Perform the following procedure to ensure ports do not accept superior BPDUs or claims from other non-root bridges trying to become the root bridge.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...][slot/all][all]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure MSTP Restricted Role (Root Guard):

```
spanning-tree mstp restricted-role enable
```

NEW! Configure Restricted Topology Change Notification

About This Task

Perform the following procedure to stop a switch port from propagating Topology Change Notifications (TCN) to other ports.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...] [slot/all] [all]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Restricted TCN:

```
spanning-tree mstp restricted-tcn enable
```

Configure MSTP MSTI Options

Use the following procedure to configure MSTP multiple spanning tree instance (MSTI) options.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure MSTP MSTI:

```
spanning-tree mstp msti <1-63> priority <0-65535>
```

Example

Configure MSTP MSTI:

```
Switch:1(config)#spanning-tree mstp msti 62 priority 4096
```

Variable Definitions

Use the data in the following table to use the **spanning-tree mstp msti <1-63> priority <0-65535>** command.

Variable	Value
<1-63>	Specifies the instance ID.
<0-65535>	Specifies the priority value. Enter values in increments of 4096: <ul style="list-style-type: none"> • 4096 • 8192 • 12288 • 16384 • 20480 • 24576 • 28672 • 32768 • 36864 • 40960 • 45056 • 49152 • 53248 • 57344 • 61440

Configure Ethernet MSTP

Configure Ethernet MSTP on a port to enable this feature.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...][slot/all][all]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Ethernet MSTP:

```
spanning-tree mstp [cost <1-2000000000>] [edge-port <false|true>]
[force-port-state enable] [hello-time <100-1000>] [msti <1-63>] [p2p
{auto|force-false|force-true}] [port {slot/port[/sub-port]}] [priority
<0-240>] [protocol-migration <false|true>]
```

3. (Optional) Enable RSTP migration:

```
spanning-tree mstp allow-rstp-migration enable
```

Example

Configure Ethernet MSTP:

```
Switch:1(config)#spanning-tree mstp cost 1 edge-port true force-port-state enable hello-time 100 p2p auto priority 2 protocol-migration true allow-rstp-migration enable
```

Variable Definitions

Use the data in the following table to use the **spanning-tree mstp** command.

Variable	Value
<i>allow-rstp-migration enable</i>	Enables a switch in MSTP mode to operate in RSTP mode and send RSTP BPDUs on a specific port. The default is disabled.
<i>cost <1-200000000></i>	Configures the path cost for a port. Valid values are 1 to 200000000
<i>edge-port <false true></i>	Enables or disables the port as an edge port.
<i>force-port-state enable</i>	Enables STP.
<i>hello-time <100-1000></i>	Configures the hello-time for a port.
<i>msti <1-63></i>	Configures the port MSTP MSTI.
<i>p2p {auto force-false force-true}</i>	Enables or disables point-to-point for a port.
<i>{slot/port[/sub-port]}</i>	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Variable	Value
<code>priority <0-240></code>	Configures priority for the port.
<code>protocol-migration {false true}</code>	<p>If you chose true, the option initiates protocol migration for a port. If you chose false, the option terminates protocol migration for a port.</p> <p>An MSTP-compatible port transmits and receives only RSTP BPDUs. If an MSTP port receives an STP BPDU, it becomes an STP port. User intervention is required to change this port back to MSTP mode. This process is called Port Protocol Migration.</p> <p>You must configure protocol migration to true on all spanning-tree enabled interfaces when you change the spanning tree version from STP-compatible to MSTP for those interfaces to work in the proper mode.</p>

Configure Ethernet MSTP MSTI

Use the following procedure to configure the Ethernet MSTP MSTI parameters on a port.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...][slot/all][all]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Ethernet MSTP MSTI:

```
spanning-tree mstp msti <1-63> [cost <1-2000000000>] [force-port-state  
enable] [port {slot/port[-slot/port] [,...][slot/all][all]}] [priority  
<0-240>]
```

Example

Configure Ethernet MSTP MSTI:

```
Switch(config-if)#spanning-tree mstp msti 62 priority 32
```

Variable Definitions

Use the data in the following table to use the **spanning-tree mstp msti <1-63>** command.

Variable	Value
<1-63>	Specifies the instance ID.
<i>cost</i> <1-2000000000>	Configures the path cost for the port
<i>force-port-state enable</i>	Enables MSTI learning for the port.
<i>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...] [slot/all] [all]}</i>	<p>Identifies the slot and port in one of the following formats:</p> <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>
<i>priority</i> <0-240>	Configures the priority for the port. Enter the priority value (0-240) as increments of 16.

Configure MSTP Restricted Role

About This Task

Perform the following procedure to ensure ports do not accept superior BPDUs or claims from other non-root bridges trying to become the root bridge.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[, ...] [slot/all] [all]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure MSTP Restricted Role (Root Guard):

```
spanning-tree mstp restricted-role enable
```

Display MSTP Configurations

Perform the following procedure to display the MSTP-related bridge-level VLAN and region information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the MSTP configurations:

```
show spanning-tree mstp config
```

Example

Display the MSTP configurations:

```
Switch:1>show spanning-tree mstp config
```

```
=====

=====
```

Display MSTP Status

Perform the following procedure to display the MSTP-related status information known by the selected bridge.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the MSTP status:

```
show spanning-tree mstp status
```

Example

Display the MSTP status:

```
Switch:1>show spanning-tree mstp status
```

```
=====
                        MSTP Status

Display MSTP Port Information

Perform the following procedure to display the MSTP, CIST port, and MSTI port information maintained by every port of the common spanning tree.

Procedure

- 1. To enter User EXEC mode, log on to the switch.
- 2. Display the MSTP port information:
`show spanning-tree mstp port role [{slot/port[-slot/port]][,...][slot/all][all]}`

Note
If your platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Example

Display the MSTP port information:

```
Switch:1>show spanning-tree mstp port role 1/3
```

CIST Port Roles and States				
Port-Index	Port-Role	Port-State	PortSTPStatus	PortOperStatus
1/3	Disabled	Discarding	Enabled	Disabled

NEW Display MSTP Port Configuration Information

About This Task

Perform the following procedure to display MSTP port confirmation information in your network.

Procedure

- 1. Enter GigabitEthernet Interface Configuration mode:
`interface GigabitEthernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]}`

Note
If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- 2. Display MSTP port configuration information in your network:
`show spanning-tree mstp port config {slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]}`

Example

Display MSTP port configuration information:

```
Switch:1>#show spanning-tree mstp port config 1/7
=====
MSTP Cist Port Information
(Port Priority Vector)
=====
Port Number           : 1/7
Cist Port Priority     : 128 (0x80)

Cist Port Oper P2P Status : False

Cist Port Hello Time : 2
Cist Port Oper Proto-Version : Mstp
Cist Port Rstp Migration : Disabled
Cist Port Restricted Role : Disabled
Cist Port Restricted TCN : Disabled
```

Display MSTP MSTI Information

Display MSTP MSTI information to ensure the feature is configured correctly for your network.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display MSTI information:

```
show spanning-tree mstp msti [config <1-63>] [port config {slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]} | role {slot/port[-slot/port][,...][slot/all][all]} | statistics {slot/port[-slot/port][,...][slot/all][all]}
```

Note

If your platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Example

Display MSTI information:

```
Switch:1>#show spanning-tree mstp msti config 62
=====
MSTP Instance Status
=====
```

```

Instance Id                : 62

Msti Port Transmitted BPDUs : 0
Msti Port Invalid BPDUs Rcvd : 0

```

Variable Definitions

Use the data in the following table to use the **show spanning-tree mstp msti** command.

Variable	Value
<i>config</i> [<i><1-63></i>]	Shows the configuration for one or all MSTP instance IDs.
<i>port</i>	Shows the configuration, role, or statistics information of a MSTP port. <ul style="list-style-type: none"> <code>config {slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]</code> <code>role {slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]</code> <code>statistics {slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]</code>

Display MSTP Statistics

Display MSTP MSTI information to ensure the feature is configured correctly for your network.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display MSTP statistics:

```
show spanning-tree mstp statistics
```

Example

Display MSTP statistics:

```
Switch:1>show spanning-tree mstp statistics
```

```

New Root Bridge Count   : 1
```

Configure tc-receive-alarm-threshold

About This Task

You can establish a threshold rate for receiving TC/TCN packets by configuring values for count and interval. If the threshold rate is exceeded, you receive a warning message.

Use the following procedure to configure values for **tc-receive-alarm-threshold count** and **tc-receive-alarm-threshold interval**.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure a value for count:

```
spanning-tree tc-receive-alarm-threshold count <1-1000>
```
3. Configure a value for interval:

```
spanning-tree tc-receive-alarm-threshold interval <1-15>
```

Example

Configure count and interval values:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#spanning-tree tc-receive-alarm-threshold count 3
Switch:1(config)#spanning-tree tc-receive-alarm-threshold interval 2
```

Display the alarm threshold configuration:

```
Switch:1#show spanning-tree tc-receive-alarm-threshold
```

```
=====
                        Spanning Tree TC/TCN Rx Alarm Threshold Configuration
=====
Interval           : 2 minutes
Count              : 3
```

Variable definitions

Use the data in the following table to use the **tc-receive-alarm-threshold** command.

Variable	Value
count <1-1000>	Specifies the number of packets used to establish the threshold rate. The default is 2.
interval <1-15>	Specifies the time interval (in minutes) used to establish the threshold rate. The default is 1.

Display the tc-receive-alarm-threshold Configuration

About This Task

You can configure a threshold rate for receiving TC/TCN packets. If the threshold is exceeded, you receive a warning message.

Use the following procedure to display the tc-receive-alarm-threshold configuration.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the tc-receive-alarm-threshold configuration:
`show spanning-tree tc-receive-alarm-threshold`

Example

```
Switch:1(config)#show spanning-tree tc-receive-alarm-threshold
```

```
=====
Spanning Tree TC/TCN Rx Alarm Threshold Configuration
=====
Interval          : 1 minutes
Count             : 2
```

Spanning Tree Configuration Using EDM

This section describes how to create, manage, and monitor spanning tree groups (STG). It also describes how to configure the Rapid Spanning Tree Protocol (RSTP) and the Multiple Spanning Tree Protocol (MSTP) using Enterprise Device Manager (EDM).

Important

The switch supports up to 64 STGs in a device, however, SPBM uses STG 63 and MSTI 62 for internal use. STG 63 or MSTI 62 cannot be used by other VLANs or MSTIs.

Configure the Spanning Tree Mode

About This Task

Configure the Spanning Tree mode to change the mode to MSTP or RSTP mode.

Important

After you change the mode, save the configuration, and then restart the system for the changes to take effect.

Procedure

1. In the navigation pane, expand **Configuration > VLAN > Spanning Tree**.
2. Select **Globals**.
3. Select the required spanning tree mode.
4. Select **Apply**.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
SpanningTreeAdminMode	Configures the spanning tree mode as either RSTP or MSTP. The default is MSTP.
SpanningTreeOperMode	Specifies the current mode of the spanning tree.

Configure BPDU Guard

About This Task

Configure BPDU Guard to block the root selection process or to prevent BPDU flooding from unknown devices.

To configure multiple ports simultaneously, select more than one port in the Device Physical View tab. The system displays the **BPDU Guard** tab as a table-based tab.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **Interface** tab.
5. Select **BpduGuardAdminEnabled** to enable BPDU Guard for the port.
6. (Optional) Type a value in **BpduGuardTimeout** to configure the timer for port-state recovery.
7. Select **Apply**.

Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
Index	Displays the index of the port, written in the slot/port[/sub-port] format.
Name	Configures the name of the port.
Descr	Displays the description of the port. A textual string containing information about the interface.
Type	Displays the type of connector plugged in the port.
Mtu	Displays the Maximum Transmission Unit (MTU) for the port. The size of the largest datagram which can be sent or received on the interface, specified in octets. For interfaces that are used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface.
PhysAddress	Displays the physical address of the port. The address of the interface at the protocol layer immediately below the network layer in the protocol stack. For interfaces which do not have such an address, for example, a serial line, this object should contain an octet string of zero length.
VendorDescr	Displays the vendor of the connector plugged in the port.
DisplayFormat	Identifies the slot and port numbers (slot/port). If the port is channelized, the format also includes the sub-port in the format slot/port/sub-port
AdminStatus	Configures the port as enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.
OperStatus	Displays the current status of the port. The status includes enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.
ShutdownReason	Indicates the reason for a port state change.
LastChange	Displays the timestamp of the last change.
LinkTrap	Enable or disable link trapping.

Name	Description
AutoNegotiate	Enables or disables Auto-Negotiation for this port. The default Auto-Negotiation behavior depends on the switch model and transceiver type.
AutoNegAd	Specifies the port speed and duplex abilities to advertise during link negotiation. Supported speeds and duplex modes vary, depending on your hardware. The abilities specified in this object are only used when auto-negotiation is enabled on the port. If all bits in this object are disabled, and auto-negotiation is enabled on the port, then the physical link process on the port is disabled (if hardware supports this ability). Any change to this configuration restarts the auto-negotiation process, which has the same effect as physically unplugging and reattaching the cable attached to the port. If you select default , all capabilities supported by the hardware are advertised.
AdminDuplex	Configures the administrative duplex setting for the port.
OperDuplex	Indicates the operational duplex setting for the port.
AdminSpeed	Configures the administrative speed for the port.
OperSpeed	Indicates the operational speed for the port.
QoSLevel	Selects the Quality of Service (QoS) level for this port. The default is level1.
DiffServ	Enables the Differentiated Service feature for this port. The default is disabled.
Layer3Trust	Configures if the system should trust Layer 3 packets coming from access links or core links only. The default is core.
Layer2Override8021p	Specifies whether Layer 2 802.1p override is enabled (selected) or disabled (cleared) on the port. The default is disabled (clear).
MltId	Shows the MLT ID associated with this port. The default is 0.
Locked	Shows if the port is locked. The default is unlocked.

Name	Description
UnknownMacDiscard	Discards packets that have an unknown source MAC address, and prevents other ports from sending packets with that same MAC address as the destination MAC address. The default is disabled.
DirectBroadcastEnable	<p>Specifies that an Isolated Routing Port (IRP) can forward directed broadcast traffic. A directed broadcast is a frame sent to the subnet broadcast address on a remote IP subnet. By disabling or suppressing directed broadcast on an interface, all frames sent to the subnet broadcast address for a local router interface are dropped. Disabling this function protects a host from possible denial of service (DoS) attacks.</p> <p>With the feature enabled, the Control Processor (CP) does not receive a copy of the directed broadcast. As a result, the system does not respond to a subnet broadcast ping sent from a remote subnet.</p> <p>The default is disabled.</p>
OperRouting	Shows the routing status of the port.
HighSecureEnable	Enables or disables the high secure feature for this port.
RmonEnable	Enables or disables Remote Monitoring (RMON) on the interface. The default is disabled.
FlexUniEnable	Enables Flex UNI on the port. The default is disabled.
EgressRateLimitState	Enables or disables egress port-based shaping to bind the maximum rate at which traffic leaves the port. The default is disabled.
EgressRateLimit	<p>Specifies the egress rate limit in Kbps. You cannot configure the egress shaper rate to exceed the port capability.</p> <p>If you configure this value to 0, shaping is disabled on the port.</p>
TxFlowControl	<p>Configures if the port sends pause frames. By default, an interface does not send pause frames.</p> <p>You must also enable the flow control feature globally before an interface can send pause frames.</p>
TxFlowControlOperState	Shows the operational state of flow control.

Name	Description
BpduGuardTimerCount	Shows the time, starting at 0, since the port became disabled. When the BpduGuardTimerCount reaches the BpduGuardTimeout value, the port is enabled. Displays in 1/100 seconds.
BpduGuardTimeout	Specifies the value to use for port-state recovery. After a BPDU guard disables a port, the port remains in the disabled state until this timer expires. The default is 120 seconds. If you configure the value to 0, the expiry is infinity.
BpduGuardAdminEnabled	Enables BPDU Guard on the port. The default is disabled.
ForwardErrorCorrection	Configures one of the following options for Forward Error Correction (FEC) on the port: <ul style="list-style-type: none"> • CL 91 • CL 108 • CL 74 • disable • auto The disable option disables this configuration on the port.
ForwardErrorCorrectionApplicability	Displays whether FEC is applicable on the interface.
OperAutoNegotiate	Shows the operational state of Auto-Negotiation.
OperForwardErrorCorrection	Shows the negotiated operational FEC clause. If the value is off, the port supports FEC and is up but not configured for FEC. If the value is notApplicable, the port does not support FEC. If the value is unknown, the port supports FEC but is down.
Action	Performs one of the following actions on the port <ul style="list-style-type: none"> • none - none of the following actions • flushMacFdb - flush the MAC forwarding table • flushArp - flush the ARP table • flushIp - flush the IP route table • flushAll - flush all tables • triggerRipUpdate — manually triggers a RIP update The default is none.
Result	Displays the result of the selected action. The default is none.

Name	Description
AutoSense	Enables or disables Auto-sense on the specific port. The default value is disabled for existing configurations but enabled for new Zero Touch Fabric Configuration deployments.
AutoSenseKeepAutoConfig	Retains the Auto-sense configuration if you disable Auto-sense on the port. The dynamic configuration becomes a manual configuration and is visible in the show running-config output.
CustomAutoNegAdOrigin	Specifies the origin of Custom Auto Negotiation Advertisements (CANA) configuration on the port. The supported values are: <ul style="list-style-type: none"> • config - Set by the user. • radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.
BpduGuardOrigin	Specifies the origin of BPDU Guard configuration on the port. The supported values are: <ul style="list-style-type: none"> • config - Set by the user. • radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.
AutoSenseState	Displays the Auto-sense port state.
LinkDebounce	Specifies the extended debounce timer on the port. The value 0 milliseconds disables debounce time. The default value is 1000. Note: This field does not apply to Auto-sense ports. To configure Link Debounce on Auto-sense ports, see Configure Link Debounce for Auto-sense Ports on page 65.
AutoSenseDataIsid	Specifies the Auto-sense data I-SID per port.
AutoSenseWaitInterval	Specifies the Auto-sense Wait Interval for the port. The default is 35.
NodeAliasEnable	Enables or disables Node Alias on this specific port. The default is enabled on Auto-sense ports.

Name	Description
NodeAliasClear	Clears Node Alias on this specific port.
IpfixEnable	Enables or disables IPFIX on the port. The default is true, which means enabled. If you enable IPFIX globally, the switch learns flows on both UNI ports and NNIs automatically, because IPFIX is enabled on those interfaces by default. You must explicitly disable IPFIX on those interfaces to stop flow learning. If you disable IPFIX globally, no flow learning occurs, regardless of the UNI port or NNI configuration.

Configure RSTP Global Parameters

Perform this procedure to configure the RSTP global parameters.

Procedure

1. In the navigation pane, expand **Configuration > VLAN > Spanning Tree**.
2. Select **RSTP**.
3. Configure the parameters as required.
4. Select **Apply**.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
PathCostDefault	Specifies the version of the spanning tree default path costs that are used by this bridge. A value of 8021d1998 indicates the use of the 16-bit default path costs from IEEE Std. 802.1d-1998. A value of stp8021t2001 indicates the use of the 32-bit default path costs from IEEE Std. 802.1t.
TxHoldCount	Specifies the value used by the port transmit state machine to limit the maximum transmission rate. The default is 3.
Version	Specifies the version of STP that the bridge currently runs. The value stpCompatible indicates that the Spanning Tree Protocol as specified in IEEE 802.1d is in use; rstp indicates that the Rapid Spanning Tree Protocol as specified in IEEE 802.1w is in use.
EnableStp	Indicates whether the spanning tree protocol is active in this STG. The default is enabled.

Name	Description
Priority	Specifies the RSTP bridge priority.
BridgeMaxAge	Specifies the value that all bridges use for MaxAge while this bridge acts as the root.
BridgeHelloTime	The value that all bridges use for HelloTime while this bridge acts as the root.
BridgeForwardDelay	Specifies the value that all bridges use for forward delay while this bridge acts as the root.
DesignatedRoot	Specifies the unique bridge identifier of the bridge recorded as the root in the configuration BPDUs transmitted by the designated bridge for the segment to which the port is attached.
RootCost	Specifies the cost of the path to the root from this bridge.
RootPort	Specifies the port number of the port which offers the lowest cost path from this bridge to the root bridge.
MaxAge	Specifies the maximum age of Spanning Tree Protocol information in hundredths of a second learned from the network on any port before the port is discarded.
HelloTime	Specifies the amount of time in hundredths of a second between the transmission of configuration bridge PDUs by this node on any port while it is the root of the spanning tree (or trying to become the root).
ForwardDelay	Specifies a time value, measured in hundredths of a second, controls how fast a port changes its spanning state after moving towards the forwarding state. The value determines how long the port stays in each of the listening and learning states, which precede the forwarding state. This value is also used after a topology change is detected, and is underway, to age all dynamic entries in the forwarding database.
RstpUpCount	Specifies the number of times the RSTP module is enabled. A trap is generated on the occurrence of this event.
RstpDownCount	Specifies the number of times the RSTP module is disabled. A trap is generated on the occurrence of this event.
NewRootIdCount	Specifies the number of times this bridge detects a root identifier change. A trap is generated on the occurrence of this event.

Name	Description
TimeSinceTopology Change	Specifies the time (in hundredths of a second) since the TcWhile Timer for any port in this bridge was nonzero for Common Spanning Tree.
TopChanges	Specifies the number of times that there was at least one nonzero TcWhile Timer on this bridge for Common Spanning Tree.

Configure RSTP Ports

About This Task

Configure RSTP to reduce the recovery time after a network breakdown.

Procedure

1. In the navigation pane, expand **Configuration > VLAN > Spanning Tree**.
2. Select **RSTP**.
3. Select the **RSTP Ports** tab.
4. Use the fields in the **RSTP Ports** tab to configure the RSTP ports.
5. Select **Apply**.

RSTP Ports Field Descriptions

Use the data in the following table to use the **RSTP Ports** tab.

Name	Description
Port	Specifies a unique value, greater than zero, indicating the port number.
Priority	Specifies the value of the priority field.
PathCost	Specifies the contribution of this port to the path cost of paths towards the root that includes this port.
ProtocolMigration	Specifies a port to transmit RSTP BPDUs if operating in RSTP mode. Any other operation on this object has no effect, and RSTP mode returns false if read.
AdminEdgePort	Specifies the administrative value of the Edge Port parameter. A value of true indicates that this port is an edge-port, and a value of false indicates that this port is a nonedge-port.
OperEdgePort	Specifies the operational value of the Edge Port parameter. The object is initialized to the value of AdminEdgePort and is configured to false on reception of a BPDU.

Name	Description
AdminPointToPoint	Specifies the administrative point-to-point status of the LAN segment attached to this port. A value of forceTrue indicates that this port is treated as if it is connected to a point-to-point link. A value of forceFalse indicates that this port is treated as having a shared media connection. A value of auto indicates that this port is considered to have a point-to-point link if it is an aggregator and all of its members are aggregatable, or if the MAC entity is configured for full-duplex operation, either through autonegotiation or by management means.
OperPointToPoint	Specifies the operational point-to-point status of the LAN segment attached to this port. It indicates whether a port is considered to have a point-to-point connection or not. The value is determined by management or by autodetection as described in the AdminPointToPoint object.
OperVersion	Indicates if the port is in MSTP mode, RSTP mode or STP-compatible mode. MSTP mode transmits MST BDUs, RSTP mode transmits RST BPDUs and STP-compatible transmits Config/TCN BPDUs.

View RSTP Port Status

About This Task

View the RSTP port status to ensure proper functioning of RSTP.

Procedure

1. In the navigation pane, expand **Configuration > VLAN > Spanning Tree**.
2. Select **RSTP**.
3. Select the **RSTP Status** tab.

RSTP Status *Field Descriptions*

Use the data in the following table to use the **RSTP Status** tab.

Name	Description
Port	Specifies a unique value, greater than zero, indicating the port number.
State	Specifies the current state of the port as defined by application of the Spanning Tree Protocol. This state controls what action a port takes on reception of a frame.
Role	Indicates the current port role assumed by this port.
OperVersion	Indicates whether the port is operationally in the RSTP- or STP-compatible mode; that is, whether the port transmits RSTP BPDUs or Config/TCN BPDUs.
EffectivePortState	Specifies the effective operational state of the port. This object is configured to true if the port is operationally up in the Interface Manager, and if Force Port State for this port and the specified port state is enabled. Otherwise, this object is configured to false.

View RSTP Status Statistics**About This Task**

You can view status statistics for Rapid Spanning Tree Protocol (RSTP).

Procedure

1. In the navigation pane, expand **Configuration > VLAN > Spanning Tree**.
2. Select **RSTP**.
3. On the **RSTP Status** tab, select a port, and then select **Graph**.

RSTP Stats *Field Descriptions*

Use the data in the following table to use the **RSTP Stats** tab.

Name	Description
RxRstBpduCount	Specifies the number of RSTP BPDUs this port received.
RxConfigBpduCount	Specifies the number of configuration BPDUs this port received.
RxTcnBpduCount	Specifies the number of TCN BPDUs this port received.
TxRstBpduCount	Specifies the number of RSTP BPDUs this port transmitted.

Name	Description
TxConfigBpduCount	Specifies the number of Config BPDUs this port transmitted.
TxTcnBpduCount	Specifies the number of TCN BPDUs this port transmitted.
InvalidRstBpduRxCount	Specifies the number of invalid RSTP BPDUs this port received. A trap is generated on the occurrence of this event.
InvalidConfigBpduRx Count	Specifies the number of invalid configuration BPDUs this port received. A trap is generated on the occurrence of this event.
InvalidTcnBpduRxCount	Specifies the number of invalid TCN BPDUs this port received. A trap is generated on the occurrence of this event.
ProtocolMigrationCount	Specifies the number of times this port migrated from one STP protocol version to another. The relevant protocols are STP-Compatible and RSTP. A trap is generated on the occurrence of this event.

View Port Spanning Tree Statistics

About This Task

View port spanning tree statistics to manage network performance.

Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand **Configuration > Graph**.
3. Select **Port**.
4. Select the **Spanning Tree** tab.

Spanning Tree Field Descriptions

The following table describes parameters on the **Spanning Tree** tab.

Name	Description
InConfigBpdus	The number of Config BPDUs received.
InTcnBpdus	The number of Topology Change Notifications BPDUs received.
InBadBpdus	The number of unknown or malformed BPDUs received.
OutConfigBpdus	The number of Config BPDUs transmitted.
OutTcnBpdus	The number of Topology Change Notifications BPDUs transmitted.

Configure MSTP Global Parameters

Before You Begin

- The system must be in MSTP mode.

About This Task

Configure the global MSTP parameters to determine how MSTP operates for the system. Interface-level parameters override global settings.

Procedure

1. In the navigation pane, expand **Configuration > VLAN > Spanning Tree**.
2. Select **MSTP**.
3. Select the **Globals** tab.
4. Configure MSTP as required.
5. Select **Apply**.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
PathCostDefaultType	Specifies the version of the spanning tree default path costs to be used by this bridge. A value of 8021d1998 denotes the use of the 16-bit default path costs from IEEE 802.1d-1998. A value of stp8021t2001 denotes the use of the 32-bit default path costs from IEEE 802.1t.
TxHoldCount	Specifies the value used by the port transmit state to limit the maximum transmission rate. The default is 3.
MaxHopCount	Assigns the MSTP bridge maximum hop count. The range is 100 to 4000 one hundredths of a second. The original MIB erroneously designated the value in hundredths of a second, when it should have been in hops. The replacement MIB kept the range at 100-4000 to remain backwards compatible. To convert this value to hops, divide by 100 so 100-4000 equals 1-40 hops.
NoOfInstancesSupported	Indicates the maximum number of spanning tree instances supported.
MstpUpCount	The number of times the MSTP module is enabled. A trap is generated on the occurrence of this event.
MstpDownCount	The number of times the MSTP module is disabled. A trap is generated on the occurrence of this event.

Name	Description
ForceProtocolVersion	<p>Specifies the version of Spanning Tree Protocol that the bridge currently runs. stpCompatible indicates that the Spanning Tree Protocol as specified in IEEE 802.1d is in use; rstp indicates that the Rapid Spanning Tree Protocol as specified in IEEE 802.1w is in use; and mstp indicates that the multiple spanning tree protocol as specified in IEEE 802.1s is in use.</p> <p>Although STP and MSTP are variations of the same spanning tree protocol, they communicate information differently. A switch in MSTI mode cannot recognize the spanning tree groups running on a chassis configured with STP. MSTP spanning tree groups are not the same as STP spanning tree groups. Using a switch in MSTP mode with a chassis in STP mode can create a loop in the network.</p> <p>The default is MSTP.</p>
BrgAddress	<p>Specifies the MAC address used by this bridge if it must be referred to in a unique fashion. This should be the numerically smallest MAC address of all ports that belong to this bridge. If concatenated with MstCistBridgePriority or MstBridgePriority, a unique bridge identifier is formed, which is used in the STP.</p>
Root	<p>Specifies the bridge identifier of the root of the common spanning tree as determined by the STP by this node. This value is used as the CIST root identifier parameter in all configuration bridge PDUs originated by this node.</p>
RegionalRoot	<p>Specifies the bridge identifier of the root of the multiple spanning tree region as determined by the STP as executed of this node. This value is used as the common and internal spanning tree (CIST) regional root identifier parameter in all configuration bridge PDUs originated by this node.</p>
RootCost	<p>Specifies the cost of the path to the CIST root from this bridge.</p>
RegionalRootCost	<p>Specifies the cost of the path to the CIST regional root from this bridge.</p>
RootPort	<p>Specifies the port number of the port which offers the lowest path cost from this bridge to the CIST root bridge.</p>

Name	Description
BridgePriority	Specifies the value of the writable portion of the bridge identifier comprising the first two octets. The values you enter for bridge priority must be in steps of 4096. The default is 32768.
BridgeMaxAge	Specifies the value that all bridges use for MaxAge while this bridge acts as the root. The granularity of this timer is specified as 1 second. An agent can return a bad value error if you attempt to configure a value which is not a whole number of seconds. The default is 2000.
BridgeForwardDelay	Specifies the value that all bridges use for forward delay if this bridge acts as the root. Note that 802.1d specifies that the range for this parameter is related to the value of BridgeMaxAge. The granularity of this timer is specified as 1 second. An agent can return a bad value error if you attempt to configure a value which is not a whole number of seconds. The default is 1500.
HoldTime	Determines the interval length in hundredths of a second during which no more than two configuration bridge PDUs can be transmitted by this node.
MaxAge	Specifies the maximum age of Spanning Tree Protocol information learned from the network on any port before it is discarded. This is the value that this bridge currently uses.
ForwardDelay	Specifies the time value, measured in units of hundredths of a second, that controls how fast a port changes its spanning state after moving towards the forwarding state. This value determines how long the port stays in a particular state before moving to the next state.
TimeSinceTopology Change	Specifies the time (in hundredths of a second) since the TcWhile Timer for any port in this bridge was nonzero for Common Spanning Tree.
TopChanges	Specifies the number of times that there was at least one nonzero TcWhile Timer on this bridge for Common Spanning Tree.
NewRootBridgeCount	Specifies the number of times this bridge detects a root bridge change for Common Spanning Tree. A trap is generated on the occurrence of this event.

Name	Description
RegionName	Specifies the name for the region configuration. By default, the region name is equal to the bridge MAC Address.
RegionVersion	Specifies the version of the MST region.
ConfigIdSel	Specifies the configuration identifier format selector used by the bridge. This has a fixed value of 0 to indicate RegionName. RegionVersions are specified as in the standard.
ConfigDigest	Specifies the configured MD5 digest value for this region, which must be 16 octets long.
RegionConfigChange Count	Specifies the number of times a region configuration identifier change is detected. A trap is generated on the occurrence of this event.

Configure CIST Ports for MSTP

About This Task

Configure Common and Internal Spanning Tree (CIST) ports to configure ports for MSTP.

Procedure

1. In the navigation pane, expand **Configuration > VLAN > Spanning Tree**.
2. Select **MSTP**.
3. Select the **CIST Port** tab.

Note

The MSTP, CIST Port tab contains information for each port that is common to all bridge and spanning tree instances.

4. Use the fields in the **CIST Port** box to configure the MSTP CIST port.
5. Select **Apply**.

CIST Port Field Descriptions

Use the data in the following table to use the **CIST Port** tab.

Name	Description
Port	Specifies the port number of the port for which this entry contains spanning tree information.
PathCost	Specifies the contribution of this port to the path cost of paths towards the CIST root that includes this port.

Name	Description
Priority	<p>Specifies the four most significant bits of the port identifier of the spanning tree instance which are modified by setting the CistPortPriority value. The values that are configured for port priority must be in steps of 16.</p> <p>Although port priority values can range from 0 to 255, only the following values are used: 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, 240.</p> <p>The default is 128.</p>
DesignatedRoot	Specifies the unique bridge identifier of the bridge recorded as the CIST root in the configuration BPDUs transmitted.
DesignatedCost	Specifies the path cost of the designated port of the segment that connects to this port.
DesignatedBridge	Specifies the unique bridge identifier of the bridge which that port considers to be the designated bridge for the ports segment.
DesignatedPort	Specifies the port identifier of the port on the designated bridge for this port segment.
RegionalRoot	Specifies the unique bridge identifier of the bridge recorded as the CIST regional root identifier in the configuration BPDUs transmitted.
RegionalPathCost	Specifies the contribution of this port to the path cost of paths towards the CIST regional root that include this port.
ProtocolMigration	<p>Specifies the protocol migration state of this port. If you chose true, the option initiates protocol migration for a port. If you chose false, the option terminates protocol migration for a port.</p> <p>An MSTP-compatible port transmits and receives only RSTP BPDUs. If an MSTP port receives an STP BPDU, it becomes an STP port. User intervention is required to change this port back to MSTP mode. This process is called Port Protocol Migration.</p> <p>You must configure protocol migration to true on all spanning-tree enabled interfaces when you change the spanning tree version from STP-compatible to MSTP for those interfaces to work in the proper mode.</p>

Name	Description
AdminEdgeStatus	Specifies the administrative value of the Edge Port parameter. A value of true indicates that this port is an edge-port, and a value of false indicates that this port is a nonedge-port.
OperEdgeStatus	Specifies the operational value of the Edge Port parameter. The object is initialized to the value of AdminEdgeStatus and is configured to false on reception of a BPDU.
AdminP2P	Specifies the administrative point-to-point status of the LAN segment attached to this port. A value of forceTrue indicates that this port is treated as if it connects to a point-to-point link. A value of forceFalse indicates that this port is treated as having a shared media connection. A value of auto indicates that this port is considered to have a point-to-point link if it is an aggregator and all of its members are aggregatable, or if the MAC entity is configured for full-duplex operation, either through autonegotiation or by management means.
OperP2P	Specifies the operational point-to-point status of the LAN segment attached to this port. It indicates whether a port is considered to have a point-to-point connection or not. The value is determined by management or by autodetection as described in the AdminP2P object.
HelloTime	Specifies the amount of time in hundredths of a second between the transmission of configuration bridge PDUs by this node on this port.
OperVersion	Specifies whether the port is operationally in the MSTP mode, the RSTP mode, or the STP-compatible mode; that is, whether the port transmits MST BPDUs, RST BPDUs, or Config/TCN BPDUs. Although STP and MSTP are variations of the same spanning tree protocol, they communicate information differently. A switch in MSTI mode cannot recognize the spanning tree groups running on a chassis configured with STP. MSTP spanning tree groups are not the same as STP spanning tree groups. Using a switch in MSTP mode with another chassis in STP mode can create a loop in the network.

Name	Description
EffectivePortState	Specifies the effective operational state of the port for CIST. This is true only if the port is operationally up at the interface and protocol levels for CIST. This is configured to false for all other conditions.
State	Specifies the current state of the port as defined by the common spanning tree protocol. It can be disabled, discarding, learning, or forwarding.
ForcePortState	Specifies the current state of the port. You can change the port to either Disabled or Enabled for the base spanning tree instance.
SelectedPortRole	Specifies the selected port role of the port for this spanning tree instance.
CurrentPortRole	Specifies the current port role of the port for this spanning tree instance.
RSTPMigration	Specifies whether the port operates in RSTP mode to send RSTP BPDUs. You can change the port to either Enabled or Disabled. The default is disabled.
RestrictedRole	Specifies whether the port accepts superior BPDUs or claims from other non-root bridges trying to become the root bridge. The default is disabled.
RestrictedTcn	Specifies whether the port propagates Topology Change Notifications (TCN) to other ports. The default is disabled.

Configure MSTI Bridges for MSTP

About This Task

Perform this procedure to configure multiple spanning tree instance (MSTI) bridges for MSTP.

Procedure

1. In the navigation pane, expand **Configuration > VLAN > Spanning Tree**.
2. Select **MSTP**.

3. Select the **MSTI Bridges** tab.

**Note**

The system generates MSTI bridge instances after you create a VLAN in MSTP mode.

4. Use the fields in the **MSTI Bridges** box to configure the MSTP bridge.
5. Select **Apply**.

MSTI Bridges *Field Descriptions*

Use the data in the following table to use the **MSTI Bridges** tab.

Name	Description
Instance	Specifies the spanning tree instance to which this information belongs.
RegionalRoot	Specifies the MSTI regional root identifier value for the instance. This value is used as the MSTI regional root identifier parameter in all configuration bridge PDUs originated by this node.
Priority	Specifies the writable portion of the MSTI bridge identifier comprising the first two octets. The values that are configured for bridge priority must be in steps of 4096. The default is 32768.
RootCost	Specifies the cost of the path to the MSTI regional root as seen by this bridge.
RootPort	Specifies the port number of the port that offers the lowest path cost from this bridge to the MSTI region root bridge.
TimeSinceTopologyChange	Specifies the time (in hundredths of a second) since the TcWhile Timer for any port in this bridge was nonzero for this spanning tree instance.
TopChanges	Specifies the number of times that there was at least one nonzero TcWhile Timer on this bridge for this spanning tree instance.
NewRootCount	Specifies the number of times this bridge detects a root bridge change for this spanning tree instance. A trap is generated on the occurrence of this event.
InstanceUpCount	Specifies the number of times a new spanning tree instance is created. A trap is generated on the occurrence of this event.
InstanceDownCount	Specifies the number of times a spanning tree instance is deleted. A trap is generated on the occurrence of this event.

Configure MSTI Ports for MSTP

About This Task

Perform the following procedure to configure MSTI ports for MSTP.

Procedure

1. In the navigation pane, expand **Configuration > VLAN > Spanning Tree**.
2. Select **MSTP**.
3. Select the **MSTI Port** tab.
4. Use the fields in the **MSTI Port** box to configure the MSTP.
5. Select **Apply**.

MSTI Port Field Descriptions

Use the data in the following procedure to use the **MSTI Port** tab.

Name	Description
Port	Specifies the port number of the port for which this entry contains spanning tree information.
Instance	Specifies the spanning tree instance to which the information belongs.
PathCost	Specifies the contribution of this port to the path cost of paths towards the MSTI root that includes this port.
Priority	Specifies the four most significant bits of the port identifier for a given spanning tree instance can be modified independently for each spanning tree instance supported by the bridge. The values configured for port priority must be in steps of 16. The default is 128.
DesignatedRoot	Specifies the unique bridge identifier of the bridge recorded as the MSTI regional root in the configuration BPDUs transmitted.
DesignatedBridge	Specifies the unique bridge identifier of the bridge that this port considers to be the designated bridge for the port segment.
DesignatedPort	Specifies the port identifier of the port on the designated bridge for this port segment.
State	Specifies the current state of the port, as defined by the MSTP. A port which is in forwarding state in one instance can be in discarding (blocking) state in another instance.

Name	Description
ForcePortState	Specifies the current state of the port, that is changed to either disabled or enabled for the specific spanning tree instance.
DesignatedCost	Specifies the path cost of the designated port of the segment connected to this port.
CurrentPortRole	Specifies the current port role of the port for this spanning tree instance.
EffectivePortState	Specifies the effective operational state of the port for a specific instance. This is configured to true if the port is operationally up at the interface and protocol levels for the specific instance. This is configured to false at all other times.

View VLAN and Spanning Tree CIST Statistics

About This Task

View CIST port statistics to manage network performance.

Procedure

1. In the navigation pane, expand **Configuration > VLAN > Spanning Tree**.
2. Select **MSTP**.
3. Select the **CIST Port** tab.
4. Select a port, and then select **Graph**.

CIST Field Descriptions

The following table describes parameters on the **CIST** tab.

