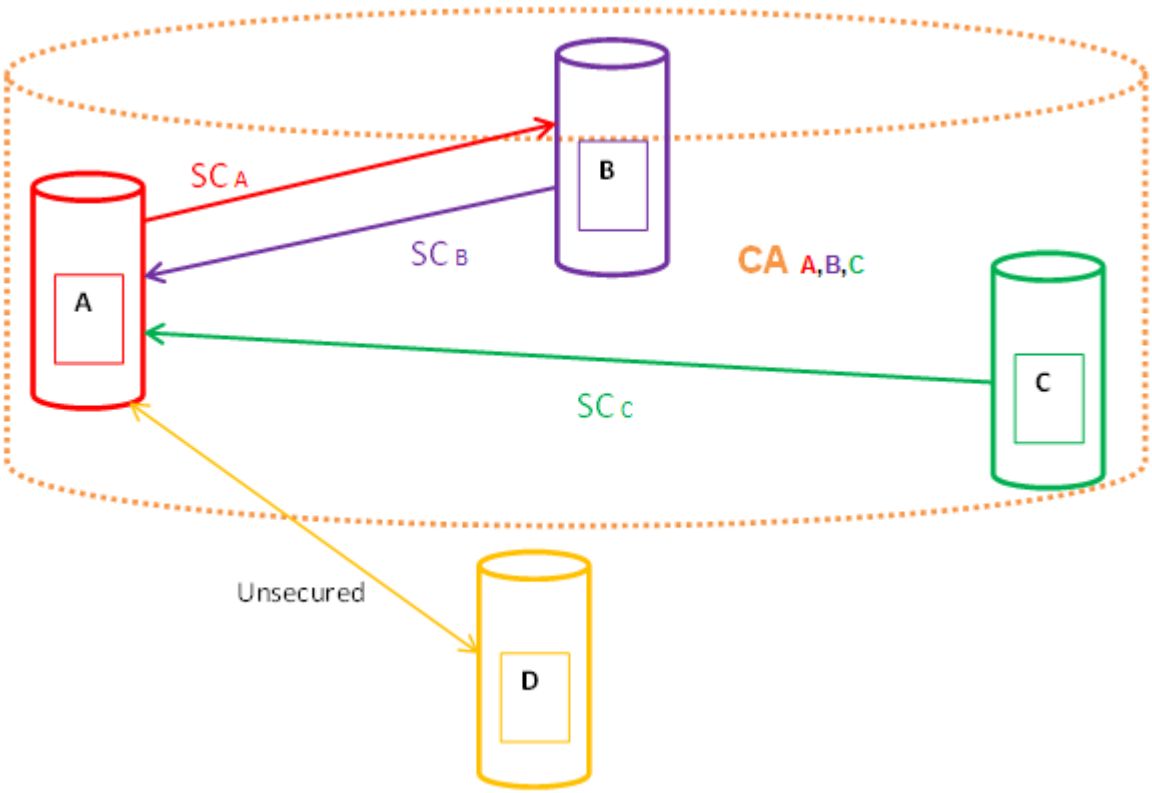
- Integrity check verification or Cryptographic entity

  The Cryptographic entity provides integrity check protection and validation for frames transmitted or received through the SecY layer. The integrity check verification (ICV) is calculated for the frame

source address/destination address (SA/DA), SecTag, User Payload, and Cyclic Redundancy Check (CRC). The calculated ICV is appended at the end-of-frame, recalculated at the receiver side of MACsec link and validated to see if they are equal. The frames that pass the integrity check are further processed, while the system drops the frames that fail the integrity check.

MACsec configuration provides an option to encrypt the user payload. There is also the option to start the encryption from N bytes after the Ethernet header.

In the following figure, CA connects switches A, B, and C by their respective SC and SAK. Switch D cannot participate in the secure communication between A, B, or C as switch D does not know the SAK.



MACsec Key Agreement Protocol

MKA protocol performs key server election and generates Secure Association Keys (SAK) . SAKs and other MKA information is distributed in MACsec Key Agreement Protocol Data Units (MKPDU) between peers in the Connectivity Association (CA).

Initially you configure pre-shared keys on both ends of an Ethernet link, including values for the CAK and the connectivity association key name (CKN). The CAK and CKN values must match at both ends of the link.

You enable the MKA process by configuring pre-shared keys. MKA performs peer detection, identifies a live peer, and elects the peer with the highest priority as the key server.

The key server generates and distributes SAKs. After the key server and the peer successfully install the generated SAKs, the link can securely transmit encrypted data. The key server maintains the secure link by periodically generating and distributing SAKs for as long as MACsec is enabled.

The following figure illustrates the deployment of MACsec using MKA protocol.

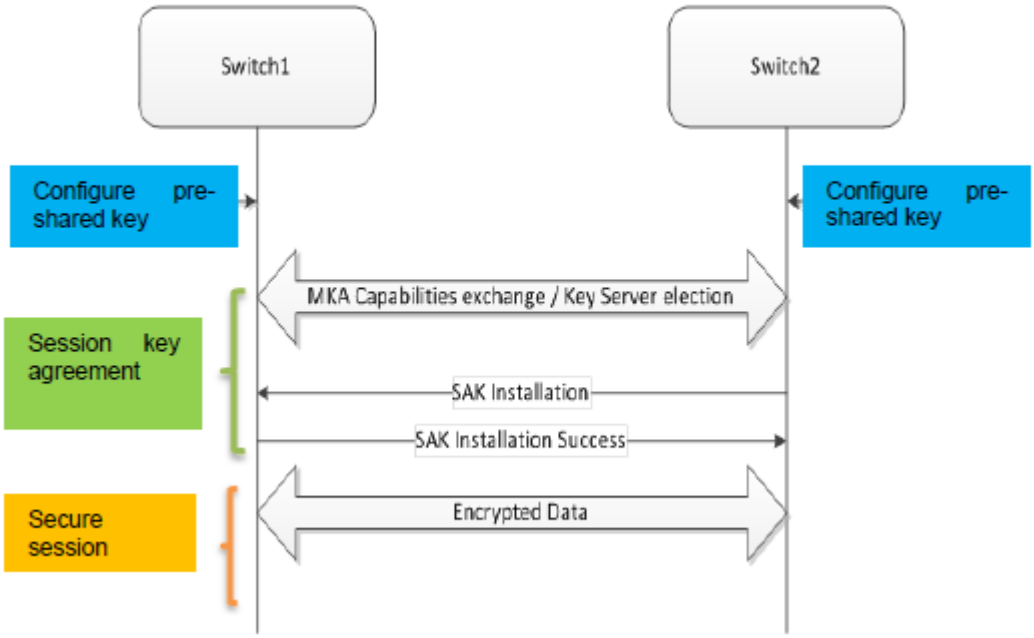


Figure 174: Switch to switch MACsec deployment scenario

You can create and configure an MKA profile and then apply that profile to a port. After applying the profile to the port and associating the port with a connectivity association, you can enable MKA on the port and optionally assign a value for actor priority.

Note

If you enable MKA MACsec on a port, traffic is not sent or received on that link until the MKA session is active.

You can configure an MKA actor priority value for each MKA participant. You select priority values from the range 0x00 to 0xff, where lower numbers indicate higher priority. Each participant advertises an actor priority value, and the participant advertising the highest priority is elected as the key server. If there is a tie for the highest priority, the participant with the highest priority MAC address is seletcted.

Note

Do not configure both peers in an MKA session with an actor priority value of 0xff. If both peers are configured with an actor priority value of 0xff, key server election fails.

You can enable replay protect and configure a replay window size to protect against out-of-sequence packets. Window size specifies the maximum acceptable difference in packet ID numbers between out of order packets. If a packet ID number differs from the ID number of the previously received packet by more than the specified window size, the packet is dropped.

Confidentiality offset specifies the bytes after the Ethernet header from which data encryption begins. Valid values are 30 and 50. Configuring the offset to 30 allows an IPv4 header and TCP/UDP header to

remain unencrypted, while configuring the offset to 50 allows an IPv6 header and TCP/UDP header to remain unencrypted.

MKA Interoperability with EXOS and Switch Engine

Switches configured with MKA MACsec in Fabric Engine 8.6, or later, can interoperate with EXOS 30.3, or later, and Switch Engine 31.6, or later, switches.

Note

Traffic loss occurs on the EXOS or Switch Engine to Fabric Engine MKA MACsec link when interoperating with EXOS and Switch Engine, using the Fabric Engine devices as the keyserver. As a best practice, use EXOS or Switch Engine as the keyserver.

MACsec Encryption Cipher Suites

MACsec cipher suites specify a set of encryption algorithms used to encrypt traffic on an Ethernet link that is secured with Media Access Control Security (MACsec).

MACsec supports two cipher suites, the GCM-AES-128 with a maximum key length of 128 bits and the GCM-AES-256 with a maximum key length of 256 bits. The default cipher suite is the GCM-AES-128. The 256-bit algorithm provides enhanced data security and also includes the security provided by the 128-bit algorithm.

Both the GCM-AES-128 and GCM-AES-256 cipher suites use a 32-bit packet number (PN) as part of the unique initial value for every packet transmitted with a given secure association key (SAK). The system refreshes the SAK when all the permutations of the 32-bit PN are exhausted.

You typically configure a MACsec cipher suite at the port level on the switch. The configuration is optional. When you configure a cipher suite, ensure that you configure the same cipher suite on both MACsec peers.

5320 Series Encryption and Decryption

The 5320 Series models support differing encryption and decryption rates.

Table 138: MACsec encryption and decryption rates

Model	Encryption rate	Decryption rate
48-port models	Up to 50 Gbps	Up to 50 Gbps
24-port models	Up to 25 Gbps	Up to 25 Gbps
16-port models	Up to 25 Gbps	Up to 25 Gbps

MACsec Operation

As shown in the following figure, a host that connects to Switch A sends an Ethernet frame to a host that connects to Switch B. Switch A encrypts the frame, excluding the Ethernet header and optionally the 802.1Q header. Switch A also appends MACsec information like SecTag and ICV to the encrypted payload and transmits the frame using normal frame transmission. This process ensures data confidentiality.

Switch B decrypts the frame. Switch B recalculates the ICV using a MACsec key and the SecTag present in the frame. If the ICV present in the received frame matches the recalculated ICV, the switch processes the frame. If the two ICVs do not match, the switch discards the frame. This process ensures data origin authenticity and data integrity.

The encryption and decryption algorithms follow either the AES-GCM-128 standard or the AES-GCM-256 standard depending on the configured cipher suite. The default is the AES-GCM-128 standard.

The MACsec connectivity association key (CAK) between switches A and B are statically pre-configured.

Important

MACsec will be operational between two switches across Point-to-Point Connectivity only when the switches are either directly connected or across a network cloud that provides P2P connectivity between the two switches.