Name	Descriptions
ForwardTransitions	Specifies the number of times this port has transitioned to the forwarding state.
RxMstBpduCount	Specifies the number of MSTP BPDUs received on this port.
RxRstBpduCount	Specifies the number of RSTP BPDUs received on this port.
RxConfigBpduCount	Specifies the number of configuration BPDUs received on this port.
RxTcnBpduCount	Specifies the number of TCN BPDUs received on this port.
TxMstBpduCount	Specifies the number of MSTP BPDUs transmitted from this port.

Name	Descriptions
TxRstBpduCount	Specifies the number of RSTP BPDUs transmitted from this port.
TxConfigBpduCount	Specifies the number of configuration BPDUs transmitted from this port.
TxTcnBpduCount	Specifies the number of TCN BPDUs transmitted from this port.
InvalidMstBpduRxCount	Specifies the number of Invalid MSTP BPDUs received on this port.
InvalidRstBpduRxCount	Specifies the number of Invalid RSTP BPDUs received on this port.
InvalidConfigBpduRxCount	Specifies the number of invalid configuration BPDUs received on this port.
InvalidTcnBpduRxCount	Specifies the number of invalid TCN BPDUs received on this port. The number of times this port has migrated from one STP protocol version to another. The relevant protocols are STP-compatible and RSTP/MSTP. A trap is generated on the occurrence of this event.
ProtocolMigrationCount	Specifies the number of times this port has migrated from one STP protocol version to another. The relevant protocols are STP-compatible and RSTP. A trap is generated on the occurrence of this event.

View VLAN and Spanning Tree MSTI Statistics

About This Task

View multiple spanning tree instance (MSTI) port statistics to manage network performance.

Procedure

1. In the navigation pane, expand **Configuration > VLAN > Spanning Tree**.
2. Select **MSTP**.
3. Select the **MSTI Port** tab.
4. Select a port, and then select **Graph**.

MSTI Field Descriptions

The following table describes parameters on the **MSTI** tab.

Name	Description
ForwardTransitions	Specifies the number of times this port has transitioned to the forwarding state for this specific instance.
ReceivedBPDUs	Specifies the number of BPDUs received by this port for this spanning tree instance.

Name	Description
TransmittedBPDUs	Specifies the number of BPDUs transmitted on this port for this spanning tree instance.
InvalidBPDUsRcvd	Specifies the number of invalid BPDUs received on this port for this spanning tree instance.

SPB-PIM Gateway configuration includes controller and gateway nodes, and Multicast Source Discovery Protocol (MSDP) configuration.

The following topics provide necessary concepts and procedures to configure SPB-PIM Gateway.

SPB-PIM Gateway Fundamentals

This section provides conceptual content to help you configure and customize SPB-PIM Gateway (SPB-PIM GW) on the switch.

IP Multicast over Fabric Connect in Protocol Independent Multicast Networks

IP Multicast over Fabric Connect provides simplicity in provisioning and deploying IP multicast bridging and routing. Also, due to the fact that only one control plane protocol (IS-IS) exists, convergence times in the event of a network failure, are typically sub second.

IP Multicast over Fabric Connect

IP Multicast over Fabric Connect introduces extensions to the SPBM IS-IS control plane to exchange IP multicast stream advertisement and membership information. IP Multicast over Fabric Connect uses these extensions, along with the Internet Group Management Protocol (IGMP) Snooping and Querier functions at the edge of the SPBM cloud, to create sub-trees of the VSN SPB for each multicast group to transport IP multicast data.

With IP Multicast over Fabric Connect, the switch supports the following:

- Layer 2 Virtual Services Network with IGMP support on the access networks for optimized forwarding of IP multicast traffic in a bridged network (Layer 2 VSN with IP Multicast over Fabric Connect). Example application: Multicast in data centers.
- IP multicast routing support for IP Shortcuts using SPBM in the core and IGMP on the access (IP Shortcuts with IP Multicast over Fabric Connect). Example applications: Video surveillance, TV/Video/Ticker/Image distribution, VX-LAN.
- Layer 3 Virtual Services Network with VRF based routing support for IP Multicast over Fabric Connect in the core and IGMP on the access (Layer 3 VSN with IP Multicast over Fabric Connect). Example applications: Video surveillance, TV/Video/Ticker/Image Distribution, VXLAN, Multi-tenant IP multicast.

Important

Sources must be IGMP enabled to support discovery functions specific to the multicast applications in use.

IP Multicast over Fabric Connect Restrictions

- IP Multicast over Fabric Connect cannot connect to an IP Multicast router outside the SPB network.
- You can only deploy IP Multicast over Fabric Connect in environments where there are no multicast routers between the edge of the SPB network and the IP Multicast hosts that connect to the network.
- An existing network which is Protocol Independent Multicast (PIM) based cannot participate in the SPB network either by connecting to SPB originated streams or by injecting PIM network streams into the SPB network.
- In certain environments it is not possible to deploy an SPB network all the way to the point where the SPB network directly connects to an IGMP edge.

You encounter these restrictions during the following typical deployment scenarios:

- **Scenario 1:** You deployed IP Multicast using PIM and want to expand the network by deploying SPB for the new portion of the network. You want multicast applications to work across the old and new portion of the network.
- **Scenario 2:** Multicast traffic is exchanged between independent network operators at the boundary between their networks. PIM is the multicast routing protocol. A network operator wants to upgrade or replace the existing network to an SPB network. The inter-domain multicast traffic exchanges with other networks should not be disrupted.

The following figure shows the traditional Multicast over Fabric Connect environment with no PIM routers.

Figure 225: IP Multicast over Fabric Connect streams

In the previous figure, sources and receivers on the edges of the SPB network are IGMP hosts and sources of multicast data. Hence, the traditional Multicast over Fabric Connect host-to-host deployment works.

The following figure shows the traditional Multicast over Fabric Connect environment with PIM routers.

Figure 226: IP Multicast over Fabric Connect Streams

In the previous figure, sources and receivers on the edges of the SPB network, which are IGMP or source hosts can communicate over the SPB network. Sources and receivers connected to PIM routers cannot participate in the SPB network.

SPB-PIM Gateway

Multicast over Fabric Connect cannot connect to a PIM router that is external to the SPB network. When a receiver joins the SPB network for a specific group, the receiver must receive multicast streams in the neighboring multicast domains (PIM network). Similarly, a receiver in the neighboring multicast domain (PIM network) must receive multicast streams from sources in the SPB network. SPB-PIM Gateway (SPB-PIM GW) provides multicast inter-domain communication between an SPB network and a PIM network. SPB-PIM GW accomplishes this inter-domain communication across a special gateway VLAN. The gateway VLAN communicates with the PIM network through a subset of the full protocol messaging required for RFC 4601 compliance of a PIM interface, and translates the PIM network requirements into SPB language and vice versa.

SPB-PIM GW provides the following functionality:

- One or more SPB domains can share streams with one or more PIM domains.

- SPB-PIM GW can connect two independent SPB domains. The independent SPB domains connected by SPB-PIM GW share a subset of multicast streams without a PIM network in between.

SPB-PIM GW is supported in the GRT and in VRFs.

Multicast over Fabric Connect with SPB-PIM GW

In a Multicast over Fabric Connect environment with SPB-PIM GW, the SPB network connects sources and receivers from one or more PIM networks. The multicast traffic is then delivered across the domain boundaries through a path that transports the multicast traffic.

Multicast over Fabric Connect with SPB-PIM GW functionality consists of SPB nodes, which act as SPB-PIM Controller nodes and SPB-PIM Gateway nodes. The SPB Controller uses the Multicast Source Discovery Protocol (MSDP) to discover foreign sources.

The following figure shows the Multicast over Fabric Connect environment with SPB-PIM GW.

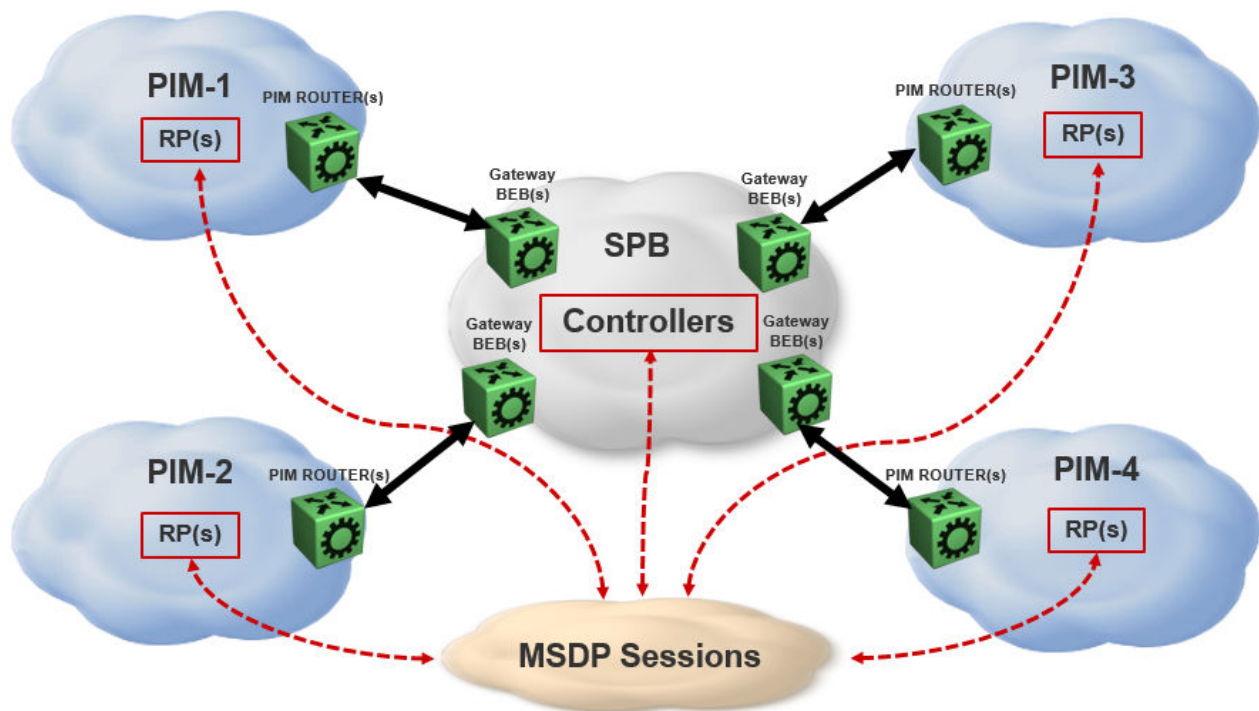

Figure 227: Multicast over Fabric Connect with SPB-PIM GW

SPB-PIM GW Components

SPB-PIM GW has two functional components:

- SPB-PIM Gateway Controller Nodes (Controller), which are used for multicast source discovery.
- SPB-PIM Gateway Nodes (Gateway), on which the SPB-PIM Gateway interfaces reside.

Note

The Controller and Gateway can reside in a single node.

The following figure shows the SPB-PIM GW components.

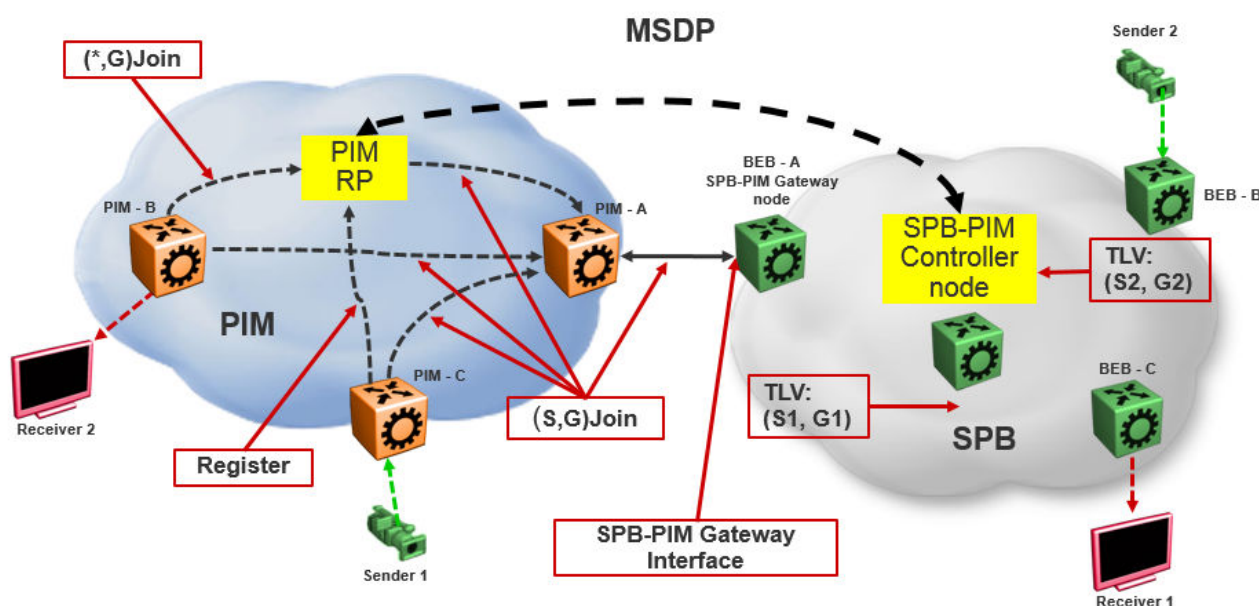

Figure 228: SPB-PIM GW components

SPB-PIM Gateway Controller Node

SPB-PIM Gateway Controller Node (Controller) shares stream information between the local SPB domain and a foreign domain. The foreign domain is the PIM network Rendezvous point (RP) or another SPB domain Controller.

The following list outlines Controller functionality:

- The Controller discovers PIM sources for a specific multicast group and distributes them to the Gateways.

**Note**

PIM source discovery is either through MSDP or static configuration of foreign streams at the Controller.

- The Controller advertises local SPB originated streams through MSDP to another PIM domain or another SPB domain.
- The Controller references the Unicast IP route table to determine which Gateway has the best route to the PIM source. The Controller then assigns the stream to the selected Gateway.

The Controller Node has the following components:

- Source Discovery (MSDP and static configuration)
- Gateway Selection Controller

Source Discovery (MSDP and Static Configuration)

MSDP resides in the Controller BEB or Controller BCB and PIM network RP that want to advertise multicast source information between domains.

You can implement SPB-PIM GW under the following scenarios:

- The multicast source resides in the Protocol Independent Sparse Module (PIM-SM) domain. The multicast source must be discovered by MSDP residing on the Gateway Controller in the SPB domain.
- The multicast source resides in the SPB domain. The multicast source must be advertised to the neighboring PIM domain through MSDP peers.

For more information on MSDP, see [MSDP Overview](#) on page 3567.

**Note**

You can also configure multicast sources statically on the Controller. Static configuration is useful for SSM multicast group range streams in the foreign domain, which are not advertised by MSDP. Static configuration is also useful for when two SPB domains are connected through a PIM Gateway, and want to only advertise a subset of streams to each other, without enabling MSDP.

Gateway Selection Controller

The Gateway Selection Controller resides in the Controller BEB or Controller BCB node in the SPB network. The Gateway Selection Controller receives source information from MSDP or through static configuration. The source information consists of the following components:

- Sender IP address (S)
- Group IP address (G)
- VRF ID of the stream
- RP of the source (optional)

Gateway Selection Controller finds the best BEB (Gateway Node) in the SPB network through which the sender sends traffic to group G. The Gateway Selection Controller performs the following tasks:

- The Gateway Selection Controller uses Layer 3 reachability information to reach S, which is retrieved from the ISIS IP Shortcuts (IPSC) database.
- The VSN identifier (I-SID) is determined by using the VRF ID provided by MSDP.
- The Gateway Selection Controller uses the VRF ID and searches the IP shortcut database to determine which Gateway is closest to S.

**Note**

If multiple BEBs have a route to S, the BEB with the lowest Layer 3 metric is selected as the Gateway.

**Note**

If a Gateway link fails or the cost of the route changes, the selection process identifies the link failure as a route change and selects another best Gateway BEB.

The selected Gateway BEB for a stream must satisfy the following criteria:

- The selected Gateway BEB for a stream must announce a route to the source of the foreign stream through ISIS.

**Note**

Among all the routes to the source of the foreign stream announced by different BEBs through ISIS, the route announced by the selected Gateway has the longest prefix match and has the lowest external route metric.

- If multiple BEBs meet the Gateway selection criteria, a deterministic hash function of system ID, source IP address, and group IP address is used. The deterministic hash function is computed for each of the BEBs that meet the Gateway selection criteria. The BEB that generates the lowest hash value is selected as the Gateway for the stream.

The result of the Gateway selection process is saved in the Gateway assignment table. The Gateway assignment table consists of VSN identifier or I-SID, S, G, and the selected Gateway BEB. Having only one selected Gateway BEB ensures that traffic from source S is drawn into the SPB network by only one BEB, the selected Gateway BEB. The selection Controller then distributes the Gateway assignment table information to all the Gateway nodes.

SPB-PIM Gateway Node

The SPB-PIM Gateway Node (Gateway) has the following components:

- Gateway Selection Agent
- SPB-PIM Gateway interface

Gateway Selection Agent

The Gateway Selection Agent (Agent) resides in the Gateway BEB Node in the SPB network. The Gateway BEB has connections into the foreign network over SPB-PIM

Gateway Interfaces. The Agent receives foreign network source information from the Controller BEB or the Controller BCB Node. The source information consists of the following components:

- Sender IP address (S)
- Group IP address (G)
- VSN identifier (I-SID)
- Gateway assigned to the stream

The Agent interacts with SPB-PIM Gateway interface and creates the multicast path. The Agent receives foreign source information from the Controller and creates a foreign source address (SA) cache after validating the reachability to S. The Agent interacts with the SPB-PIM Gateway interface to validate that the next-hop ip address toward the source is a valid PIM adjacency. The foreign SA cache includes the following components:

- Source IP address (information received from the Gateway Controller)
- Group IP address (information received from the Gateway Controller)
- Ingress port (The port through which S is accessible)
- Upstream IP address (The next-hop IP address, which is also the PIM neighbor across the SPB-PIM Gateway interface which is used to reach S as indicated by the unicast routing entry)
- Ingress VLAN ID

If multiple next-hops are available, then the first valid PIM neighbor next-hop is used for the upstream.

**Note**

If the Agent receives the same source information from multiple Controllers, then the Agent takes action only for the information received from the preferred Controller. The Controller with the lowest system ID is the preferred Controller.

SPB-PIM Gateway Interface

The SPB-PIM Gateway interface provides inter-domain multicast services. The SPB-PIM Gateway interface connects senders and receivers of multicast streams across a PIM Domain and a SPB network boundary over a Gateway interface. The SPB-PIM Gateway interface provides the following functionality:

- PIM HELLO exchanges
- Issuing Joins and Leaves
- Process received Joins and Leaves
- Implements the Gateway assignment table by acting as the Ingress BEB for streams for which the SPB-PIM Gateway interface is the selected Gateway
- Enforces the Gateway assignment table and does not forward streams for which the SPB-PIM Gateway interface is not the selected Gateway

- Forwards local and remote SPB streams to satisfy stream requests from neighboring multicast domains
- SPB-PIM Gateway Interfaces supports both SM and SSM multicast group range joins and prunes. *G joins are only supported in SM group range.

The PIM Gateway interface resides in the SPB-PIM Gateway Node (Gateway). The SPB-PIM Gateway interface connects to a PIM router in a PIM network or to another Gateway BEB in an SPB network. Local hosts (IGMP member hosts and multicast data source hosts) are not supported on SPB-PIM Gateway interfaces, only PIM Routers or another SPB BEB with SPB-PIM Gateway interface configured. Multicast data from local source hosts and IGMP reports from local hosts are dropped. An SPB Node must be configured as a SPB-PIM Gateway Node if the SPB Node is connected to a foreign PIM network or a foreign SPB network. A single Gateway Node can have multiple SPB-PIM Gateway interfaces. The SPB-PIM Gateway interface can be a VLAN or a router port, can reside on an MLT and is fully virtualized. The SPB-PIM Gateway interface is a translation mechanism between the PIM protocol and SPB TLVs.

**Note**

- Only PIM protocol messages are communicated over the SPB-PIM Gateway interface
- Only SPB TLVs are communicated over Fabric Connect over SPB
- The SPB-PIM Gateway interface is the only component that handles the translation mechanism

The SPB-PIM Gateway interface communicates with the PIM router through the standard PIM protocol messaging HELLO, JOIN, and PRUNE. The SPB-PIM Gateway interface then forms a normal PIM adjacency with the PIM router or another SPB Gateway Node. The SPB-PIM Gateway Interface processes received SG joins and prunes, *G joins and prunes, and SG-RPT joins and prunes. The SPB-PIM Gateway interface transmits SG joins and prunes, but never *G joins. The SPB-PIM Gateway Interface does not have RP capabilities, and therefore has no need for group-to-RP mapping configurations. A *G JOIN received on a SPB-PIM Gateway Interface is accepted if the destination IP is the IP address of the interface or of a neighbor on the interface if the neighbor is learned on another port in the interface. However, the RP address within the *G JOIN message is ignored by the SPB-PIM Gateway Interface.

MSDP Overview

MSDP enables advertisement of multicast source information between different PIM-SM domains. This function of MSDP in SPB-PIM GW topologies is to advertise multicast source information between SPB domains and PIM domains. MSDP routers in a PIM-SM or SPB domain have a peering relationship with MSDP peers in another domain. The peering relationship is a TCP connection in which the control information is exchanged. The TCP connection between peers uses the underlying unicast routing system.

Source Active Messages

In a PIM domain, MSDP enabled routers are RPs. MSDP routers form adjacencies through TCP port 639 to share multicast source information. This functionality is similar to the Border Gateway Protocol (BGP). When an MSDP router receives multicast source information, the routers use reachability information to perform Reverse Path Forwarding (RPF) checks. The reachability information is exchanged through BGP or any other unicast routing protocol.

When a RP router learns of a new (S,G), the RP router saves the (S,G) information and the RP address in the MSDP Source Active (SA) local cache. The RP router learns the new (S,G) through a directly connected source or PIM register message. The RP router then sends an SA update message which contains (S,G,RP) information to the MSDP peers. The MSDP peers broadcast the SA to RPs in their local domains and to their MSDP peers in other PIM-SM domains.

**Note**

A PIM domain is a set of routers in a single Autonomous System (AS), which uses the same RP for any given multicast group.

When an SPB-PIM Gateway Controller in the SPB domain learns of a new (S,G) in its own domain, the Controller saves the (S,G) information in the local SA cache. The Controller learns the new (S,G) through a directly connected source or Intermediate-System-to-Intermediate-System (IS-IS). The controller sends an SA update message to the MSDP peers in the PIM domain. SA uses the CLIP address configured on the controller as the RP address.

**Note**

Configure CLIP before you enable MSDP. Peer connections use the CLIP address as the local address.

Reverse Path Forwarding Check

When an MSDP peer receives the SA from a peer, the MSDP performs an RPF check. The RPF check ensures that the SA received from the MSDP peer is the closest to the originating RP. An RPF check prevents SA loops.

**Note**

This RPF check is different from the multicast routing RPF check.

If the RPF checks pass, then the receiving MSDP enabled router saves the SA information in the SA foreign cache and makes it available to the local domain. Each MSDP peer floods the SA information away from the originating RP. The flooding process is called peer RPF flooding.

SA Redistribution and Filtering

Redistribution and filtering is used to control SA flooding. The MSDP redistribute policy is applied on the MSDP node that originates the SAs to control which SAs are advertised on all MSDP peers. An SA filter is applied to a specific MSDP peer in the

inbound direction or outbound directions or both inbound and outbound direction on any MSDP router. Filtering is multicast group based.

When configuring MSDP redistribution, use prefix lists to create the route policies. When a route policy is created it must match the group prefix with the name of the prefix list created for the group address. If deny action is set for the lists in the route-policy, the policy blocks the matching groups from all the sources. If permit action is set for the lists in the route-policy, the policy accepts the matching groups from all the sources. MSDP redistribution does not refer to the redistribution of SPB domain sources to MSDP. MSDP redistribution refers to SAs which needs to be redistributed to other MSDP peers.

**Note**

MSDP redistribution is applied globally to all MSDP peers. SA filtering is used to filter SAs on a peer-to-peer level.

MSDP and SPB-PIM GW

The SPB-PIM GW functional component for MSDP resides in the SPB-PIM Gateway Controller node (Controller).

Overview

Controllers from an SPB network discover sources through MSDP sessions with RPs from a PIM network. Once the SA packed is received at the MSDP module of the Controller, the IP routing table is examined to determine which peer is the next hop towards the originating RP of the SA message. Once the SA RPF test passes, the SA packet is saved in the foreign cache and passed to the Controller.

The Controller nodes also distribute the sources from an SPB domain to a PIM domain through an MSDP session with RPs in the PIM network. Similar to RP, when a Controller in the SPB domain learns of a new (S,G), through a directly connected source or ISIS, the Controller saves the new (S,G) in its local SA cache. The Controller then transmits an SA update message for this source to its MSDP peers in the PIM domain. The Controller that sends the SA to the MSDP is viewed as the RP (circuitless IP interface is used).

MSDP as Ppart of SPB-PIM GW

MSDP does not work with the traditional PIM implementation. MSDP communicates only with the Controller and should be configured as an IP endpoint.

MSDP configuration considerations:

- A circuitless IP interface (CLIP) is used in the context of global router or VRF, hence at least one CLIP in each VRF should be configured.
- MSDP should use a single CLIP address as the source for establishing all MSDP connections in the same VRF.
- For SPB sources, this CLIP is used as the RP in all SA messages advertised.

- MSDP source IP address should be one of the CLIP interfaces pre-configured on the global router or VRF.
- The originator-id should be configured before enabling MSDP.

**Note**

MSDP transmits encapsulated multicast data packets inside forwarded MSDP messages. If the received SA is an encapsulated SA, then the switch parses the TTL value of the encapsulated data and compares it against the configured value. If the configured value is less than or equal to the parsed value, then the switch forwards the encapsulated data along with the SA, otherwise the switch forwards the SA alone by stripping the encapsulate data. By default, MSDP forwards encapsulated data along with the SA message. MSDP does not forward the encapsulated data to the local receivers.

When MSDP generates SA messages for SPB sources, the local cache miss data cannot be encapsulated into the SA messages that are sent to the peers.

The switch supports forwarding SA messages with encapsulated data from sources to MSDP peers but not from MSDP peers to the receivers.

For more information on MSDP configuration, see [Multicast Source Discovery Protocol Configuration](#) on page 3571.

Full Mesh Group

MSDP mesh groups are full mesh of MSDP peers and is a subset of MSDP speakers. MSDP mesh groups are used for SA flooding which is similar to the BGP route reflector concept. MSDP floods the SA to all the members of the mesh group when:

- The MSDP peers are fully meshed
- The MSDP enabled router learns a new SA from a non-member of its mesh group
- The SA passes the RPF check

The receiving routers accept the SA and forwards it only to any non-mesh Group MSDP peers.

The SPB-PIM Gateway is deployed in two models:

- Model 1: All multicast networks have peering agreements with one another. The full mesh MSDP is setup.
- Model 2 : An inter-domain multicast provider exists. All multicast networks setup MSDP peering with the provider.

The controllers relay SA messages between individual networks.

**Note**

Consider the following when you deploy SPB-PIM Gateway:

- Use mesh group of MSDP peers (PIM RP's and SPB-PIM Gateway Controller nodes) to avoid flooding and RPF failure.

**Note**

Since MSDP uses CLIP interface in its peering relation, the MSDP peer may not fall in any of the RFC rules and the MSDP SA messages will be rejected.

- Controllers from the same SPB network must not have MSDP sessions with each other, regardless of whether mesh groups are used or not.
- When using mesh groups, all Controllers within one SPB domain should peer with the same set of RPs and Controllers in adjacent domains, ie, one Controller should not peer with an RP that the other Controllers do not peer with.

Multicast Source Discovery Protocol Configuration

This section provides procedures to configure Multicast Source Discovery Protocol (MSDP) using the Command Line Interface (CLI) and Enterprise Device Manager (EDM).

Basic MSDP Configuration Using CLI

This section provides procedures to configure Basic MSDP using the command line interface (CLI).

Configure the MSDP Originator ID

About This Task

Configure the originator ID to set the Rendezvous Point (RP) address inside the Source Active (SA) message. The RP address must be a pre-configured CLIP interface on the global router or a VRF. The RP address is also the local IP address in all peer relations.

**Note**

To delete the originator ID, you must first disable MSDP.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

Note

You cannot use the derived name for the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF to enter this mode.

2. Configure the MSDP originator ID:

```
ip msdp originator-id {A.B.C.D}
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp originator-id 2.0.2.2
```

Variable Definitions

The following table defines parameters for the **ip msdp originator-id** command.

Variable	Value
{A.B.C.D}	Specifies the MSDP source IP address. The IP address must be one of the CLIP interfaces configured on the global router or a VRF.

Configure MSDP on a VRF

About This Task

Create an MSDP instance on a user defined VRF to allow further configuration to take place. This command does not exist in the Global Configuration mode because the MSDP instance for a default VRF is created by default.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

Note

You cannot use the derived name for the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF to enter this mode.

2. Create the MSDP instance:

```
ip msdp
```

Enable MSDP Globally

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable MSDP globally on the switch:

```
ip msdp enable
```

Create an MSDP Peer

About This Task

Perform the following procedure to establish a peer relationship between the local MSDP enabled router and a peer in another domain.

Important

Do not enable more than 20 active peers.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional:

```
router vrf WORD<1-16>
```

Note

You cannot use the derived name for the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF to enter this mode.

2. Create an MSDP peer:

```
ip msdp peer {A.B.C.D}
```
3. Enable an MSDP peer:

```
ip msdp peer {A.B.C.D} enable
```

Note

MSDP peer is disabled by default.

4. (Optional) Specify the remote autonomous system (AS) number of the MSDP peer:

```
ip msdp peer {A.B.C.D} remote-as WORD<0-11>
```

Example

```
Switch:1>enable  
Switch:1#configure terminal
```

```
Switch:1(config)#ip msdp peer 21.0.0.2
Switch:1(config)#ip msdp peer 21.0.0.2 enable
Switch:1(config)#ip msdp peer remote-as 1
```

Variable Definitions

The following table defines parameters for the **ip msdp peer** command.

Variable	Value
{A.B.C.D}	Specifies the MSDP peer IP address.
WORD<0-11>	Specifies the AS number of the MSDP peer, 0-65535 (2-Byte AS) 0-4294967295 (4-Byte AS).

MSDP Peer Configuration Using CLI

This section provides procedures to configure MSDP peer using the command line interface (CLI).

Configure a Peer Description

About This Task

Configure a peer description to add descriptive text to an MSDP peer for easy identification of a peer.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

Note

You cannot use the derived name for the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF to enter this mode.

2. Configure the peer description:

```
ip msdp description {A.B.C.D} WORD<1-255>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp peer 21.0.0.2 primary
```

Variable Definitions

The following table defines parameters for the **ip msdp description** command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the MSDP peer IP address.
<code>WORD<1-255></code>	Specifies a descriptive text to a MSDP peer in the range of 1-255 characters. To include spaces in the peer description, enclose the text string in quotation marks.

Secure Control Messages

About This Task

Configure Message Digest (MD) 5 authentication to secure control messages on the TCP connection between MSDP peers.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

Note

You cannot use the derived name for the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF to enter this mode.

2. Enable MD5 authentication:

```
ip msdp md5-authentication {A.B.C.D} [enable]
```

3. Specify the case sensitive password for MD5 authentication:

```
ip msdp password peer {A.B.C.D} WORD<1-80>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp md5-authentication 21.0.0.2 enable
Switch:1(config)#ip msdp password peer 21.0.0.2 helloworld
```

Variable Definitions

The following table defines parameters for the **ip msdp** command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the MSDP peer IP address.
<code>WORD<1-80></code>	Specifies the MD5 authentication password.

Configure the MSDP Peer SA Limit

About This Task

Configure the SA limit to limit the number of SA messages from an MSDP peer that the router saves in the SA cache. The default value is 6,144 messages.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

Note

You cannot use the derived name for the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF to enter this mode.

2. Configure the SA limit:

```
ip msdp sa-limit {A.B.C.D} <0-6144>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp sa-limit 21.0.0.2 6100
```

Variable Definitions

The following table defines parameters for the `ip msdp sa-limit` command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the MSDP peer IP address.
<code><0-6144></code>	Specifies the maximum number of SA messages to keep in SA cache.

Configure the Time-To-Live Threshold

About This Task

Configure the time-to-live (TTL) threshold to limit which multicast data packets the router encapsulated in SA Messages forwarded to an MSDP peer. The TTL limits the number of hops a packet can take before the router drops the packet. The router sends out SA Messages with encapsulated data only if TTL equals or exceeds the value you

configure. If the TTL is lower than the value you configure, the router drops the data packet and forwards the SA Message without the encapsulated data.

Note

MSDP transmits encapsulated multicast data packets inside forwarded MSDP messages. If the received SA is an encapsulated SA, then the switch parses the TTL value of the encapsulated data and compares it against the configured value. If the configured value is less than or equal to the parsed value, then the switch forwards the encapsulated data along with the SA, otherwise the switch forwards the SA alone by stripping the encapsulate data. By default, MSDP forwards encapsulated data along with the SA message. MSDP does not forward the encapsulated data to the local receivers.

When MSDP generates SA messages for SPB sources, the local cache miss data cannot be encapsulated into the SA messages that are sent to the peers.

The switch supports forwarding SA messages with encapsulated data from sources to MSDP peers but not from MSDP peers to the receivers.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

Note

You cannot use the derived name for the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF to enter this mode.

2. Configure the MSDP peer TTL threshold:

```
ip msdp ttl-threshold {A.B.C.D} <1-255>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp ttl-threshold 21.0.0.2 10
```

Variable Definitions

The following table defines parameters for the **ip msdp ttl-threshold** command.

Variable	Value
{A.B.C.D}	Specifies the MSDP peer IP address.
<1-255>	Specifies the TTL value. Default value is 1.

*Configure the MSDP Peer Keep Alive Messages***About This Task**

Configure keep alive messages to adjust the interval in seconds at which an MSDP peer sends keep alive messages (default is 60 seconds) and the interval at which the MSDP peer waits for keep alive messages from other peers before it declares them down (default is 75 seconds).

**Note**

In a peer relationship, the keep alive interval configured on one peer must be at least 1 second less than the hold time configured on the other side of the peer relationship. This is not applicable when the hold time is set to 0 seconds.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

**Note**

You cannot use the derived name for the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF to enter this mode.

2. Configure the MSDP peer keep alive interval:

```
ip msdp keepalive {A.B.C.D} <0-21845> <0-65535>
```

Example

```
Switch:1>enable
Switch:1#configure termina
Switch:1(config)#ip msdp keepalive 21.0.0.2 70 71
```

Variable Definitions

The following table defines parameters for the **ip msdp keepalive** command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the MSDP peer IP address.
<code><0-21845></code>	Specifies the keep alive interval in seconds. The default is 60 seconds.
<code><0-65535></code>	Specifies the hold time interval in seconds. The default is 75 seconds. Note: 0 seconds means the peer never expires. Values 1 and 2 are not allowed.

Configure the MSDP Peer Connect-Retry Period

About This Task

Configure the connect-retry period to specify the amount of time, in seconds, between connection attempts for peering sessions. The default is 30 seconds.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

Note

You cannot use the derived name for the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF to enter this mode.

2. Configure the MSDP peer connect-retry period:

```
ip msdp connect-retry {A.B.C.D} <1-65535>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp connect-retry 21.0.0.2 40
```

Variable Definitions

The following table defines parameters for the **ip msdp connect-retry** command.

Variable	Value
{A.B.C.D}	Specifies the MSDP peer IP address.
<1-65535>	Specifies the connect-retry interval in seconds. The default is 30 seconds.

Clear the Peer Connection

About This Task

Clear the peer connection to clear the TCP connection to the specified MSDP peer and reset all MSDP message counters.

Note

This procedure does not clear the SA cache entries the router learns from the peer.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Clear the peer connection:

```
clear ip msdp peer {A.B.C.D} [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#clear ip msdp peer 21.0.0.2
```

Variable Definitions

The following table defines parameters for the **clear ip msdp peer** command.

Variable	Value
{A.B.C.D}	Specifies the MSDP peer IP address.
vrf WORD<0-16>	Specifies the VRF name.
vrfids WORD<0-512>	Specifies the VRF ID.

Delete an MSDP Peer

Procedure

1. Enter Privileged EXEC mode:
enable
2. Clear the peer connection:
no ip msdp peer {A.B.C.D}

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#no ip msdp peer 21.0.0.2
```

MSDP Message Control Using CLI

Filter PIM Routes

About This Task

Filter SPB routes to filter which (S,G,RP) entries sent out to all MSDP peers. This procedure applies only to the rendezvous point (RP) that originates the MSDP SA messages and not the intermediate MSDP peers that forward the received SA messages.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

Note

You cannot use the derived name for the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF to enter this mode.

2. Create the MSDP filter:

```
ip msdp redistribute
```

3. Create the route policy name:

```
ip msdp redistribute route-policy WORD<1-64>
```

4. Apply the redistribution filters:

```
ip msdp apply redistribute
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp redistribute
Switch:1(config)#ip msdp redistribute route-policy helloworld
Switch:1(config)#ip msdp apply redistribute
```

Variable Definitions

The following table defines parameters for the **clear ip redistribute** command.

Variable	Value
<i>WORD<1-64></i>	Specifies the route policy name.

Filter SA Messages

About This Task

Filter SA messages to determine which SA messages to accept from a peer and which SA messages to send to a peer. By default, no inbound or outbound filter exists.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

Note

You cannot use the derived name for the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF to enter this mode.

2. Create the inbound filter:

```
ip msdp sa-filter in {A.B.C.D}
```

3. Create the inbound filter route policy name:

```
ip msdp sa-filter in {A.B.C.D} route-policy WORD<1-64>
```

4. Create the outbound filter:

```
ip msdp sa-filter out {A.B.C.D}
```

5. Create the outbound filter route policy name:

```
ip msdp sa-filter out {A.B.C.D} route-policy WORD<1-64>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp sa-filter in 21.0.0.2 route-policy helloworld
```

Variable Definitions

The following table defines parameters for the **ip msdp sa-filter** command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the MSDP peer IP address.
<code>route-policy WORD<1-64></code>	Specifies the route policy name for an inbound or outbound filter.

Configure MSDP Mesh Groups

About This Task

Configure mesh groups to reduce SA flooding. A mesh group does not forward SA messages to other group members. The originator, which is also a mesh group member, forwards SA messages to all group members. Create MSDP mesh groups from a group of meshed MSDP speakers from a domain.

Note

The MSDP router does not belong to any mesh group by default.

Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

Note

You cannot use the derived name for the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF to enter this mode.

2. Configure the MSDP mesh group:

```
ip msdp mesh-group WORD<1-64> {A.B.C.D}
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp mesh-group helloworld 21.0.0.2
```

Variable Definitions

The following table defines parameters for the **ip msdp mesh-group** command.

Variable	Value
<i>WORD<1-64></i>	Specifies the mesh group name.
<i>{A.B.C.D}</i>	Specifies the MSDP peer IP address.

Clear the MSDP SA Cache

About This Task

Clear the SA cache to clear the SA entries the router learns from all peers or a specific peer.

Note

This procedure clears the foreign cache. This procedure does not clear the local cache.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Clear the SA cache for all peers:

```
clear ip msdp sa-cache [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

3. Clear the SA cache for a specific peer:

```
clear ip msdp sa-cache peer {A.B.C.D} [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

4. Clear the SA cache for a specific group range, source range, and RP.

```
clear ip msdp sa-cache [source prefix/len] [group prefix/len] [rp
{A.B.C.D}] [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#clear ip msdp sa-cache peer 21.0.0.2
```

Variable Definitions

The following table defines parameters for the **clear ip msdp sa-cache** command.

Variable	Value
{A.B.C.D}	Specifies the MSDP peer IP address.
vrf WORD<0-16>	Specifies the VRF names.
vrfids WORD<0-512>	Specifies the VRF ID.

MSDP Verification Using CLI

This section provides procedures to verify MSDP using the command line interface (CLI).

Display the Peer Information

About This Task

Use the following procedure to display the peer configuration and SA message information.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display the peer information:
show ip msdp peer {A.B.C.D} [vrf WORD<0-16>] [vrfids WORD<0-512>]

Example

```
Switch:#enable
Switch:1#show ip msdp peer 2.2.2.2

Variable Definitions

The following table defines parameters for the **show ip msdp peer** command.

Variable	Value
{A.B.C.D}	Specifies the MSDP peer IP address.
vrf WORD<0-16>	Displays configuration info for a particular VRF.
vrfids WORD<0-512>	Displays configuration info for a particular VRF ID.