For example, in the following figure you can enable MACsec between two switches across a network cloud where P2P connectivity between the switches is provided via services such as P2P, MPLS, Layer 2 VPN (ELINE), or connectivity across Dark Fiber. However, it is important to note that MACsec will not be operational between two switches across a network cloud if the intermediate routers/switches need to inspect the VLAN tag or IP header for service classification. This is because MACsec encrypts the entire data frame including the VLAN header and as such the intermediate switches/routers will not have visibility into the same to perform service classification.

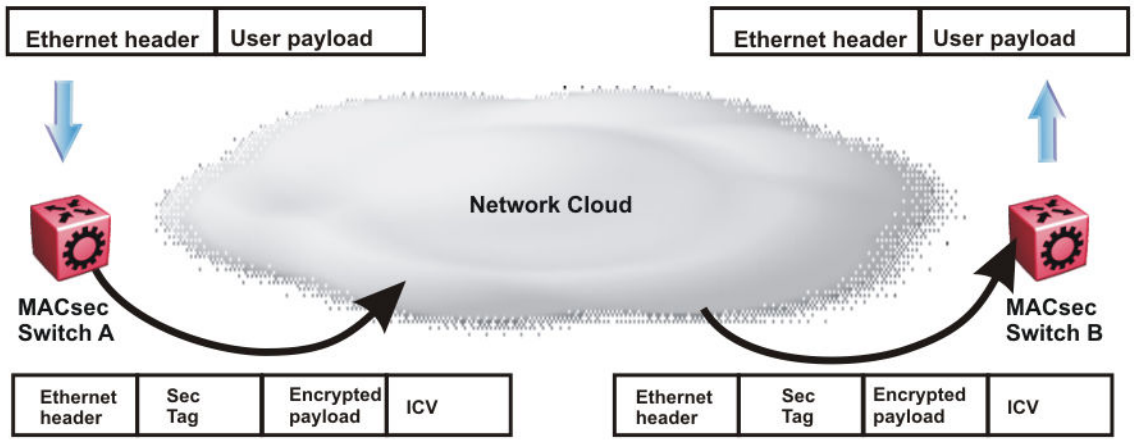

Figure 175: MACsec operation

MACsec Configuration Using CLI

Before You Begin

Product Notice: Before you enable MACsec on the 5320 Series and 5420 Series, you must enable the boot configuration flag: **`boot config flags macsec`**. The **`boot config flags ipv6-egress-filter`** and **`boot config flags macsec`** commands are mutually exclusive.

Configure MACsec Encryption on a Port

Use the following procedure to enable or disable encryption on a MACsec capable port. The default is disabled.

About This Task

If you disable encryption, MACsec forwards traffic in clear text. You can view that data that is not encrypted in the Ethernet frame that travels across the link. Even if you disable encryption the MACsec header applies to the frame and integrity checks make sure that traffic has not been tampered with.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable MACsec encryption on the port:

   ```
   macsec encryption enable
   ```

3. Disable MACsec encryption on the port:

   ```
   no macsec encryption enable
   ```

Example

Configure MACsec encryption on a port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabit 1/2
Switch:1(config-if)#macsec encryption enable
```

Configure a MACsec Cipher Suite on a Port

Note

Configuring a MACsec cipher suite is optional and is not supported on all hardware platforms. For more information on the physical hardware restrictions, see your hardware documentation.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure a MACsec encryption cipher suite:

   ```
   macsec cipher-suite {gcm-aes-128 | gcm-aes-256}
   ```

   The default cipher suite is GCM-AES-128.

   Ensure that you configure the same cipher suite on both MACsec peers.

3. Verify the configuration:

   ```
   show macsec status {slot/port[/sub-port] [-slot/port[/sub-port]]
   [,...]}
   ```

Example

Configure the 256-bit MACsec cipher suite on the port `1/3` and verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/3
Switch:1(config-if)#macsec cipher-suite gcm-aes-256
Switch:1#show macsec status 1/3

================================================================================
                                MACSEC Port Status
================================================================================
      MACSEC Encryption Replay  Replay   Encryption Cipher CA  MKA-Profile MKA
PortId Status Status    Protect Protect                                   Connect

1/3   enabled disabled enabled  50 ipv4Offset(30) AES-256 mkanka extreme   pending
```

The system displays the following error message if you attempt to configure a cipher suite on a port that is not MACsec capable.

```
Switch:1>enable
Switch:1(config)#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/2
Switch:1(config-if)#macsec cipher suite gcm-aes-256

Error: port 1/2, Port is not MACSec capable. No MACSec configurations allowed on port
```

The system displays the following error message if your hardware does not support the MACsec 256-bit cipher suite.

```
Switch:1>enable
Switch:1(config)#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 5/1
Switch:1(config-if)#macsec cipher-suite gcm-aes-256

Error: port 5/1, MACSec cipher-suite cannot be modified on port. Cipher-suite is by
default AES-128
```

Variable Definitions

The following table defines parameters for the **`macsec cipher-suite`** command.

Variable	Definition
{gcm-aes-128 | gcm-aes-256}	Configures the cipher suite for encrypting traffic with MACsec. The supported cipher suites are: • AES-GCM-128, with a maximum key length of 128 bits • AES-GCM--256, with a maximum key length of 256 bits The default is the AES-GCM-128 cipher suite.

Configure a Connectivity Association

Use the following procedure to configure a connectivity association (CA) in static Connectivity Association Key (CAK) security mode with static Secure Association Keys (SAK).

Important

For static MACsec, you can configure a different connectivity association name for local and peer nodes but you must configure the same value for the connectivity association key at both ends of the link with, either even or odd mode.

For MKA MACsec, you must configure the same value for the connectivity association name and the connectivity association key for local and peer nodes. Even or odd mode does not apply to a connectivity association for MKA MACsec .

Procedure

1. Enter Global Configuration mode:

   ```
   enable

   configure terminal
   ```

2. Configure a CA:

   ```
   macsec connectivity association WORD <5-16> connectivity-association-
   key WORD<10-64> [key-parity even|odd]
   ```

   Note

   If you do not specify a key-parity value, the CA is created in 2AN mode.

   This applies only to platforms that support 2AN mode.

3. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

4. Associate a port with a CA:

   ```
   macsec connectivity-association WORD<5-16>
   ```

Example

Configure a connectivity association and enable MACsec on a port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#macsec connectivity-association caname1 connectivity-association-key
1029384756abcdef key-parity even
Switch:1(config)#interface gigabitethernet 1/2
Switch:1(config-if)#macsec connectivity-association caname12
```

Variable Definitions

The following table defines parameters for the **macsec** command.

Variable	Value
connectivity-association WORD<5-16>	Specifies the connectivity-association name as an alpha-numeric ASCII string up to 16 characters long. The device uses this value for the connectivity-association key name (CKN).
connectivity-association-key WORD<10-64>	Specifies the connectivity-association key (CAK) value as a 32-character (128-bit) or a 64 character (256-bit) hexadecimal string. **Note:** Always select the 128-bit CAK value for AES-GSM-128 and the 256-bit CAK value for AES-GSM_256.
key-parity <even | odd> **Note:** This parameter only applies to static MACsec configurations.	Specifies Tx key parity using the following values: • even — generates even-numbered keys for Tx • odd — generates odd-numbered keys for Tx **Note:** If you do not specify a key-parity value, the connectivity association (CA) is created in 2AN mode. This only applies to platforms that support 2AN mode.

The following table defines parameters for the **interface gigabitethernet** command.

Variable	Value
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Specifies the port that you want to associate with the CA. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Update the Connectivity Association for a port

Use the following procedure to change the Connectivity Association (CA) to which a port is associated.

Before You Begin

Ensure that the new CA is created at the global level. For information about configuring a CA, see Configure a Connectivity Association on page 2057.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Disable MACsec on the port:

   ```
   no macsec enable
   ```

3. Change the CA to which the port is associated:

   ```
   macsec connectivity-association WORD<5-16>
   ```

4. Enable MACsec on the port:

   ```
   macsec enable
   ```

Example

Change the CA to which a port is associated:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabit 1/2
Switch:1(config-if)#no macsec enable
Switch:1(config-if)#macsec connectivity-association caname12
Switch:1(config-if)#macsec enable
```

Variable Definitions

The following table defines parameters for the **macsec** command.

Variable	Value
connectivity-association WORD<5-16>	Specifies the connectivity-association name as an alpha-numeric ASCII string up to 16 characters long. The device uses this value for the connectivity-association key name (CKN). Tip: Configure the CKN in multiples of 4 characters to avoid MKA interoperability issues between Fabric Engine switches and EXOS or Switch Engine switches. For example, Macsecma (8 chararcters) or Macsecmka123 (12 characters) are valid, but Macsec (6 characters) is not valid.

The following table defines parameters for the **interface gigabitethernet** command.

Variable	Value
{slot/port[/sub-port][-slot/port[/sub-port]] [,...]}	Specifies the port to associate with the connectivity association (CA). Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

View MACsec Status

Perform this procedure to view MACsec status.

About This Task

This command displays the status for the following:

- MACsec status
- MACsec encryption status
- MACsec encryption cipher suite, if supported on your hardware platform
- The associated Connectivity Association (CA) name

Note

If you do not specify a port number, the information on all MACsec capable interfaces is displayed.

Procedure

1. Enter Privileged EXEC mode:

   ```
   enable
   ```

2. View the MACsec status:

   ```
   show macsec status {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
   ```

3. Display all MACsec related information:
   ```
   show macsec
   ```

Examples

Note

The switch does not support replay protect.

View MACsec status:

```
Switch:1#show macsec status

View the MACsec Connectivity Association Details

Perform this procedure to view the MACsec connectivity association (CA) details.

Procedure

1. Enter Privileged EXEC mode:
   `enable`
2. View the MACsec CA details:
   `show macsec connectivity-association` *`[WORD<5-15>]`*

Note

This command displays the MACsec CA details, including the MD5 hashed value of the CA key.

Example

View the MACsec connectivity association details:

```
Switch:1>show macsec connectivity-association

```

Configure Static MACsec using CLI

Use the following procedures to configure static MACsec using the Command Line Interface (CLI).

Enable Static MACsec on a Port

Use the following procedure to enable MACsec with static Secure Association Keys (SAK) on a port.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable MACsec on the port:

   ```
   macsec enable
   ```

Variable Definitions

The following table defines parameters for the **`macsec enable`** command.

Variable	Value
`{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}`	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configure the Confidentiality Offset on a Port

Use the following procedure to configure the confidentiality offset on a port. The default is disabled.

About This Task

The confidentiality offset provides a way to start encryption after a few bytes following the Ethernet header. The confidentiality offset facilitates traffic flow inspection and classification on intermediate devices by not encrypting the Network Layer header for IPv4 or IPv6. For instance, if you configure the offset to 30, the IPv4 header and the TCP/UDP header are not encrypted. If you configure the offset to 50, the IPv6 header and the TCP/UDP header are not encrypted.

Note

On a MACsec-enabled port with confidentiality offset configured to 50 on the 5320 Series or 5420 Series, all packets less than 67 bytes drop and discarded packets increment.

As a best practice, do not configure the confidentiality offset to 50 on the 5320 Series or 5420 Series.

Note

On a MACsec-enabled port with data encryption enabled and confidentiality offset configured to 30 or 50 on the 5320 Series 5420 Series, InOctetsValidated counter also increments in addition to InOctetsDecrypted counters in Macsec secure channel Inbound statistics.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure confidentiality offset on the port:

   ```
   macsec confidentiality-offset <30–50>
   ```

3. Disable the confidentiality offset on the port:

   ```
   no macsec confidentiality-offset
   ```

Example

Configuring the confidentiality offset on the port:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabit 1/2
Switch:1(config-if)#macsec confidentiality-offset 30
```

Variable Definitions

The following table defines parameters for the **macsec confidentiality-offset** command.