Display the SA Cache

About This Task

Use the following procedure to display the (S,G) state learned from MSDP peers and the local (S,G) state. The local (S,G) is the SPB (S,G) sent to MSDP.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Display the SA cache:

```
show ip msdp sa-cache [local] [vrf WORD<0-16>] [vrfids WORD<0-512>]
[group {A.B.C.D}] [rp {A.B.C.D}] [source {A.B.C.D}]
```

Example

```

```

Variable Definitions

The following table defines parameters for the **show ip msdp show-all** command.

Variable	Value
<code>file WORD<1-99></code>	Specifies the file name to save the display output.
<code>vrf WORD<0-16></code>	Displays configuration information for a particular VRF.
<code>vrfids WORD<0-512></code>	Displays configuration information for a particular VRF ID.

Clear IPv4 MSDP Statistics

About This Task

Use the following procedure to clear all IPv4 Multicast Source Discovery Protocol (MSDP) statistics for all peers or a specific peer.

If you do not specify a VRF or VRF ID, the switch defaults to GRT.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Clear IPv4 MSDP statistics for all peers:
`clear ip msdp statistics [vrf WORD<0-16>] [vrfids WORD<0-512>]`
3. Clear IPv4 MSDP statistics for a specific peer:
`clear ip msdp statistics {A.B.C.D.} [vrf WORD<0-16>] [vrfids WORD<0-512>]`

Variable Definitions

Use the data in the following table to use the **clear ip msdp statistics** command.

Variable	Value
<code>vrf WORD<0-16></code>	Specifies a VRF instance by VRF name.
<code>vrfids WORD<0-512></code>	Specifies the ID of the VRF.
<code>{A.B.C.D.}</code>	Specifies the IPv4 MSDP address for a specific peer.

Basic MSDP Configuration Using EDM

This section provides procedures to configure basic MSDP using EDM. You can perform many tasks on the same EDM tab. For a quick look at field descriptions for that tab, see [Globals Field Descriptions](#) on page 3596. For additional tasks, see [MSDP Message Control using EDM](#) on page 3605

Configure the MSDP Originator ID

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted

(*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

About This Task

Configure the originator ID to set the RP address inside the SA message. The RP address must be a pre-configured CLIP interface on the global router or a VRF. The RP address is also the local IP address in all peer relations.

Note

Originator ID cannot be deleted if MSDP is enabled.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Globals** tab.
4. In the **RPAddress** box, type the IP address to use as the originator ID.
5. Select **Apply**.

Enable MSDP

Before You Begin

- You must configure the originator ID before you enable MSDP.
- To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

About This Task

Enable or disable MSDP globally on the switch to permit further configuration to take place.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Globals** tab.
4. Select **Enabled** to enable MSDP.
5. Select **Apply**.

What to Do Next

[Create an MSDP Peer](#) on page 3596

Globals *Field Descriptions*

Use the data in the following table to use the **Globals** tab.

Name	Description
Enabled	Enables MSDP. The default is clear (disabled).
CacheLifetime	Configures the lifetime given to SA cache entries when created or refreshed.
NumSACacheEntries	Displays the total number of entries in the SA cache.
RPAddress	Specifies the IP address to use as the originator ID. If the address is not a system local address, the system rejects the configuration.
RouteMapName	Specifies the name of the optional route policy to create or modify. You do not need to create a route policy to use the redistribution filter. Note: To delete the route map name, clear the field and select Apply .
RedistributeFilterEnabled	Filters the (S,G,RP) entries provided by PIM to MSDP. The default is clear (disabled).
RedistruteFilterApply	Applies the changes made to the redistribute filter.
StatsClear	Clears MSDP statistics.

MSDP Peer Configuration using EDM

This section provides procedures to configure MSDP peer using EDM. You can perform many tasks on the same EDM tab. For a quick look at field descriptions for that tab, see [Peers Field Descriptions](#) on page 3601. For additional tasks, see [MSDP Message Control using EDM](#) on page 3605.

Create an MSDP Peer

Create an MSDP peer to establish a peer relationship between the local MSDP enabled router and a peer in another domain.

**Important**

Do not enable more than 20 active peers.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about

how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. Select **Insert**.
5. In **RemoteAddress**, type the IP address of the peer.
6. Select **Insert**.

Secure Control Messages

Configure Message Digest (MD) 5 authentication to secure control messages on the TCP connection between MSDP peers.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. In the row for the peer, double-click **Md5AuthEnabled**, and then select true.
5. In the row for the peer, double-click **Md5AuthPassword**, and then type a password.
6. Select **Apply**.

Configure the MSDP Peer SA Limit

Configure the SA limit to limit the number of SA messages from an MSDP peer. The router saves the SA messages in the local cache.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.

4. In the row for the peer, double-click **SALimit**, and then type a value.
5. Select **Apply**.

Configure a Peer Description

Configure a peer description to add a descriptive text to an MSDP peer, for easy identification of a peer.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. In the row for the peer, double-click **Description**, and then type a description for the peer.
5. Select **Apply**.

Configure the MSDP Peer Time-to-Live Threshold

Configure the time-to-live (TTL) threshold to limit which multicast data packets the router encapsulated in SA Messages forwarded to an MSDP peer. The TTL limits the number of hops a packet can take before the router drops the packet. The router sends out SA Messages with encapsulated data only if TTL equals or exceeds the value you configure. If the TTL is lower than the value you configure, the router drops the data packet and forwards the SA Message without the encapsulated data.

Note

MSDP transmits encapsulated multicast data packets inside forwarded MSDP messages. If the received SA is an encapsulated SA, then the switch parses the TTL value of the encapsulated data and compares it against the configured value. If the configured value is less than or equal to the parsed value, then the switch forwards the encapsulated data along with the SA, otherwise the switch forwards the SA alone by stripping the encapsulate data. By default, MSDP forwards encapsulated data along with the SA message. MSDP does not forward the encapsulated data to the local receivers.

When MSDP generates SA messages for SPB sources, the local cache miss data cannot be encapsulated into the SA messages that are sent to the peers. The switch supports forwarding SA messages with encapsulated data from sources to MSDP peers but not from MSDP peers to the receivers.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. In the row for the peer, double-click **Md5AuthEnabled**, and then select true.
5. In the row for the peer, double-click **DataTtl**, and then type a value.
6. Select **Apply**.

Configure the MSDP Peer Keepalive Messages

About This Task

Configure keepalive messages to adjust the interval in seconds at which an MSDP peer sends keep alive messages (default is 60 seconds) and the interval at which the MSDP peer waits for keep alive messages from other peers before it declares them down (default is 75 seconds).

Note

In a peer relationship, the keep alive interval configured on one peer must be at least 1 second less than the hold time configured on the other side of the peer relationship. This is not applicable when the hold time is set to 0 seconds.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. In the row for the peer, double-click **KeepAliveConfigured**, and then type the interval at which to send keepalive messages.
5. In the row for the peer, double-click **HoldTimeConfigured**, and then type the interval at which to wait for keepalive messages.
6. Select **Apply**.

Configure the MSDP Peer connect-retry Period

Configure the connect-retry period to specify the amount of time, in seconds, between connection attempts for peering sessions. The default is 30 seconds.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted

(*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. In the row for the peer, double-click **ConnectRetryInterval**, and then type the interval.
5. Select **Apply**.

Change the MSDP Peer Status

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

About This Task

Change the peer status to administratively enable or disable a configured peer. Disable the peer to stop the peering relationship.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. In the row for the peer, double-click **AdminEnabled**, and then select **true**.
5. Select **Apply**.

Clear the MSDP Peer Connection

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

About This Task

Clear the TCP connection to the specified MSDP peer, and reset all MSDP message counters.

The default is disabled (false).

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. In the row for the peer, double-click **ClearPeer**, and then select **true**.
5. Select **Apply**.

Delete an MSDP Peer

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. Select a row from the peer to delete.
5. Select **Delete**.
6. Select **Yes**.

View Peer Information

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.

Peers Field Descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
RemoteAddress	Shows the IP address of the remote MSDP peer.
State	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.

Name	Description
AdminEnabled	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
ClearPeer	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
ConnectRetryInterval	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
HoldTimeConfigured	The default value is 75 seconds.
KeepAliveConfigured	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
DataTtl	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
InSAFilterEnabled	Activates the inbound SA filter for the peer.
InSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
OutSAFilterEnabled	Activates the outbound SA filter for the peer.
OutSAFilterRouteMapName	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
Description	Specifies the text description, up to 255 characters, for the peer.
SALimit	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.

Name	Description
Md5AuthEnabled	Activates MD5 authentication on the TCP connection between peers. The default is false.
Md5AuthPassword	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
RemotePort	Shows the remote port for the TCP connection between the MSDP peers.
LocalPort	Shows the local port for the TCP connection between the MSDP peers.
OperEnabled	Shows the operational status of the peer.
RPFFailures	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAs	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAs	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSARRequests	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSARRequests	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InSAResponses	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutSAResponses	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
InControlMessages	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutControlMessages	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
OutDataPackets	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
FsmEstablishedTransitions	Shows the total number of times the BGP transitioned to the established state.
FsmEstablishedTime	Shows the time when the peer transitioned to the established state.
InMessageTime	Shows the time when the last MSDP message was received from the peer.
ConnectionAttempts	Shows the number of times the state machine has transitioned from inactive to connecting.
DiscontinuityTime	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
AsNumber	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.

Name	Description
TooShortMessages	Shows the number of short messages received from this peer.
InBadMessages	Shows the number of bad MSDP messages received from this peer.
InKeepAliveMessages	Shows the number of keepalive messages received from this peer.
OutKeepAliveMessages	Shows the number of keepalive messages transmitted to this peer.
SAsLearnedFromThisPeer	Shows the total number of SAs learned from this peer.
SAsAdvertisedToThisPeer	Shows the total number of SAs advertised from this peer.
UpOrDownTime	Shows the duration a peer has been up or down.
ConnAndStatsClearedTime	Shows the duration of connection and statistics cleared.

MSDP Message Control using EDM

This section provides procedures to configure MSDP message control using EDM.

Filter PIM Routes

Configure MSDP global filter for which the SA local cache are distributed to all MSDP peers. All SA local cache entries generate SA messages.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Globals** tab.
4. Select **RedistributeFilterEnabled**.
5. Type the name of the route policy in **RouteMapName**.
6. Select **RedistributeFilterApply** to apply the changes to the redistribute filter.

You do not need to apply the changes in the following situations:

- You create the redistribute filter without a route policy.
- You disable the redistribute filter.
- You remove a route policy from the redistribute filter.

7. Select **Apply**.

Filter SA Messages

Filter SA messages to determine which SA messages to accept from a peer and which SA messages to send to a peer. By default, no inbound or outbound filter exists.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. In the row for the peer, double-click **InSAFilterEnabled**, and then select true.
5. In the row for the peer, double-click **InSAFilterRouteMapName**, and then type the route map name for the IN SA Filter of the peer.
6. In the row for the peer, double-click **OutSAFilterEnabled**, and then select true.
7. In the row for the peer, double-click **OutSAFilterRouteMapName**, and then type the route map name for the OUT SA Filter of the peer.
8. Select **Apply**.

Configure the MSDP Mesh Groups

Configure mesh groups to reduce SA flooding. A mesh group does not forward SA messages to other group members in the same mesh group. The originator, which is also a mesh group member, forwards SA messages to all group members. Create MSDP mesh groups from a group of meshed MSDP speakers from a domain. Do not create MSDP peerings between Controllers within the same SPB domain.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Mesh Group** tab.
4. Select **Insert**.
5. In **Name**, type a name for the mesh group.

6. In **PeerAddress**, type the IP address of the peer to add the mesh group.
7. Select **Insert**.

Mesh Group Field Descriptions

Use the data in the following table to use the **Mesh Group** tab.

Name	Description
Name	Specifies the mesh group ID; the name of the mesh group from 1-64 characters.
PeerAddress	Specifies the IP address of the MSDP router that is the peer.

Clear the MSDP SA Cache

Clear the SA cache to clear the SA entries the router learns from all the peers or a specific peer.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **SA-Cache** tab.
4. Select **Clear SA-Cache**.

SA-Cache Field Descriptions

Use the data in the following table to use the **SA-Cache** tab.

Name	Description
GroupAddr	Shows the group IP address of the SA cache entry.
SourceAddr	Shows the source IP address of the SA cache entry.
OriginRP	Shows the RP address of the SA cache entry.
PeerLearnedFrom	Shows the peer from which this SA cache entry was accepted.
RPFPeer	Shows the peer from which an SA message corresponding to the cache entry is accepted.

Name	Description
InSAs	Discontinuities in the value of this counter can occur at reinitialization of the management system.
InDataPackets	Shows the number of MSDP encapsulated data packets received that are relevant to this cache entry.
UpTime	Shows the time since this entry was first placed in the SA cache.
ExpiryTime	Shows the time remaining before this entry expires from the SA cache.

MSDP Verification using EDM

This section provides procedures to verify MSDP using EDM. You can perform many tasks on the same EDM tab. For a quick look at field descriptions for that tab, see [SA-Cache-Records Field Descriptions](#) on page 3609.

View the Local SA Cache

View the local SA cache to display the (S, G) state the router learns from local Protocol Independent Multicast - Sparse Mode (PIM-SM) entries.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **SA-Cache-Records** tab.

View the Foreign SA Cache

View the foreign SA cache to display the (S, G) state the router learns from SA messages.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **SA-Cache-Records** tab.

SA-Cache-Records Field Descriptions

Use the data in the following table to use the **SA-Cache-Records** tab.

Name	Description
TypeInformation	Shows the SA cache type. The SA cache type can be local or foreign cache.
GroupAddr	Shows the group IP address of the SA cache entry.
SourceAddr	Shows the source IP address of the SA cache entry.
OriginRP	Shows the RP address of the SA cache entry.
OriginatorAsNumber	Shows the AS number of the originator.
RouteType	Shows the type of route used for Reverse Path Forwarding checking. The value can be rip (1), ospf (2), static (3), bgp (4), isis(5) or none (6).

Controller Configuration

This section provides procedures to configure the Controller using Command Line Interface (CLI) and Enterprise Device Manager (EDM).

The Controller functionality is configured at the global (switch-wide) level.

Controller Configuration using CLI

This section provides procedures to configure controller using the command line interface (CLI).

Enable the Controller Globally

Procedure

1. Enter IS-IS Router Configuration mode:
`enable`
`configure terminal`
`router isis`
2. Enable the Controller globally:
`spbm <1-100> multicast spb-pim-gw controller enable`

Variable Definitions

The following table defines parameters for the **spb** command.

Variable	Value
<1-100>	Specifies the IS-IS SPBM instance-id to create the SPBM instance.
<i>controller enable</i>	Enables the SPB-PIM Gateway Controller.

Display the Controller Admin Status

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the Controller Status:

```
show isis spbm
```

Example

Note

The SPB-PIM-GW column displays either Controller, Gateway, or Controller/Gateway if the Controller and or Gateway functionality is configured.

```
Switch:1>show isis spbm

Configure a Static Foreign Source on the Global Router

About This Task

Configure a static foreign source on the global router. Configuration is done at the Controller. Statically configure foreign sources, such as streams in a Source Specific Multicast (SSM) group range that are not advertised by the foreign network through MSDP. Non-SSM range group multicast address streams are advertised by MSDP and do not need to be statically configured.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure a static foreign source:

```
ip spb-pim-gw foreign-source {A.B.C.D} group {A.B.C.D}
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip spb-pim-gw foreign-source 10.0.0.1 group 240.0.0.1
```

Variable Definitions

The following table defines parameters for the **ip spb-pim-gw** command.

Variable	Value
<i>foreign-source</i> {A.B.C.D}	Specifies the multicast foreign source IP address.
<i>group</i> {A.B.C.D}	Specifies the group IP address.

Configure a Static Foreign Source on a VRF

About This Task

Configure a static foreign source on a VRF; configuration is done at the Controller.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

Note

You cannot use the derived name for the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF to enter this mode.

2. Configure a static foreign source:

```
ip spb-pim-gw foreign-source {A.B.C.D} group {A.B.C.D}
```

Example

In the following example, vrf-10 is configured with vrf id 10.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf vrf-10
Switch:1(router-vrf)#ip spb-pim-gw foreign-source 10.0.0.1 group 240.0.0.1
```

Variable Definitions

The following table defines parameters for the **ip spb-pim-gw** command.

Variable	Value
<i>foreign-source</i> {A.B.C.D}	Specifies the multicast foreign source IP address.
<i>group</i> {A.B.C.D}	Specifies the group IP address.

Display Foreign Sources

About This Task

Use the following procedure to display the foreign sources learned from MSDP or statically configured at the Controller.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the foreign source information:

```
show ip spb-pim-gw foreign-source [all] [controller | gateway] [vrf
WORD<0-16>] [vrfs WORD<0-512>] [source {A.B.C.D}] [group {A.B.C.D}]
[static | msdp] [spb-node-as-mac]
```

Example

Note

The command **show ip spb-pim-gw**, which specifies the parameter *controller*, the OWNER column displays the RP address of the MSDP peer from which the foreign source was learned. If the *gateway* parameter is specified, then the OWNER column displays MSDP rather than the actual RP address.

```
Switch:1>show ip spb-pim-gw foreign-source controller
=====
SPB-PIM-GW Controller Foreign Source
=====
SOURCE    GROUP    SPB-PIM-GW    VRF    OWNER
-----
10.0.0.1  240.0.0.1  beeb-1        GlobalRouter  47.17.0.1
10.0.0.2  240.0.0.2  beeb-1        GlobalRouter  static
10.0.0.3  240.0.0.3  -             GlobalRouter  47.17.0.2
=====
```

Display the foreign sources from a specific VRF:

```
Switch:1>show ip spb-pim-gw foreign-source controller vrf green
=====
SPB-PIM-GW Controller Foreign Source
=====
SOURCE    GROUP    SPB-PIM-GW    VRF    OWNER
-----
10.0.0.1  240.0.0.1  beeb-1        green    47.17.0.1
10.0.0.2  240.0.0.2  beeb-1        green    static
10.0.0.3  240.0.0.3  -             green    47.17.0.2
=====
```

Display all the foreign sources at the Controller with the Gateway in the SPB-PIM-GW shown as a mac address rather than a nickname:

```
Switch:1>show ip spb-pim-gw foreign-source controller vrf green spb-node-as-mac
=====
SPB-PIM-GW Controller Foreign Source
=====
SOURCE    GROUP    SPB-PIM-GW    VRF    OWNER
-----
10.0.0.1  240.0.0.1  00:0b:eb:00:00:a1  green    47.17.0.1
10.0.0.2  240.0.0.2  00:0b:eb:00:00:a1  green    static
10.0.0.3  240.0.0.3  -             green    47.17.0.2
=====
```

Variable Definitions

The following table defines parameters for the **show ip spb-pim-gw foreign source** command.

Variable	Value
<i>all</i>	Displays information for all the VRF IDs from the Controller and Gateway foreign source database.
<i>controller</i>	Displays information from the Controller foreign source database. Only displays information on nodes configured as Controller.
<i>gateway</i>	Displays information from the Gateway foreign source database. Only displays information on nodes configured as Gateway.
<i>vrf WORD<0-16></i>	Displays information from the Controller foreign source database for a specific VRF name.
<i>vrfids WORD<0-512></i>	Displays information from the Controller foreign source database for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.
<i>source {A.B.C.D}</i>	Displays information for the specific source IP address from the Controller foreign source database.
<i>group {A.B.C.D}</i>	Displays information for the specific multicast group IP address from the Controller foreign source database.
<i>static</i>	Displays information from the Controller foreign source database that is configured statically.
<i>msdp</i>	Displays information from the Controller foreign source database that is learned through MSDP.
<i>spb-node-as-mac</i>	Displays the MAC address for the assigned SPB-PIM Gateway.

Display Multicast over Fabric Connect Sources

About This Task

Use the following procedure to display all the SPB Multicast over Fabric Connect sources distributed to MSDP. This procedure is only valid on a Controller node.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB source information:

```
show ip spb-pim-gw spbmc-source [vrf WORD<1-32>] [vrfrids WORD<0-512>]
[source {A.B.C.D}] [group {A.B.C.D}] [originator WORD<1-32>] [spb-
node-as-mac]
```

Example

```
Switch:1>show ip spb-pim-gw spbmc-source
```

```
=====
```

```
SPB-PIM-GW SPB Source
```

```
=====
```

SOURCE	GROUP	VRF	ORIGINATOR
10.0.0.1	240.0.0.1	GlobalRouter	bcb-1
10.0.0.2	240.0.0.2	GlobalRouter	bcb-2
10.0.0.3	240.0.0.3	GlobalRouter	bcb-2

```
=====
```

Display the SPB Multicast over Fabric Connect from a specific VRF:

```
Switch:1>show ip spb-pim-gw spbmc-source vrf green
```

```
=====
```

```
SPB-PIM-GW Foreign Source
```

```
=====
```

SOURCE	GROUP	SPB-PIM-GW	VRF	OWNER	CONTROLLER
10.0.0.1	240.0.0.1	beb-1	green	47.17.0.1	bcb-2
10.0.0.2	240.0.0.2	beb-1	green	static	bcb-2
10.0.0.3	240.0.0.3	-	green	47.17.0.2	bcb-2

```
=====
```

Display all the SPB Multicast over Fabric Connect sources advertised to MSDP with the originator value shown as a MAC address rather than a host name:

```
Switch:1>show ip spb-pim-gw spbmc-source vrf green spb-node-as-mac
```

```
=====
```

```
SPB-PIM-GW SPB Source
```

```

10.0.0.3	240.0.0.3	green	00:0b:cb:00:00:c2

```
=====
```

Variable Definitions

The following table defines parameters for the **show ip spb-pim-gw spbmc-source** command.

Variable	Value
<code>vrf WORD<1-32></code>	Displays SPB originated sources for a specific VRF.
<code>vrfids WORD<0-512></code>	Displays SPB originated sources for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.
<code>source {A.B.C.D}</code>	Displays information for a specific source IP address from SPB originated sources database.
<code>group {A.B.C.D}</code>	Displays information for a specific multicast group IP address from SPB originated sources database.
<code>originator WORD<0-32></code>	Displays information for a specific originator host name from SPB originated sources database.
<code>spb-node-as-mac</code>	Displays the originator of SPB originated sources as a MAC address rather than a nickname.

Controller Configuration using EDM

This section provides procedures to configure controller using EDM.

Enable the Controller

About This Task

Enable the Controller globally.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. Select the **SPBM** tab.
4. In the row for the ID, double-click **McastSpbPimGwControllerEnable**, and then select **true**.
5. Select **Apply**.

Display the Controller and Gateway Admin Status

About This Task

Use the following procedure to display the admin status of the Controller and Gateway.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. Select the **SPBM** tab.

Display Active Controller and Gateway Nodes

About This Task

Use the following procedure to display the active Controllers and Gateways in the SPBM domain.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **SPB-PIM-GW**.
3. Select the **Node** tab.

Node Field Descriptions

Use the data in the following table to use the **Node** tab.

Name	Description
MacAddress	Shows the MAC address of the active node.
HostName	Shows the host name of the active node.
RoleType	Shows the role of the active node: either gateway, controller, or both.

Configure a Static Foreign Source

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

About This Task

Configure a static foreign source on the global router or VRF. Configuration is done at the Controller.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **SPB-PIM-GW**.
3. Select the **Controller-Foreign-Source** tab.
4. Select **Insert**.

5. In **SourceAddress**, type the multicast foreign source IP address.
6. In **GroupAddress**, type the group IP address.
7. Select **Insert**.

Controller-Foreign-Source Field Descriptions

Use the data in the following table to use the **Controller-Foreign-Source** tab.

Name	Description
SourceAddress	Specifies the source IP address from a foreign multicast domain.
GroupAddress	Specifies the multicast group IP address associated with the foreign source.
GatewaySysId	Displays the system ID of the node selected as the Gateway for this foreign source. GatewaySysId field will have a valid value if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is 0.
GatewayHostName	Displays the host name of the node selected as the Gateway for this foreign source. GatewayHostName field will have valid values if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is NULL.
Type	Displays the owner type for this source.
Owner	Displays the IP address of the MSDP peer if the foreign source is MSDP.

Display Foreign Sources for the Controller

About This Task

Use the following procedure to display the foreign sources learned from MSDP or statically configured at the Controller.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **SPB-PIM-GW**.
3. Select the **Controller-Foreign-Source** tab.

Controller-Foreign-Source Field Descriptions

Use the data in the following table to use the **Controller-Foreign-Source** tab.

Name	Description
SourceAddress	Specifies the source IP address from a foreign multicast domain.
GroupAddress	Specifies the multicast group IP address associated with the foreign source.

Name	Description
GatewaySysId	Displays the system ID of the node selected as the Gateway for this foreign source. GatewaySysId field will have a valid value if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is 0.
GatewayHostName	Displays the host name of the node selected as the Gateway for this foreign source. GatewayHostName field will have valid values if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is NULL.
Type	Displays the owner type for this source.
Owner	Displays the IP address of the MSDP peer if the foreign source is MSDP.

Display Multicast over Fabric Connect Sources

About This Task

Use the following procedure to display all the SPB Multicast over Fabric Connect sources distributed to MSDP.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **SPB-PIM-GW**.
3. Select the **spbm-source** tab.

Spbmc-Source Field Descriptions

Use the data in the following table to use the **Spbmc-Source** tab.

Name	Description
SourceAddress	Displays the source IP address from SPBM multicast domain.
GroupAddress	Displays the multicast group IP address associated with the SPBM source.
OriginatorSysId	Displays the system ID of the node from which the source originates.
OriginatorHostName	Displays the host name of the node from which the source originates.

Gateway Configuration

This section provides procedures to configure the Gateway using Command Line Interface (CLI) and Enterprise Device Manager (EDM).

The Gateway functionality is configured at the global (switch-wide) level. SPB-PIM Gateway Interfaces are configured at the interface level. For more information on SPB-PIM Gateway Interfaces configuration, see [SPB-PIM Gateway Interface Configuration](#) on page 3626.

Gateway Configuration using CLI

This section provides procedures to configure gateway using the command line interface (CLI).

Enable the Gateway

About This Task

Enable the Gateway at the global (switch-wide) level.

Procedure

- 1. Enter IS-IS Router Configuration mode:
enable

configure terminal

router isis
- 2. Enable the Gateway globally:
spbm <1-100> multicast spb-pim-gw gateway enable

Variable Definitions

The following table defines parameters for the **spb** command.

Variable	Value
<1-100>	Specifies the IS-IS SPBM instance-id to create the SPBM instance.
gateway enable	Enables the SPB-PIM Gateway.

Display the Gateway Admin Status

Procedure

- 1. To enter User EXEC mode, log on to the switch.
- 2. Display the Gateway admin status:
show isis spbm

Example

```
Switch:1>show isis spbm

Display Foreign Sources Information

About This Task

Use the following procedure to display the Gateway foreign sources database. If executed on a Gateway node, it displays the foreign sources assigned to the Gateway by the Controller. Foreign sources are originally learned from MSDP or statically configured on the Controller.

Procedure

- 1. To enter User EXEC mode, log on to the switch.

2. Display the foreign sources information:

```
show ip spb-pim-gw foreign-source [all] [controller | gateway] [vrf
WORD<0-16>] [vrfsids WORD<0-512>] [source {A.B.C.D}] [group {A.B.C.D}]
[from-controller <0x00:0x00:0x00:0x00:0x00:0x00> | preferred][static |
msdp] [spb-node-as-mac]
```

Example

```
Switch:1>show ip spb-pim-gw foreign-source gateway
=====
SPB-PIM-GW Gateway Foreign Source
=====
```

SOURCE	GROUP	SPB-PIM-GW	VRF	PORT	VLAN	CONTROLLER	OWNER
10.0.0.1	240.0.0.1	beb-2	GlobalRouter	1/1	200	bcb-2	msdp
10.0.0.2	240.0.0.2	beb-2	GlobalRouter	1/1	200	bcb-2	static
10.0.0.3	240.0.0.3	beb-2	GlobalRouter	-	-	bcb-2	msdp

```
=====
```

Note

The SPB-PIM-GW column displays the node that is selected as the Gateway for the particular source or group stream. The OWNER column displays either msdp or static depending on how the source was originally learned at the assigning Controller. The PORT and VLAN columns represent the port or VLAN toward the source.

Display the foreign sources from a specific VRF:

```
Switch:1>show ip spb-pim-gw foreign-source gateway vrf green
=====
SPB-PIM-GW Gateway Foreign Source
=====
```

SOURCE	GROUP	SPB-PIM-GW	VRF	PORT	VLAN	CONTROLLER	OWNER
10.0.0.1	240.0.0.1	beb-2	green	1/1	200	bcb-2	msdp
10.0.0.2	240.0.0.2	beb-2	green	1/1	200	bcb-2	static
10.0.0.3	240.0.0.3	beb-2	green	-	-	bcb-2	msdp

```
=====
```

Display all the foreign sources available at the Gateway with SPB-PIM-GW and Controller as mac:

```
Switch:1>show ip spb-pim-gw foreign-source gateway vrf green spb-node-as-mac
=====
SPB-PIM-GW Gateway Foreign Source
=====
```

SOURCE	GROUP	SPB-PIM-GW	VRF	PORT	VLAN	CONTROLLER	OWNER
10.0.0.1	240.0.0.1	00:0b:eb:00:00:a2	green	1/1	200	00:0b:cb:00:00:c2	msdp
10.0.0.2	240.0.0.2	00:0b:eb:00:00:a2	green	1/1	200	00:0b:cb:00:00:c2	static
10.0.0.3	240.0.0.3	00:0b:eb:00:00:a2	green	-	-	00:0b:cb:00:00:c2	msdp

```
=====
```

Display all the foreign sources available at the Gateway which are statically configured at the Controller:

```
Switch:1>show ip spb-pim-gw foreign-source gateway vrf green static
```

```
=====
SPB-PIM-GW Gateway Foreign Source
=====
```

SOURCE	GROUP	SPB-PIM-GW	VRF	PORT	VLAN	CONTROLLER	OWNER
10.0.0.2	240.0.0.2	beb-2	green	1/1	200	bcb-2	static

```
=====
```

Variable Definitions

The following table defines parameters for the **show ip spb-pim-gw foreign source** command.

Variable	Value
<i>all</i>	Displays information for all the VRF IDs from the Controller and Gateway foreign source database.
<i>controller</i>	Displays information from the Controller foreign source database. Only displays information on nodes configured as Controller.
<i>gateway</i>	Displays information from the Gateway foreign source database. Only displays information on nodes configured as Gateway.
<i>vrf WORD<0-16></i>	Displays information from the Gateway foreign source database for a specific VRF name.
<i>vrfids WORD<0-512></i>	Displays information from the Gateway foreign source database for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.
<i>source {A.B.C.D}</i>	Displays information for the specific source IP address from the Gateway foreign source database.
<i>group {A.B.C.D}</i>	Displays information for the specific multicast group IP address from the Gateway foreign source database.
<i>from-controller</i> <i>0x00:0x00:0x00:0x00:0x00:0x00</i>	Displays information filtering on a specific Controllers assignments, where the Controller is specified as a mac address.

Variable	Value
<i>from-controller preferred</i>	Displays information from Gateway source database filtering on a preferred Controller or chosen by the Gateway.
<i>static</i>	Displays information from the Gateway foreign source database that is configured statically at the assigning Controller.
<i>msdp</i>	Displays information from the Gateway foreign source database that is learned through MSDP.
<i>spb-node-as-mac</i>	Displays the MAC address for the assigned PIM-GW.

Gateway Configuration using EDM

This section provides procedures to configure gateway using EDM.

Enable the Gateway Globally

About This Task

Use this procedure to enable the Gateway at the global (switch-wide) level.

Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. Select the **SPBM** tab.
4. In the row for the ID, double-click **McastSpbPimGwGatewayEnable**, and then select **true**.
5. Select **Apply**

Display Foreign Sources for the Gateway

About This Task

Use the following procedure to display the Gateway foreign source database. Foreign sources are originally learned from MSDP or statically configured on the Controller.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **SPB-PIM-GW**.
3. Select the **Gateway-Foreign-Source** tab.

Gateway-Foreign-Source Field Descriptions

Use the data in the following table to use the **Gateway-Foreign-Source** tab.

Name	Description
SourceAddress	Displays the foreign source IP address.
GroupAddress	Displays the multicast group IP address associated with the foreign source.
ControllerSysId	Displays the system ID of the controller node that sends this foreign source.
ControllerHostName	Displays the host name of the controller node that sends this foreign source.
GatewaySysId	Displays the system ID of the node selected as the gateway for this foreign source.
GatewayHostName	Displays the host name of the node selected as the gateway for this foreign source.
InVid	Displays the VLAN ID of the SPB-PIM Gateway interface through which the source of this source is reachable.
InPort	Displays the physical interface through which the source of this source is reachable.
OwnerType	Displays if the owner is MSDP or static.

SPB-PIM Gateway Interface Configuration

This section provides procedures to configure the SPB-PIM Gateway interface using the Command Line Interface (CLI) and Enterprise Device Manager (EDM).

The SPB-PIM Gateway interface is either a VLAN or a Brouter port interface. An SPB-PIM Gateway interface is configured separately from the global (switch-wide) Gateway functionality. The global Gateway configuration does not affect the administrative or the operational state of the SPB-PIM Gateway interfaces which function independently. However, the Gateway node functionality works in conjunction with the Gateway Interface functionality. Configure SPB-PIM Gateway on an interface that connects to a router in a foreign PIM or SPB multicast domain.

SPB-PIM Gateway Interface Configuration using CLI

This section provides procedures to configure SPB-PIM gateway interface using the command line interface (CLI).

*Enable SPB-PIM Gateway on a VLAN***Procedure**

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Enable SPB-PIM Gateway on a VLAN:

```
ip spb-pim-gw enable
```

**Note**

SPB-PIM Gateway cannot be enabled under the following circumstances:

- If the IP interface does not exist on the VLAN. An IP Address must first be configured on the VLAN.
- If the **spbm_config_mode** boot flag is set to false.
- If the VLAN is configured with a circuitless IP.
- If the interface is a management VLAN.
- If **ip igmp snooping** is enabled.
- If the spb-multicast is enabled on the VLAN.
- If the VLAN has SMLT ports.
- If the VLAN has an i-sid configured.
- If the VLAN is a vIST VLAN.

*Enable SPB-PIM Gateway on a Brouter Port Interface***Procedure**

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...][slot/all][all]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable SPB-PIM Gateway on a brouter port:

```
ip spb-pim-gw enable
```

**Note**

SPB-PIM Gateway cannot be enabled under the following circumstances:

- If the IP interface is not configured using the **brouter** command
- If the IP interface does not exist on the brouter port
- If the **spbm_config_mode** boot flag is set to false
- If **ip igmp snooping** is enabled
- If the spb-multicast is enabled on the brouter port
- If the brouter port is part of an SMLT or vIST Vlan
- If the brouter port has an i-sid configured

Configure the SPB-PIM Gateway VLAN Optional Parameters

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Configure the SPB-PIM Gateway VLAN HELLO interval:

```
ip spb-pim-gw hello-interval <0-18724>
```

3. Configure the SPB-PIM Gateway VLAN JOIN PRUNE interval:

```
ip spb-pim-gw ip join-prune-interval <1-18724>
```

Variable Definitions

The following table defines parameters for the **ip spb-pim-gw** command.

Variable	Value
<i>hello-interval</i> <0-18724>	Specifies the HELLO interval in seconds. The default value is 30 seconds.
<i>join-prune-interval</i> <1-18724>	Specifies the JOIN PRUNE interval in seconds. The default value is 60 seconds.

*Configure the SPB-PIM Gateway Brouter Port Optional Parameters***Procedure**

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...][slot/all][all]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the SPB-PIM Gateway brouter port HELLO interval:

```
ip spb-pim-gw hello-interval <0-18724>
```

3. Configure the SPB-PIM Gateway brouter port JOIN PRUNE interval:

```
ip spb-pim-gw join-prune-interval <1-18724>
```

Variable Definitions

The following table defines parameters for the **ip spb-pim-gw** command.

Variable	Value
<i>hello-interval</i> <0-18724>	Specifies the HELLO interval in seconds. The default value is 30 seconds.
<i>join-prune-interval</i> <1-18724>	Specifies the JOIN PRUNE interval in seconds. The default value is 60 seconds.

*Display the SPB-PIM Gateway Interface Default Values***About This Task**

Use the following procedure to display the default values used for the SPB-PIM Gateway interface HELLO and JOIN PRUNE intervals unless specifically configured on the individual interface.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway interface default values:

```
show ip spb-pim-gw
```

Example

```
Switch:1>show ip spb-pim-gw
```

```
=====
                        Spb-pim-gw General Group
=====
Hello Interval           : 30
Join-Prune Interval      : 60
```

Display the SPB-PIM Gateway Brouter Port Information

About This Task

Use the following procedure to display the SPB-PIM Gateway brouter port information. This procedure displays the administrative (configured) state of the interface as well as the operational state, and the HELLO and JOIN PRUNE intervals. An interface can be administratively ENABLED but operationally DISABLED if, for example, mvpn is not enabled on the VRF, or `spbm <spbm-instance> multicast enable` is not configured.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. Display the SPB-PIM Gateway interface information:

```
show ip spb-pim-gw interface [gigabitethernet{slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]] [vrf WORD<1-16>] [vrfrids WORD<0-512>]
```

Example

Switch:1#show ip spb-pim-gw interface gigabitethernet 1/2

Port Ip Spb-pim-gw				
ORT-NUM	OPSTATE	ADMINSTATE	HELLOINT	JPINT
1/2	Disabled	Enabled	30	60

Variable Definitions

The following table defines parameters for the `show ip spb-pim-gw interface gigabit` command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...] [slot/all] [all]}</code>	<p>Identifies the slot and port in one of the following formats:</p> <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>
<code>vrf WORD<1-16></code>	Displays SPB-PIM Gateway interface information for a specific VRF.
<code>vrfids WORD<0-512></code>	<p>Displays SPB-PIM Gateway interface information for a range of VRF IDs.</p> <p>Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.</p>

Display the SPB-PIM Gateway VLAN Information

Use the following procedure to display the SPB-PIM Gateway VLAN interface information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway VLAN interface information:

```
show ip spb-pim-gw interface [vlan]
```

Example

```
Switch:1>show ip spb-pim-gw interface
=====
Spb-pim-gw Interface - GlobalRouter
=====
```

IF	ADDR	MASK	JPINT	HELLOINT	OPSTATE	ADMINSTATE
Vlan50	50.1.1.1	255.255.255.0	60	30	Disabled	Enabled
Vlan123	123.1.1.1	255.255.255.0	60	30	Disabled	Disabled
Vlan142	142.1.1.1	255.255.255.0	60	30	Enabled	Enabled
Vlan400	100.1.1.2	255.255.255.0	60	30	Disabled	Disabled

```
Total spb-pim-gw Interfaces Displayed 4/4
```

Variable Definitions

The following table defines parameters for the **show ip spb-pim-gw interface** command.

Variable	Value
vlan-id	The VLAN ID of an interface to display.

Display the SPB-PIM Gateway Neighbor Information

Use the following procedure to display the SPB-PIM Gateway interfaces neighbor information.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway neighbor information:

```
show ip spb-pim-gw neighbor [vrf WORD<1-16>] [vrfrids WORD<0-512>]
```

Example

```
Switch:1>show ip spb-pim-gw neighbor

=====
                        Spb-pim-gw Neighbor - GlobalRouter
=====
INTERFACE ADDRESS      UPTIME                EXPIRE
Vlan26      26.1.1.10          0 day(s), 00:11:36    0 day(s), 00:01:28

Total SPB-PIM-GW Neighbors Displayed = 1/1
=====
```

Variable Definitions

The following table defines parameters for the **show ip spb-pim-gw neighbor** command.

Variable	Value
vrf WORD<1-16>	Displays the SPB-PIM Gateway interface neighbor information for a specific VRF name.
vrfrids WORD<0-512>	Displays the SPB-PIM Gateway interface neighbor information for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.

*Display the SPB-PIM Gateway Multicast Routes***About This Task**

Use the following procedure to display the SPB-PIM Gateway multicast routes. This procedure displays upstream (toward the foreign source) information and downstream (receiver) information on the SPB-PIM Gateway interfaces. This command does not display the following information:

- Upstream information for streams ingressing on spb-multicast interfaces
- Upstream information for streams ingressing from a remote SPB node
- Receivers in spb-multicast interfaces

Use the **show isis spbm ip-multicast-route** command to display information on all multicast streams and the multicast streams ingress interfaces and egress interfaces.

Use the **show ip spb-pim-gw mroute** command to display information only on SPB-PIM Gateway interfaces.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway multicast routes:

```
show ip spb-pim-rw mroute [source {A.B.C.D}] [group {A.B.C.D}] [vrf
WORD<1-16>] [vrfids WORD<0-512>]
```

Example**Note**

The **show ip spb-pim-gw mroute** command displays active upstream information and active downstream information per (*,g) and (s,g) per port, which includes *G Join or Prune pending state, SG join or prune pending state, and SG Rpt PRUNE or PRUNE pending state.. There can be upstream information for a specific SG and no downstream, and vice-versa, as the information in the command **show ip spb-pim-gw mroute** reflects only information known on the SPB-PIM Gateway interfaces. For example, there might be downstream receivers on a SPB-PIM Gateway Interface for a particular stream which is ingressing on an spb-multicast interface; thus, the upstream information will not be displayed using this command.

```
Switch:1>show ip spb-pim-gw mroute
=====

Variable Definitions

The following table defines parameters for the **show ip spb-pim-gw mroute** command.

Variable	Value
<i>vrf</i> <i>WORD</i> <1-16>	Displays the SPB-PIM Gateway mroute information for a specific VRF name.
<i>vrfids</i> <i>WORD</i> <0-512>	Displays the SPB-PIM Gateway interface mroute information for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.
<i>group</i> { <i>A.B.C.D</i> }	Displays mroute information specific to a group IP address.
<i>source</i> { <i>A.B.C.D</i> }	Displays mroute information specific to a source IP address.

Display the IP mroute Routes

About This Task

Use the following procedure to display multicast routes ingressing on either SPB-PIM Gateway interfaces or SPB multicast interfaces.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the multicast routes:

```
show ip mroute mroute
```

Example

Note

The UPSTREAM_NBR field is populated only if the stream was learned across a spb-pim-gw interface, and the upstream neighbor is the PIM neighbor IP address toward the source. The PROT field equals spb-pim-gw when the stream's source is learned on a VLAN configured for protocol spb-pim-gw. If the stream's source is learned on a VLAN configured for spb-multicast, the PROT field equals spb.

```
Switch:1>show ip mroute route
```

```

Total 4
```

Variable Definitions

The following table defines parameters for the **show ip mroute route** command.

Variable	Value
<code>vrf WORD<1-32></code>	Displays the multicast mroute information for a specific VRF name.
<code>vrfids WORD<0-512></code>	Displays the multicast mroute information for a range of VRF IDs. Note: Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.

SPB-PIM Gateway Interface Configuration using EDM

This section provides procedures to configure SPB-PIM gateway interface using EDM.

*Enable SPB-PIM Gateway on a VLAN***Procedure**

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Advanced** tab.
4. In the row for the VLANs, double-click **SpbPimGatewayMulticast**, and then select **enable**.
5. Select **Apply**.

*Enable SPB-PIM Gateway on a Brouter Port Interface***About This Task**

Enable SPB-PIM Gateway on a Brouter port.

Procedure

1. In the Device Physical View tab, select the port you need to configure.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **IP**.
4. Select the **SPB-PIM-GW** tab.
5. Select **Enable**.
6. Select **Apply**.

SPB-PIM-GW Field Descriptions

Use the data in the following table to use the **SPB-PIM-GW** tab.

Name	Description
Enable	Enables SPB-PIM Gateway on the interface. The default is disabled.
OperState	Displays the current operational state of this SPB-PIM Gateway interface.
Address	Displays the primary IP address of this router on this SPB-PIM Gateway interface.
AddressMask	Displays the primary IP address mask of this router on this SPB-PIM Gateway interface.
HelloInterval	Configures the PIM HELLO transmission interval.
JoinPruneInterval	Configures the PIM JOIN PRUNE transmission interval.

*Configure SPB-PIM Gateway VLAN Optional Parameters***About This Task**

Configure the SPB-PIM Gateway interface parameters on a VLAN.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select a row for the VLAN, and then select **IP**.
5. Select the **SPB-PIM-GW** tab.
6. In **HelloInterval**, type the hello transmission interval.
7. In **JoinPruneInterval**, type the join prune transmission interval.
8. Select **Apply**.

SPB-PIM-GW Field Descriptions

Use the data in the following table to use the **SPB-PIM-GW** tab.

Name	Description
OperState	Displays the current operational state of this SPB-PIM Gateway interface.
Address	Displays the primary IP address of this router on this SPB-PIM Gateway interface.
AddressMask	Displays the primary IP address mask of this router on this SPB-PIM Gateway interface.
HelloInterval	Configures the PIM HELLO transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global SPB-PIM Gateway HELLO interval setting. Setting the HELLO Interval to 0 causes the neighbors to never expire its neighborship with this local SPB-PIM Gateway interface.
JoinPruneInterval	Configures the PIM JOIN PRUNE transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global level JOIN PRUNE transmission interval setting.

Configure the SPB-PIM Gateway Optional Parameters

About This Task

Perform this procedure to configure the optional parameters on existing SPB-PIM Gateway interfaces.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **SPB-PIM-GW**.
3. Select the **Interfaces** tab.
4. In the row for the interfaces, double-click **HelloInterval**, and then type the hello interval in seconds.

5. In the row for the interfaces, double-click **JoinPruneInterval**, and then type the join prune interval in seconds.
6. Select **Apply**.

Interfaces Field Descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
IfIndex	Shows the interface index.
OperState	Shows the operational state of the interface.
AddressType	Shows the address type of the interface.
Address	Shows the address assigned to the interface.
AddressMask	Shows the address mask associated with the interface address.
HelloInterval	Configures the PIM HELLO transmission interval. The default is 30 seconds.
JoinPruneInterval	Configures the PIM JOIN PRUNE transmission interval. The default is 60 seconds.

Display the SPB-PIM Gateway Interface Default Values

About This Task

Use the following procedure to display the default values used for the SPB-PIM Gateway interface HELLO and JOIN PRUNE intervals unless specifically configured on the individual interface.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **SPB-PIM-GW**.
3. Select the **Globals** tab.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
HelloInterval	Displays the PIM HELLO transmission interval.
JoinPruneInterval	Displays the PIM JOIN PRUNE transmission interval.

*Display the SPB-PIM Gateway Router Port Information***About This Task**

Use the following procedure to display the SPB-PIM Gateway interface information.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **SPB-PIM-GW**.
3. Select the **Interfaces** tab.

Interfaces Field Descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
IfIndex	Shows the interface index.
OperState	Shows the operational state of the interface.
AddressType	Shows the address type of the interface.
Address	Shows the address assigned to the interface.
AddressMask	Shows the address mask associated with the interface address.
HelloInterval	Configures the PIM HELLO transmission interval. The default is 30 seconds.
JoinPruneInterval	Configures the PIM JOIN PRUNE transmission interval. The default is 60 seconds.

*Display the SPB-PIM Gateway VLAN Information***About This Task**

Use the following procedure to display the SPB-PIM Gateway VLAN information.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select a row for the VLAN, and then select **IP**.
5. Select the **SPB-PIM-GW** tab.

SPB-PIM-GW Field Descriptions

Use the data in the following table to use the **SPB-PIM-GW** tab.

Name	Description
OperState	Displays the current operational state of this SPB-PIM Gateway interface.
Address	Displays the primary IP address of this router on this SPB-PIM Gateway interface.
AddressMask	Displays the primary IP address mask of this router on this SPB-PIM Gateway interface.
HelloInterval	Configures the PIM HELLO transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global SPB-PIM Gateway HELLO interval setting. Setting the HELLO Interval to 0 causes the neighbors to never expire its neighborship with this local SPB-PIM Gateway interface.
JoinPruneInterval	Configures the PIM JOIN PRUNE transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global level JOIN PRUNE transmission interval setting.

*Display the SPB-PIM Gateway Neighbor Information***About This Task**

Use the following procedure to display the SPB-PIM Gateway neighbor information

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **SPB-PIM-GW**.
3. Select the **Neighbors** tab.

Neighbors Field Descriptions

Use the data in the following table to use the **Neighbors** tab.

Name	Description
IfIndex	Specifies the IfIndex for the interface which is used to reach this SPB-PIM Gateway neighbor.
AddressType	Specifies the address type of this SPB-PIM Gateway neighbor.
Address	Specifies the primary IP address of this router on this SPB-PIM Gateway neighbor.

Name	Description
UpTime	Specifies the time since this SPB-PIM Gateway neighbor last became a neighbor of the local router.
ExpiryTime	Specifies the minimum time remaining before this SPB-PIM Gateway neighbor times out.

Display the IP mroute Routes

About This Task

Use the following procedure to display multicast routes ingressing on either SPB-PIM Gateway interfaces or SPB multicast interfaces.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **Multicast**.
3. Select the **Routes** tab.

Routes Field Descriptions

Use the data in the following table to use the **Routes** tab.

Name	Description
Group	Displays the IP multicast group address for this entry that contains multicast routing information.
Source	Displays the network address that, when combined with the corresponding route SourceMask value, identifies the source that contains multicast routing information.
SourceMask	Displays the network mask that, when combined with the corresponding route Source value, identifies the multicast source.
UpstreamNeighbor	Shows the address of the upstream neighbor from which the IP datagrams from these sources are received. The address is 0.0.0.0 if the network is local.
Interface	Displays the interface, slot and portnumber, or VLAN ID where IP datagrams sent by these multicast sources to this multicast address are received.

Name	Description
ExpiryTime	Displays the amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging.
Protocol	Displays the protocol as one of the following: <ul style="list-style-type: none"> • other(1): none of the following • local(2): manually configured • netmgmt(3): configured by a network management protocol • pimSparseMode(8): PIM-SMv2 • igmpOnly(10) • pimSsmMode(11) • spb (12) • spbpimgw(13)

SPB-PIM Gateway Interface Deployment Scenarios

This section provides information about different deployment scenarios for SPB-PIM gateway interface.

SPB-PIM Gateway Base Case Deployment Scenario

There are several different customer topology scenarios for the SPB-PIM Gateway (SPB-PIM GW) feature deployment . One of these scenarios, shown in [Figure 229](#) on page 3643, is fully described here, along with configuration details, and display information.

The deployment scenario described here has two domains:

- SPB domain
- PIM domain

The PIM network has 5 PIM routers:

- RP
- PIM-A1
- PIM-A2
- PIM-B
- PIM-C

The RP router is the PIM-SM rendezvous point. PIM router PIM-B has receiver host R2 attached to it and source S1 is connected to PIM router PIM-C.

The SPB domain has the following components:

- SPB-PIM Gateway Controller node
- Two Gateway nodes, BEB-A1 and BEB-A2
- BEB-A1 is connected to the PIM network through a SPB-PIM Gateway interface to the PIM router PIM-A1

- BEB-A2 is connected to the PIM network through a SPB-PIM Gateway interface to the PIM router PIM-A2

**Note**

PIM-A1 and PIM-A2 routers attached to the BEBs SPB-PIM Gateway interface have standard PIM configured on their side of the interface.

- The SPB cloud has a BEB-B to which the source S2 is connected
- The SPB cloud has a BEB-C to which a receiver R1 is connected

**Note**

You can place the controller anywhere in the SPB cloud. The controller can be in the boundary or the core. Anywhere there is a connection into the PIM network from the SPB network, there must be a Gateway node(s) and Gateway interface(s).

Figure 229: SPB-PIM Gateway base case configuration

The SPB-PIM Gateway nodes BEB-A1 and BEB-A2 from the SPB cloud are connected to the PIM network. The connection is established by SPB-PIM Gateway interface connections to PIM routers PIM-A1 and PIM-A2. A MSDP connection is established between the RP from the PIM domain and the SPB-PIM Gateway Controller from the SPB domain. A MSDP connection is established to exchange the multicast source information between the RP and the SPB Controller. Unicast routing or reachability is setup before establishing the MSDP connection between the RP and the Gateway controller. The Unicast setup is not shown in the previous figure.

*SPB-PIM Gateway Base Case Configuration Example***Before You Begin**

- The Shortest Path Bridging (SPB) infrastructure must be configured and setup in the SPB domain (not shown in this example)
- Protocol Independent Multicast (PIM) infrastructure must be configured and setup in the PIM domain (not shown in this example)
- Unicast routing table must be setup in the PIM domain to ensure reachability of the Multicast Source Discovery Protocol (MSDP) peer and source S2 from the SPB network
- Unicast routing table must be setup in the SPB domain to ensure reachability of the MSDP peer and source S1 from the PIM network

Example

Node: Gateway controller

Configure ISIS and SPBM:

```
Switch:1#configure terminal
Switch:1(config)#spbm
Switch:1(config)#router isis
Switch:1(config-isis)#system-id 0026.0026.0026
Switch:1(config-isis)#manual-area 01.0202.0303.04
Switch:1(config-isis)#spbm 1
Switch:1(config-isis)#spbm 1 nick-name 0.00.26
Switch:1(config-isis)#spbm 1 b-vid 10,20 primary 10
Switch:1(config-isis)#vlan create 10 name bvlan1 type spbm-bvlan
Switch:1(config)#vlan create 20 name bvlan2 type spbm-bvlan
Switch:1(config)#router isis enable
```

NNI Configuration:

```
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config-if)#isis
Switch:1(config-if)#isis spbm 1
Switch:1(config-if)#isis enable
Switch:1(config-if)#no shutdown
```

- Enable IPSC to setup Unicast route table. This setup ensures reachability of Rendezvous Point (RP) in the PIM network
- Create a loopback interface 2.0.2.2 to enable IPSC and MSDP originator-id
- Enable Multicast over Fabric Connect
- Configure static route and direct route redistribution
- Apply the static route and direct route redistribution

**Note**

The following configuration uses a static route to reach the RP.

```
Switch:1(config)#interface loopback 1
Switch:1(config-if)#ip address 2.0.2.2/32
Switch:1(config)#router isis
Switch:1(config-isis)#ip-source-address 2.0.2.2
Switch:1(config-isis)#spbm 1 ip enable
Switch:1(config-isis)#spbm 1 multicast enable
Switch:1(config-isis)#
```

```
Switch:1(config-isis)#redistribute static
Switch:1(config-isis)#redistribute static enable
Switch:1(config-isis)#redistribute direct
Switch:1(config-isis)#redistribute direct enable
Switch:1(config-isis)#
Switch:1(config-isis)#end
Switch:1#isis apply redistribute static
Switch:1#isis apply redistribute direct
```

MSDP Configuration:

Create an instance for the MSDP session. This IP interface is used for establishing an MSDP session with an RP in the PIM network. The source IP address used for the MSDP session must not be the newly created IP interface. The originator-id specifically configured for MSDP is used as the source IP address to establish the MSDP session. The originator-id is also used by the RP in the source active (SA) messages sent to the MSDP peers. The CLIP configured earlier is used as the originator-id.

```
Switch:1#configure terminal
Switch:1(config)#vlan create 2100 type port-mstprstp 0
Switch:1(config)#vlan members add 2100 1/3 portmember
Switch:1(config)#interface vlan 2100
Switch:1(config-if)#ip address 21.0.0.1/24
Switch:1(config-if)#exit

Switch:1(config)#ip msdp originator-id 2.0.2.2
Switch:1(config)#ip msdp enable
Switch:1(config)#ip msdp peer 21.0.0.2
Switch:1(config)#ip msdp peer 21.0.0.2 enable
```

SPB-PIM Gateway Controller configuration:

Enable SPB-PIM Gateway Controller

```
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 multicast spb-pim-gw controller enable
```

Node: BEB-A1 (SPB-PIM Gateway)

Configure ISIS and SPBM:

```
Switch:1#configure terminal
Switch:1(config)#spbm
Switch:1(config)#
Switch:1(config)#router isis
Switch:1(config-isis)#system-id 0015.0015.0015
Switch:1(config-isis)#manual-area 01.0202.0303.04
Switch:1(config-isis)#spbm 1
Switch:1(config-isis)#spbm 1 nick-name 0.00.15
Switch:1(config-isis)#spbm 1 b-vid 10,20 primary 10
Switch:1(config-isis)#
Switch:1(config-isis)#vlan create 10 name bvlan1 type spbm-bvlan
Switch:1(config)#vlan create 20 name bvlan2 type spbm-bvlan
Switch:1(config)#router isis enable
```

NNI Configuration:

```
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config-if)#isis
Switch:1(config-if)#isis spbm 1
Switch:1(config-if)#isis enable
Switch:1(config-if)#no shutdown
```

- Enable IP Shortcuts (IPSC) to setup Unicast route table. This setup ensures reachability of sources in the PIM network
- Create a loopback interface 1.0.1.1 to enable IPSC
- Enable Multicast over Fabric Connect
- Configure static route and direct route redistribution
- Apply the static route and direct route redistribution

**Note**

The following configuration uses a static route to reach sources in the PIM network.

```
Switch:1(config)#interface loopback 1
Switch:1(config-if)#ip address 1.0.1.1/32
Switch:1(config-if)#router isis
Switch:1(config-isis)#ip-source-address 1.0.1.1
Switch:1(config-isis)#spbm 1 ip enable
Switch:1(config-isis)#spbm 1 multicast enable
Switch:1(config-isis)#
Switch:1(config-if)#router isis
Switch:1(config-isis)#redistribute static
Switch:1(config-isis)#redistribute static enable
Switch:1(config-isis)#redistribute direct
Switch:1(config-isis)#redistribute direct enable
Switch:1(config-isis)#
Switch:1(config-isis)#end
Switch:1#isis apply redistribute static
Switch:1#isis apply redistribute direct
```

SPB-PIM Gateway interface configuration:

- Create an IP interface
- Enable SPB-PIM Gateway on the IP interface

**Note**

For the following sample configuration, the SPB-PIM Gateway interface is on VLAN 2000 with IP address 20.0.0.1

```
Switch:1#configure terminal
Switch:1(config)#vlan create 2000 type port-mstprstp 0
Switch:1(config)#vlan members add 2000 1/1 portmember
Switch:1(config)#interface vlan 2000
Switch:1(config-if)#ip address 20.0.0.1/24
Switch:1(config-if)#ip spb-pim-gw enable
```

Enable SPB-PIM Gateway node functionality:

```
Switch:1(config-if)#router isis
Switch:1(config-isis)#spbm 1 multicast spb-pim-gw gateway enable
```

Similar configuration is done for the SPB-PIM Gateway node BEB-A2.

PIM Sparse Mode (PIM-SM) is enabled at the PIM routers PIM-A1 and PIM-A2 on the interfaces connecting SPB-PIM Gateway nodes BEB-A1 and BEB-A2. The SPB-PIM Gateway nodes BEB-A1 and BEB-A2 see the PIM routers PIM-A1 and PIM-A2 as PIM neighbors. The PIM routers PIM-A1 and PIM-A2 see the SPB-PIM Gateway nodes as PIM neighbors. The SPB-PIM Gateway nodes BEB-A1 and BEB-A2 have IP reachability to the PIM source S1 with PIM neighbors as the next hop.

The route to reach source S1 is distributed to the Gateway controller through IPSC. The Gateway controller uses this route information to select only one of the Gateways to which the source S1 will be assigned for a specific group. The Gateway node is the only node that can draw the source S1 stream into the SPB network on behalf of SPB receivers, by sending an SG Join across a Gateway Interface to the nexthop toward the source S1. This ensures that the data is not duplicated from multiple ingress interfaces from the PIM network. Other Gateway nodes that are not assigned as the Gateway to the source S1 will not establish multicast path.

When S1 from the PIM network sends traffic to G1, RP from the PIM network sends MSDP SA message for (S1,G1) to the Gateway Controller. If the Gateway Controller selects BEB-A1 as the Gateway for the foreign source S1 and group G1, the Gateway Controller assigns BEB-A1 to (S1,G1). The Gateway Controller then sends the Gateway assignment information to all the nodes. When BEB-A1 receives the assignment information, it sees that it is assigned as the Gateway to (S1,G1). The BEB-A1 then checks if the next hop to reach S1 is a valid PIM neighbor. If the next hop is a valid PIM neighbor, the BEB-A1 interacts with Multicast over Fabric Connect and advertises a sender TLV for the (S1,G1) into the SPB cloud. The BEB-A2 also receives the Gateway assignment information but silently saves the received Gateway assignment information since it is not the selected Gateway. If the interested receiver R1 is found at BEB-C, as part of Multicast over Fabric Connect processing, BEB-C sends receiver TLV for the group G1 to the advertising node, BEB-A1. Upon receiving this receiver TLV, BEB-A1 establishes the multicast stream through its Gateway interface which is upstream towards the PIM neighbor, by sending out a PIM SG Join message toward the source S1. This causes PIM-A1 node to forward multicast data from S1 to BEB-A1.

When the local source S2 (local to the SPB network) at BEB-B in the SPB network sends traffic to group G1, BEB-B advertises a sender TLV for (S1,G1). The controller sees this sender TLV and sends an MSDP SA message for (S2,G1) to the RP in the PIM network.

**Note**

The controller does not send SA messages for (S1,G1) to the PIM network since S1 is a foreign source.

When PIM network receiver R2 is interested in group G1, the PIM router PIM-B sends PIM a (*,G) Join message to the RP. RP in turn sends (S2,G1) Join towards the source S2. The unicast IP reachability to source S2 which is setup in the RP is used for sending (S2,G1) joins hop-by-hop towards the source. From the RP point of view, the next hop to reach the source S2 is one of the PIM routers PIM-A1 or PIM-A2 (depending on the unicast route table next hop address). For this example, the next hop is PIM-A1. The RP sends the (S2,G1) Join message towards the PIM-A1. PIM-A1 then sends an SG Join

to BEB-A1. Upon receiving the Join for (S2,G1) from the PIM network, BEB-A1 sends a receiver TLV into the SPB network to the S2 advertising router BEB-B. When the BEB-B receives the receiver TLV, the BEB-B establishes the multicast stream from source S2 toward the receiver.

Source Specific Multicast

PIM-SSM does not use a Rendezvous Point to centralize the receivers and sources. A PIM-SSM router which has a receiver for a group multicast address in the SSM address range joins directly to a source for that group by sending an SG join toward the source, not a *G join toward the RP for the group. Because of this, MSDP is not required in order for the PIM Network to learn of an SSM range stream in the SPB network. However, in order for the SPB network to know where a PIM SSM source resides, it must statically configure S1,SSM-G1 at the controllers. In this way, a Gateway can be chosen for the stream, even in the absence of MSDP.

The following figure shows a non-MSDP SSM environment where stream PIM network source S1, for an SSM group, must be statically configured at the SPB Controllers:

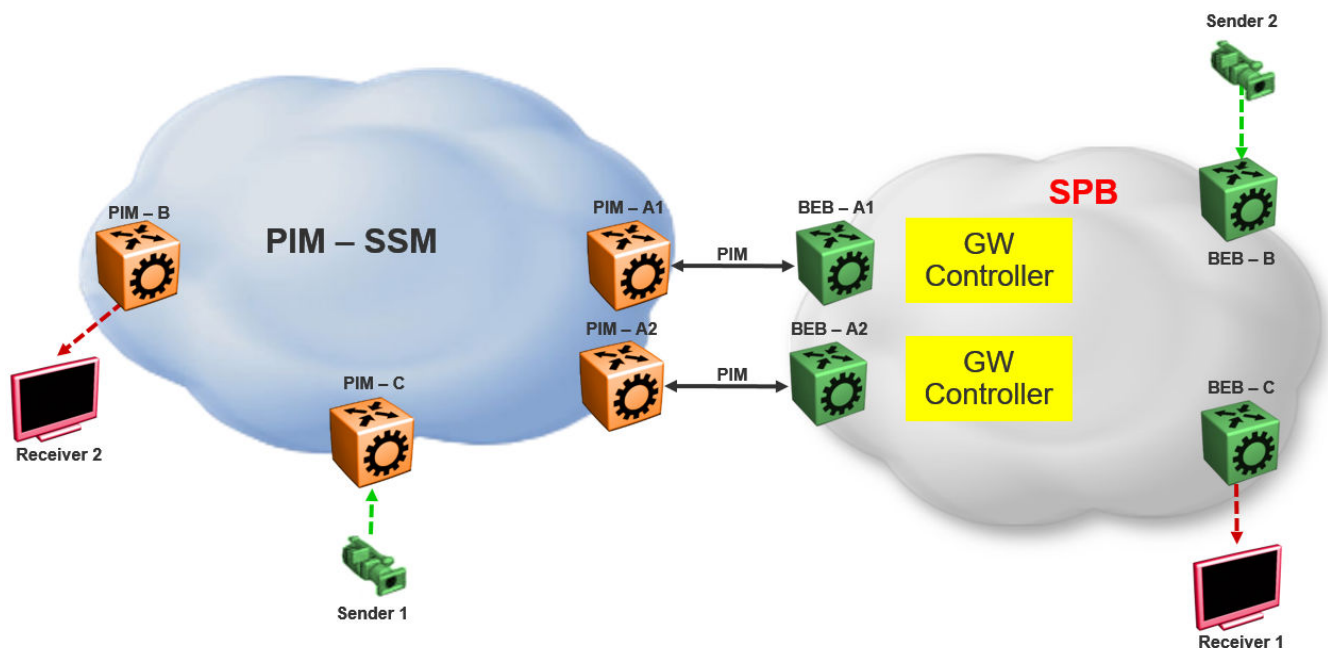

Figure 230: Static configuration of SSM groups in Controllers

Peer Mesh Group

The following figure shows the Peer Mesh Group configuration:

Note

Controllers within a single SPB network must never peer with each other, regardless of whether mesh groups exist. In addition, both Controllers must have the same peerings configured with other networks RPs.

Figure 231: Peer Mesh Group

MSDP Peer Mesh Group Configuration Example

Example

Configure MSDP:

If the MSDP speakers are fully meshed, the speakers can be configured into a mesh group in order to prevent excessive SA forwarding and RPF checks. To configure a mesh group, specify a name along with the MSDP peer. For example, on router RP1, configure a mesh group which includes RP2, RP3, and both Gateway controllers. On RP2, configure the same mesh group with members RP1, RP3, and both Gateway controllers. On RP3, configure the same mesh group with members RP1, RP2, and both Gateway controllers. On each Gateway controller, configure the same mesh group with members RP1, RP2, and RP3, but never with another Gateway controller in the same SPB domain.

```
Switch:1(config)#ip msdp originator-id 2.0.2.2
Switch:1(config)#ip msdp enable
Switch:1(config)#ip msdp peer 21.0.0.2 enable
Switch:1(config)#ip msdp mesh-group mgTest 21.0.0.2
```

Multi Domain

The following figure shows a multi domain scenario, where two PIM domains and one SPB domain share multicast streams:

Figure 232: Multi domain configuration

SPB Domain Interconnect

The following figure shows the SPB domain interconnect configuration. In this scenario, two SPB domains are connected by PIM Gateway interfaces, and there is no traditional PIM Network involved. The Controllers from each SPB domain form MSDP adjacencies the Controllers in the other domain (but not within the same domain) other to share their multicast sources. The SPB-PIM Gateway nodes see the other SPB-PIM Gateway nodes as PIM neighbors on the SPB-PIM Gateway interfaces.

TACACS+ Fundamentals

The switch supports the TACACS+ client. TACACS+ is a remote authentication protocol that provides centralized validation of users who attempt to gain access to a router or Network Access Server (NAS).

The TACACS+ feature is a client and server-based protocol that allows the switch to accept a user name and password and send a query to a TACACS+ authentication server, sometimes called a TACACS+ daemon. The TACACS+ server allows access or denies access based on the response by the client.

The TACACS+ feature facilitates the following services:

- Login authentication and authorization for CLI access through Secure Shell (SSH), Telnet, or serial port.
- Login authentication for web access through EDM.
- Command authorization for CLI through SSH, Telnet, or serial port.
- Accounting of CLI through SSH, Telnet, and serial port.

The following figure displays the basic layout of the switch and the TACACS+ server for a remote user connection.

Figure 234: Switch and TACACS+ server

The TACACS+ feature uses Transmission Control Protocol (TCP) for its transport to ensure reliable delivery of packets. TACACS+ provides security by encrypting all traffic between the switch, which acts as the Network Access Server, and the TACACS+ server.

TACACS+ is a newer version of TACACS and provides separate authentication, authorization, and accounting (AAA) services. TACACS+ does not support earlier versions of TACACS.

TACACS+ Operation

The switch acts as an NAS to provide a connection to a single user, to a network, subnetwork or interconnected networks. The switch acts as a gateway to guard access to the TACACS+ server and network. Encryption relies on a secret key that is known to the client and the TACACS+ server.

Similar to the Remote Access Dial-In User Services (RADIUS) protocol, TACACS+ provides the ability to centrally manage the users who want to access a remote device. TACACS+ provides management of remote and local users who try to access a device through:

- Secure Shell (SSHv2)
- Telnet
- serial port
- web management

A TACACS+ daemon, which typically runs on a UNIX or Windows NT workstation, maintains the TACACS+ authentication, authorization, and accounting services.

You configure users in the TACACS+ server. If you enable authentication, authorization, and accounting services, the following occurs:

- During the logon process, the TACACS+ client initiates the TACACS+ authentication session with the TACACS+ server.
- After successful authentication the TACACS+ client initiates the TACACS+ authorization session with the TACACS+ server. This is transparent to the user. The switch receives the user access level after a successful TACACS+ authorization. The TACACS+ server authorizes every command the user issues if TACACS+ command authorization is enabled for that user access level.
- After successful authorization, if you enable TACACS+ accounting, the TACACS+ client sends accounting information to the TACACS+ server.

A TACACS+ session establishes with the server in one of two ways:

- Multi-connection mode (also known as per-session): For every authentication, authorization, and accounting (AAA) request the switch establishes a session with the TACACS+ server, and then after the request finishes, the session is torn down. Multi-connection mode is the default mode.
- Single-connection mode: The first AAA request establishes the session, which is only torn down if TACACS+ is disabled or due to inactivity.

TACACS+ Architecture

You can connect the TACACS+ server to the switch:

- In-band through one of the data ports.
- Out-of-band through the management port.

Connect the TACACS+ server through a local interface. Management PCs can reside on an out-of-band management Ethernet port, or on the corporate network. Place the TACACS+ server on the corporate network so you can route it to the switch.

Before you configure the switch, you must configure at least one TACACS+ server and a key.

The TACACS+ server and the switch must have the same:

- Encryption key
- Connection mode (single connection or per-session connection. Per-session connection is the same as multi-connection mode.)
- TCP port number

You can configure a secondary TACACS+ server for backup authentication. You specify the primary authentication server when you configure the switch.

Authentication, Authorization, and Accounting

A fundamental feature of TACACS+ is the separation of authentication, authorization, and accounting (AAA) services, which allows you to selectively implement one or more TACACS+ services.

TACACS+ Authentication

TACACS+ authentication provides control of authentication through login and password.

Authentication uses a database of users and passwords to determine:

- who a user is
- to grant or deny the user access to the NAS

Important

Prompts for log on and password occur prior to the authentication process. If TACACS+ fails because no valid servers exist, the device uses the user name and password from the local database. If TACACS+ or the local database returns an access denied packet, the authentication process stops. The device attempts no other authentication methods.

The following figure illustrates the authentication process after the user attempts to make a connection to the switch.

Figure 235: Authentication process

TACACS+ Authorization

The transition from TACACS+ authentication to the authorization phase is transparent to the user. After successful completion of the authentication session, an authorization

session starts with the authenticated user name. The authorization session provides access level functionality.

Authorization cannot occur without authentication.

Authorization:

- determines what a user can do
- allows administrators fine-grained control over the capabilities of users during sessions

The following figure illustrates the authorization process after the user attempts to make a connection to the switch..

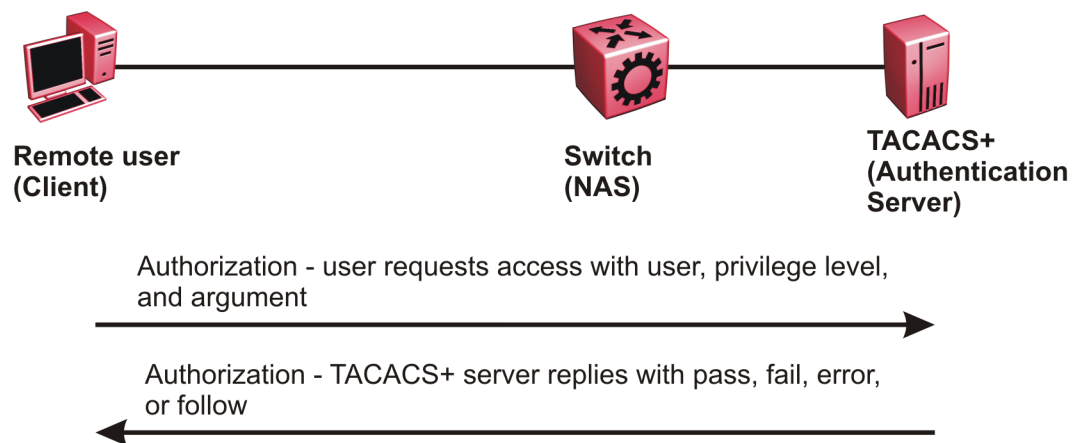

Figure 236: Authorization process

Authorization determines what a user can do. Authorization gives you the ability to limit network services to certain users and to limit the use of certain commands to certain users. The TACACS+ feature enhances the security by tightly policing the command execution for a particular user. After you enable command authorization, all commands, no matter the access level to which they belong, are sent to the TACACS+ server for authorization. Authorization cannot occur without first enabling authentication. You must configure command authorization globally and at individual access levels.

Two kinds of authorization requests exist:

1. Login authorization: Login authorization happens immediately after authentication and is transparent to the user. When the user logs on to the device, authorization provides the user access level. With log on, the device does not send a command to the TACACS+ server. You cannot configure login authorization.
2. Command authorization: When you configure command authorization for a particular level, all commands that you issue are sent to the TACACS+ server for authorization. The device can only issue the commands the TACACS+ server

authorizes. You need to configure command authorization globally and at individual access levels, which are visible to the users.

**Note**

You must verify that the switch can reach the TACACS+ server and that you configure TACACS+ properly before you enable command authorization.

If a user is TACACS+ authenticated and command authorization is enabled for that level, then if the switch cannot reach the TACACS+ server, the switch does not allow the user to issue any command that has privilege level command authorization enabled. In such a case, the user can only issue logout and exit commands.

If a user tries to log in and the TACACS+ server does not exist or is not reachable, then, as discussed before, a local database in the switch authenticates the user. The switch authorizes a locally authenticated user and a locally authenticated user is not eligible for TACACS+ command authorization.

After the switch requests authorization, the logon credentials are sent to the TACACS+ daemon for authorization. If logon authorization fails, the user receives a permission denied message.

If TACACS+ logon authorization succeeds, the switch uses information from the user profile, which exists in the local user database or on the TACACS+ server, to configure the session for the user.

After you enable TACACS+ command authorization all commands are visible to all users; however, the user can only issue those commands that the TACACS+ server configuration allows.

The switch cannot enforce command access level. The TACACS+ server returns an access level to the switch. The switch allows the user to access the switch according to the access level. The device grants the user access to a command only if the profile for the user allows the access level.

You preconfigure command authorization on the TACACS+ server. You specify a list of regular expressions that match command arguments, and you associate each command with an action to deny or permit.

All members in a group have the same authorization. If you place a user in a group, the daemon looks in the group for authorization parameters if it cannot find them in the user profile.

TACACS+ Accounting

TACACS+ accounting enables you to track the services users access and the amount of network resources users consume.

TACACS+ accounting allows you to track:

- what a user does
- when a user does certain actions

The accounting record includes the following information:

- User name
- Date
- Start/stop/elapsed time
- Access server IP address
- Reason

You can use accounting for an audit trail, to bill for connection time or resources used, or for network management. TACACS+ accounting provides information about user sessions using the following connection types: Telnet, SSH, and web-based management.

With separation of AAA, accounting can occur independently from authentication and authorization.

The following figure illustrates the accounting process after the user attempts to make a connection to the switch..

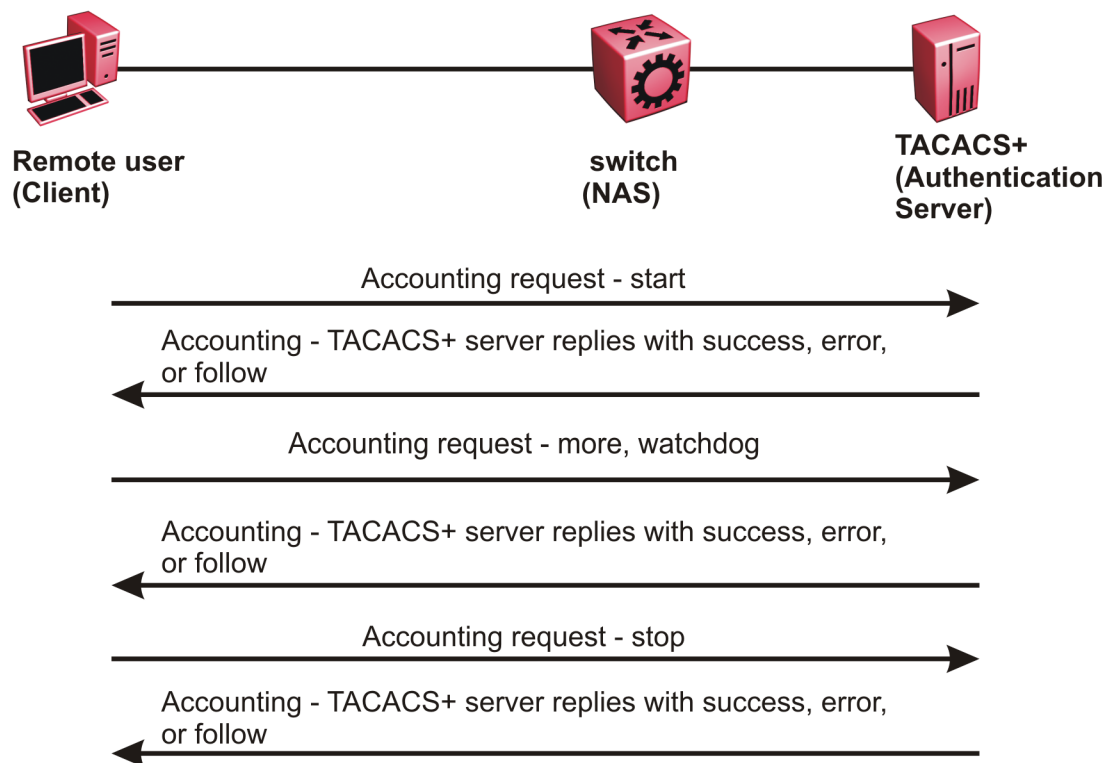

Figure 237: Accounting process

After you enable accounting, the switch reports user activity to the TACACS+ server in the form of accounting records. Each accounting record contains accounting attribute value (AV) pairs. AV pairs are strings of text in the form “attribute-value” sent between

the switch and a TACACS+ daemon as part of the TACACS+ protocol. The TACACS+ server stores the accounting records.

You cannot customize the set of events the switch monitors and logs with TACACS+ accounting. TACACS+ accounting logs the following events:

- User logon and logoff
- Logoff generated because of activity timeout
- Unauthorized command
- Telnet session closed (not logged off)

Privilege Level Changes at Runtime

You can change your privilege level at runtime with the **tacacs switch level** command.

You need to configure separate profiles in the TACACS+ server configuration file for the switch level. The switch supports only levels 1 to 6 and level 15. The switch uses the profile when you issue the command **tacacs switch level <1-15>**. As part of the profile, you specify a user name, level, and password. To preconfigure a dummy user for that level on the TACACS+ daemon, the format of the user name for the dummy user is **\$enab<n>\$**, where **<n>** is the privilege level to which you want to allow access.

The following is an example of a TACACS+ server profile, which you configure on the TACACS+ server:

```
user = $enab6$ {
member = level6
login = cleartext get-me-on-6
}
```

The following table maps user accounts to TACACS+ privilege level.

Switch access level	TACACS+ privilege level	Description
NONE	0	If the TACACS+ server returns an access level of 0, the user is denied access. You cannot log into the device if you have an access level of 0.
READ ONLY	1	Permits you to view only configuration and status information.
LAYER 1 READ WRITE	2	Permits you to view most of the switch configuration and status information and change physical port settings.

Switch access level	TACACS+ privilege level	Description
LAYER 2 READ WRITE	3	Permits you to view and change configuration and status information for Layer 2 (bridging and switching) functions.
LAYER 3 READ WRITE	4	Permits you to view and change configuration and status information for Layer 2 and Layer 3 (routing) functions.
READ WRITE	5	Permits you to view and change configuration and status information across the switch. This level does not allow you to change security and password settings.
READ WRITE ALL	6	Permits you to have all the rights of read-write access and the ability to change security settings, including command line interface (CLI) and web-based management user names and passwords, and the SNMP community strings.

Switch access level	TACACS+ privilege level	Description
NONE	7 to 14	If the TACACS+ server returns an access level of 7 to 14, the user is denied access. You cannot log into the device if you have an access level of 7 to 14.
READ WRITE ALL	15	Permits you to have all the rights of read-write access and the ability to change security settings, including command line interface (CLI) and web-based management user names and passwords, and the SNMP community strings. Note: Access level 15 is internally mapped to access level 6, which ensures consistency with other vendor implementations. The switch does not differentiate between an access level of 6 and an access level of 15.

Note

If you enable enhanced secure mode with the **boot config flags enhancedsecure-mode** command, you enable different access levels, along with stronger password complexity, length, and minimum change intervals. With enhanced secure mode enabled, the switch supports the following access levels for RADIUS authentication:

- Administrator
- Privilege
- Operator
- Auditor
- Security

The switch associates each user name with a certain role and appropriate authorization rights to view and configure commands. For more information, see [Enhanced Secure Mode](#) on page 266.

TACACS+ Command Authorization

After you enable TACACS+ authorization, the current privilege-level to command mapping on the switch is no longer relevant because the TACACS+ server has complete

responsibility for command authorization. TACACS+ authorization provides access to the system based on user name, not based on privilege level.

After you enable TACACS+ command authorization for a particular privilege level, and a user with that privilege level logs on, the user can access commands based on his user name.

TACACS+ Switch Level and TACACS+ Switch Back Commands

The user can only issue the **tacacs switch level** command after TACACS+ authenticates the user. Locally authenticated users, which means users authenticated only by the switch and not by the TACACS+ server, cannot use the **tacacs switch level** command.

Consider a user, called X, with a privilege level of 4, who uses the **tacacs switch level <1-15>** command to change the privilege level from 4 to 6.

If user X successfully changes the switch level to 6, the user name changes from X to "\$enab6\$", and the privilege level changes from 4 to 6. If TACACS+ command authorization is enabled for privilege level 6, then the TACACS+ server authorizes commands issued based on the rules defined for (dummy) user "\$enab6\$".

If TACACS+ command authorization is not enabled for privilege level 6, then the switch locally authorizes the user X based on the privilege level of the user.

The user can return to his previous privilege level using the **tacacs switch back** command. In the preceding scenario, if the user issues the **tacacs switch back** command, the user name changes for user X from "\$enab6\$" to X, and the privilege level changes from 6 to 4.

TACACS+ switch level supports up to eight levels, and TACACS+ switch level allows a user to switch level up to eight times from his original privilege level. The switch stores all of the previous privilege levels in the same order in which the user switches levels. After switching eight times, if the user tries to switch a level the ninth time, the following error message displays:

```
Only allowed to switch level 8 times!
```

The user can switch back to his previous privilege levels using the **tacacs switch back** command. The **tacacs switch back** command switches back in the reverse order in which you issued the **tacacs switch level** command. Consider a user who switched levels from 4 to 5, and then to 6. If the user used the **tacacs switch back** command, the user first moves from 6 to 5, and then using the **tacacs switch back** command again moves from 5 to 4.

Note

If you want to switch to a privilege level 'X' using **tacacs switch level <1-15>** command, you must create a user "\$enabX\$" on the TACACS+ server. X is the privilege level that you want to change.

TACACS+ Switch Level Functionality:

The following table explains TACACS+ switch level functionality.

User logs in with	TACACS+ server available	Result
TACACS+ authentication	Yes	The user can issue the tacacs switch level <1-15> command.
Local authentication	No	The user cannot issue the tacacs switch level <1-15> command.
Local authentication	Yes	Even if a TACACS+ server becomes reachable, the user remains locally authenticated and cannot issue the tacacs switch level <1-15> command.

TACACS+ Command Authorization Functionality:

The following table explains TACACS+ command authorization functionality.

User logs in with	Command authorization	Result
Local authentication		The switch authorizes the user locally.
TACACS+ authentication	Not enabled for the logged-in level.	The switch authorizes the user locally. If the server connection is lost, the switch authorizes the user locally.
TACACS+ authentication	Enabled for the logged-in level.	The TACACS+ server authorizes the user. If the server connection is lost, the user can only issue exit and logout commands.

**Note**

A user who configures TACACS+ is locally authenticated and authorized by the switch, so even after the user configures TACACS+, the switch continues to locally authorize the user.

TACACS+ and RADIUS Differences

TACACS+ and RADIUS are security protocols that you can use on network devices.

You can enable TACACS+ and RADIUS together. However, TACACS+ has a higher priority. If the TACACS+ server is not available the authentication is sent to RADIUS, if RADIUS is enabled. However, if TACACS+ authentication fails, then requests are not sent to RADIUS.

Following is a list of differences between TACACS+ and RADIUS.

TACACS+	RADIUS
Separates Authorization, Authentication and Accounting (AAA). As a result, you can selectively implement one or more TACACS+ services. With TACACS+ you can use different servers for each service.	Combines authentication and authorization.
Uses TCP. TCP is connection-oriented. TCP immediately indicates if a server crashes or is not running. TCP offers an acknowledgement that a request has been received.	Uses UDP. UDP is best-effort delivery. RADIUS uses re-transmit attempts and timeouts to make up for the support TCP has.
Encrypts the entire body of the packet, which includes the password and user name.	Encrypts only the password from the client to the server.
Used for administrator access. Usually used for administrator access to network devices.	Used for subscriber access. Usually used to authenticate remote users to a network.
Can control which access level of commands a user or group can access.	Cannot control which access level of commands can be used.

TACACS+ Feature Limitations

TACACS+ does not support the following features:

- Point-to-Point Protocol (PPP) authentication and accounting
- IPv6 for TACACS+
- S/KEY (One Time Password) authentication
- PAP/CHAP/MSCHAP authentication methods
- The FOLLOW response of a TACACS+ server, in which the AAA services are redirected to another server. The response is interpreted as an authentication failure.
- User capability to change passwords at runtime over the network. The system administrator must change user passwords locally, on the server.
- TACACS+ command authorization when the user accesses the switch through EDM and SNMP.
- Restriction of command authorization for a specific kind of access. After you enable command authorization, command authorization applies for Telnet, SSH, and serial-port access. You cannot restrict command authorization to just one kind of access.

If a user is TACACS+ authenticated and command authorization is enabled for that level, then if the switch cannot reach the TACACS+ server, the switch does not permit the user to execute any command that has privilege level command authorization enabled.

TACACS+ configuration using CLI

This section provides procedures to configure TACACS+ using the command line interface (CLI).

Enable TACACS+

Enable TACACS+ globally on the switch.

The switch supports the TACACS+ client. TACACS+ is a security application implemented as a client and server-based protocol that provides centralized validation of users who attempt to gain access to a router or network access server (the switch).

By default, TACACS+ is disabled.

Before You Begin

- You must have access to and you must configure a TACACS+ server before the TACACS+ features on your switch are available.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable TACACS+ globally:
`tacacs protocol enable`
3. Disable TACACS+ globally:
`no tacacs protocol enable`
`default tacacs protocol enable`

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs protocol enable
```

Add a TACACS+ Server

Add a primary and secondary TACACS+ server and specify the authentication process.

If you have a backup server configured, the AAA request goes to the backup server if the primary server is not available.

About This Task

The TACACS+ server and the switch must have the same:

- Encryption key
- Connection mode (single connection or per-session connection. Per-session connection is the same as multi-connection mode)
- TCP port number

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Add a primary TACACS+ server with an encryption key:

```
tacacs server host {A.B.C.D} key WORD<0-128>
```

3. (Optional) Configure the parameters for the primary TACACS+ server as required.

- a. (Optional) Specify a single connection to maintain a constant connection between the switch and the TACACS+ daemon:

```
tacacs server host {A.B.C.D} single-connection
```

Note

The TACACS+ daemon must also support this mode. If you do not configure this, the switch uses the default connection type, which is the per-session connection. Per-session is the same as multi-connection mode.

- b. (Optional) Specify the TCP port to use when the switch connects to the TACACS+ daemon:

```
tacacs server host {A.B.C.D} port <1-65535>
```

The default port is 49.

- c. (Optional) Specify the period of time (in seconds) the switch waits for a response from the TACACS+ daemon before it times out and shows an error:

```
tacacs server host {A.B.C.D} timeout <10-30>
```

4. Specify the IP address of the secondary TACACS+ server and specify an encryption key:

```
tacacs server secondary-host {A.B.C.D} key WORD<0-128>
```

5. (Optional) Configure the optional parameters on the secondary TACACS+ server as required.

- a. (Optional) Specify a single connection for the secondary TACACS+ server to maintain a constant connection between the switch and the TACACS+ daemon:

```
tacacs server secondary-host {A.B.C.D} single-connection
```

Note

The TACACS+ daemon must also support this mode. If you do not configure this, the switch uses the default connection type, which is the per-session connection. Per-session is the same as multi-connection mode.

- b. (Optional) Specify the TCP port to use when the switch connects to the TACACS+ daemon:

```
tacacs server secondary-host {A.B.C.D} port <1-65535>
```

- c. (Optional) Specify the period of time (in seconds) the switch waits for a response from the TACACS+ daemon before it times out and shows an error:

```
tacacs server secondary-host {A.B.C.D} timeout<10-30>
```
6. Display the status of the TACACS+ configuration:

```
show tacacs
```
7. (Optional) Delete a primary TACACS+ server:

```
no tacacs server host{A.B.C.D} [single-connection]
```
8. (Optional) Delete a backup TACACS+ server:

```
no tacacs server secondary-host{A.B.C.D} [single-connection]
```
9. (Optional) Configure a primary TACACS+ server or secondary TACACS+ server to the default settings:

```
default tacacs server {A.B.C.D} [port][single-connection][timeout]
```

Example

Configure the primary server with the IP address 192.0.2.1 and the encryption key 1dt4ly. Configure the secondary server with the IP address 198.51.100.2 with the same encryption key 1dt4ly. Display the configuration to ensure proper configuration.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs server host 192.0.2.1 key 1dt4ly
Switch:1(config)#tacacs server secondary-host 198.51.100.2 key 1dt4ly
Switch:1(config)#show tacacs
```

Global Status:

```

global enable : true

authentication enabled for : cli

accounting enabled for : none

authorization : disabled

User privilege levels set for command authorization : None

```

Server:

```

create :

```

Prio	Status	Key	Port	IP address	Timeout	Single	Source
SourceEnabled							
Primary	Conn	*****	49	192.0.2.1	10	false	0.0.0.0
false							
Backup	NotConn	*****	49	198.51.100.2	10	false	0.0.0.0
false							

```

Switch:1(config)#no tacacs server host 192.0.2.1
Switch:1(config)#no tacacs server secondary-host 198.51.100.2

```

Variable Definitions

The following table defines parameters for the **tacacs server host** and the **tacacs server secondary-host** commands.

Variable	Value
<i>{A.B.C.D}</i>	Specifies the IP address of the TACACS+ server you want to add. Only IPv4 addresses are valid.
<i>key WORD</i> <0-128>	Configures the authentication and encryption key for all TACACS+ communications between the device and the TACACS+ server. If the key length is zero, that indicates no encryption is used. You must configure the same encryption key for the TACACS+ server and the switch.
<i>port</i> <1-65535>	Configures the TCP port, on which the client establishes a connection to the server. A value of 0 indicates the system specified default value is used. The default is 49. You must configure the same TCP port for the TACACS+ server and the switch.
<i>single-connection</i>	Specifies if the TCP connection between the device and the TACACS+ server is a single connection. If you specify the single connection parameter, the connection between the switch and the TACACS+ daemon remains open, which is more efficient because it allows the daemon to handle a higher number of TACACS+ operations. The single-connection is torn down if TACACS+ is disabled due to inactivity. If you do not configure this, the switch uses the default connection type, which is the multi-connection. With the multi-connection, the connection opens and closes each time the switch and TACACS+ daemon communicate. Note: You must configure the same connection mode for the TACACS+ server and the switch. To enable single-connection, the TACACS+ daemon has to support this mode as well.
<i>timeout</i> <10-30>	Configures the maximum time, in seconds, to wait for this TACACS+ server to reply before it times out. The default value is 10 seconds.

Configure TACACS+ Authentication

Configure what application TACACS+ authenticates: CLI, web, or all.

TACACS+ authentication provides control of authentication through login and password.

By default, CLI authentication is enabled.

Before You Begin

- You must enable TACACS+ globally for TACACS+ authentication to function.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure TACACS+ authentication:

```
tacacs authentication <all/cli/web>
```
3. (Optional) Disable TACACS+ authentication:

```
no tacacs authentication <all/web>
```
4. (Optional) Configure TACACS+ authentication to the default settings (default is cli authentication enabled):

```
default tacacs authentication <all/cli/web>
```
5. Display the configuration:

```
show tacacs
```

Example

Configure TACACS+ to authenticate CLI and display the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs authentication cli
Switch:1(config)#show tacacs
Global Status:

    global enable : true

    authentication enabled for : cli

    accounting enabled for : none

Server:

    create :

Prio    Status  Key      Port  IP address  Timeout  SingleSource  Source  Enabled
Primary Conn    * 49    192.0.2.1    10    false        0.0.0.0 false
Backup  NotConn * 49    198.51.100.2 10    false        0.0.0.0 false
```

Variable Definitions

The following table defines parameters for the **tacacs authentication** command.

Variable	Value
<i>all</i>	Specifies TACACS+ authentication for all applications. By default, CLI authentication is enabled.
<i>cli</i>	Specifies TACACS+ authentication for command line connections. By default, CLI authentication is enabled.
<i>web</i>	Specifies TACACS+ authentication for web connections. By default, CLI authentication is enabled.

Configure TACACS+ Accounting

Determines for which applications TACACS+ collects accounting information. Use TACACS+ accounting to track the services that users access and the amount of network resources that users consume. If unassigned, TACACS+ does not perform the accounting function.

If enabled, TACACS+ accounting logs the following events:

- User log on and log off
- Log off generated because of activity timeout
- Unauthorized command
- Telnet session closed (not logged off)

If unassigned, TACACS+ does not perform the accounting function. No default value exists.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enable TACACS+ accounting:
`tacacs accounting enable cli`
3. (Optional) Disable TACACS+ accounting:
`no tacacs accounting cli`

`tacacs accounting disable [cli]`

Example

Enable TACACS+ accounting:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs accounting enable cli
```

Configure Command Authorization with TACACS+

Use this procedure to enable TACACS+ authorization for a particular privilege level. Use this option to limit the use of certain commands to certain users.

If command authorization fails, the following log message displays: Command <command> not authorized for user <username>.

By default, command authorization is disabled on the switch. The default for the command authorization level is none.

Before You Begin

- You must have access to and you must configure a TACACS+ server before the TACACS+ features on your switch are available. You must verify that the switch can reach the TACACS+ server and that you configure TACACS+ properly before you

enable command authorization. If a user is TACACS+ authenticated and command authorization is enabled for that level, then if the switch cannot reach the TACACS+ server, the switch does not allow you to issue any command that has privilege level command authorization enabled. If the switch cannot reach the TACACS+ server, you can only issue logout and exit commands.

- To use TACACS+ authorization, you must enable TACACS+ authentication.

About This Task

Two kinds of authorization requests exist:

1. Login authorization: Login authorization happens immediately after authentication when the user logs on to the device, authorization provides the user access level. You cannot configure login authorization.
2. Command authorization: When you configure command authorization for a particular level, all commands that you issue are sent to the TACACS+ server for authorization. You need to configure command authorization globally and at individual access levels.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Enable TACACS+ authorization:
`tacacs authorization enable`
3. Configure TACACS+ privilege level for TACACS+ command authorization:
`tacacs authorization level <1-6>`

`tacacs authorization level all`

`tacacs authorization level none`
4. (Optional) Disable TACACS+ authorization:
`tacacs authorization disable`

`default tacacs authorization`

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs authorization enable
Switch:1(config)#tacacs authorization level 6
```

Variable Definitions

The following table defines parameters for the **tacacs authorization** command.

Variable	Value
<code>level <1-6></code>	Enables command authorization for a specific privilege level. The default for the command authorization level is none.
<code>level all</code>	Enables command authorization for all privilege levels. The default for the command authorization level is none.
<code>level none</code>	Disables command authorization for all privilege levels. The default for the command authorization level is none.

Change Privilege Levels at Runtime

Users can change their privilege levels at runtime. The privilege level determines what commands a user can access through TACACS+ server authorization.

A user can only use the **tacacs switch level** command, after TACACS+ authenticates the user. Locally authenticated users, which means users authenticated only by the switch and not by the TACACS+ server, cannot use the **tacacs switch level** command.

Before You Begin

- You need to configure separate profiles in the TACACS+ server configuration file for switch level. As part of the profile, you specify a user name, level, and password.

About This Task

After you enable TACACS+ authorization, the current privilege-level to command mapping on the switch is no longer relevant because the TACACS+ server has complete responsibility for command authorization. TACACS+ authorization provides access to the system based on user name, not based on privilege level.

After you enable TACACS+ command authorization for a particular privilege level, and a user with that privilege level logs on, the user can access commands based on his user name.

Note

If you want to switch to a privilege level 'X' using **tacacs switch level <1-15>** command, you must create a user "\$enabX\$" on the TACACS+ server. X is the privilege level to which you want to change.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
- Change the privilege level for a user at runtime:

```
tacacs switch level <1-15>
```
- Return to the original privilege level:

```
tacacs switch back
```

Example

Change the privilege level for a user at runtime. Return to the original privilege level:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs protocol enable
Switch:1(config)#tacacs switch level 5
Password:*****
```

Return to the original privilege level:

```
Switch:1(config)#tacacs switch back
```

Variable Definitions

The following table defines parameters for the **tacacs switch** command.

Variable	Value
<i>level</i> <1-15>	<p>Specifies the privilege level you want to access. You can change your privilege level at runtime by using this parameter. You are prompted to provide the required password. If you do not specify a level in the command, the administration level is selected by default.</p> <p>Note: For switch level, you need to configure separate profiles in the TACACS+ server configuration file. As part of the profile, you specify a user name, level, and password. To preconfigure a dummy user for that level on the TACACS+ daemon, the format of the user name for the dummy user is \$enab<n>\$, where <n> is the privilege level to which you want to allow access.</p>
<i>back</i>	Specifies that you want to return to the original privilege level.

TACACS+ configuration using EDM

This section provides procedures to configure TACACS+ using Enterprise Device Manager (EDM).

Configure TACACS+ Globally

Before You Begin

- You must have access to and you must configure a TACACS+ server before the TACACS+ features on your switch (network access server) are available.

You must verify that the switch can reach the TACACS+ server and that you configure TACACS+ properly before you enable command authorization.

- If a user is TACACS+ authenticated and command authorization is enabled for that level, then if the switch cannot reach the TACACS+ server, the switch does not allow the user to issue any command that has privilege level command authorization enabled. In such a case, the user can only issue logout and exit commands.

- You must enable TACACS+ globally for TACACS+ authentication to function.
- You must enable TACACS+ authentication for TACACS+ authorization to function.

About This Task

Enable TACACS+ globally on the switch. TACACS+ is a security application implemented as a client and server-based protocol that provides centralized validation of users. By default, TACACS+ is disabled.

Configure what application TACACS+ authenticates. TACACS+ authentication provides control of authentication through login and password dialog, challenge and response. By default, CLI authentication is enabled.

After authentication is complete, the switch starts the authorization process. By default, command authorization is disabled on the switch. The default for the command authorization level is none. If command authorization fails, the following log message displays: `Command <command> not authorized for user <username>.`

Two kinds of authorization requests exist:

1. Login authorization: Login authorization happens immediately after authentication when the user logs on to the device, authorization provides the user access level. You cannot configure login authorization.
2. Command authorization: When you configure command authorization for a particular level, all commands that you issue are sent to the TACACS+ server for authorization. You need to configure command authorization globally and at individual access levels.

Enable TACACS+ accounting function and determine which application TACACS+ accounts. After you enable accounting, the switch reports user activity to the TACACS+ server in the form of accounting records. The default for accounting is none.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **TACACS+**.
3. Select the **TACACS+ Globals** tab.
4. Select **GlobalEnable** to enable TACACS+ globally.
5. Select **cli** to enable the **Accounting** option.
6. Select **cli** or **web** to enable the **Authentication** option.
7. Select **CliCommandAuthorizationEnabled** to enable TACACS+ authorization.
8. Select the level in **CliCommandAuthorizationLevels**.
9. Select **Apply**.

TACACS+ Globals Field Descriptions

Use the data in the following table to use the **TACACS+ Globals** tab.

Name	Description
GlobalEnable	Enables or disables the TACACS+ feature globally.
Accounting	<p>Determines for which applications TACACS+ collects accounting information. Use TACACS+ accounting to track the services that users access and the amount of network resources that users consume. If unassigned, TACACS+ does not perform the accounting function. The default is none.</p> <p>If enabled, TACACS+ accounting logs the following events:</p> <ul style="list-style-type: none"> • User log on and log off • Log off generated because of activity timeout • Unauthorized command • Telnet session closed (not logged off)
Authentication	<p>Configures what application TACACS+ authenticates. The options include:</p> <ul style="list-style-type: none"> • cli • web <p>TACACS + authentication provides control of authentication through login and password dialog, challenge and response. By default, CLI authentication is enabled.</p>
LastUserName	Displays the last user for which the system attempted authentication.
LastAddressType	Displays the type of address to access the TACACS+ server.
LastAddress	Displays the last address to access the TACACS+ server.
CliCommandAuthorizationEnabled	<p>Enables TACACS+ authorization for a particular privilege level. Use this option to limit the use of certain commands to certain users. To use TACACS+ authorization, you must also use TACACS+ authentication.</p> <p>The switch allows the user to access the switch according to the access level. The default is disabled.</p>
CliCommandAuthorizationLevels	<p>Enables command authorization for a specific privilege level.</p> <p>The default for the command authorization level is none.</p>

Add a TACACS+ Server

Add a TACACS+ server, configure the TACACS+ server, and specify the authentication process.

If you have a secondary server configured, the AAA request goes to the backup server if the primary server is not available.

Before You Begin

You must have access to and you must configure a TACACS+ server before the TACACS+ features on your switch are available.

About This Task

The TACACS+ server and the switch must have the same:

- Encryption key
- Connection mode (single connection or per-session connection. Per-session is the same as multi-connection mode.)
- TCP port number

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **TACACS+**.
3. Select the **TACACS+ Servers** tab.
4. Select **Insert**.
5. In **AddressType**, select **ipv4**.
6. In **Address**, type the IP address of the TACACS+ server.
7. (Optional) In **PortNumber**, type the TCP port on which the client establishes a connection to the TACACS+ server.
8. (Optional) In **ConnectionType**, select either **singleConnection** or **perSessionConnection** to specify the TCP connection type between the switch and TACACS+ server.
9. (Optional) In **Timeout**, type the period of time (in seconds) the switch waits for a response from the TACACS+ server.
10. In **Key**, enter the key that the switch and the TACACS+ server share.
11. In **Priority**, select either **primary** or **backup** to determine the order the switch uses the TACACS+ servers.
12. Select **Insert**.

TACACS+ Servers Field Descriptions

Use the data in the following table to use the **TACACS+ Servers** tab.

Name	Description
AddressType	Specifies the type of IP address to use on the TACACS+ server. You must set the value to IPv4.
Address	Specifies the IP address of the TACACS+ server.
PortNumber	<p>Configures the TCP port on which the client establishes a connection to the server. The default is 49. A value of 0 indicates that the system specified default value is used.</p> <p>You must configure the same TCP port for the TACACS+ server and the switch.</p>
ConnectionType	<p>Specifies if the TCP connection between the device and the TACACS+ server is a single connection. If you specify the single connection parameter, the connection between the switch and the TACACS+ daemon remains open, which is more efficient because it allows the daemon to handle a higher number of TACACS+ operations. The single-connection session is torn down if TACACS+ is disabled due to inactivity.</p> <p>If you do not configure this parameter, the switch uses the default connection type, which is the multi-connection. With the multi-connection, the connection opens and closes each time the switch and TACACS+ daemon communicate.</p> <p>Note: You must configure the same connection mode for the TACACS+ server and the switch. To enable single-connection, the TACACS+ daemon has to support this mode as well.</p>
ConnectionStatus	Specifies if the TCP connection between the device and TACACS+ server is connected or not connected.
Timeout	Configures the maximum time, in seconds, to wait for this TACACS+ server to reply before it times out. The default value is 10 seconds.

Name	Description
Key	Configures the authentication and encryption key for all TACACS+ communications between the device and the TACACS+ server. If the key length is zero, that indicates no encryption is used. You must configure the same encryption key for the TACACS+ server and the switch.
Priority	Determines the order in which the switch uses the TACACS+ servers, where 1 is the highest priority. The priority values are primary and backup. If more than one server shares the same priority, the device uses the servers in the order they exist in the table.

Modify a TACACS+ Configuration

About This Task

Modify an existing TACACS+ configuration to customize the server.

Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **TACACS+**.
3. Select **TACACS+ Servers** tab.
4. Double-click in the fields that you want to modify.
In some of the fields, the text becomes bold, which indicates that you can edit them.
In other fields, the system displays a list.
5. In the fields that you can edit, type the desired values.
6. In the fields with lists, select the desired option.
7. Select **Apply**.

TACACS+ Configuration Example

This section provides a configuration example to configure the switch to use TACACS+.

Figure 238: Switch connects to the TACACS+ server

TACACS+ Configuration on the Switch

The following section shows the steps required to configure TACACS+ on the switch.

The example displays how to:

- Configure a key to be used by the TACACS+ server and the switch. In the example, the key is configured to the word `secret`.
- Configure an IP address for the TACACS+ server. In the example the IP address for the primary server is 192.0.2.8, which is accessible by the management interface.
- Configure the TACACS+ server to authenticate CLI sessions.
- Enable TACACS+.

Switch

```
TACACS CONFIGURATION

tacacs server host 192.0.2.8 key *****
tacacs protocol enable
tacacs accounting enable cli
tacacs authorization enable
tacacs authorization level 6
```

Verify your configuration

The **show tacacs** output must show as `global enable: true` to confirm TACACS is enabled.

The output for the **show tacacs** command must display the IP addresses for the TACACS+ server. The IP addresses must be accessible to the management interface on the switch.

If you want to use the TACACS+ server to authenticate sessions in CLI, the output must display as `authentication enabled for: cli`. If you want to authenticate EDM sessions, the output must display as `authentication enabled for: web`.

Ensure the other parameters match what you have configured.

```
Global Status:
```

```
global enable : true

authentication enabled for : cli

accounting enabled for : cli

authorization : enabled

User privilege levels set for command authorization : rwa

Server:
        create :

Prio      Status  Key      Port  IP address  Timeout Single Source

Traffic Filtering

[Traffic Filtering Fundamentals](#) on page 3681

[Access Control List Configuration using CLI](#) on page 3708

[Access Control List Configuration using EDM](#) on page 3721

[Access Control Entry Configuration using CLI](#) on page 3734

[Access Control Entry Configuration using EDM](#) on page 3758

Traffic filtering can generally provide a mechanism to accurately manage and secure network flows or prioritize crucial information over other network traffic.

The following topics provide necessary concepts and procedures to configure an access control list (ACL) and access control entry (ACE) to filter traffic.

Traffic Filtering Fundamentals

Use the information in this section to help you understand filtering. This section describes a range of features that you can use with the switch to allocate network resources to apply filters.

In a large and busy network, traffic management is very important and can be complex. Traffic filtering can generally provide a mechanism to accurately manage and secure network flows or prioritize crucial information over other network traffic. Some of the primary uses of filtering are:

- Manage traffic flows.
- Implement security permissions on network traffic.
- Prioritize mission critical traffic flows.
- Redirect traffic to firewalls or other devices to efficiently manage bandwidth.

Overview of Traffic Filtering

Traffic filtering on the switch is based on ACL filter implementation. Access Control List (ACL) based filters are a means to provide predictable and flexible traffic filtering. ACL Traffic filters can be configured using the Command Line Interface (CLI) or the Enterprise Device Manager (EDM). ACL filters set a list of criteria for the network traffic to be matched against, performing a predefined set of actions. Access Control Lists and Action Control Entries provide traffic filtering services on the switch.

Traffic filtering supports IPv6 ingress and egress port/vlan security and QoS ACL/filters. IPv6 egress QoS ACL/filters are not supported.

QoS and Filters

The switch has functions you can use to provide appropriate QoS levels to traffic for each customer, application, or packet. These functions include port-based shapers, DiffServ access or core port settings, and ingress port-rate limiting or policing. The switch also provides access control list (ACL)-based filters. You do not need to use filters to provide QoS; however, filters aid in prioritizing customer traffic. Filters also provide protection by blocking unwanted traffic.

Port rate limiting or policing apply at ingress; shapers apply at egress. ACL-based filters apply at ingress and egress.

The switch supports two ingress filter groups, where each type can hold both Security and QoS actions in both Primary Bank and Secondary Bank ranges.

Filters help you provide QoS by permitting or dropping traffic based on the parameters you configure. You can use filters to mark packets for specific treatment.

Typically, filters act as firewalls or are used for Layer 3 redirection. In more advanced cases, traffic filters can identify Layer 3 and Layer 4 traffic streams. The filters cause the streams to be re-marked and classified to attain a specific QoS level at both Layer 2 (802.1p) and Layer 3 (DSCP).

Traffic filtering is a key QoS feature. The switch, by default, determines incoming packet 802.1p or DiffServ markings, and forwards traffic based on their assigned QoS levels. However, situations exist where the markings are incorrect, or the originating user application does not have 802.1p or DiffServ marking capabilities. Also, you can give a higher priority to select users (executive class). In these situations, use filters to prioritize specific traffic streams.

You can use filters to assign QoS levels to devices and applications. To help you decide whether to use a filter, key questions include:

1. Does the user or application have the ability to mark QoS information on data packets?
2. Is the traffic source trusted? Are the QoS levels configured appropriately for each data source?

Users can maliciously configure QoS levels on their devices to take advantage of higher priority levels.

3. Do you want to prioritize traffic streams?

This decision-making process is outlined in the following figure.

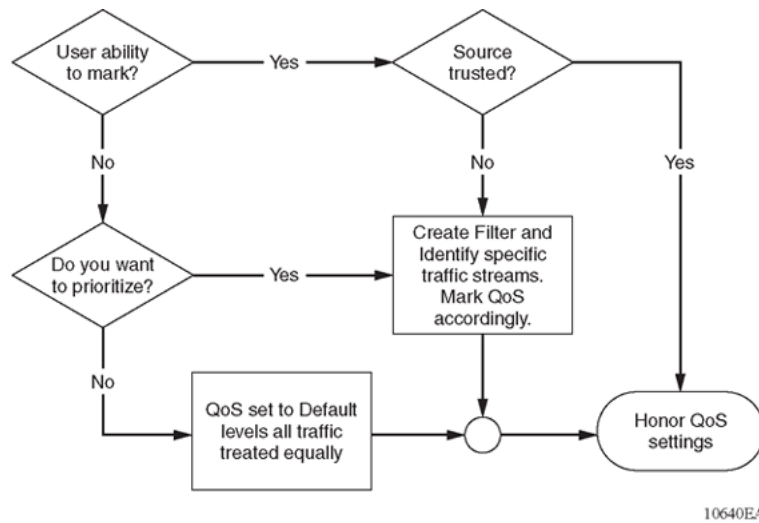

Figure 239: Filter decision-making process

Configure filters through the use of Access Control Lists (ACL) and Access Control Entries (ACE), which are implemented in hardware. An ACL can include both security and QoS type ACEs.

The following steps summarize the filter configuration process:

1. Determine your desired match fields.
2. Create an ACL.
3. Create an ACE within the ACL.
4. Configure the desired precedence, traffic type, and action.

You determine the traffic type by creating an ingress or egress ACL.

5. Modify the parameters for the ACE.

Access Control Lists

Table 309: Access Control List product support

Feature	Product	Release introduced
IPv4 Ingress and Egress port ACLs	4220 Series	Fabric Engine 9.2
	5320 Series	Fabric Engine 8.6

	VSP 7400 Series	VOSS 8.5

Apply rules to incoming and outgoing traffic. The total number of ACLs that you can configure differs depending on the switch.

An ACL can filter either IPv6 or non-IPv6 packets. By default, an ACL filters non-IPv6 packets. You must specify the packet type as IPv6 at the ACL level to enable IPv6 filtering. You cannot change the packet type for the ACL after you configure it. If you need a different packet type, you must delete the ACL, and then re-create it with the other packet type.

**Note**

All ACLs are enabled when a DvR Leaf node is created. When creating the DvR Leaf node, or when you enable IS-IS globally, the message `dvr leaf [x]` displays in CLI. If the DvR Leaf node is reset or reconnects to the DvR domain, this message does not display but the same principle applies. As a best practice, delete ACLs not used on DvR Leaf nodes, rather than disable them, because the ACLs re-enable without warning after a DvR domain transition caused by reset, or protocol or link bounce.

You can associate an ACL with the following interfaces:

- Ingress port (inPort)
- Ingress VLAN (inVLAN)

**Note**

VLAN-based ACL filters are not supported on a DvR Leaf node.

- Ingress VSN (inVSN)
- Egress port (outPort)

**Note**

Exception: does not apply to 7830 Series.

The ingress VLAN ACL associations apply to all active port members of a VLAN. An ACL is created in the enabled state by default.

The InVSN Filter is an Access Control List (ACL) that can be used with MAC-in-MAC (MIM) encapsulated packets that are received on the network-to-network interface (NNI) ingress ports and are routed or bridged to UNI ports or terminated on the fabric node. The InVSN Filter matches and filters IPv4 and IPv6 packet headers coming on UNI ports only, NNI ports only, or both UNI and NNI ports. The InVSN Filter does not filter packets that arrive on NNI ingress ports but are bridged to other NNI ports or are for transit traffic.

An ACL can contain multiple filter rules called Access Control Entries (ACE). ACEs provide match criteria and rules for ACL-based filters. An ACE can provide actions such as dropping a packet, monitoring a packet, or remarking QoS on a packet. Complete lists of actions are provided in the Access Control Entries section. After an ingress or egress packet meets the match criteria specified in ACEs within an ACL, the system executes the predefined action.

ACLs provide the ability to configure default and global actions. A default action is applied when no filter rule (ACE) matches on a packet flow. The global action runs after

any filter rule (ACE) matches on a packet flow. The default action mode for ACLs is permit. ACL global actions are:

- monitor-dst-mlt
- monitor-dst-ports

The following figure shows the relationships between ACEs and VLAN- and port-based ACLs.

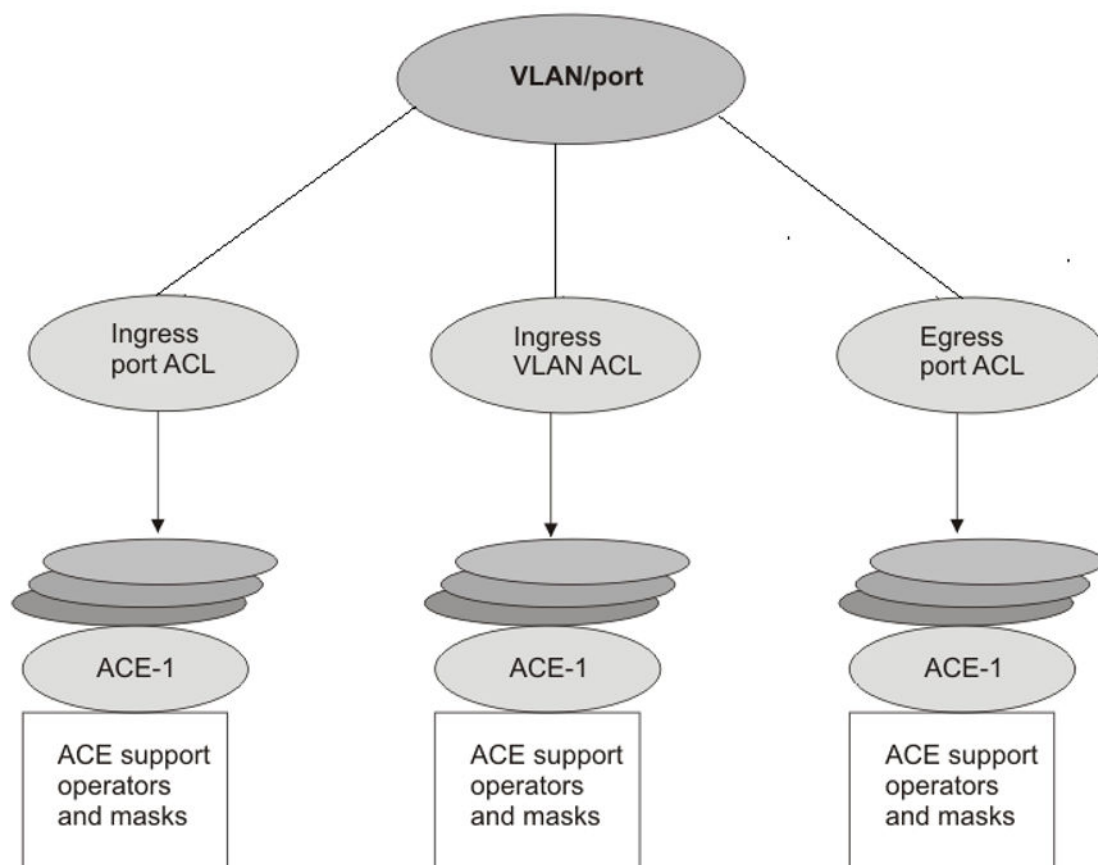

Figure 240: ACE and ACL relationships

Access Control Entries

Table 310: Access Control Entry product support

	7830 Series	Fabric Engine 9.3
	VSP 4900 Series	VOSS 8.1
	VSP 7400 Series	VOSS 8.0

The switch filter rules are defined using Access Control Entries (ACE). An ACE is an ordered set of filter rules contained in an Access Control List (ACL). ACE rules are divided into the following three components:

- Operators
- Attributes
- Actions

An ACE generally operates on fields in a packet. If a packet field matches an ACE rule, the system executes the action specified. As each packet enters through an interface with an associated ACL, the system scans the ACE list configured on that ACL and matches on the packet fields. If multiple ACE rules are associated with the ACL, the lower ACE ID will have a higher precedence.

Operators

ACEs use operators to match on packet fields. The switch supports the following operators:

- Equal-to

This rule operator looks for an exact match with the field defined. If the field matches exactly with the rule, the system will return a match (hit). If the rule does not match, the search continues and at the end of the search a miss is returned.

- Mask

ACL-based filters provide the mask operator to match on Layer 2, Layer 3, and Layer 4 packet fields. The mask operator is used to mask bits in packet fields during a search or to match on a partial value of a packet field. This section provides examples of the mask operator.

If a mask bit is set to 1, it means it is not part of the match criteria (treated as do not care), and a mask bit of 0 means that the value represented is part of the match criteria. You can use the mask operator for the following attributes:

- source MAC address
- destination MAC address
- VLAN ID
- Dot1p
- IPv4/IPv6 source address
- IPv4/IPv6 destination address
- destination IP address
- DSCP
- Layer 4 source port
- Layer 4 destination port
- TCP flags

**Note**

MAC Address cannot be configured as attributes for IPv6 filters.

The syntax for ACL and ACE configuration of a mask is similar to the use of equal operator, except that you provide the mask value. You can specify a mask value (number) to represent the bits to mask in the attribute. You can define a mask in different ways depending on the attribute you need to mask:

- If you use a decimal number for an IP address mask, it specifies the most significant bits of the provided IP address to match on. For example, a mask of 24 used with an IP address is the same as a mask of 0.0.0.255, and a mask of 8 used with an IP address is the same as a mask of 0.255.255.255.
- If you use a decimal number for a MAC address mask, it specifies the least significant bits of the provided MAC address to ignore. For example, a mask of 32 used with a MAC address is the same as a mask of 0x0000ffffff, and a mask of 16 used with a MAC address is the same as a mask of 0x00000000ffff.

**Note**

Unlike the standard convention, for ACL filter configuration, a mask bit value of '1' specifies a do-not-care bit, and value of '0' signifies must-match bit.

The following table explains the mask operator for MAC addresses.

Table 311: Mask operator for MAC address

Rule	Result
<pre>filter acl ace ethernet 10 10 dst-mac mask 01:00:5e:00:00:01 0x000000FFFFFF</pre>	The rule matches only on the most significant 24 bits as they are not masked, for example, 01:00:5e, and does not care about the least significant 24 bits because they are masked; the least significant 24 bits can have a value of 00:00:00 - FF:FF:FF.
<pre>filter acl ace ethernet 10 10 dst-mac mask 01:00:5e:00:00:01 0xFFFFFFFF0000</pre>	The rule matches only on the least significant 16 bits because they are not masked, for example, 00:01, and does not care about the most significant 32 bits because they are masked; the most significant 32 bits can have a value of 00:00:00:00 – FF:FF:FF:FF.
<pre>filter acl ace ethernet 10 10 dst-mac mask 01:00:5e:00:00:01 0xFF00FF0000FF</pre>	The rule matches only on the unmasked bits, for example, 0xXX:00:XX:00:00:XX. The rule matches only on the bits not masked, for example, all the zeroes and the x represents a do not care (0xXX:00:XX:00:00:XX)

The following table explains the mask operator for IP addresses.