Variable	Value
<30–50>	Specifies the bytes after the Ethernet header from which data encryption begins. Valid values are 30 and 50.

The following table defines parameters for the **interface gigabitethernet** command.

Variable	Value
{slot/port[/sub-port][-slot/port[/sub-port]][,...]}	Specifies the port that you want to associate with the connectivity association (CA). Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configure MKA MACsec using CLI

Use the following proceudres to configure MACsec Key Agreement (MKA) MACsec using the Command Line Interface (CLI).

Create an MKA Profile

About This Task

Use the following procedure to create a MACsec Key Agreement (MKA) profile. Creating an MKA profile changes the CLI command mode to mka profile mode.

You can also use this procedure to enter mka profile CLI command mode for an existing MKA profile.

Procedure

1. Enter Global Configuration mode:
   ```
   enable

   configure terminal
   ```
2. Create an MKA profile:
   ```
   macsec mka profile WORD<1-16>
   ```

   Note
   An MKA profile name consists only of alphanumeric characters (0-9, A-Z, and a-z). The profile name is case sensitive.

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
```

```
Switch:1(config)#macsec mka profile extreme19
Switch:1(mka-profile)#
```

Variable Definitions

The following table defines parameters for the **macsec mka profile** command.

Variable	Value
WORD<1-16>	Specifies the MKA profile name. An MKA profile name consists only of alphanumeric characters (0-9, A-Z, and a-z). The profile name is case sensitive.

Apply an MKA Profile to a Port

Before You Begin

You must configure an MKA profile globally before you can apply it to a port.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note

   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Apply an MKA profile to the port:

   ```
   macsec mka profile WORD<1-16>
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/3
Switch:1(config-if)#macsec mka profile test030519
```

Variable Definitions

The following table defines parameters for the **macsec mka profile** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
WORD<1-16>	Specifies the MKA profile name. An MKA profile name consists only of alphanumeric characters (0-9, A-Z, and a-z). The profile name is case sensitive.

Configure MKA Actor Priority

About This Task

The MKA participant with the highest actor priority is designated as the key server.

Before You Begin

- Apply an MKA profile to the port.
- Disable MKA on the port before you configure a value for actor priority. Enable MKA on the port after you configure an actor priority value.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure a value for actor priority:

   ```
   macsec actor-priority <0x00-0xff>
   ```

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitethernet 1/4
Switch:1(config-if)#macsec actor-priority 0x0f
```

Variable Definitions

The following table defines parameters for the **macsec actor-priority** command.

Variable	Value
<0x00-0xff>	Specifies a hexadecimal value for actor priority, which determines key server selection. Lower values indicate a higher priority. The default is 10.
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Enable MKA on a Port

Before You Begin

- Apply an MKA profile to the port.
- Before you enable MKA on a port, the port must be a member of a connectivity association.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

   ```
   enable

   configure terminal

   interface GigabitEthernet {slot/port[/sub-port][-slot/port[/sub-port]]
   [,...]}
   ```

   Note
   If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable MKA on a port:

   ```
   macsec mka enable
   ```

Example

```
Switch:1#enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/3
Switch:1(config-if)#macsec mka enable
```

Variable Definitions

The following table defines parameters for the **macsec mka enable** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configure MKA Confidentiality Offset

About This Task

Use the following procedure to configure the confidentiality offset for an MKA profile. The confidentiality offset specifies the number of unencrypted bytes that precede MACsec encryption.

Procedure

1. Enter mka profile Configuration mode:

   ```
   enable

   configure terminal

   macsec mka profile WORD<1-16>
   ```

2. Configure a value for confidentiality offset:

   ```
   confidentiality-offset <30-50>
   ```

   Note

   The configuration should be the same at both ends of the link, either enabled or disabled.

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#macsec mka profile test030519
Switch:1(mka-profile)#confidentiality-offset 30
```

Variable Definitions

The following table defines parameters for the **confidentiality-offset** command.

Variable	Value
WORD<1-16>	Specifies the MKA profile name. An MKA profile name consists only of alphanumeric characters (0-9, A-Z, and a-z). The profile name is case sensitive.
<30 | 50>	Specifies the number of bytes after the Ethernet header from which data encryption begins. Possible values are 30 (IPv4 plus TCP/UDP header) and 50 (IPv6 plus TCP/UDP header). The default is no offset.

Configure MKA Replay Protect

About This Task

Use the following procedure to configure replay protect for an MKA profile. Replay protect provides a configurable window that accepts a specified number of out-of-sequence frames.

Procedure

1. Enter mka profile Configuration mode:

   ```
   enable

   configure terminal

   macsec mka profile WORD<1-16>
   ```

2. Enable replay protection and configure the window size:

   ```
   replay-protect enable window-size <5-500>
   ```

   Note

   The configuration should be the same at both ends of the link, either enabled or disabled.

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1(config)#macsec mka profile test030519
Switch:1(mka profile)#replay-protect enable window-size 200
```

Variable Definitions

The following table defines parameters for the **replay-protect** command.