Table 312: Mask operator for IP address

Rule	Result
<pre>filter acl ace ip 10 10 src-ip mask 2.10.10.12 0.255.255.255</pre>	The rule matches only the most significant 8 bits, and does not care about the value of the remaining 24 bits as they are considered masked. For example, 10.10.12. Packets with a source IP address of 2.15.16.122 or 2.3.4.5 match on the filter rule while packets with a source IP address of 3.10.10.12 and 4.10.10.12 do not match on the filter rule.
<pre>filter acl ace ip 10 10 src-ip mask 3.4.5.6 255.255.255.0</pre>	The rule matches only the least significant 8 bits, for example, 6, and does not care about the most significant 24 bits, 3.4.5. Packets with a source IP address of 17.16.5.6 or 192.168.1.6 match on the filter rule while packets with a source IP address of 3.4.5.4 or 3.4.5.7 do not match on the filter rule.

The following table explains the mask operator for Layer 4 source port.

Table 313: Mask operator for Layer 4 source port

Rule	Result
<pre>filter acl ace protocol 10 10 src- port mask 80 0xF</pre>	The filter rule matches on Layer 4 source port 80 (1010000). The mask value 0xF (1111) masks the least significant 4 bits, which means source port 81 (1010001) through 95 (1011111) also match this filter rule. This means the range 80–95 is a match on this rule.

The following table demonstrates the resulting action based on mask configuration and example packets.

Table 314: Mask operator configuration examples

Filter configuration	Address examples that match the filter	Address examples that do not match the filter
<p>Ethernet mask:</p> <pre>filter acl 1000 type inport filter acl port 1000 1/5,1/11 filter acl ace 1000 12 filter acl ace ethernet 1000 12 src-mac mask 00:00:11:11:16:00 0x00ff000000f0 filter acl ace action 1000 12 permit count filter acl ace 1000 12 enable</pre>	<p>Source MAC:</p> <pre>00:01:11:11:16:10 00:10:11:11:16:f0 00:1f:11:11:16:10 00:ff:11:11:16:f0 00:00:11:11:16:60 00:e6:11:11:16:e0</pre>	<p>Source MAC:</p> <pre>00:00:11:11:16:01 00:ff:11:11:16:f1</pre>

Attributes

Attributes are fields in a packet (Layer 2, Layer 3, Layer 4) or other information related to the packet on which an ACE rule is applied like slot/port. [Table 315](#) provides a list of all the attributes and the operators that you can apply to them.

If you want to configure IPv6 attributes, you must configure an ACL to filter either IPv6 or non-IPv6 traffic. You can only configure IPv6 attributes for IPv6 packets. You cannot configure IPv6 attributes for non-IPv6 packets.

Table 315: Attribute list

Attribute Name	Operator
Slot/Port	Equal
Destination MAC (IPv4 filters only)	Equal, Mask
Source MAC (IPv4 filters only)	Equal, Mask
VLAN ID	Equal, Mask
.1p bits	Equal, Mask
Ether Type	Equal
ARP Opcode	Equal
Source IP	Equal, Mask
Destination IP	Equal, Mask
Protocol Type	Equal
Type of Service	Equal, Mask
IP Fragmentation	Equal
Note: Exception: not supported on 7830 Series.	
IP Options	Equal
Layer 4 Destination Port	Equal, Mask
Layer 4 Source Port	Equal, Mask
TCP Flags	Equal, Mask
ICMP Message Type	Equal
Source IPv6 (IPv6 only)	Equal, Mask
Destination IPv6 (IPv6 only)	Equal, Mask
Next header (IPv6 only)	Equal
Traffic class (IPv6 only)	Equal
Routed only	Equal

4220 Series Restrictions

Note the following restrictions to the attribute list:

- 4220 Series supports the following for IPv4 ACLs only.
 - .1p bits
 - TCP flags
 - ICMP Message Type

- 4220 Series models are restricted to a maximum of 15 distinct values for each source/destination port. The following list identifies the reserved entries in the 15 number set:
 - 67-68 [DHCP]
 - 546-547 [DHCPv6]
 - 53 [DNS]
 - 23, 2323 [Telnet]

5320 Series Restrictions

Note the following restrictions to the attribute list:

- 48-port 5320 Series models support .1p bits for both IPv4 and IPv6 ACLs. 16-port and 24-port 5320 Series models support .1p bits for IPv4 ACLs only.
- 16-port and 24-port 5320 Series models are restricted to a maximum of 15 distinct values for each source/destination port. The following list identifies the reserved entries in the 15 number set:
 - 67-68 [DHCP]
 - 546-547 [DHCPv6]
 - 53 [DNS]
 - 23, 2323 [Telnet]
- 48-port 5320 Series models support TCP flags for both IPv4 and IPv6 ACLs. 16-port and 24-port 5320 Series models support TCP flags for IPv4 ACLs only.
- 48-port 5320 Series models support ICMP Message Type for both IPv4 and IPv6 ACLs. 16-port and 24-port 5320 Series models support ICMP Message Type for IPv4 ACLs only.
- Only the 48-port 5320 Series models support the attributes identified as IPv6 only.

Actions

Actions occur when the filter rule is hit or missed. The types of actions that the filter configuration can execute are split into two categories:

- security actions
- QoS actions

Note

- Ingress ACLs support security and QoS ACE actions. Egress ACLs do not support QoS ACEs.

For Fabric Engine switches, except for 4220 Series and 5320 Series, the ACE ID range for the Primary Bank is 1-1000 and for the Secondary Bank, the ACE ID range is 1001-2000. The switch performs a parallel search on both ACE lists. If actions do not conflict, both actions apply. If actions conflict, the action from the range with higher priority applies.

The 4220 Series and 5320 Series switches use a modified implementation for IPv4 ACL filters. In this implementation, there is no distinction between ACE IDs used for Security

or QoS actions. You can configure Security and QoS actions in the ACE ID range 1-2000 and hence the switch does not perform a parallel search on the two ACE types.

If you apply multiple ACE rules, the lower ACE ID has a higher precedence.

Note

The ACE ID range for both security and QoS actions is different for different hardware platforms. For more information, see [ACL Filters Behavior Differences](#) on page 3706.

The following tables show the supported switch actions:

Table 316: Security ACE Actions

Security ACE Actions	User supplied parameters	Comments
count	None	Collect ACE statistics. Applies to Ingress and Egress ACLs.
mode	Permit or Deny	Applies to both Ingress and Egress ACLs.
monitor-dst-mlt	mlt-id	Applies to Ingress ACLs only. Note: This option is not supported on 7830 Series.
monitor-dst-ports	Port	Applies to Ingress ACLs only.
monitor-isid-offset	Offset-id	Determines the actual monitor I-SID value to which packets are mirrored. Note: This option is not supported on 7830 Series. Note: This option is not supported on Multi-area SPB Boundary Nodes.

Table 316: Security ACE Actions (continued)

Security ACE Actions	User supplied parameters	Comments
redirect-next-hop	IP address, Mode	Redirects the packet to the user supplied IP address. If the switch cannot resolve ARP for the user-specified next-hop, packets that match the filter are dropped. Applies to ingress IPv4 ACLs only (routed and Layer 2).
unreachable	permit or deny	Denies or permits packet dropping when the next hop for the packet is unreachable.

Table 317: QoS ACE Actions

QoS ACE Actions	User supplied parameters	Comments
count	None	Applies to Ingress and Egress ACLs.
<ul style="list-style-type: none"> internal-qos remark-dot1p remark-dscp 	<ul style="list-style-type: none"> Internal-qos dot1p (ingress only) DCSP 	<p>Applies to Ingress ACLs.</p> <p>Note: remark-dot1p and internal-qos do not apply to IPv6 filtering.</p> <p>Note: Some hardware platforms do not support remark-dot1p and support remark-DSCP for Layer 3 routed packets only.</p>

When you configure an IPv6 ACL with an ACE action of remark DSCP for a mirrored packet, the mirrored copy does not include the remark DSCP value. Because of port-mirroring functionality, the mirrored copy does not reflect the changes that occur in the switch to the outgoing packet. As a result, the mirrored copy is not identical to the outgoing packet. For more information, see [Port Mirroring](#) on page 3870.

Internal QoS Level and Remarking

Setting the internal QoS level is an ingress action. Remarking is an egress action.

The internal-qos action assigns a new value to the packet internal-qos. It determines the packet egress queue, outgoing packet dot1p value and egress-DSCP value.

The remark-dot1p action assigns a new dot1p value to the outgoing packet. The remark-DSCP action assigns a new DSCP value to the outgoing packet.

If a packet is filtered by a rule set to internal-qos action only, then the packet internal qos, egress queue, egress dot1p and egress DSCP will be derived from the filter internal-qos value.

If a packet is filtered by a rule set to remark-dot1p only or remark-DSCP only or both remark actions, then the packet will be remarked with the new dot1p or DSCP, or both. However, these remarked values will not have any impact on the internal-qos packet. It will be based on the native packet coming into the switch.

If a packet is filtered by a rule set with all three qos actions, then the internal-qos will determine the egress queue, but the remark-dot1p determines the egress dot1p and the remark-DSCP determines the egress DSCP.

If you want to change the internal QoS for remarked incoming packets, you have to add the **permit internal-qos** command as shown in the following ACL filter example.

```
filter acl 10 type inPort name "ACL-CTI"
filter acl port 10 1/2-1/50
filter acl ace 10 1302 name "CIFS-SCCM Source"
filter acl ace action 10 1302 permit remark-dscp phbaf11 remark-dot1p 1 count
filter acl ace action 10 1302 permit internal-qos 0
filter acl ace ethernet 10 1302 ether-type eq ip
filter acl ace ip 10 1302 src-ip mask 0.0.0.0 255.255.255.255
filter acl ace ip 10 1302 ip-protocol-type eq tcp
filter acl ace protocol 10 1302 src-port mask 0 0xffff
```

When a packet goes through the switch, the internal QoS level governs which queue the packet uses on egress. To verify which queue the packets are egressing on, use the **show qos cosq-stats interface [value]** command. For more information, see [View Port Egress CoS Queue Statistics](#) on page 3027 or [View Port Egress CoS Queue Statistics](#) on page 3037.

Conflict and Precedence

The switch supports both port-based and VLAN-based ACLs. A port can be associated with both Port-based ACL and a VLAN-based ACL, as shown in [Access Control Lists](#) on page 3684. Within an ACL, a rule match can generate security actions and QoS actions. The system goes through a set of precedence levels to resolve any conflicting actions between port-based ACL and VLAN-based ACL lookup.

The following table provides a list of search results and actions for all possible conflicts between port and VLAN-based ACLs and security and QoS ACE for each ACL.

Table 318: Conflict and Precedence resolution

Port-based ACL look up		Actions performed on Port-based ACL		If VLAN-based ACL is enabled		Actions performed on VLAN-based ACL search	
Security	QoS	Security action	QoS action	Security	QoS	Security action	QoS action
Security ACE search is a Miss and ACL mode is Permit.	QoS ACE search is a Miss	Default security statistics collected	Default QoS statistics collected	Security ACE search is a Miss and mode is set to Permit	QoS ACE search is a Miss	Collect default Miss statistics	Collect default Miss statistics
				Security ACE search is a Miss and mode is set to Permit	QoS ACE search returns a Hit	Collect default Miss statistics	Execute configured ACE and default ACL actions
				Security ACE search is a Miss and mode is set to Deny	Search result is invalid, since security mode is set to Deny	Drop packet and collect default Miss statistics	No action is executed
				Security ACE search is a Hit and mode is set to Permit	QoS ACE search returns a Miss	Execute configured ACE and default ACL actions	Collect default Miss statistics
				Security ACE search is a Hit and mode is set to Permit	QoS ACE search is a Hit	Execute configured ACE and default ACL actions	Execute configured ACE and default ACL actions
				Security ACE search is a Hit and mode is set to Deny	QoS ACE search returns a Hit	Discard the packet and execute configured ACE and global actions	No action is executed
Security ACE is Miss and ACL mode is Deny	Search result is invalid since security mode is set to Deny	Discard the packet and collect default statistics	No action is executed	VLAN-based ACL is not configured	VLAN-based ACL is not configured	No action is executed	No action is executed

Table 318: Conflict and Precedence resolution (continued)

Port-based ACL look up		Actions performed on Port-based ACL		If VLAN-based ACL is enabled		Actions performed on VLAN-based ACL search	
Security	QoS	Security action	QoS action	Security	QoS	Security action	QoS action
Security ACE search is a Miss and ACL mode is set to Permit	QoS ACE search is a Hit	Default search statistics collected	Execute configured ACE and default ACL actions	Security ACE search is a Miss and mode is set to Permit	Port-based ACL's QoS action take precedence. QoS search result invalid.	Collect default Miss statistics	No action is executed
				Security ACE search is a Miss and mode is set to Deny	Port-based ACL's QoS action take precedence. QoS search result invalid.	Drop packet and collect default Miss statistics	No action is executed
				Security ACE search is a Hit and mode is set to Permit	Port-based ACL's QoS action take precedence. QoS search result invalid.	Execute configured ACE and default ACL actions	No action is executed
				Security ACE search is a Hit and mode is set to Deny	Port-based ACL's QoS action take precedence. QoS search result invalid.	Discard the packet and execute configured ACE and global Actions	No action is executed
Security ACE search is a Hit and ACE mode is Permit	QoS ACE search is a Miss	Execute configured ACE and default ACL actions	Collect default Miss statistics	Port-based ACL's Security action take precedence. Security search result invalid	QoS ACE search returns a Miss	No action is executed	Collect default Miss statistics
				Port-based ACL's Security action take precedence. Security search result invalid.	QoS ACE search returns a Hit	No action is executed	Execute configured ACE and default ACL actions

Table 318: Conflict and Precedence resolution (continued)

Port-based ACL look up		Actions performed on Port-based ACL		If VLAN-based ACL is enabled		Actions performed on VLAN-based ACL search	
Security	QoS	Security action	QoS action	Security	QoS	Security action	QoS action
Security ACE search is a Hit and ACE mode is Permit	QoS ACE search is a Hit	Execute configured ACE and default ACL actions	Execute configured ACE and default ACL actions.	Port-based ACL's Security action take precedence. Security search result invalid	Port-based ACL's QoS action take precedence. QoS search result invalid.	No action is executed	No action is executed
Security ACE search is a Hit and ACE mode is Deny	Search result is invalid since Security mode is set to Deny	Discard the packet and collect default statistics	No action is executed	Port-based ACL's Security action take precedence. Security search result invalid	Port-based ACL's QoS action take precedence. QoS search result invalid.	No action is executed	No action is executed

Common ACE Uses and Configuration

The following table describes configurations you can use to perform common actions.

Table 319: Common ACE uses and configurations

Function	ACE configuration
Permit a specific host to access the network	<ul style="list-style-type: none"> Use action permit. Configure the source IP address to be the host IP address. <pre>filter acl ace 1 5 name "Permit_access_to_198.51.100.0" filter acl ace action 1 5 permit filter acl ace ethernet 1 5 ether-type eq ip filter acl ace ip 1 5 src-ip eq 198.51.100.0 filter acl ace 1 5 enable</pre>
Deny a specific host from accessing the network	<ul style="list-style-type: none"> Use action deny. Configure the source IP address to be the host IP address. <pre>filter acl ace 1 5 name "Deny_access_to_198.51.100.0" filter acl ace action 1 5 deny filter acl ace ethernet 1 5 ether-type eq ip filter acl ace ip 1 5 src-ip eq 198.51.100.0 filter acl ace 1 5 enable</pre>

Table 319: Common ACE uses and configurations (continued)

Function	ACE configuration
Permit a specific range of hosts to access the network	<ul style="list-style-type: none"> Use action permit. Configure the source IP address to be the range of host IP addresses. <pre>filter acl ace 1 5 name "Permit_access_to_1.2.3.4-1.2.3.7" filter acl ace action 1 5 permit filter acl ace ethernet 1 5 ether-type eq ip filter acl ace ip 1 5 src-ip mask 1.2.3.4 0.0.0.3 filter acl ace 1 5 enable</pre>
Deny Telnet traffic	<ul style="list-style-type: none"> Use action deny. Configure the protocol as TCP and the TCP destination port to be 23. <pre>filter acl ace 1 5 name "Deny_telnet" filter acl ace action 1 5 deny filter acl ace ethernet 1 5 ethertype eq ip filter acl ace ip 1 5 ip-protocol-type eq tcp filter acl ace protocol 1 5 dst-port eq 23 filter acl ace 1 5 enable</pre>
Deny FTP traffic	<ul style="list-style-type: none"> Use action deny. Configure the protocol as TCP and the TCP destination port to be 21. <pre>filter acl ace 1 5 name "Deny_ftp" filter acl ace action 1 5 deny filter acl ace ethernet 1 5 ethertype eq ip filter acl ace ip 1 5 ip-protocoltype eq tcp filter acl ace protocol 1 5 dst-port eq 21 filter acl ace 1 5 enable</pre>

Switched UNI ACL Filters

InPort and OutPort filters are available on Switched UNI (S-UNI) and Fabric Attach ports for traffic mapped to an I-SID without an associated platform VLAN. The Customer VLAN-ID (CVID) can be used as a VLAN-ID qualifier in both InPort and OutPort filters. For traffic mapped to an I-SID with an associated platform VLAN, InPort, OutPort, and inVLAN filters are supported on S-UNI and Fabric Attach ports. In this case, the platform VLAN should be used as the VLAN-ID in InPort and inVLAN filters, while the CVID should be used as the VLAN-ID in the OutPort filter.

Traffic Filter Configuration

Traffic filtering manages traffic by defining filtering conditions and associating these conditions with specific actions. The following steps summarize the filtering configuration process:

1. Determine your desired match fields.
2. Configure an ACL and associate it with Ingress or Egress traffic flow.
3. Configure an ACE within the ACL.
4. Configure the desired precedence, attributes, and action.
5. Enable the ACE.

Ingress Policer and Port Rate Limiter

Table 320: Port-Based Rate Limiting, Policing, and Shaping product support

Feature	Product	Release introduced
Egress port shaper	4220 Series	Fabric Engine 9.2
	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	7830 Series	Fabric Engine 9.3
	VSP 4900 Series	VOSS 8.1
	VSP 7400 Series	VOSS 8.0
Ingress policer and port rate limiter	4220 Series	Fabric Engine 9.2
	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.5
	5520 Series	VOSS 8.5
	5720 Series	Fabric Engine 8.7
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	7830 Series	Not Supported

QoS ingress port-based rate limiter	4220 Series	Not Supported
	5320 Series	Not Supported
	5420 Series	Not Supported
	5520 Series	Not Supported
	5720 Series	Not Supported
	7520 Series	Not Supported
	7720 Series	Not Supported
	7830 Series	Not Supported
	VSP 4900 Series	VOSS 8.1
	VSP 7400 Series	Not Supported

Ingress policer and port rate limiter functionality handles congestion, meters traffic, and takes action based on the ACL filter rules. A policer can be attached directly to an ACL ACE entry to perform flow-based rate limiting. You can configure the service rate

and peak rate. All traffic that qualifies for a filter is metered. Every packet that exceeds the service rate is marked as yellow, and every packet that exceeds the peak rate is marked as red and drops. The line rate of the port is the maximum rate that you can configure.

The ingress policer and port rate limiter feature is available on the following interfaces:

- Ingress port (inPort)
- Ingress VLAN (inVLAN)
- Ingress VSN (inVSN)

Operation Considerations

The following section describes operational considerations for ingress policer and port rate limiter functionality:

- IPv4 policer statistics are available for red, yellow, and green packets and bytes.
- Egress port (outPort) interface is not supported.
- Policers are not supported on IPv6 ACLs.
- Supports QoS ACEs only.
- You can configure the default action policer within an ACL for permit action mode only.
- Drop action mode is not supported.
- **monitor-dst-ports**, **monitor-dst-mlt**, or **monitor-isid-offset** actions are supported. All traffic received is mirrored.
- The filter with policer and redirect-next-hop actions redirect only the traffic that passes the policer (if the stream is 100 Mbps, and the policer peak-rate is 50 Mbps, only 50 Mbps is redirected).

ACL and ACE Configuration Guidelines

To find the maximum number of ACLs and ACEs that the switch supports, see the *Fabric Engine Release Notes*.

ACL Filters Behavior Differences

The implementation of ACL filters is similar in all switches but there are some differences as summarized in the following tables.

Note

The InVSN Filter shares the port-based groups in the following table.

Table 321: Action behavior

Filter	4220 Series 5320 Series	5420 Series 5520 Series 5720 Series 7520 Series 7720 Series 7830 Series
ACE ID ranges supported	<ul style="list-style-type: none"> IPv4 and IPv6 filters: <ul style="list-style-type: none"> ACEs: 1–2000 support both Security and QoS actions 	<ul style="list-style-type: none"> IPv4 filters support both Security and QoS actions in both Primary Bank and Secondary Bank ranges: <ul style="list-style-type: none"> Primary Bank: 1-1000 Secondary Bank: 1001-2000 IPv6 filters: <ul style="list-style-type: none"> ACEs: 1–2000 support both Security and QoS actions
redirect-next-hop support	<p>Supported in both the Global Routing Table and VRF contexts.</p> <p>The 4220 Series switches support only a single active VRF with IP configuration.</p> <p>For the 5320 Series, only the following models support more than one VRF with IP configuration:</p> <ul style="list-style-type: none"> 5320-16P-2MXT-2X 5320-24T-4X-XT 5320-24T-24S-4XE-XT 	<p>Supported in both the Global Routing Table and VRF contexts.</p>

Table 321: Action behavior (continued)

Filter	4220 Series 5320 Series	5420 Series 5520 Series 5720 Series 7520 Series 7720 Series 7830 Series
	<ul style="list-style-type: none"> • 5320-48P-8XE • 5320-48T-8XE 	

Table 322: ACL statistics behavior

4220 Series 5320 Series	5420 Series 5520 Series 5720 Series 7520 Series 7720 Series 7830 Series
Does not support viewing ACL statistics by the ACE type, Security and QoS. The output displays N/A.	Supports viewing ACL statistics by the ACE type, Primary Bank and Secondary Bank.

Table 323: ACE match criteria

4220 Series 5320 Series	5420 Series 5520 Series 5720 Series 7520 Series 7720 Series 7830 Series

<ul style="list-style-type: none"> protocol ACE: <ul style="list-style-type: none"> dst-port src-port <p>Note: 4220 Series and 16-port and 24-port 5320 Series models are restricted to a maximum of 15 distinct values for each source/destination port. For more information, see Attributes on page 3694.</p> <p>Support on the 48-port models is the same as 5420 Series and 5520 Series.</p>	<p>Note: 7830 Series does not support IPv6 ACE.</p> <ul style="list-style-type: none"> protocol ACE: <ul style="list-style-type: none"> dst-port icmpv6-msg-type src-port tcp-flags

For QoS scaling and filter scaling information, see *Fabric Engine Release Notes*.

Access Control List Configuration using CLI

Use an access control list (ACL) to specify an ordered list of access control entries (ACEs), or filter rules. The ACEs provide specific actions that you want the filter to perform.

Create an IPv4 ACL

Create an ACL to specify an ordered list of ACEs, or filter rules.

About This Task

Do not configure IPv4 egress ACL filters on network-to-network interface (NNI) ports because the system-generated egress vIST filter rules and the user-created IPv4 egress rules use the same filter hardware.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Create an ACL:

```
filter acl <1-2048> type <inVlan|inPort|outPort|inVsn> [matchType
<both|terminatingNNIOnly|uniOnly> ] [name WORD<0-32>] [enable]
```

3. Enable an ACL:

```
filter acl [enable]
```

4. Ensure the configuration is correct:

```
show filter acl [<1-2048>]
```

Variable Definitions

The following table defines parameters for the **filter acl** command.

Variable	Value
<1-2048>	Specifies the ACL ID.
<i>enable</i>	Enables the ACL state, and all associated ACEs. Enabled is the default state.
<i>matchType</i> < <i>both</i> <i>terminatingNNIOnly</i> <i>uniOnly</i> >	For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <i>both</i> for traffic ingressing on both UNI ports and network-to-network interface (NNI) ports terminating on this node <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node <i>uniOnly</i> for traffic ingressing on UNI ports only The default value is <i>both</i> .
<i>name</i> WORD<0-32>	Specifies an optional descriptive name for the ACL.
<i>type</i> < <i>inVlan</i> <i>inPort</i> <i>outPort</i> <i>inVsn</i> >	Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL.

Create an IPv6 ACL

Create an IPv6 ACL to specify an ordered list of ACEs, or filter rules.

You must specify the packet type as IPv6 at the ACL level to enable IPv6 filtering. By default, an ACL filters non IPv6 packets.

**Note**

You cannot change packet type for the ACL after you have configured it. If you want a different packet type, you must delete the ACL and re-create it using the other packet type.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create an IPv6 ACL:

```
filter acl <1-2048> type <inVlan|inPort|outPort|inVsn> [matchType
<both|terminatingNNIOnly|uniOnly> ] [name WORD<0-32>] [pktType ipv6]
[name <0-32>]
```

**Note**

IPv6 egress QoS ACL/Filters are not supported.

3. Enable the ACL:

```
filter acl <1-2048> enable
```

4. Ensure the configuration is correct:

```
show filter acl [<1-2048>]
```

Variable Definitions

The following table defines parameters for the **filter acl** command.

Variable	Value
<code><1-2048></code>	Specifies the ACL ID.
<code>enable</code>	Enables the ACL state, and all associated ACEs. Enabled is the default state.
<code>matchType <both terminatingNNIOnly uniOnly></code>	For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <code>both</code> for traffic ingressing on both UNI ports and NNI ports terminating on this node <code>terminatingNNIOnly</code> for traffic ingressing on NNI ports only and terminating on this node <code>uniOnly</code> for traffic ingressing on UNI ports only The default value is <code>both</code> .
<code>name WORD<0-32></code>	Specifies an optional descriptive name for the ACL.
<code>type <inVlan inPort outPort inVsn></code>	Specifies the ACL type. The values <code>inVlan</code> , <code>inPort</code> , and <code>inVsn</code> are ingress ACLs. The value <code>outPort</code> configures IPv6 egress filters. A port-based ACL has precedence over a VLAN-based ACL.
<code>pktType <ipv6></code>	Specifies the IP version as IPv6. The default is <code>nonipv6</code> . <p>Note: You cannot change packet type for the ACL after you have configured it. If you want a different packet type, you must delete the ACL and re-create it using the other packet type.</p>

Associate VLANs with an ACL

Associate VLANs with an ACL to apply filters to VLAN traffic.

A VLAN can be part of two different ACLs of different types: IPv6 and non-IPv6.

Before You Begin

- The ACL exists.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Add VLAN interfaces to an ACL:

```
filter acl vlan <1-2048> <1-4059>
```
3. Remove specified VLAN interfaces from an ACL:

```
no filter acl vlan <1-2048> <1-4059>
```

Variable Definitions

The following table defines parameters for the **filter acl vlan** command.

Variable	Value
<1-2048>	Specifies the ACL ID.
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Associate Ports with an ACL

Associate ports with an ACL to apply filters to port traffic.

A port can be part of two different ACLs of different types: IPv6 and non-IPv6.

Before You Begin

- The ACL exists.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Associate port interfaces with a particular ACL:

```
filter acl port <1-2048> {slot/port[-slot/port]}[,...][slot/all][all]}
```
3. Remove port interfaces from a particular ACL:

```
no filter acl port <1-2048> {slot/port[-slot/port]}[,...][slot/all][all]}
```

Variable Definitions

The following table defines parameters for the **filter acl port** command.

Variable	Value
<1-2048>	Specifies the ACL ID.
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...][slot/all][all]}	<p>Identifies the slot and port in one of the following formats:</p> <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>

Associate an I-SID with an ACL

Before You Begin

- The inVsn ACL exists.
- This I-SID is already configured on the fabric node.

About This Task

For inVsn ACL types, specify the I-SID associated with the customer VLAN (Layer 2 VSN), the customer VRF (Layer 3 VSN), or the IP Shortcut.

Note

For IP Shortcut traffic, the inVsn ACL match type must be *both*. In this case, the I-SID is zero (0).

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Specify the I-SID.

```
filter acl i-sid <1-2048> <0-15999999>
```

Variable definitions

Use the data in the following table to use the **filter acl i-sid** command.

Variable	Value
<1-2048>	Specifies the ACL ID.
<0-15999999>	<p>Specifies the I-SID associated with the customer VLAN (Layer 2 VSN) or the customer VRF (Layer 3 VSN). This I-SID must already be configured on the fabric node.</p> <p>The InVSN Filter supports IP Shortcut traffic if the inVsn ACL match type is <i>both</i>. In this case, the I-SID is zero (0).</p> <p>Important: You can specify a Switched UNI I-SID if the I-SID is associated with a platform VLAN.</p>

Configure Global and Default Actions for an ACL

Configure the default action to specify packet treatment if a packet does not match an ACE.

Configure the global action to specify packet treatment if a packet does match an ACE. You can only configure the global action for ingress ACLs.

Before You Begin

Ensure that the ACL exists.

Procedure

- Enter Global Configuration mode:

```
enable
configure terminal
```
- Configure the global action for an ACL:

```
filter acl set <1-2048> global-action [monitor-dst-ports {slot/port[-slot/port][,...][slot/all][all]] [monitor-dst-mlt <1-512>]
```
- Configure the default action for an ACL using one of the following commands:
 - Configure the default action to permit:

```
filter acl set <1-2048> default-action permit [policer svc-rate <0-4000000000> peak-rate <8-4000000000>]
```
 - Configure the default action to deny:

```
filter acl set <1-2048> default-action deny [control-packet-action <deny | permit>]
```

Variable Definitions

The following table defines parameters for the **filter acl set** commands.

Variable	Value
<1-2048>	Specifies the ACL ID.
<i>control-packet-action</i> <deny permit>	Specifies the action to apply on control packets when none of the ACEs match. The default is permit. To use this optional parameter, you must configure the <i>default-action</i> to deny .
<i>default-action</i> <permit deny>	Specifies the default action to take when none of the ACEs match. Options are <permit deny>. The default is permit.
<i>monitor-dst-mlt</i> <1-512>	Configures mirroring to a destination MLT in the range of 1 to 512.
<i>monitor-dst-ports</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...][slot/all][all]}	Specifies the global action to take for matching ACEs: <ul style="list-style-type: none"> monitor destination ports—Configures mirroring to a destination port or ports. Identifies the slot and port in one of the following formats: <ul style="list-style-type: none"> a single slot and port (slot/port) a range of slots and ports (slot/port-slot/port) a series of slots and ports (slot/port,slot/port,slot/port) all ports on the same slot (slot/all) all ports on the switch (all) If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<i>policer svc-rate</i> <0-4000000000> <i>peak-rate</i> <8-4000000000>	Specifies the policer for filter with service rate and peak transfer rate of packets. The service rate value specifies the rate of traffic committed to be delivered. Packets above the specified peak rate value are dropped on ingress. To use this optional parameter, you must configure the <i>default-action</i> to permit .

Rename an ACL

Perform this procedure to change the name of an existing ACL.

Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Rename an ACL:

```
filter acl <1-2048> name WORD<0-32>
```

3. Reset the ACL name to the default name:

```
default filter acl <1-2048> name
```

Variable Definitions

The following table defines parameters for the **filter acl** command.

Variable	Value
<1-2048>	Specifies the ACL ID.
<i>enable</i>	Enables the ACL state, and all associated ACEs. Enabled is the default state.
<i>matchType</i> < <i>both</i> <i>terminatingNNIOnly</i> <i>uniOnly</i> >	For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <i>both</i> for traffic ingressing on both UNI ports and network-to-network interface (NNI) ports terminating on this node <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node <i>uniOnly</i> for traffic ingressing on UNI ports only The default value is <i>both</i> .
<i>name</i> WORD<0-32>	Specifies an optional descriptive name for the ACL.
<i>type</i> < <i>inVlan</i> <i>inPort</i> <i>outPort</i> <i>inVsn</i> >	Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL.

Disable an ACL

Perform this procedure to disable an ACL and all ACEs that belong to it.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Disable an ACL:

```
no filter acl <1-2048> enable
```

Variable Definitions

The following table defines parameters for the **filter acl** command.

Variable	Value
<1-2048>	Specifies the ACL ID.
<i>enable</i>	Enables the ACL state, and all associated ACEs. Enabled is the default state.

Variable	Value
<i>matchType</i> < <i>both</i> <i>terminatingNNIOnly</i> <i>uniOnly</i> >	For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> • <i>both</i> for traffic ingressing on both UNI ports and network-to-network interface (NNI) ports terminating on this node • <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node • <i>uniOnly</i> for traffic ingressing on UNI ports only The default value is <i>both</i> .
<i>name</i> WORD<0–32>	Specifies an optional descriptive name for the ACL.
<i>type</i> < <i>inVlan</i> <i>inPort</i> <i>outPort</i> <i>inVsn</i> >	Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL.

Reset an ACL to Default Values

Reset an ACL to change the ACL name to the default name and the filter ACL mode to a default of enable.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Reset an ACL to default values:

```
default filter acl <1-2048>
```

Variable Definitions

The following table defines parameters for the **filter acl** command.

Variable	Value
<1–2048>	Specifies the ACL ID.
<i>enable</i>	Enables the ACL state, and all associated ACEs. Enabled is the default state.

Variable	Value
<i>matchType</i> < <i>both</i> <i>terminatingNNIOnly</i> <i>uniOnly</i> >	For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <i>both</i> for traffic ingressing on both UNI ports and network-to-network interface (NNI) ports terminating on this node <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node <i>uniOnly</i> for traffic ingressing on UNI ports only The default value is <i>both</i> .
<i>name</i> WORD<0-32>	Specifies an optional descriptive name for the ACL.
<i>type</i> < <i>inVlan</i> <i>inPort</i> <i>outPort</i> <i>inVsn</i> >	Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL.

Delete an ACL

Delete an ACL to remove an ordered list of filter rules.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Delete an ACL:

```
no filter acl <1-2048>
```

The system displays the following message:

```
WARNING: All ACE entries under this ACL will be Deleted.
Do you wish to delete this ACL? (y/n)?
```

3. Enter *y*.

Variable Definitions

The following table defines parameters for the **filter acl** command.

Variable	Value
<1-2048>	Specifies the ACL ID.
<i>enable</i>	Enables the ACL state, and all associated ACEs. Enabled is the default state.

Variable	Value
<i>matchType</i> < <i>both</i> <i>terminatingNNIOnly</i> <i>uniOnly</i> >	For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <i>both</i> for traffic ingressing on both UNI ports and network-to-network interface (NNI) ports terminating on this node <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node <i>uniOnly</i> for traffic ingressing on UNI ports only The default value is <i>both</i> .
<i>name</i> WORD<0-32>	Specifies an optional descriptive name for the ACL.
<i>type</i> < <i>inVlan</i> <i>inPort</i> <i>outPort</i> <i>inVsn</i> >	Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL.

Clear ACL Statistics

Clear default ACL statistics if you no longer require previous statistics.

Note

The ACL statistics do not support security action on some hardware platforms.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Enter the following command to clear default ACL statistics:
clear filter acl statistics default <1-2048>
3. Enter the following command to clear global ACL statistics:
clear filter acl statistics global <1-2048>
4. Enter the following command to clear all ACL statistics:
clear filter acl statistics all
5. Enter the following command to clear statistics associated with a particular ACL, ACE, or ACE type:
clear filter acl statistics <1-2048> <1-2000> [qos] [security]

Variable Definitions

The following table defines parameters for the **clear filter acl statistics** command.

Variable	Value
<1-2048>	Specifies the ACL ID.
<1-2000>	Specifies the ACE ID.

Enable IPv6 Egress Filters

Use the **boot config flags** command to enable IPv6 egress filters and to add IPv6 egress qualifiers at startup.

Note

This procedure does not apply to 4220 Series.

Before You Begin

If more than 200 IPv4 egress entries exist in the configuration file, make a backup of the configuration file before you enable IPv6 egress filters. Only a maximum of 200 IPv4 egress entries are saved in the configuration file after you use the **save config** command.

For example, you can enter more than 200 IPv4 egress entries in the configuration file prior to enabling IPv6 egress filters. However, the entries are stored in ascending numerical order with ACL ID and ACE ID respectively, and not in the order in which they were added. Therefore, after you enable IPv6 egress filters and restart, and because the configuration file is read in ascending order, you receive an error message after the 200 maximum has been reached, such as:

```
CP1 [2017-09-28T00:44:24.077+05:30] 7K-Fi-94-I6:1 0x001049d4 00000000
GlobalRouter FILTER ERROR Unable to allocate data path resources for ACL
ID 12.
```

About This Task

This flag is disabled by default.

Note

Product Notice: For 5320 Series and 5420 Series platforms, the **boot config flags ipv6-egress-filter** and **boot config flags macsec** commands are mutually exclusive.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Enable the IPv6-egress-filter boot config flag:
`boot config flags ipv6-egress-filter`
3. Save the configuration, and then restart the switch for the change to take effect.
4. After you restart the switch, verify that the IPv6-egress-filter boot config flag is configured to true:
`show boot config flags`

Example

```
Switch:1>enable
Switch:1#configure terminal
```

```
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags ipv6-egress-filter
Warning: Please save the configuration and reboot the switch
        for this configuration to take effect.
```

Note

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
flags block-snmp false
flags debug-config false
flags debugmode false
flags dvr-leaf-mode false
flags enhancedsecure-mode false
flags factorydefaults false
flags flow-control-mode true
flags ftpd true
flags hsecure false
flags ipv6-egress-filter true
flags ipv6-mode false
flags logging true
flags macsec false
flags nni-mstp false
flags reboot true
flags spanning-tree-mode mstp
flags spbm-config-mode true
flags spbm-node-scaling true
flags sshd true
flags syslog-rfc5424-format true
flags telnetd true
flags tftpd true
flags trace-logging false
flags urpf-mode true
flags verify-config true
flags vrf-scaling true
flags vxlan-gw-full-interworking-mode false
```

Display Filter Access Control List Configuration

About This Task

Perform this procedure to display the filter Access Control List (ACL) configuration on the switch.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display filter ACL configuration:
show filter acl

Example

```
Switch:1(config)#show filter acl
```

```
=====

Access Control List Configuration using EDM

Use traffic filtering to provide security by blocking unwanted traffic and prioritizing other traffic.

Configure an Access Control List

About This Task

Use an access control list (ACL) to specify an ordered list of access control entries (ACE), or filter rules. The ACEs provide specific actions for the filter to perform.

Do not configure IPv4 egress ACL filters on network-to-network interface (NNI) ports because the system-generated egress vIST filter rules and the user-created IPv4 egress rules use the same filter hardware.

You cannot change a parameter that the system displays it dimmed; in this case, delete the ACL, and then configure a new one.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select **Insert**.

5. In **AcId**, type an ACL ID, or accept the default value .
 6. In **Type**, specify the type of ACL.
 7. In **Name**, specify a name for the ACL.
 8. Perform one of the following if the ACL is VLAN-based or port-based:
 - a. If the ACL is VLAN-based, select the **VlanList** ellipsis, and then choose a VLAN list.
 - b. If the ACL is port-based, select the **PortList** ellipsis, and then choose a port list.
 9. Select the desired ports, and then select **Ok**.
 10. Configure the **DefaultAction**.
 11. Configure the **ControlPktAction**.
-  **Note**
There is no control packet action support for the InVSN Filter. Control packets go to the CPU after termination.
12. Enable or disable the **State**, as required.
 13. In **PktType**, select the packet type to create either IPv4 or IPv6 ACLs.
 14. If the ACL type is inVsn, do the following:
 - a. In **MatchType**, select the match type to associate with the ACL that the traffic is ingressing on.
 - b. In **Isid**, type the I-SID associated with the customer VLAN (Layer 2 VSN) or the customer VRF (Layer 3 VSN) or enter 0 for IP shortcut.
 15. Configure the remaining fields, as appropriate.
 16. Select **Insert**.
 17. (Optional) To delete an ACL, select the ACL, and then select **Delete**.

ACL Field Descriptions

Use the data in the following table to use the **ACL** tab.

Name	Description
AcId	Specifies a unique identifier for the ACL.
Type	<p>Specifies the ACL type. Valid options are</p> <ul style="list-style-type: none"> • inVlan • inPort • outPort • inVsn <p>Important: The inVlan ACLs drop packets if you add a VLAN after ACE creation.</p> <p>Important: You can insert an inVsn ACL type for a Switched UNI only if the Switched UNI I-SID is associated with a platform VLAN.</p>
Name	Specifies a descriptive user-defined name for the ACL.

Name	Description
VlanList	For inVlan ACL types, specifies all VLANs to associate with the ACL.
PortList	For inPort and outPort ACL types, specifies the ports to associate with the ACL.
DefaultAction	Specifies the action taken when no ACEs in the ACL match. Valid options are deny and permit, with permit as the default. Deny means the system drops the packets; permit means the system forwards packets.
ControlPktAction	Specifies the action taken for control packets. Valid options are deny and permit.
State	Enables or disables all of the ACEs in the ACL. The default value is enable.
PktType	Indicates the packet type to which this ACL applies.
MirrorMltId	Configures mirroring to a destination MLT.
MirrorDstPortList	Configures mirroring to a destination port or ports.
MatchType	<p>For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are:</p> <ul style="list-style-type: none"> • <i>both</i> for traffic ingressing on both UNI ports and network-to-network interface (NNI) ports terminating on this node • <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node • <i>uniOnly</i> for traffic ingressing on UNI ports only <p>The default value is <i>both</i></p>
Isid	<p>For inVsn ACL types, specifies the I-SID associated with the customer VLAN (Layer 2 VSN) or the customer VRF (Layer 3 VSN). This I-SID should already be configured on the fabric node.</p> <p>The InVSN Filter supports IP Shortcut traffic if the inVsn ACL match type is <i>both</i>. In this case, the I-SID is zero (0).</p> <p>Important: You can specify a Switched UNI I-SID if the I-SID is associated with a platform VLAN.</p>
Origin	<p>Indicates the origin of the ACL:</p> <ul style="list-style-type: none"> • config - ACL created by the user. • eap - ACL created by Extensible Authentication Protocol (EAP) through Remote Authentication Dial-In User Service (RADIUS) response.
DefaultSvcRate	Specifies the service rate limit in kbps {8-4000000000}.The granularity is 8 kbps.
DefaultPeakRate	Specifies the value when exceeded causes packets to drop on ingress. Peak rate limit in kbps {8-4000000000}.The granularity is 8 kbps.

View ACL Statistics

About This Task

Graph statistics for a specific ACL ID to view default statistics.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select an ACL.
5. Select **Graph**.
6. (Optional) Select **Clear Counters** to clear the data.

Statistics Field Descriptions

Use the data in the following table to use the **Statistics** tab.

Note

Based on your hardware platform, the output can display the ACL packets by ACE type or Primary Bank or Secondary Bank.

Name	Description
AcId	Specifies the ACL ID.
MatchDefaultSecurityPkts	Shows a security packet count of traffic that does not match an ACE rule or hits the default action if count is configured in the ACL global action.
MatchDefaultSecurityOctets	Shows a security byte count of traffic that does not match an ACE rule or hits the default action if count is configured in the ACL global action.
MatchDefaultQosPkts	Shows a QoS packet count of traffic that does not match an ACE rule or hits the default action if count is configured in the ACL global action.
MatchDefaultQosOctets	Shows a QoS byte count of traffic that does not match an ACE rule or hits the default action if count is configured in the ACL global action.
MatchGlobalSecurityPkts	Shows a security packet count of traffic that matches an ACE rule or hits the default action if count is configured in the ACL global action.
MatchGlobalSecurityOctets	Shows a security byte count of traffic that matches an ACE rule or hits the default action if count is configured in the ACL global action.
MatchGlobalQosPkts	Shows a QoS packet count of traffic that matches an ACE rule or hits the default action if count is configured in the ACL global action.
MatchGlobalQosOctets	Shows a QoS byte count of traffic that matches an ACE rule or hits the default action if count is configured in the ACL global action.

Name	Description
MatchDefaultAllOctets	Shows byte count hits on Default Action if count is configured.
MatchDefaultAllPackets	Shows packet count hits on Default Action if count is configured.
MatchGlobalAllOctets	Shows byte count matching any of the ACE rules if count is configured.
MatchGlobalAllPackets	Shows packet count matching any of the ACE rules if count is configured.
MatchDefaultPrimaryBankPkts	Shows a Primary Bank packet count of traffic that does not match an ACE rule or hits the default action if count is configured in the ACL global action.
MatchDefaultPrimaryBankOctets	Shows a Primary Bank byte count of traffic that does not match an ACE rule or hits the default action if count is configured in the ACL global action.
MatchDefaultSecondaryBankPkts	Shows a Secondary Bank packet count of traffic that does not match an ACE rule or hits the default action if count is configured in the ACL global action.
MatchDefaultSecondaryBankOctets	Shows a Secondary Bank byte count of traffic that does not match an ACE rule or hits the default action if count is configured in the ACL global action.
MatchGlobalPrimaryBankPkts	Shows a Primary Bank packet count of traffic that matches an ACE rule or hits the default action if count is configured in the ACL global action.
MatchGlobalPrimaryBankOctets	Shows a Primary Bank byte count of traffic that matches an ACE rule or hits the default action if count is configured in the ACL global action.
MatchGlobalSecondaryBankPkts	Shows a Secondary Bank packet count of traffic that matches an ACE rule or hits the default action if count is configured in the ACL global action.
MatchGlobalSecondaryBankOctets	Shows a Secondary Bank byte count of traffic that matches an ACE rule or hits the default action if count is configured in the ACL global action.
DefaultGreenBytes	Shows byte count of traffic sent with a rate lower than committed-rate matching any of the ACE rules or hits on Default Action.
DefaultGreenPackets	Shows packet count of traffic sent with a rate lower than committed-rate matching any of the ACE rules or hits on Default Action.
DefaultYellowBytes	Shows byte count of traffic sent with a rate lower than peak-rate and higher than committed-rate matching any of the ACE rules or hits on Default Action.

Name	Description
DefaultYellowPackets	Shows packet count of traffic sent with a rate lower than peak-rate and higher than committed-rate matching any of the ACE rules or hits on Default Action.
DefaultRedBytes	Shows byte count of traffic sent with a rate higher than peak-rate matching any of the ACE rules or hits on Default Action.
DefaultRedPackets	Shows packet count of traffic sent with a rate higher than peak-rate matching any of the ACE rules or hits on Default Action.

Clear ACL Statistics

About This Task

Clear ACL statistics when you want to gather a new set of statistics.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select a field.
5. Select **ClearStats**.

Enable IPv6 Egress Filters

Enable IPv6 egress filters to add IPv6 egress qualifiers at startup.

Note

This procedure does not apply to 4220 Series

Before You Begin

If more than 200 IPv4 egress entries exist in the configuration file, make a backup of the configuration file before you enable IPv6 egress filters. Only a maximum of 200 IPv4 egress entries are saved in the configuration file after you save the configuration.

For example, you can enter more than 200 IPv4 egress entries in the configuration file prior to enabling IPv6 egress filters. However, the entries are stored in ascending numerical order with ACL ID and ACE ID respectively, and not in the order in which they were added. Therefore, after you enable IPv6 egress filters and restart, and because the configuration file is read in ascending order, you receive an error message after the 200 maximum has been reached, such as:

```
CP1 [2017-09-28T00:44:24.077+05:30] 7K-Fi-94-I6:1 0x001049d4 00000000
GlobalRouter FILTER ERROR Unable to allocate data path resources for ACL
ID 12.
```

About This Task

This flag is disabled by default.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **Boot Config** tab.
4. Select **EnableIpv6EgressFilterMode**.
5. Select **Apply**.
6. Save the configuration, and then restart the switch for the change to take effect.

Boot Config *Field Descriptions*

Use the data in the following table to use the **Boot Config** tab.

Name	Description
SwVersion	Specifies the software version that currently runs on the switch.
LastRuntimeConfigSource	Specifies the last source for the run-time image.
PrimaryConfigSource	Specifies the primary configuration source.
PrimaryBackupConfigSource	Specifies the backup configuration source to use if the primary does not exist.

Name	Description
EnableFactoryDefaultsMode	<p>Specifies whether the switch uses the factory default settings after you reboot the switch. The options are:</p> <ul style="list-style-type: none"> • false: The node does not use factory default settings. • fabric: This mode is not supported. • noFabric: The node uses the factory default mode settings. <p>Removes the configuration files, primary and secondary config file names, all user account passwords, digital certificates, IKE/OSPF/IS-IS keys, and SNMP communities. All ports are disabled and assigned to VLAN 1. License files are not removed.</p> <ul style="list-style-type: none"> • config-only <p>Boots the switch with a blank configuration.</p> <p>This parameter preserves configuration files, primary and secondary configuration file names, user accounts and passwords, digital certificates, IKE/OSPF/IS-IS keys, license files, and SNMP communities. All ports are disabled and assigned to VLAN 1.</p> <p>Use this parameter as a temporary troubleshooting option to test or investigate if something is wrong with the configuration without permanently removing the configuration files, user accounts, and other preserved items.</p> <ul style="list-style-type: none"> • reset-all-files: <p>Equivalent to a switch that ships from the factory. The switch has no configuration files, default user accounts, default security mode, Auto-sense-enabled ports, and performs a ZTP+ configuration after reboot. The 30-day factory license is also reset. If required, you must revoke the license file. The 30-day factory license does not apply to 4220 Series.</p> <p>Important:</p> <p>Only CLI provides two options to achieve the same behavior; there is no option other than reset-all-files in EDM.</p> <ul style="list-style-type: none"> • zero-touch:

Name	Description
	<p>Boots the switch with a default configuration that enables Auto-sense. This parameter resets secure files but keeps the security mode and performs a ZTP+ configuration after reboot. License files are not removed.</p> <ul style="list-style-type: none"> • zero-touch-config-only <p>Boots the switch with a blank configuration that enables Auto-sense and performs a ZTP+ configuration.</p> <p>This parameter preserves configuration files, primary and secondary configuration file names, user accounts and passwords, digital certificates, IKE/OSPF/IS-IS keys, license files, and SNMP communities.</p> <p>Note: Feature support can vary across platforms. For more information, see <i>Fabric Engine and VOSS Feature Matrix</i>.</p> <p>Use this parameter as a temporary troubleshooting option to test or investigate if something is wrong with the configuration without permanently removing the configuration files, user accounts, and other preserved items.</p> <p>The default value is false. This flag is automatically reset to the default value after the switch restarts.</p> <p>If you select an option but then want to select a different option and have not yet rebooted the switch, you must disable the first option before you select the second option.</p>
EnableDebugMode	<p>Enabling the debugmode allows a user to enable TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. It only works on console connection. The default value is disabled.</p> <p>Important: Do not change this parameter.</p>

Name	Description
EnableRebootOnError	Activates or disables automatic reboot on a fatal error. The default value is activated. Important: Do not change this parameter.
EnableTelnetServer	Activates or disables the Telnet server service. The default value is disabled.
EnableFtpServer	Activates or disables the FTP server on the switch. The default value is disabled. To enable FTP, ensure that the TFTPD flag is disabled.
EnableTftpServer	Activates or disables Trivial File Transfer Protocol server service. The default value is disabled.
EnableSshServer	Activates or disables the SSH server service. The default value is disabled.
EnableSpbmConfigMode	Enables you to configure SPB and IS-IS, but you cannot configure PIM and IGMP either globally or on an interface. The boot flag is enabled by default.
EnableIpv6Mode Note: Exception: does not apply to 4220 Series	Enable this flag to support IPv6 routes with prefix-lengths greater than 64 bits. This flag is disabled by default.
EnableEnhancedsecureMode	Enables or disables the enhanced secure mode. Select either jitc or non-jitc to enable the enhanced secure mode in one of these sub-modes. The default is disabled. Note: As a best practice, enable the enhanced secure mode in the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.
EnableUrpMode Note: Exception: does not apply to 4220 Series	Enables Unicast Reverse Path Forwarding (uRPF) globally. You must enable uRPF globally before you configure it on a port or VLAN. The default is disabled.

Name	Description
EnableVxlanGwFullInterworkingMode Note: Exception: only supported on 7520 Series and 7720 Series.	Enables VXLAN Gateway in Full Interworking Mode, which supports SPB, SMLT, and vIST. By default, the Base Interworking Mode is enabled and Full Interworking Mode is disabled. You change modes by enabling this boot configuration flag. In Base Interworking Mode, VXLAN Gateway supports Layer 2 gateway communication between VXLAN and traditional VLAN environments.
EnableFlowControlMode	Enables or disables flow control globally. When disabled, the system does not generate nor configure the transmission of flow control messages. The system always honors received flow control messages regardless of the flow control mode status. You must enable this mode before you configure an interface to send pause frames. The default is disabled.

Name	Description
<p>AdvancedFeatureBwReservation</p> <p>Note: Exception: high is supported on 4220 Series, 5720 Series, 7520 Series, and 7720 Series . Exception: low is not supported on 5720 Series. Exception: vim is only supported on 5520 Series and 5720 Series.</p>	<p>Enables the switch to support advanced features by reserving ports as loopback ports. When disabled, you can use all ports on the switch, but advanced features do not work.</p> <p>When you select low or high, the corresponding bandwidth of the reserved Ethernet ports is allocated to the loopback required for advanced feature functionality.</p> <p>When you select vim, the bandwidth is allocated from the unused vim slot capacity; you cannot select this parameter if the VIM is present.</p> <p>The default varies depending on the platform:</p> <ul style="list-style-type: none"> • The default for 4220 Series is enabled with high level. • The default for 5320 Series, 5420 Series, 7520 Series, and 7720 Series is enabled with low level. • The default for 5520 Series is enabled with vim level if Versatile Interface Module (VIM) is not installed, else low level is enabled. • The default for 5720 Series is enabled with vim level if Versatile Interface Module (VIM) is not installed, else high level is enabled. <p>If you change this parameter, you must restart the switch.</p>
<p>EnableDvrLeafMode</p> <p>Note: Exception: does not apply to 4220 Series</p>	<p>Enables the switch to be configured as a DvR Leaf.</p> <p>When enabled, you cannot configure the switch to operate as a DvR Controller.</p>
<p>EnablevrfScaling</p> <p>Note: Exception: does not apply to 4220 Series</p>	<p>Changes the maximum number of VRFs and Layer 3 VSNs that the switch supports. If you select this check box, the maximum number increases. The default is disabled.</p> <p>Important: If you select both this check box and the EnableSpbmConfigMode check box, the switch reduces the number of configurable VLANs. For more information about maximum scaling numbers, see <i>Fabric Engine Release Notes</i>.</p>

Name	Description
EnableSyslogRfc5424Format	Enables or disables the RFC 5424 syslog format. The default is enabled. If the pre-existing configuration file is for a release prior to this enhancement, then the flag is disabled automatically.
NniMstp Note: Exception: does not apply to 4220 Series	Enables MSTP, and allows non SPBM B-VLAN configuration on SPBM network-to-network interface (NNI) ports. The default is disabled. Note: Spanning Tree is disabled on all SPBM NNIs. You cannot add an SPBM NNI port or MLT port to any non SPBM B-VLAN.
EnableIpv6EgressFilterMode Note: Exception: does not apply to 4220 Series	Enables IPv6 egress filters. The default is disabled. If you change this parameter, you must restart the switch. For 5320 Series, 5420 Series, and 5720 Series platforms, EnableIpv6EgressFilterMode and EnableMacsec are mutually exclusive.
EnableMacsec Note: Exception: only required for MACsec supporting models of 5320 Series and 5420 Series.	Enables Media Access Control Security (MACsec) mode globally. To enable MACsec mode, you must configure the boot flag. EnableIpv6EgressFilterMode and EnableMacsec are mutually exclusive.
EnableSpbmNodeScaling Note: Exception: only applies to 5320 Series (not 5320-16P-2MXT-2X or 5320-24T-4X-XT) and 5420 Series.	Enables the switch to increase the number of supported SPB nodes per area. By default, the switch supports up to 350 SPB nodes per area. The default is disabled. If you change this parameter, you must restart the switch.
Slot	Specifies the slot number.
TftpHash	Enables TFTP hashing.
TftpRetransmit	Set TFTP retransmit timeout counter.
TftpTimeout	Set TFTP timeout counter.
User	Configure host user.
Password	Configure host password.

Access Control Entry Configuration using CLI

Use an access control entry (ACE) to provide an ordered list of traffic filtering rules. You can configure up to 1000 ACEs in a single ACL.

Note

For information about the supported ACE IDs ranges on all hardware platforms, see [ACL Filters Behavior Differences](#) on page 3706.

Configure ACEs

Use an ACE to define packet attributes and the desired behavior for packets that carry the attribute or list of attributes.

Before You Begin

- The ACL exists. If you want to use IPv6 filters, you must specify the packet type as IPv6 at the ACL level to enable IPv6 filtering.

About This Task

ACLs are by default created in enabled state while ACEs are by default created in disabled state. Use CLI commands to enable an ACE.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create and name an ACE:

```
filter acl ace <1-2048> <1-2000> [name WORD<0-32>]
```

The ACE ID determines ACE precedence (that is, the lower the ID, the higher the precedence).

3. Configure the mode as deny or permit:

```
filter acl ace action <1-2048> <1-2000> <deny|permit>
```

4. Configure ACE actions as required.

5. Ensure the configuration is correct:

```
show filter acl ace <1-2048> <1-2000>
```

6. Ensure the filter is enabled:

```
filter acl ace <1-2048> <1-2000> enable
```

7. Optionally, reset an ACE to default values (reset the ACE name to the default name and the administrative state to the default value of disable):

```
default filter acl ace <1-2048> <1-2000>
```

8. Optionally, delete an ACE ID:

```
no filter acl ace <1-2048> <1-2000>
```

Variable Definitions

Use the data in the following table to use the **filter acl ace** and the **filter acl ace action** commands.

Variable	Value
<code><1-2048></code>	Specifies the ACL ID.
<code><1-2000></code>	Specifies the ACE ID.
<code><deny permit></code>	Configures the action mode for security ACEs. Note: For each Security ACE, you must define one or more actions as well as the associated action mode (permit or deny). Otherwise, the security ACE cannot be enabled. There is no default configuration for Security ACEs. With QoS ACE, the action mode is not configurable. QoS ACEs are always set to action mode permit.
<code>enable</code>	Enables an ACE within an ACL. After you enable an ACE, to make changes, first disable it.
<code>name WORD<0-32></code>	Specifies an optional descriptive name for the ACE that uses 0-32 characters.

Configure ACE Actions

Configure ACE actions to determine the process that occurs after a packet matches an ACE.

Before You Begin

- Create ACE and ACL.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure ACE actions:

```
filter acl ace action <1-2048> <1-2000> <permit | deny>
```
3. (Optional) Configure ACE actions to count matching packets:

```
filter acl ace action <1-2048> <1-2000> <permit | deny> count
```

4. (Optional) Configure the QoS level for matching packets:

```
filter acl ace action <1-2048> <1-2000> <permit | deny> internal-qos
<0-7>
```

Note

This step does not apply to IPv6 filtering.

5. (Optional) Enable mirroring on destination MLT for matching packets:

```
filter acl ace action <1-2048> <1-2000> <permit | deny> monitor-dst-
mlt <1-512>
```

6. (Optional) Enable mirroring on a port for matching packets:

```
filter acl ace action <1-2048> <1-2000> <permit | deny> monitor-
dst-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...] [slot/all]
[all]}
```

7. (Optional) Enable mirroring on destination I-SID for matching packets:

```
filter acl ace action <1-2048> <1-2000> <permit | deny> monitor-isid-
offset <1-1000>
```

8. (Optional) Configure the next hop IPv4 or IPv6 address for redirect mode for matching packets:

```
filter acl ace action <1-2048> <1-2000> <permit | deny> redirect-next-
hop WORD<1-45> [count | unreachable | vrf {WORD <1-16>}]
```

Important

Ensure you configure the ACE match rules so that you only collect the desired traffic. For example, routed packets.

9. (Optional) Configure the next hop IPv4 or IPv6 address for redirect mode for matching packets for a VRF:

Note

If the next hop is unreachable, you can also configure ACE actions to permit or deny packet dropping within the VRF.

```
filter acl ace action <1-2048> <1-2000> <permit | deny> redirect-next-
hop WORD<1-45> vrf WORD <1-16> unreachable <permit | deny>
```

10. (Optional) Configure the next hop IPv4 or IPv6 address for redirect mode for matching packets for a VRF:

Note

If the next hop is unreachable, you can also configure ACE actions to count matching packets, or to permit or deny packet dropping within the VRF

```
filter acl ace action <1-2048> <1-2000> <permit | deny> redirect-next-
hop WORD<1-45> vrf WORD <1-16> unreachable <permit | deny> count
```

11. (Optional) Configure the QoS dot1p priority for matching packets:

```
filter acl ace action <1-2048> <1-2000> <permit | deny> remark-dot1p
<0-7>
```

**Note**

This step does not apply to IPv6 filtering.

12. (Optional) Configure the QoS phb and dscp for matching packets:

```
filter acl ace action <1-2048> <1-2000> <permit | deny> remark-dscp
[phbcs0 | phbcs1 | phbaf11 | phbaf12 | phbaf13 | phbcs2 | phbaf21 |
phbaf22 | phbaf23 | phbcs3 | phbaf31 | phbaf32 | phbaf33 | phbcs4 |
phbaf41 | phbaf42 | phbaf43 | phbcs5 | phbef | phbcs6 | phbcs7]
```

13. (Optional) Configure the mode when next hop is unreachable:

```
filter acl ace action <1-2048> <1-2000> <permit | deny> unreachable
[permit | deny]
```

14. Ensure the configuration is correct:

- `show filter acl action <1-2048> <1-2000>`
- `show filter acl config`
- `show filter acl ace`

Example

Configure ACE actions:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#filter acl ace action 1 47 permit redirect-next-hop 192.0.2.5
unreachable deny count
```

Display the configuration using the **show filter ace action** command:

```
Switch:1(config)#show filter acl action
```

Variable Definitions

Use the data in the following table to use the **filter acl ace action** command.

Variable	Value
<1-2048>	Specifies the ACL ID.
<1-2000>	Specifies the ACE ID.
<i>count</i>	Enables the ability to count matching packets. Use this parameter with either a security or QoS ACE. The default is disabled.
<deny permit>	Configures the action mode for security ACEs. Note: For each Security ACE, you must define one or more actions as well as the associated action mode (permit or deny). Otherwise, the security ACE cannot be enabled. There is no default configuration for Security ACEs. With QoS ACEs, the action mode is not configurable. QoS ACEs are always set to action mode permit.

Variable	Value
<code>monitor-isid-offset <1-1000></code>	Specifies the offset ID which will be mapped to the actual monitor I-SID where packets are mirrored. Monitor I-SID = base monitor I-SID + offset ID. The base monitor I-SID is 16776000.
<code>internal-qos <0-7></code>	This variable is a QoS action. The default value is 1. Note: This does not apply to IPv6 filtering.
<code>monitor-dst-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...] [slot/all] [all]}</code>	Configures mirroring to a destination port or ports. This action is a security action. Identifies the slot and port in one of the following formats: <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>monitor-dst-mlt <1-512></code>	Configures mirroring to a destination MLT in the range of 1 to 512.
<code>redirect-next-hop WORD <1-45></code>	Specifies the nexthop IPv4 or IPv6 address for redirect node. This action is a security action.
<code>unreachable <permit deny></code>	Denies or permits packet dropping when the next hop for the packet is unreachable. The default value is deny. This action is a security action.
<code>vrf WORD <1-16></code>	Specifies the direct next hop VRF name. The name must be in the ranger of 1 to 16 characters.

Variable	Value
<code>remark-dscp <phbcs0 phbcs1 phbaf11 phbaf12 phbaf13 phbcs2 phbaf21 phbaf22 phbaf23 phbcs3 phbaf31 phbaf32 phbaf33 phbcs4 phbaf41 phbaf42 phbaf43 phbcs5 phbcs6 phbef phbcs7></code>	<p>Specifies the new Per-Hop Behavior (PHB) for matching packets: phbcs0, phbcs1, phbaf11, phbaf12, phbaf13, phbcs2, phbaf21, phbaf22, phbaf23, phbcs3, phbaf31, phbaf32, phbaf33, phbcs4, phbaf41, phbaf42, phbaf43, phbcs5, phbef, phbcs6, phbcs7.</p> <p>This action is a QoS action.</p> <p>Note: This action applies to IPv6 filtering.</p>
<code>remark-dot1p <0-7></code>	<p>Specifies the new 802.1 priority bit for matching packets: zero, one, two, three, four, five, six, or seven.</p> <p>This action is a QoS action.</p> <p>Note: This does not apply to IPv6 filtering.</p>

Configure ARP ACEs

Use ACE Address Resolution Protocol (ARP) entries to ensure the filter looks for ARP requests or responses.

You cannot configure ARP attributes for IPv6 filters.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Configure an ACE for ARP packets:

```
filter acl ace arp <1-2048> <1-2000> operation eq <arprequest|
arpresponse>
```
3. Ensure the configuration is correct:

```
show filter acl arp <1-2048> <1-2000>
```
4. Optionally, delete the individual attributes from the ARP portion of the ACE:

```
no filter acl ace arp <1-2048> <1-2000> [operation]
```
5. Optionally, delete all the attributes from the ARP portion of the ACE:

```
default filter acl ace arp <1-2048> <1-2000>
```

Variable Definitions

Use the data in the following table to use the **filter acl ace arp** command.

Variable	Value
<1-2048>	Specifies the ACL ID.
<1-2000>	Specifies the ACE ID.
<i>operation</i> eq <arprequest arpresponse>	Specifies the type of ARP operation to filter: arpRequest or arpResponse.

Configure an Ethernet ACE

Configure an Ethernet ACE to filter on Ethernet parameters.

You do not need to configure Ethertype for IPv6 filters. If you try to configure an Ethertype other than 0x86dd or IPv6 the device displays an error.

Before You Begin

- The ACL exists.
- The ACE exists.

About This Task

The *eq* and *mask* parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure an ACE for the destination or source MAC address attribute:

```
filter acl ace ethernet <1-2048> <1-2000> <dst-mac|src-mac> eq WORD<1-1024>
```

OR

```
filter acl ace ethernet <1-2048> <1-2000> <dst-mac|src-mac> mask  
WORD<1-1024> WORD<1-1024>
```

Note

This is supported only for IPv4 filters.

3. Configure an ACE for an Ethernet type attribute:

```
filter acl ace ethernet <1-2048> <1-2000> ether-type eq WORD<1-200>
```
4. Configure an ACE for a port attribute:

```
filter acl ace ethernet <1-2048> <1-2000> port eq {slot/port[sub-port]}
```

5. Configure an ACE for a VLAN attribute:

```
filter acl ace ethernet <1-2048> <1-2000> vlan-id eq <1-4059>
```

OR

```
filter acl ace ethernet <1-2048> <1-2000> vlan-id mask <1-4059>  
<0-0xFFF>
```

6. Configure an ACE for a VLAN tagged priority attribute:

```
filter acl ace ethernet <1-2048> <1-2000> vlan-tag-prio eq <0-7>
```

OR

```
filter acl ace ethernet <1-2048> <1-2000> vlan-tag-prio mask <0-7> <0-  
0x7>
```

7. Ensure the configuration is correct:

```
show filter acl ethernet <1-2048> <1-2000>
```

8. (Optional) Delete the individual attributes from the Ethernet portion of the ACE:

```
no filter acl ace ethernet <1-2048> <1-2000>
```

9. (Optional) Delete all the attributes from the Ethernet portion of the ACE:

```
default filter acl ace ethernet <1-2048> <1-2000>
```

Variable Definitions

The following table defines parameters for the **filter acl ace ethernet** command.

Variable	Value
<0-7>	Specifies the priority bits (3-bit field) from the 802.1Q/p tag.
<0-0x7>	Specifies the mask value for VLAN tagged priority attribute.
<0-0xFFF>	Specifies the mask value for a VLAN attribute. For example: filter acl ace ethernet 10 10 vlan-id eq 10 filter acl ace ethernet 10 10 vlan-id mask 1025 0xF
<1-2048>	Specifies the ACL ID.
<1-2000>	Specifies the ACE ID.
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Variable	Value
<code>{slot/port[/sub-port]}</code>	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>WORD<1-200></code>	<p>Specifies an ether-type name or number:</p> <ul style="list-style-type: none"> • 0x0–0xffff • ip, arp, ipx802dot3, ipx802dot2, ipxSnap, ipxEthernet2, appleTalk, decLat, decOther, sna802dot2, snaEthernet2, netBios, xns, vines, ipv6, rarp, or PPPoE <p>Note: Ethernet ACE filter configured with ether-type eq ipx802dot3 does not match the packet with format destination MAC address, source MAC address, length, 0xFFFF, payload and FCS. Ethernet ACE filter configured with ether-type eq ipx802dot2 does not match the packet with format destination MAC address, source MAC address, length, 0xE0E0, payload and FCS.</p>
<code>WORD<1-1024></code>	<p>If the operator is mask, the <code>WORD<1-1024></code> parameter is {"" 1..48 , mac address mask 0x0..FFFFFFFFFFFFFF}}</p> <p>If the operator is eq, the <code>WORD<1-1024></code> parameter is the destination or source MAC address: AA:BB:CC:DD:EE:FF</p> <p>For example:</p> <pre>filter acl ace ethernet 10 10 dst-mac eq 01:00:5:00:00:01 filter acl ace ethernet 10 10 dst-mac mask 01:00:5:00:00:01 24 filter acl ace ethernet 10 10 src-mac mask 01:00:5:00:00:01 0xFFFFFFFFF0000</pre>

Configure an IP ACE

Configure an IP ACE to filter on the source IP address, destination IP address, DiffServ Code Point (DSCP), protocol, IP options, IP fragmentation, and routed packets only.

Before You Begin

- The ACL exists.
- The ACE exists.

About This Task

The `eq` and `mask` parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure an ACE for the DSCP attribute:

```
filter acl ace ip <1-2048> <1-2000> dscp
eq {<0..63>|<0x00..0x3f>|phbcs0|phbcs1|phbaf11|phbaf12|phbaf13|phbcs2|
phbaf21|phbaf22|phbaf23|phbcs3|phbaf31|phbaf32|phbaf33|phbcs4|phbaf41|
phbaf42|phbaf43|phbcs5|phbef|phbcs6|phbcs7}
```

OR

```
filter acl ace ip <1-2048> <1-2000>
dscp mask {<0..63>|<0x00..0x3f>|phbcs0|phbcs1|phbaf11|
phbaf12|phbaf13|phbcs2|phbaf21|phbaf22|phbaf23|phbcs3|phbaf31|phbaf32|
phbaf33|phbcs4|phbaf41|phbaf42|phbaf43|phbcs5|phbef|phbcs6|phbcs7}
WORD<0x0-0x40>
```

3. Configure an ACE for the destination or source IP address attribute:

```
filter acl ace ip <1-2048> <1-2000> <dst-ip|src-ip> eq WORD<1-1024>
```

OR

```
filter acl ace ip <1-2048> <1-2000> <dst-ip|src-ip> mask WORD<1-1024>
{<0-32>|null|<A.B.C.D>}
```

4. Configure an ACE for the IP fragmentation attribute:

```
filter acl ace ip <1-2048> <1-2000> ip-frag-flag eq <noFragment|
anyFragment>
```

5. Configure an ACE for the IP options attribute:

```
filter acl ace ip <1-2048> <1-2000> ip-options any
```

6. Configure an ACE for the protocol type attribute:

```
filter acl ace ip <1-2048> <1-2000> ip-protocol-type eq WORD<1-256>
```

7. Configure an ACE for routed packets only:

```
filter acl ace ip <1-2048> <1-2000> routed-only
```

8. Ensure the configuration is correct:

```
show filter acl ip <1-2048> <1-2000>
```

9. (Optional) Delete all the attributes from the IP (Layer 3) portion of the ACE:

```
default filter acl ace ip <1-2048> <1-2000>
```

Example

```
Switch:1(config)#filter acl ace ip 1 12 dst-ip eq 198.51.100.0
```

Variable definitions

Use the data in the following table to use the **filter acl ace ip** command.

Variable	Value
<1-2000>	Specifies the ACE ID.
<1-2048>	Specifies the ACL ID.
{<0-32> <i>null</i> <A.B.C.D>}	Specifies the mask value for the destination or source IP address For example: <pre>filter acl ace ip 10 10 dst-ip mask 198.51.100.0 25 filter acl ace ip 10 10 dst-ip mask 198.51.100.1 203.0.113.0 filter acl ace ip 10 10 src-ip mask 198.51.100.2 22 filter acl ace ip 10 10 src-ip mask 198.51.100.3 203.0.113.1</pre>
< <i>noFragment</i> <i>anyFragment</i> >	Specifies a match option for IP fragments <i>noFragment</i> or <i>anyFragment</i> .

Variable	Value
<code>{<0..63> <0x00..0x3f> phbcs0 phbcs1 phbaf11 phbaf12 phbaf13 phbcs2 phbaf21 phbaf22 phbaf23 phbcs3 phbaf31 phbaf32 phbaf33 phbcs4 phbaf41 phbaf42 phbaf43 phbcs5 phbcs6 phbef phbcs7}</code>	<p>Specifies the DSCP value using one of the following formats:</p> <ul style="list-style-type: none"> Enter as an integer (0–63) or hex (0x00–0x3f), or as a string: <ul style="list-style-type: none"> phbcs0 — Enter as string “phbcs0”, integer 0 or hex 0x00 phbcs1 — Enter as string “phbcs1”, integer 8 or hex 0x08 phbaf11 — Enter as string “phbaf11” integer 10 or hex 0x0a phbaf12 — Enter as string “phbaf12”, integer 12 or hex 0x0c phbaf13 — Enter as string “phbaf13”, integer 14 or hex 0x0e phbcs2 — Enter as string “phbcs2”, integer 16 or hex 0x10 phbaf21 — Enter as string “phbaf21”, integer 18 or hex 0x12 phbaf22 — Enter as string “phbaf22”, integer 20 or hex 0x14 phbaf23 — Enter as string “phbaf23”, integer 22 or hex 0x16 phbcs3 — Enter as string “phbcs3”, integer 24 or hex 0x18 phbaf31 — Enter as string “phbaf31”, integer 26 or hex 0x1a phbaf32 — Enter as string “phbaf32”, integer 28 or hex 0x1c phbaf33 — Enter as string “phbaf33”, integer 30 or hex 0x1e phbcs4 — Enter as string “phbcs4”, integer 32 or hex 0x20 phbaf41 — Enter as string “phbaf41”, integer 34 or hex 0x22 phbaf42 — Enter as string “phbaf42”, integer 36 or hex 0x24 phbaf43 — Enter as string “phbaf43”, integer 38 or hex 0x26 phbcs5 — Enter as string “phbcs5”, integer 40 or hex 0x28 phbef — Enter as string “phbef”, integer 46 or hex 0x2e phbcs6 — Enter as string “phbcs6”, integer 48 or hex 0x30 phbcs7 — Enter as string “phbcs7”, integer 56 or hex 0x38
<code>WORD<0x0-0x40></code>	<p>Specifies the mask value, for example, <code>filter acl ace ip 10 10 dscp mask 129 0x40</code></p>

Variable	Value
<i>WORD</i> <1-256>	Specifies one or more IP protocol types: (1-256), or tcp, udp, ipsecesp, vrrp, snmp or undefined.
<i>WORD</i> <1-1024>	Specifies the destination or source IP address (a.b.c.d).

Configure an IPv6 ACE

Configure an IPv6 ACE to filter traffic based on Source IPv6 address, Destination IPv6 address, IPv6 next header, and IPv6 traffic class, and routed packets only.

Source IPv6 and destination IPv6 support equal (eq) and mask operators. Next header and traffic class attributes support the equal (eq) operator. The equal to rule operator looks for an exact match with the field defined. If the field matches exactly with the rule, the system will return a match (hit). ACL-based filters provide the mask operator to match on Layer 2, Layer 3, and Layer 4 packet fields. The mask operator is used to mask bits in packet fields during a search or to match on a partial value of a packet field.

Before You Begin

- The ACL exists with the IPv6 packet type. You can only configure ACE IPv6 attributes to filter on an IPv6 packet.
- The ACE exists.

About This Task

The *eq* and *mask* parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Create and name an ACE:

```
filter acl ace <1-2048> <1-2000> [name Word<1-32>]
```
3. Configure an ACE for the destination IPv6 address attribute:

```
filter acl ace ipv6 <1-2048> <1-2000> dst-ipv6 eq WORD<0-255>
```

OR

```
filter acl ace ipv6 <1-2048> <1-2000> dst-ipv6 mask WORD<1-128> WORD<0-255>
```
4. Configure an ACE for the source IP address attribute:

```
filter acl ace ipv6 <1-2048> <1-2000> src-ipv6 eq WORD<0-255>
```

OR

```
filter acl ace ipv6 src-ipv6 <1-2048> <1-2000> mask WORD<1-128> WORD<0-255>
```

- Specify the next header of the IP header:

```
filter acl ace ipv6 <1-2048> <1-2000> nxt-hdr eq {fragment|hop-by-hop|
icmpv6|ipsecah|ipsecesp|noHdr|routing|tcp|udp|undefined}
```

You must configure next header to configure the protocol attributes.

- Specify the traffic class attribute of the IPv6 header:

```
filter acl ace ipv6 <1-2048> <1-2000> traffic-class eq WORD<0-255>
```

- Configure an ACE for routed packets only:

```
filter acl ace ipv6 <1-2048> <1-2000> routed-only
```

- Ensure that your configuration is correct:

```
show filter acl ipv6 <1-2048> <1-2000>
```

Example

```
Switch:1(config)#filter acl ace ipv6 15 15 dst-ipv6 eq 30:0:0:0:0:0:ffff/64
```

Configure a Protocol ACE

Configure a protocol ACE to filter on the source port, destination port, ICMP and ICMPv6 message type, or TCP flags.

Note

For IPv6 filters, you must configure next header to configure the protocol attributes.

Before You Begin

- The ACL exists.
- The ACE exists.

About This Task

The *eq* and *mask* parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Configure an ACE for destination port attributes:

```
filter acl ace protocol <1-2048> <1-2000> dst-port eq WORD<1-60>
```

OR

```
filter acl ace protocol <1-2048> <1-2000> dst-port mask WORD<1-60>
WORD<1-256>
```

3. Configure an ACE for source port attributes:

```
filter acl ace protocol <1-2048> <1-2000> src-port eq WORD<1-65535>
```

OR

```
filter acl ace protocol <1-2048> <1-2000> src-port mask WORD<1-65535>
WORD<1-256>
```

4. Configure an ACE for ICMP message type attributes:

```
filter acl ace protocol <1-2048> <1-2000> icmp-msg-type eq WORD<1-200>
```

5. Configure an ACE for TCP flags attributes:

```
filter acl ace protocol <1-2048> <1-2000> tcp-flags eq WORD<1-50>
```

OR

```
filter acl ace protocol <1-2048> <1-2000> tcp-flags mask {0-0x3F|
0-0x3F}
```

6. Ensure the configuration is correct:

```
show filter acl protocol <1-2048> <1-2000>
```

7. (Optional) Delete the individual attributes from the protocol portion of the ACE:

```
no filter acl ace protocol <1-2048> <1-2000> [dst-port] [icmp-msg-
type] [icmpv6-msg-type] [routing-type] [src-port] [tcp-flags]
```

8. (Optional) Delete all the attributes from the protocol portion of the ACE:

```
default filter acl ace protocol <1-2048> <1-2000>
```

Examples

Specify ICMP packets:

```
Switch:1(config)#filter acl ace protocol 1 12 icmpv6-msg-type eq echoRequest
```

Table 324: TCP Flags Order in Packet

32 (decimal)	16 (decimal)	8 (decimal)	4 (decimal)	2 (decimal)	1 (decimal)
Urgent	Ack	Push	Reset	Syn	Fin

Configure an ACE for TCP flags attributes: Example 1

The mask is set for an 'ack' tcp flag bit regardless of whether any other tcp flag bits are also set:

```
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask ack ?
<0-0x3F | 0-63> Mask value <Hex | Decimal>: This six bit mask is a reverse mask where
0:care
                                about, 1:do not care about

Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask ack 0x2f
Hex Value 20 10 8 4 2 1
TCP Flags _ack _ _ _ _
Binary Value 1 0 1 1 1 1 or in hex = 0x2F
```

Configure an ACE for TCP flags attributes: Example 2

A packet will match this filter if the 3 tcpflag bits are set in the tcp header (and only those 3 bits).