Variable	Value
enable	Enables replay protection on an MKA profile. The default is disabled.
window-size <5-500>	Specifies the maximum acceptable difference in packet ID numbers between out of order packets. If a packet ID number differs from the ID number of the previously received packet by more than the specified window size, the packet is dropped.
WORD<1-16>	Specifies the MKA profile name. An MKA profile name consists only of alphanumeric characters (0-9, A-Z, and a-z). The profile name is case sensitive.

Configure SCI Tagging for a MACsec Enabled Switch

About This Task

Use the following procedure to configure SCI tagging on a MACsec-enabled switch. The default is disabled.

If you are running VOSS 8.4.2 or earlier, disable SCI tagging on the switch.

Procedure

1. Enter mka profile Configuration mode:

   ```
   enable

   configure terminal

   macsec mka profile WORD<1-16>
   ```

2. Enable SCI tagging on the switch:

   ```
   include-sci enable
   ```

   Note
   The configuration should be the same at both ends of the link, either enabled or disabled.

Display MKA Profiles

About This Task

Use the following procedure to display information about all MKA profiles configured on the switch. Optionally, you can view information about a specific MKA profile.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all MKA profiles on the switch:

   ```
   show macsec mka profile
   ```

3. (Optional) Display a specific MKA profile:

   ```
   show macsec mka profile WORD<1-16>
   ```

Example

The following example displays MACsec MKA profile information:

```
Switch:1#show macsec mka profile

================================================================================
                              MACsec MKA Profile
================================================================================
Profile    Profile  Cipher    Confidentiality  Replay   Window  Port  Include-SCI
Name        Id      Suite      Offset          Protect  Size
--------------------------------------------------------------------------------
test030519   1     gcm-aes-128   30            Enabled    200    1/3    false
test031519   2     gcm-aes-128   50            Enabled    225    1/4    false
test032019   3     gcm-aes-128   30            Enabled    240    2/2    false

All 3 out of 3 Total Num of MACsec MKA Profiles displayed
--------------------------------------------------------------------------------
```

The following example displays MACsec MKA information for a specific profile.

```
Switch:1#show macsec mka profile test030519

================================================================================
```

```
                            MACsec MKA Profile
================================================================================
Profile   Profile Cipher   Confidentiality  Replay   Window  Port  Include-SCI
Name       Id     Suite      Offset         Protect   Size
--------------------------------------------------------------------------------
test030519  1     gcm-aes-128  30           Enabled    200   1/3    false
--------------------------------------------------------------------------------
```

Variable Definitions

The following table defines parameters for the **show macsec mka profile** command.

Variable	Value
WORD<1-16>	Specifies the MKA profile name. An MKA profile name can consist only of alphanumeric characters (0-9, A-Z, and a-z). The profile name is case sensitive.

Display MKA Participants

About This Task

Use the following procedure to display information about all participants in an MKA session. You can also display MKA information for a specific port participating in an MKA session.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about all participants in an MKA session:
   `show macsec mka participant`
3. (Optional) Display MKA information for a specific port participating in an MKA session:
   `show macsec mka participant` *`{slot/port[/sub-port][-slot/port[/sub-port]][,...]}`* `[verbose]`

Examples

The following example displays information for all participants in an MKA session.

```
Switch:1(config)#show macsec mka participant

================================================================================================
                            MACsec MKA Participants
================================================================================================
Port     CA              MKA-Profile       MKA          Actor
Id       Name               Name           Enable       Priority
------------------------------------------------------------------------------------------------
1/3      CA120022        extreme030519     Enabled         A
1/4      CA121023        extreme031519     Enabled         14
2/2      CA122024        extreme032019     Enabled         1E
------------------------------------------------------------------------------------------------
```

The following example displays information for a specific port participating in an MKA session.

```
Switch:1(config)#show macsec mka participant 1/3

================================================================================================
                             MACsec MKA Participant
================================================================================================
Port     CA              MKA-Profile       MKA          Actor
```

```
Id       Name               Name           Enable       Priority
-------------------------------------------------------------------------------
1/3      CA120022        extreme030519     Enabled         A
-------------------------------------------------------------------------------
```

Variable Definitions

The following table defines parameters for the **show macsec mka participant** command.

Table 139:

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
verbose	Displays detailed information for a specific port participating in an MKA session.

MACsec Configuration using EDM

Use the following procedures to configure MACsec in EDM.

Before You Begin

Product Notice: Before you enable MACsec on the 5320 Series and 5420 Series, you must enable the boot configuration flag: **Configuration** > **Edit** > **Chassis** > **Boot Config**. **EnableIpv6EgressFilterMode** and **EnableMacsec** are mutually exclusive.

Configure Connectivity Associations

Use the following procedure to configure connectivity associations (CA) using EDM.

Note

- You can configure MACsec on physical ports *only*. However, the physical ports can belong to an MLT trunk group that includes: Split MultiLink Trunking (SMLT), distributed MultiLink Trunking (DMLT), or Link aggregate group (LAG).
- MACsec encryption and decryption algorithms follow either the AES-GCM-128 or the AES-GCM-256 standard, depending on the configured MAC-sec cipher suite. The default is the AES-GCM-128 standard.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Chassis**.
3. Select the **MACSec** tab.

4. Select **Insert**.
   a. In **AssociationName**, type the connectivity-association name.
   b. In **AssociationKey**, type the value of the connectivity-association key.

      Note
      The system displays the connectivity-association key as an MD5-hashed text in the MAC security table.

   c. In **AssociationTxKeyParity**, select an option for Tx key parity.

      Note
      Tx key parity configuration applies only to static MACsec configurations.

   d. Select **Insert** to save the configuration.
5. Select **Apply**.

MACSec *Field Descriptions*

Use the data in the following table to use the **MACSec** tab.

Name	Description
AssociationName	Specifies the connectivity-association name as an alpha-numeric ASCII string up to 16 characters long. The device uses this value for the connectivity-association key name (CKN). Tip: Configure the CKN in multiples of 4 characters to avoid MKA interoperability issues between Fabric Engine switches and EXOS or Switch Engine switches. For example, Macsecma (8 chararcters) or Macsecmka123 (12 characters) are valid, but Macsec (6 characters) is not valid.
AssociationKey	Specifies the connectivity-association key (CAK) value as a 32-character (128-bit) or a 64 character (256-bit) hexadecimal string. Note: Always select the 128-bit CAK value for AES-GSM-128 and the 256-bit CAK value for AES-GSM_256.

Name	Description
AssociationPortMembers	Specifies the set of ports for which this connectivity association is associated.
AssociationTxKeyParity	Specifies Tx key parity using the following values: • **None** — key parity is not specified Note: The none value only applies to platforms that support 2AN mode. If you do not specify a key parity value, the system defaults to 2AN mode. • **Even** — generates even-numbered keys • **Odd** — generates odd-numbered keys

Associate a Port with a Connectivity Association

Use the following procedure to associate a port with a connectivity association (CA) using EDM. You can optionally configure a MACsec encryption cipher suite on the port.

Note

You can configure MACsec on physical ports *only*. However, the physical ports can belong to an MLT trunk group that includes: Split MultiLink Trunking (SMLT), distributed MultiLink Trunking (DMLT), or Link aggregate group (LAG).

Note

MACsec encryption and decryption algorithms follow either the AES-GCM-128 or the AES-GCM-256 standard, depending on the configured MAC-sec cipher suite. The default is the AES-GCM-128 standard.

Procedure

1. On the **Device Physical View** tab, click on one or more ports that you want to associate with the connectivity association.
2. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
3. Select **General**.
4. Select the **MACsec** tab.
5. In **CAName**, type the connectivity-association name.
6. In **OffsetValue**, select the value of confidentiality offset to be achieved.
7. Select **EncryptionEnable** to enable encryption for the frames transmitted on the port.
8. Select **MACsec Enable** to enable MACsec on the port.
9. (Optional) In **CipherSuite**, select the MACsec encryption cipher suite.
10. Select **Apply**.

MACsec *Field Descriptions*

Use the data in the following table to configure the **MACsec** tab.

Name	Description
CAName	Specifies the name of the connectivity association attached to the port or interface.
OffsetValue	Offsets MACsec encryption in an IPv4 TCP/UDP header or IPv6 TCP/UDP header. The confidentiality offset provides a way to start encryption after a few bytes following the Ethernet header. The confidentiality offset facilitates traffic flow inspection and classification on intermediate devices by not encrypting the Network Layer header for IPv4 or IPv6. For instance, if you configure the offset to 30, the IPv4 header and the TCP/UDP header are not encrypted. If you configure the offset to 50, the IPv6 header and the TCP/UDP header is not encrypted. Note: On a MACsec-enabled port with confidentiality offset configured to 50 on the 5320 Series or 5420 Series, all packets less than 67 bytes drop and discarded packets increment. As a best practice, do not configure the confidentiality offset to 50 on the 5320 Series or 5420 Series. Note: On a MACsec-enabled port with data encryption enabled and confidentiality offset configured to 30 or 50 on the 5320 Series 5420 Series, InOctetsValidated counter also increments in addition to InOctetsDecrypted counters in Macsec secure channel Inbound statistics.
EncryptionEnable	Specifies the encryption status per port. Use this field to enable or disable encryption for each MACsec capable port.
MACsec Enable	Enables or disables MACsec on the port.
CipherSuite	Configures the cipher suite for encrypting traffic with MACsec. The following cipher suites are supported: • AES-GCM-128 standard, with a maximum key length of 128 bits • AES-GCM-256 standard, with a maximum key length of 256 bits The default is the AES-GCM-128 standard.

Configure MKA MACsec using EDM

Use the following procedures to configure MKA MACsec using EDM.

Note
You must configure MKA MACsec by performing procedures in the following order:

1. Apply an MKA Profile to a Port on page 2078
2. Associate a Port with a Connectivity Association on page 2075
3. Enable MKA on a Port on page 2078

If you apply a Connectivity Association to a port before you apply an MKA profile to the port, the port is considered to be configured with static MACsec and an error occurs.

Configure an MKA Profile

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Chassis**.
3. Select the **MACSec MKA Profile** tab.
4. Select **Insert**.
5. For **Id**, type an MKA ID value.
6. For **Name**, type the profile name.
7. (Optional) Select **ReplayProtectEnable** to enable replay protect.
8. (Optional) For **ReplayProtectWindow**, type a value for the replay protect window size.
9. (Optional) From the **OffsetValue** options, select a level for confidentiality offset.
10. Select **IncludeSCIEnable** to enable the SCI field in MACsec frames.
11. Select **Insert**.

MACSec MKA Profile Field Descriptions

Use the data in the following table to use the **MACSec MKA Profile** tab.

Name	Description
Id	Specifies a unique identification number for an MKA profile.
Name	Specifies the profile name.
ReplayProtectEnable	Specifies whether replay protect is enabled. The default is disabled.
ReplayProtectWindow	Specifies the maximum acceptable difference in packet ID numbers between out of order packets. If a packet ID number differs from the ID number of the previously received packet by more than the specified window size, it is dropped.
OffsetValue	Specifies the number of bytes after the Ethernet header from which data encryption begins. The default is no offset.

Name	Description
PortMembers	Specifies the ports that are members of an MKA profile.
IncludeSCIEnable Note: Exception: only supported on 5520 Series.	Specifies whether SCI tagging is enabled for a MACsec-enabled switch. The default is disabled.

Apply an MKA Profile to a Port

Before You Begin

You must configure an MKA profile globally before you can apply it to a port.

About This Task

Use the following procedure to apply a MACsec Key Agreement (MKA) profile on a port.

Procedure

1. In the Device Physical View, select the port to which you want to apply an MKA profile.
2. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
3. Select **General**.
4. Select the **MACsec MKA** tab.
5. For **MACsecMKAProfileName**, select the name of the MKA profile you want to apply.
6. Select **Apply**.

MACsec MKA Field Descriptions

Use the data in the following table to use the **MACsec MKA** tab.

Name	Description
MACsecMKAProfileName	Specifies the MKA profile name.
MKA Enable	Enables the MKA profile on the port. The default is disabled.

Enable MKA on a Port

Before You Begin

Ensure that you apply an MKA profile to the port and associate the port with a Connectivity Association (CA) before you enable MKA on the port.

About This Task

Use the following procedure to enable a MACsec Key Agreement (MKA) profile on a port.

Procedure

1. In the Device Physical View, select the port to which you want to apply an MKA profile.
2. In the navigation pane, expand **Configuration** > **Edit** > **Port**.
3. Select **General**.

4. Select the **MACsec MKA** tab.
5. For **MACsecMKAProfileName**, select the name of the MKA profile you want to apply.
6. Select **MKA Enable** to enable MKA on the port.
7. Select **Apply**.

MACsec MKA Field Descriptions

Use the data in the following table to use the **MACsec MKA** tab.

Name	Description
MACsecMKAProfileName	Specifies the MKA profile name.
MKA Enable	Enables the MKA profile on the port. The default is disabled.

Configure MKA Actor Priority

About This Task

Use the following procedure to configure an actor priority value for a port. The MKA participant with the highest actor priority is designated as the key server.

Note
Ensure that peers in an MKA connection are not configured with the same actor priority value.

Procedure

1. In the navigation pane, expand **Configuration** > **Edit**.
2. Select **Chassis**.
3. Select the **MACSec MKA Participants** tab.
4. Select a port.
5. For **ActorsPriority**, double-click the field and type a value for **ActorsPriority**.

MACSec MKA Participants Field Descriptions

Name	Description
PortNumber	Specifies the port number of the MKA session participant.
CAName	Specifies the Connectivity Association (CA) name associated with the MKA session participant.
MKAProfileName	Specifies the name of the MKA profile.
MKA Enable	Specifies whether MKA is enabled for the port.
ActorsPriority	Specifies a hexidecimal value for actor priority. The default is 10.

MACsec Performance

Table 140: MACsec product support

Feature	Product	Release introduced
MACsec 2AN mode (static)	5320 Series	Not Supported
	5420 Series	Not Supported
	5520 Series	Not Supported
	5720 Series	Not Supported
MACsec 4AN mode (static)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.5
	5520 Series	VOSS 8.2.5 • 5520-24T and 5520-24W - all fixed ports except 1/25 and 1/26 • 5520-12MW-36W, 5520-48SE, 5520-48T, and 5520-48W - all fixed ports except 1/49 and 1/50 • VIMs: 5520-VIM-4XE and 5520-VIM-4YE only
	5720 Series	Fabric Engine 8.7 • 5720-24MW and 5720-24MXW - all fixed ports except 1/25 and 1/26 • 5720-48MW and 5720-48MXW - all fixed ports except 1/49 and 1/50 • VIMs: 5720-VIM-2CE and 5720-VIM-6YE

Table 140: MACsec product support (continued)

Feature	Product	Release introduced
MACsec encryption cipher suites	5320 Series	Fabric Engine 8.6 Both 128 bits and 256 bits
	5420 Series	VOSS 8.5 Both 128 bits and 256 bits
	5520 Series	VOSS 8.2.5 • 5520-24T and 5520-24W - all fixed ports except 1/25 and 1/26 • 5520-12MW-36W, 5520-48SE, 5520-48T, and 5520-48W - all fixed ports except 1/49 and 1/50 • VIMs: 5520-VIM-4XE and 5520-VIM-4YE only
	5720 Series	Fabric Engine 8.7 • 5720-24MW and 5720-24MXW - all fixed ports except 1/25 and 1/26 • 5720-48MW and 5720-48MXW - all fixed ports except 1/49 and 1/50 • VIMs: 5720-VIM-2CE and 5720-VIM-6YE
MACsec Key Agreement (MKA)	5320 Series	Not Supported
	5420 Series	Not Supported
	5520 Series	VOSS 8.5 • 5520-24T and 5520-24W • 5520-12MW-36W, 5520-48SE, 5520-48T, and 5520-48W • VIMs: 5520-VIM-4XE and 5520-VIM-4YE only
	5720 Series	Fabric Engine 8.7 • 5720-24MW and 5720-24MXW - all fixed ports except 1/25 and 1/26 • 5720-48MW and 5720-48MXW - all fixed ports except 1/49 and 1/50 • VIMs: 5720-VIM-2CE and 5720-VIM-6YE