```
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags eq ?
WORD<1-50> Tcp flags
{none | fin | syn | rst | push | ack | urg | undefined}
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags eq syn,push,urg
```

You can configure a functionally equivalent filter with the mask operator as follows:

```
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask syn,push,urg 0x0
```

Configure an ACE for TCP flags attributes: Example 3

The mask operator provides more flexibility. For example a packet will match the following filter if the 'syn,push,urg' tcpflag bits are set, regardless of whether any other tcpflag bits are also set:

```
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask syn,push,urg ?
<0-0x3F | 0-63> Mask value <Hex | Decimal>: This six bit mask is a reverse mask where
0:care
                                about, 1:do not care about
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask syn,push,urg 0x15
```

Configure an ACE for ICMP message type: Example 4

```
filter acl 1 type inPort name "ICMP_TRAFFIC_FILTER"
filter acl port 1 1/3
filter acl ace 1 1
filter acl ace action 1 1 deny count
filter acl ace ethernet 1 1 ether-type eq ip
filter acl ace ip 1 1 src-ip mask 194.183.100.64 0.0.0.15
filter acl ace ip 1 1 dst-ip eq 146.97.137.42
filter acl ace ip 1 1 ip-protocol-type eq icmp
filter acl ace protocol 1 1 icmp-msg-type eq echo-request
filter acl ace 1 1 enable
filter acl ace 1 2
filter acl ace action 1 2 deny count
filter acl ace ethernet 1 2 ether-type eq ip
filter acl ace ip 1 2 src-ip mask 194.183.100.64 0.0.0.15
filter acl ace ip 1 2 dst-ip eq 146.97.137.42
filter acl ace ip 1 2 ip-protocol-type eq icmp
filter acl ace protocol 1 2 icmp-msg-type eq echoreply
filter acl ace 1 2 enable
```

Variable Definitions

Use the data in the following table to use the **filter acl ace protocol** command.

Variable	Value
{0-0x3F}	Specifies the mask value.
<1-2000>	Specifies the ACE ID.
<1-2048>	Specifies the ACL ID.
WORD<1-50>	Specifies one or more TCP flags—none, fin (finish connection), syn (synchronize), rst (reset connection), push, ack (acknowledge), urg (urgent), and undefined.

Variable	Value
<i>WORD<1-60></i>	Specifies the destination port: (0-65535), or echo, ftpdata, ftpcontrol, ssh, telnet, dns, http, hdot323, bootpServer, bootpClient, tftp, rtp, rtcp, or undefined.
<i>WORD<1-200></i>	Specifies the ICMP message type: Icmpmsg type (0-255), or echoreply, destunreach, sourcequench, redirect, echo-request, routeradv, routerselect, time-exceeded, param-problem, timestamp-request, timestamp-reply, addressmask-request, addressmask-reply, or traceroute.
<i>WORD<1-200></i>	Specifies the ICMPv6 message type: Icmpmsg type (0-255), or destUnreach, pktTooBig, timeExceeded, paramProblem, echoRequest, echoReply, mcastListenReq, mcastListenRpt, mcastListenDone, routerSolicit, routerAdvert, neighborSolicit, neighborAdvert, redirectMsg, nodeInfoReq, nodeInfoRsp, or v2McastListenRpt.
<i>WORD<1-256></i>	Specifies the mask parameter, {0-0xFFFF}.
<i>WORD<0-65535></i>	Specifies the source port (0-65535).

Configure Ingress Policer and Port Rate Limiter

Before You Begin

Ensure that both the ACL and the ACE exist.

About This Task

Perform this procedure to limit the number of packets that can be attached to an ACL ACE. If you want to modify the ingress bandwidth rate limiter values, you must first disable the ACE.

Note

You can attach one policer to ACL and ACE. Every policer is independent.

Procedure

1. Enter the Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure an ACL and ACE policer:

```
filter acl ace policer <1-2048> <1-2000> svc-rate <0-4000000000> peak-  
rate <8-4000000000>
```

Note

You must configure both svc-rate and peak-rate.

3. Ensure the configuration is correct:

```
show filter acl policer <1-2048> <1-2000>
```

Variable Definitions

The following table defines parameters for the **filter acl ace policer** command.

Variable	Value
<1-2048>	Specifies the ACL ID.
<1-2000>	Specifies the ACE ID.
<i>svc-rate</i> <0-4000000000>	Specifies the rate of the traffic committed to be delivered. Service rate limit in kbps {0-4000000000}.The granularity is 8 kbps.
<i>peak-rate</i> <8-4000000000>	Specifies the value when exceeded causes packets to drop on ingress. Peak rate limit in kbps {8-4000000000}.The granularity is 8 kbps.

View ACL and ACE Configuration Data

View your configuration to review the information and ensure it is correct.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. View ACL information:
`show filter acl <1-2048>`
3. View IPv6 ACL information:
`show filter acl ipv6 <1-2048> <1-2000>`
4. View the running configuration for an ACL and corresponding ACE:
`show filter acl config <1-2048> <1-2000>`

Variable Definitions

Use the data in the following table to use the **show filter acl** and **show filter acl config** commands.

Variable	Value
<1-2000>	Specifies the ACE ID.
<1-2048>	Specifies the ACL ID.

View ACE Statistics

View ACE statistics to ensure that the filter operates correctly.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View ACE statistics for a specific ACL, ACE, or ACE type:
show filter acl statistics <1-2048> <1-2000> [qos] [security]
3. View all ACE statistics:
show filter acl statistics all
4. View default ACE statistics:
show filter acl statistics default [<1-2048>]
5. View global statistics for ACEs:
show filter acl statistics global [<1-2048>]
6. View filter policer statistics for ACL and ACE:
show filter acl statistics <1-2048> <1-2000> policer

Examples

View ACE statistics:

```
Switch:1#show filter acl statistics all
=====
Acl Default Statistics Table

Variable Definitions

The following table defines parameters for the **show filter acl statistics** command.

Variable	Value
<1-2048>	Specifies the ACL ID.
<1-2000>	Specifies the ACE ID.
<i>policer</i>	Specifies the policer parameter for the command.

Access Control Entry Configuration using EDM

Use an access control entry (ACE) to define a pattern (found in a packet) and the desired behavior for packets that carry the pattern. You can configure up to 1000 ACEs in a single ACL.

As a best practice, create access control lists (ACL) with a default action of permit, and with an ACE mode of deny. For deny or permit ACLs or ACEs, the default action and the mode must be opposite for the ACE (filter) to have meaning.

Configure an ACE

Before You Begin

- The ACL exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the ACL to which to add an ACE.
5. Select **ACE**.
6. Select the **ACE Common** tab.

7. Select **Insert**.
8. Configure the ACE ID.
9. Name the ACE.
10. Choose the mode: **deny** (drop packets) or **permit** (forward packets).
11. Configure the ACE actions as required.
12. Select **Insert**.
13. Configure the ACE attributes as required.
14. To enable the ACE, in the **ACE Common** tab, configure **AdminState** to enable, and then select **Apply**.
15. To delete an ACE Common entry, select the entry, and then select **Delete**.

ACE Common Field Descriptions

Use the data in the following table to use the **ACE Common** tab.

Name	Description
AclId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Name	Specifies a descriptive user-defined name for the ACE. The system automatically assigns a name if you do not type one.
AdminState	Indicates the status of the ACE as enabled or disabled. You can modify an ACE only if you disable it.
OperState	Indicates the current operational state of the ACE.
Mode	Indicates the operating mode for this ACE. Valid options are deny and permit, with deny as the default.
RedirectNextHop	Redirects matching IPv4/IPv6 traffic to IPv4/IPv6 nexthop.
RedirectNextHopVrfname	Specifies the direct next hop VRF name. The name must be in the range of 1 to 16 characters.
RedirectUnreach	Denies or permits packet dropping when the next hop for the packet is unreachable. The default value is deny. This action is a security action.
InternalQos	This variable is a QoS action. The default value is 1.
RemarkDscp	Specifies whether the DSCP parameter marks nonstandard traffic classes and local-use Per-Hop Behavior. The default is disable. Use this option to create a QoS ACE.
RemarkDot1Priority	Specifies whether Dot1 Priority, as described by Layer 2 standards (802.1Q and 802.1p) is enabled. The default is disable. Use this option to create a QoS ACE.
Count	Specifies whether the count action in the ACE is enabled or disabled. The default is disabled.

Configure ACE Actions

Configure ACE actions to determine the process that occurs after a packet matches (or does not match) an ACE. Use debug actions (flags) to use filters for troubleshooting and monitoring procedures.

Before You Begin

- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select an **AceId**.
7. Select **Action**.
8. Configure the actions as required, and then select **Apply**.

Action Field Descriptions

Use the data in the following table to use the **Action** tab.

Note

The table lists the options for both Security ACEs and QoS ACEs. Dependent upon the ACE, the system displays different options on the EDM interface.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Mode	Configures the action mode for security ACEs. The default value is deny.
RemarkDscp	Specifies the new Per-Hop Behavior (PHB) for matching packets: phbcs0, phbcs1, phbaf11, phbaf12, phbaf13, phbcs2, phbaf21, phbaf22, phbaf23, phbcs3, phbaf31, phbaf32, phbaf33, phbcs4, phbaf41, phbaf42, phbaf43, phbcs5, phbef, phbcs6, phbcs7. This action is a QoS action.
RemarkDot1Priority	Specifies the new 802.1 priority bit for matching packets: zero, one, two, three, four, five, six, or seven. This action is a QoS action. Note: This does not apply to IPv6 filtering.

Name	Description
InternalQoS	This variable is a QoS action. The default value is 1. Note: This does not apply to IPv6 filtering.
RedirectNextHop	Specifies the next-hop IPv4 address (a.b.c.d) or IPv6 address (aaaa:bbbb:cccc:dddd:eeee:ffff:gggg:hhhh) for redirect mode. Applies to ingress ACLs (routed and Layer 2 packets).
Count	Enables the ability to count matching packets. Use this parameter with either a security or QoS ACE. The default is disabled.
DstPortList	Configures mirroring to a destination port or ports. This action is a security action.
DstMltd	Configures mirroring to a destination MLT. This action is a security action.
MonitoringIsidOffset	Configures the monitoring I-SID offset value. The offset ID is mapped to the actual monitor I-SID value to which the packets are mirrored.
MirroringQoS	Defines the Quality of Service (QoS) profiles for the mirrored packet into monitoring I-SID.

Configure ACE ARP Entries

Use ACE Address Resolution Protocol (ARP) entries so that the filter looks for ARP request or response packets.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select a parameter for the appropriate ACL.
5. Select **ACE**.
6. Select a parameter for the appropriate ACE.
7. Select **Arp**.
8. Select **Insert**.

9. Select ARP request or response.
10. Select **Insert**.

ARP Field Descriptions

Use the data in the following table to use the **ARP** tab.

Name	Description
AclId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Type	Specifies the ACE ARP operation. The only option is operation.
Oper	Specifies the operator for the ACE ARP operation. The only option is eq (equal).
Value	Specifies the ARP packet type. Valid options are arpRequest and arpResponse.

View ACE ARP Entries for an ACL

View all of the ACE ARP entries associated with an ACL.

Procedure

1. In the navigation tree, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **Arp**.
6. Select the parameter and modify as you need.
7. Select **Apply**.

ARP Field Descriptions

Use the data in the following table to use the **ARP** tab.

Name	Description
AclId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Type	Specifies the ACE ARP operation. The only option is operation.
Oper	Specifies the operator for the ACE ARP operation. The only option is eq (equal).
Value	Specifies the ARP packet type. Valid options are arpRequest and arpResponse.

Configure an ACE Ethernet Source Address

Use this procedure to filter on specific Ethernet source addresses.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **Eth**.
8. Select the **Source Address** tab.
9. Select **Insert**.
10. Specify the ACE Ethernet operation.
11. In the **List** dialog box, specify the Ethernet source address.
12. Select **Insert**.

Source Address Field Descriptions

Use the data in the following table to use the **Source Address** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
List	Specifies the MAC address to match.
OperMask	Specifies the MAC Address mask value in hexadecimal format. The value for this variable is empty or 000000000000 if the Oper variable is eq.

Configure an ACE Ethernet Destination Address

Perform this procedure to filter on specific Ethernet destination addresses.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **Eth**.
8. Select the **Destination Address** tab.
9. Select **Insert**.
10. Specify the ACE Ethernet operation.
11. In the **List** dialog box, specify the Ethernet source address.
12. Select **Insert**.

Destination Address Field Descriptions

Use the data in the following table to use the **Destination Address** tab.

Variable	Value
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
List	Specifies the MAC address to match.
OperMask	Specifies the MAC address mask value in hexadecimal format if the Oper variable is mask. The value of this variable is empty or 000000000000 if Oper is eq.

Configure an ACE LAN Traffic Type

Perform this procedure to filter for specific LAN traffic packets.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **Eth**.

8. Select the **Ethernet Type** tab.
9. Select **Insert**.
10. Specify the operation type.
11. In the **TypeList** box, type the Ethernet types.
12. Select **Insert**.

Ethernet Type Field Descriptions

Use the data in the following table to use the **Ethernet Type** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
TypeOper	The eq parameter specifies an operator for a field match condition: equal to.
TypeList	<p>Specifies the Ethernet type. Entries include: 0 to 0xffff or ip, arp, ipx802.3, ipx802.2, ipxSnap, ipxEthernet2, appleTalk, appleTalk-ARP, sna802.2, snaEthernet2, netBios, xns, vines, ipv6, rarp, PPPoE-discovery, and PPPoE-session.</p> <p>Note: Ethernet ACE filter configured with Ethernet Type ipx802.3 does not match the packet with format destination MAC address, source MAC address, length, 0xFFFF, payload and FCS. Ethernet ACE filter configured with Ethernet Type ipx802.2 does not match the packet with format destination MAC address, source MAC address, length, 0xE0E0, payload and FCS.</p>

Configure an ACE Ethernet VLAN Tag Priority

Perform this procedure to filter for specific VLAN tag priorities.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **Eth**.

8. Select the **Vlan Tag Priority** tab.
9. Select **Insert**.
10. Specify the operation type.
11. In the **VlanTagPrio** box, select the priority bits.
12. Select **Insert**.

VLAN Tag Priority *Field Descriptions*

Use the data in the following table to use the **Vlan Tag Priority** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
VlanTagPrio	Specifies the priority bits (3-bit field) from the 802.1Q/p tag: <ul style="list-style-type: none"> • zero • one • two • three • four • five • six • seven
OperMask	Specifies the mask value in hexadecimal format if the Oper value is mask.

Configure an ACE Ethernet Port

Use ACE Ethernet port entries so that the filter looks for traffic on specific ports. You can only insert an ACE Common Ethernet port for VLAN ACL types.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **Eth**.

8. Select the **Port** tab.
9. Select **Insert**.
10. Specify the operation type.
11. Select the **Port** ellipses (...).
12. Choose the ports.
13. Select **OK**.
14. Select **Insert**.

Port Field Descriptions

Use the data in the following table to use the **Port** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq parameter specifies an operator for a field match condition: equal to.
Port	Specifies the port or port list on which to perform a match.

Configure an ACE Ethernet VLAN ID

Use ACE Ethernet VLAN ID entries so that the filter looks for traffic on specific VLANs. You can insert an ACE Ethernet VLAN ID only for ACL VLAN types.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **Eth**.
8. Select the **Vlan Id** tab.
9. Select **Insert**.
10. Specify the operation type.
11. Enter the VLAN ID or select from a list.
12. Select **Insert**.

VLAN ID *Field Descriptions*

Use the data in the following table to use the **Vlan Id** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq parameter specifies an operator for a field match condition: equal to.
VlanId	Specifies the VLAN ID on which to perform a match.
OperMask	Specifies the mask value for a VLAN attribute.

View All ACE Ethernet Entries for an ACL

View all of the ACE Ethernet entries associated with an ACL.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **Eth**.

Ethernet *Field Descriptions*

Use the data in the following table to use the **Ethernet** tab.

Name	Description
AcId	Shows the ACL ID.
AcId	Specifies the ACE ID.
SrcAddrList	Shows the list of Ethernet source addresses to match.
SrcAddrOper	Shows the operators for the ACE Ethernet source MAC address.
SrcAddrOperMask	Shows the source MAC address mask value in hexadecimal format if the SrcAddrOper variable is mask. The value of this field is empty or 000000000000 if the SrcAddrOper field is eq.
DstAddrList	Shows the list of Ethernet destination addresses to match.
DstAddrOper	Shows the operators for the ACE Ethernet destination MAC address.
DstAddrOperMask	Shows the destination MAC address mask value in hexadecimal format if the DstAddrOper variable is mask. The value for this field is empty or 000000000000 if the DstAddrOper field is eq.

Name	Description
EtherTypeList	Shows the EtherType value from the Ethernet header. For example, ARP uses 0x0806 and IP uses 0x0800. Platform support determines the behavior for 802.1Q/p tagged packets. The EtherType for 802.1Q tagged frames is 0x8100. The range is 0–65535 and supports lists and ranges of values. An invalid Ether-type of 65536 indicates that you do not want the parameter in the match criteria.
EtherTypeOper	Shows the Ethernet type operators.
VlanTagPrio	Shows the priority bits (3-bit field) from the 802.1Q/p tag.
VlanTagPrioOper	Shows the operators for the ACE Ethernet VLAN tag priority.
VlanTagPrioOperMask	Shows the VLAN tag priority mask value in hexadecimal format if the VlanTagPrioOper field is mask.
Port	Shows the port number or port list to match.
PortOper	Shows the operator for the ACE Ethernet port.
VlanId	Shows the VLAN ID to match.
VlanIdOper	Shows the operator for the ACE Ethernet VLAN ID.
VlanIdOperMask	Shows the VLAN ID mask value in hexadecimal format if the VlanIdOper field is mask.

Configure an ACE IP Source Address

Configure ACE IP source address entries to have the filter look for specific source IP addresses.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **IP**.
8. Select the Source Address tab.
9. Select **Insert**.

10. Specify the operation type.
11. In the **IPAddr** box, enter the source IP address.
12. Select **Insert**.

Source Address *Field Descriptions*

Use the data in the following table to use the **Source Address** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
IPAddr	Specifies the source IP address.
OperMask	Specifies the mask value for the source IP address.

Configure an ACE IP Destination Address

Configure ACE IP destination address entries to have the filter look for specific destination IP addresses.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **IP**.
8. Select the **Destination Address** tab.
9. Select **Insert**.
10. Specify the operation type.
11. In the **IPAddr** box, enter the destination IP address.
12. Select **Insert**.

Destination Address *Field Descriptions*

Use the data in the following table to use the **Destination Address** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
IPAddr	Specifies the destination IP address.
OperMask	Specifies the mask value for the destination IP address.

Configure an ACE IP DSCP

Configure ACE IP DSCP entries to have the filter look for packets with specific DSCP markings.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **IP**.
8. Select the **DSCP** tab.
9. Select **Insert**.
10. Specify the operation type.
11. In the **List** box, enter the count for the DSCP values.
12. Select **Insert**.

DSCP *Field Descriptions*

Use the data in the following table to use the **DSCP** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.

Name	Description
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
List	Specifies a count for the number of discrete ranges entered for the DSCP values. Entries include 0–256, disable, phbcs0, phbcs1, phbaf11, phbaf12, phbaf13, phbcs2, phbaf21, phbaf22, phbaf23, phbcs3, phbaf31, phbaf32, phbaf33, phbcs4, phbaf41, phbaf42, phbaf43, phbcs5, phbef, phbcs6, and phbcs7.
OperMask	Specifies the mask value.

Configure an ACE IP Protocol

Configure ACE IP protocol entries to have the filter look for packets of specific protocols.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **IP**.
8. Select the **Protocol** tab.
9. Select **Insert**.
10. Specify the operation type.
11. In the **List** box, enter the IP protocol type.
12. Select **Insert**.

Protocol Field Descriptions

Use the data in the following table to use the **Protocol** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq parameter specifies an operator for a field match condition: equal to.
List	Specifies the IP protocol type. Entries include 0–256, undefined, tcp, udp, ipsecesp, vrrp, and undefined.

Configure ACE IP Options

Configure ACE IP option entries to have the filter look for packets with an IP option specified.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **IP**.
8. Select the **Options** tab.
9. Select **Insert**.
10. Specify the logical operator.
Any is the only choice.
11. Select **Insert**.

Options Field Descriptions

Use the data in the following table to use the **Options** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	Specifies the logical operator for the ACE IP options. Any is the only option.

Configure ACE IP Fragmentation

Configure ACE IP fragmentation entries to have the filter look for packets with the fragmentation flag.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.

4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **IP**.
8. Select the **Fragmentation** tab.
9. Select **Insert**.
10. Specify the operator for IP fragmentation.
Eq is the only choice.
11. Specify the fragmentation bits to match from the IP header.
12. Select **Insert**.

Fragmentation Field Descriptions

Use the data in the following table to use the **Fragmentation** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	Specifies the logical operator for the ACE IP options. Any is the only option.
Fragmentation	Specifies the IP fragmentation bits to match from the IP header: <ul style="list-style-type: none"> • noFragment • anyFragment The default is noFragment.

View all ACE IP Entries for an ACL

View all of the ACE IP entries associated with an ACL.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **IP**.

IP Field Descriptions

Use the data in the following table to use the **IP** tab.

Name	Description
AcId	Shows the ACL IP ID.
AcId	Shows the ACE ID.
SrcAddrOper	Shows the operators for the ACE IP source address.

Name	Description
SrcAddrIpAddr	Shows the IP source address to match from the IP header.
SrcAddrOperMaskRange	Shows the IP mask value if SrcAddrOper is set to mask, or the highest IP address if SrcAddrOper is set to range.
DstAddrOper	Shows the operators for the ACE IP destination address.
DstAddrIpAddr	Shows the IP destination address to match from the IP header.
DstAddrOperMaskRange	Shows the IP mask value if DstAddrIpAddr is set to mask, or the highest IP address if DstAddrIpAddr is set to range.
DscpList	Shows how the 6-bit DSCP parameter from the TOS byte in the IPv4 header encodes PHB information following RFC 2474.
DscpOper	Shows the operators for the ACE IP DSCP.
DscpOperMask	Shows the mask value in hexadecimal format when the mask option is selected in DscpOper .
ProtoList	Shows the IP protocol type from the IP header to match. The range is 0–255.
ProtoOper	Shows the operators for the ACE IP protocols.
Options	Shows the IP options to match from the IP header.
OptionsOper	Shows the logical operator. Any is the only option.
Fragmentation	Shows the IP fragmentation bits to match from the IP header.
FragOper	Shows the operator for IP fragmentation.

Configure an ACE IPv6 Source Address

Configure ACE IPv6 source address entries to have the filter look for specific source IP addresses.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.

7. Select **IPv6**.
8. Select the **Source Address** tab.
9. Select **Insert**.
10. In **Oper**, select the operation type.
11. In **List**, enter the source IP address.
12. In **OperMask**, enter the operation mask value.
13. Select **Insert**.

Source Address *Field Descriptions*

Use the data in the following table to use the **Source Address** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
List	Specifies the source IP address.
OperMask	Specifies the mask value for the source IP address.

Configure an ACE IPv6 Destination Address

Configure ACE IPv6 destination address entries to have the filter look for specific destination IP addresses.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **IPv6**.
8. Select the **Destination Address** tab.
9. Select **Insert**.
10. In **Oper**, select the operation type.
11. In **List**, enter the destination IP address.
12. In **OperMask**, enter the operation mask value.
13. Select **Insert**.

Destination Address Field Descriptions

Use the data in the following table to use the **Destination Address** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
List	Specifies the destination IP address.
OperMask	Specifies the mask value for the destination IP address.

Configure an ACE IPv6 Next Header

Configure ACE IPv6 next header entries to have the filter look for specific next headers.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **IPv6**.
8. Select the **Next Hdr** tab.
9. Select **Insert**.
10. In **Oper**, select the operation type.
11. In **NextHdr**, select the next header type.
12. Select **Insert**.

Next Hdr Field Descriptions

Use the data in the following table to use the **Next Hdr** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.

Name	Description
Oper	The eq parameter specifies an operator for an “equal to” field match condition.
NextHdr	Specifies the next header of the IPv6 header. Specifies hop-by-hop, tcp, udp, routing, fragment, ipsecESP, ipsecAH, icmpv6, noNxtHdr, or undefined.

Configure an ACE IPv6 Traffic Class

Configure ACE IPv6 traffic class.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **IPv6**.
8. Select the **Traffic Class** tab.
9. Select **Insert**.
10. In **Oper**, select the operation type.
11. In **TrafficCls**, type the traffic class number.
12. Select **Insert**.

Traffic Class Field Descriptions

Use the data in the following table to use the **Traffic Class** tab.

Name	Description
AclId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
Oper	The eq parameter specifies an operator for an “equal to” field match condition.
TrafficCls	Specifies the traffic class attribute of the IPv6 header. Traffic class identifies different classes or priorities of IPv6 packets. The range is 0–255.

View all ACE IPv6 Entries for an ACL

View all of the ACE IPv6 entries associated with an ACL.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **IPv6**.
8. Select the **IPv6** tab.

IPv6 Field Descriptions

Use the data in the following table to use the **IPv6** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
SrcAddrList	Shows the source IP address.
SrcAddrOper	Shows the operators for the ACE IP source address.
DstAddrList	Shows the destination IP address.
DstAddrOper	Shows the operators for the ACE IP destination address.
NxtHdrNxtHdr	Shows the next header of the IPv6 header.
NxtHdrOper	Shows the operators for the next header.
TrafficClsOper	Shows the operators for the traffic class.
TrafficCls	Shows the traffic class attribute of the IPv6 header.
SrcAddrMask	Shows the mask value for the source IP address.
DstAddrMask	Shows the mask value for the destination IP address.

Configure an ACE Source Port

Configure ACE source port entries to have the filter look for packets with a specific source port.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.

2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **Proto**.
8. Select the **Source Port** tab.
9. Select **Insert**.
10. Specify the operator for the source port.
11. Specify the port number or port list to match.
12. Select **Insert**.

Source Port *Field Descriptions*

Use the data in the following table to use the **Source Port** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Port	Specifies the source port (1–65535).
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
OperMask	Specifies the mask parameter, {0-0xFFFF}.

Configure an ACE Destination Port

Configure ACE destination port entries to have the filter look for packets with a specific destination port.

Before You Begin

- The ACE exists.
- The ACL exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **Proto**.
8. Select the **Destination Port** tab.
9. Select **Insert**.

10. Specify the operator for the destination port.
11. Specify the port number or port list to match.
12. Select **Insert**.

Destination Port Field Descriptions

Use the data in the following table to use the **Destination Port** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
Port	Specifies the port number. As noted at the bottom of the tab, potential entries include 0–65535, echo, ftpdata, ftpcontrol, ssh, telnet, dns, http, h.323, and undefined.
OperMask	Specifies the mask parameter, {0-0xFFFF}.

Configure an ACE ICMP Message Type

Configure ACE Internet Control Message Protocol (ICMP) message type entries to have the filter look for packets of a specific ICMP message type.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **Proto**.
8. Select the **Icmp Msg Type** tab.
9. Select **Insert**.
10. Specify the operator for the ICMP message type.
11. In the **List** box, specify the ICMP messages to match.
12. Select **Insert**.

Icmp Msg Type Field Descriptions

Use the data in the following table to use the **Icmp Msg Type** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	Specifies the operator for the ACE protocol ICMP message type. Equal (eq) is the only option.
List	Specifies the ICMP message type (0–255), or echoreply, destunreach, sourcequench, redirect, echo-request, routeradv, routerselect, time-exceeded, param-problem, timestamp-request, timestamp-reply, addressmask-request, addressmask-reply, or traceroute.

Configure an ACE ICMPv6 Message Type

Before You Begin

- The ACL exists.
- The ACE exists.

About This Task

Configure ACE Internet Control Message Protocol v6 (ICMPv6) message type entries to have the filter look for packets of a specific ICMPv6 message type.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **Proto**.
8. Select the **Icmpv6 Msg Type** tab.
9. Select **Insert**.
10. Specify the operator for the ICMPv6 message type.
11. In **List**, specify the ICMPv6 messages to match.
12. In **Count**, specify 1 through 100.
13. Select **Insert**.

Icmpv6 Msg Type *Field Descriptions*

Use the data in the following table to use the **Icmpv6 Msg Type** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	Specifies the operator for the ACE protocol ICMPv6 message type. Equal (eq) is the only option.
List	Specifies the ICMPv6 message type (0–255), or echoreply, destunreach, sourcequench, redirect, echo-request, routeradv, routerselect, time-exceeded, param-problem, timestamp-request, timestamp-reply, addressmask-request, addressmask-reply, or traceroute.
Count	Specifies 1–100. Enables the ability to count matching packets. Use this parameter with either a security or QoS ACE. The default is disabled.

Configure an ACE TCP Flag

Configure ACE TCP flag entries to have the filter look for packets with a specific TCP flag.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **Proto**.
8. Select the **TCP Flags** tab.
9. Select **Insert**.
10. Specify the operator for the TCP flags entry.
11. In the **List** box, specify the TCP flags to match.
12. Select **Insert**.

TCP Flags Field Descriptions

Use the data in the following table to use the **TCP Flags** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Oper	The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.
List	Specifies one or more TCP flags—none, fin (finish connection), syn (synchronize), rst (reset connection), push, ack (acknowledge), urg (urgent), and undefined.
OperMask	Specifies the mask value.

Configure an ACE to Filter IPv4 Routed Packets

Configure an ACE to filter IPv4 routed packets.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select **IpRouted** tab.
4. Select **Insert**.
5. In **AcId**, type the appropriate ACL ID.
6. In **AcId**, type the appropriate ACE ID.
7. **RoutedOnly**
8. Select **Insert**.

IpRouted Field Descriptions

The following table describes values on the **IpRouted** tab.

Name	Description
AcId	Specifies the ACL ID. Value range of 1 to 2048.
AcId	Specifies the ACE ID. Value range of 1 to 2000.

Configure an ACE to Filter IPv6 Routed Packets

Configure an ACE to filter IPv6 routed packets only.

Before You Begin

- The ACL exists.
- The ACE exists.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **Ipv6Routed** tab.
4. Select **Insert**.
5. In **AcId**, type the appropriate ACL ID.
6. In **AceId**, type the appropriate ACE ID.
7. Select **RoutedOnly**.
8. Select **Insert**.

Ipv6Routed *Field Descriptions*

The following table describes values on the **Ipv6Routed** tab.

Name	Description
AcId	Specifies the ACL ID.
AceId	Specifies the ACE ID.
RoutedOnly	Specifies the match for IPv6 routed packets only.

Configure Ingress Policer and Port Rate Limiter

Perform this procedure to limit the number of packets that can be attached to an ACL ACE. If you want to modify the ingress bandwidth rate limiter values, you must first disable the ACE.

**Note**

You can attach one policer to ACL and ACE. Every policer is independent.

Before You Begin

Ensure that both the ACL and the ACE exist.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the appropriate ACL.
4. Select the appropriate ACE.
5. Select **Policer**.
6. Select **Insert**.
7. For **SvcRateValue**, type the service rate value.

8. For **PeakRateValue**, type the peak rate value.
9. Select **Insert**.
10. Select **Apply**.

Policer Field Descriptions

Use the data in the following table to use the **Policer** tab.

Name	Description
AcId	Specifies the ACL identifier numeric value for the filter.
AcId	Specifies the ACE identifier numeric value for the filter.
SvcRateValue	Specifies the service rate in kilobits for the flow of packets from the filter. The range is 8 to 4000000000 and the granularity is 8 kilobits.
PeakRateValue	Specifies peak rate in kilobits for the flow of packets from the filter. The range is 8 to 4000000000 and the granularity is 8 kilobits.
Oper	Specifies the operational status of the policer.

View ACE Port Statistics

About This Task

Use port statistics to ensure that the ACE is operating correctly.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select a field on the **ACL** tab.
5. Select **ACE**.
6. Select the **Statistics** tab.

Statistics Field Descriptions

Use the data in the following table to use the **Statistics** tab.

Name	Description
AcId	Specifies the associated ACL index.
AcId	Specifies the ACE index.
MatchCountPkts	Specifies a packet count of the matching packets.
MatchCountOctets	Specifies the number of octets of the matching packets.
GreenBytes	Specifies the number of bytes sent with a rate lower than the committed-rate of the matching ACE.

Name	Description
GreenPackets	Specifies the number of packets sent with a rate lower than the committed-rate of the matching ACE.
YellowBytes	Specifies the number of bytes sent with a rate lower than peak-rate and higher than the committed-rate of the matching ACE.
YellowPackets	Specifies the number of packets sent with a rate lower than the peak-rate and higher than the committed-rate of the matching ACE.
RedBytes	Specifies the number of bytes sent with a rate higher than the peak-rate of the matching ACE.
RedPackets	Specifies the number of packets sent with a rate higher than the peak-rate of the matching ACE.

View All ACE Protocol Entries for an ACL

View all of the ACE protocol entries associated with an ACL.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **Proto**.

Protocol Field Descriptions

Use the data in the following table to use the **Protocol** tab.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
SrcPort	Specifies the port number or port list to match.
SrcPortOper	Specifies the operator for the ACE protocol source port.
SrcPortOperMaskRange	The value is displayed in hexadecimal format when SrcPortOper is set to mask. When SrcPortOper is set to range, this field is used as the high range value. in this case, the value is displayed in decimal format. When SrcPortOper is set to eq, this field is set to 0.
DstPort	Specifies port number or port list to match.
DstPortOper	Specifies the operator for the ACE protocol destination port.

Name	Description
DstPortOperMaskRange	The value is displayed in hexadecimal format when DstPortOper is set to mask. When DstPortOper is set to range, this field is used as the high range value. In this case, the value is displayed in decimal format. When SrcPortOper is set to eq, this field is set to 0.
IcmpMsgTypeList	Specifies one or a list of ICMP messages to match. The valid range is 0–255 (reserved).
IcmpMsgTypeOper	Specifies the operator for the ACE protocol ICMP message types.
TcpFlagsList	Specifies one or a list of TCP flags to match. The valid range is 0–63.
TcpFlagsOper	Specifies the operator for the ACE protocol TCP flags.
TcpFlagsOperMask	Displays the mask value in hexadecimal format when TcpFlagsOper is set to mask. When TcpFlagsOper is set to eq, this field displays 0x0.

Troubleshooting

[Data Collection Required for Technical Support Cases](#) on page 3789

[Troubleshooting Fundamentals](#) on page 3792

[Connectivity Fault Management](#) on page 3799

[Software Troubleshooting Tool Configuration](#) on page 3865

[Hardware Troubleshooting](#) on page 3933

[Upper Layer Troubleshooting](#) on page 3943

The Troubleshooting section describes common problems and error messages with the techniques to resolve them, as well as information about troubleshooting tools.

The topics in this section provide necessary concepts and procedures to troubleshoot issues with the switch and connectivity issues in the network.

Data Collection Required for Technical Support Cases

If you need to call Technical Support for assistance, you might need to provide specific switch information or files, like core files, to help the team analyze the issue.

The topics in this section provide details about how to gather information before you contact Technical Support.

Important

The following list provides best practices for working with core files:

- Use Secure Copy (SCP) to transfer the files from the switch. If you use FTP, ensure you transfer the files in binary mode. Do not transfer the files in ASCII mode.
- After you download a core file from the switch, extract it to ensure it downloaded correctly and completely. If you receive errors, download the file again.
- Do not delete the core files from the switch until Technical Support confirms that they can read the files.

Data Collection for an Outage

Perform the following data collection procedures when the switch is in an outage condition and you require Technical Support to perform a root cause analysis.

Collect Data Before You Restart

Perform this procedure before you restart the chassis.

Procedure

1. Capture the current state of the chassis:

```
terminal more disable
```

```
show tech
```

**Note**

`show tech` is an alias for `show fulltech`. Both commands provide the same output.

2. Capture Flight Recorder trace information.

```
flight-recorder all {slot[-slot][,...]}
```

The **all** command executes three separate commands: `flight-recorder snapshot`, `flight-recorder trace`, and `flight-recorder archive`.

3. Reset the chassis:

- a. Reset the chassis without creating a core file:

```
reset -y
```

- b. Create an ssio core file, a cbcx-main.x core file, skip the confirmation question, and then reset the chassis:

```
reset -coredump -y
```

- c. Create an ssio core file, a cbcx-main.x core file, prompt for the confirmation question, and then reset the chassis:

```
reset -coredump
```

**Note**

Create a core file only when there is a need to analyze a problem. If you reset the switch for any other reason the command is `reset -y`.

4. Continue with [Collecting data after you restart](#).

Example

The following example shows output of the `flight-recorder all 1` command.

```
Switch:1#flight-recorder all 1
Processing Flight-recorder snapshot for 1 ....

Flight-recorder snapshot for slot 1 complete, filename is /intflash/PMEM/1/pmem.
20111019114431.1.bin.gz.

Processing Flight-recorder trace for 1 ....

Flight-recorder trace for slot 1 complete, filename is /intflash/flrec/1/trace.2
0111019114434.1.txt.

Processing Flight-recorder archive for slot 1 ....
```

```
Flight-recorder archive for slot 1 complete, filename is /intflash/archive/1/archive.20111019114446.1.tar.
```

Collect Data After You Restart

About This Task

Perform this procedure after you restart the affected chassis.

Procedure

1. Use FTP to transfer the following information:
 - Configuration files from each chassis: Stored on the internal flash at `/intflash/`.
 - Log files from each chassis: Stored on the internal flash at `/intflash/`.
 - Generated archive files for slot: Stored on the internal flash. For example: `/intflash/archive/<slot>`

Note

For , if the core file is not on the primary control processor (CP), you can use FTP to connect to the internal flash of the primary CP. For example, `cp mnt/intflash/archive/<slot>/<file name> /intflash/<file name>`

To copy the file to internal flash or usb device in the primary CP, use the following command: `cp mnt/intflash/archive/<slot>/<file name> {/intflash/<file name> | /usb/<file name>}`

2. Show core information:

```
show core-files
```

If the timestamp for an entry in the command output matches the time the outage first occurred, or is later than that time, transfer that core file to an FTP server. Core files are stored on the internal flash at: `/intflash/coreFiles/`

3. Obtain the network diagram of the relevant nodes, down to the port level.

Data Collection for Non Outage Problems

Use the information in this section to collect data for problems that are less service-impacting than an outage.

Gathering Critical Information

This section identifies the critical information that you must gather before you contact Technical Support.

You must attempt to resolve the problem using this document. Contact Technical Support as a final step taken only after you are unable to resolve the issue using the information and steps provided in this document.

Gather the following information before you contact Technical Support:

- a detailed description of the problem
- the date and time when the problem started
- the frequency of the problem
- if this is a new installation
- if there is relevant information recorded on the support portal — Were related problem solutions found? Is there currently a work around for this issue?
For more information, see support on the Extreme Networks Portal at <https://extremeportal.force.com/ExtrSupportHome>.
- if the system was recently upgraded — Have you recently changed or upgraded the system, the network, or a custom application? (For example, has configuration or code been changed?) When were these changes made? Provide the date and time. Who made these changes? Were the changes made by a partner or customer? Provide the names of the individuals who made the changes.

Troubleshooting Fundamentals

You can better troubleshoot the problems on the network by planning for these events in advance. To do this, you must know the following:

- that the system is properly installed and routinely maintained
- the configuration of the network
- the normal behavior of the network

Network Configuration

To keep track of the network configuration, gather the information described in the following sections. This information, when kept up-to-date, is extremely helpful for locating information if you experience network or device problems.

Site network map

A site network map identifies where each device is physically located on site, which helps locate the users and applications that a problem affects. You can use the map to systematically search each part of the network for problems.

Logical connections

The switch supports virtual LANs (VLAN). With VLANs, you must know how the devices connect logically as well as physically.

Device configuration information

Maintain online and paper copies of the device configuration information. Store all online data with the regular data backup for the site. If the site does not use a backup system, copy the information onto an external storage device, and store the backup at an offsite location.

You can use the File Transfer Protocol (FTP) and Trivial FTP (TFTP) to store configuration files on a remote server.

Other important data about the network

For a complete picture of the network, have the following information available:

- all passwords

Store passwords in a safe place. A good practice is to keep records of previous passwords in case you must restore a device to a previous software version and need to use the old password that was valid for that version.

- device inventory

Maintain a device inventory, which lists all devices and relevant information for the network. The inventory allows you to easily see the device type, IP address, ports, MAC addresses, and attached devices.

- MAC address-to-port number list

If you do not manage the hubs or switches, you must keep a list of the MAC addresses that correlate to the ports on the hubs and switches.

- change control

Maintain a change control system for all critical systems. Permanently store change control records.

- contact details

Store the details of all support contracts, support numbers, engineer details, and telephone and fax numbers.

Normal Behavior on the Network

If you are familiar with the network when it is fully operational, you can be more effective at troubleshooting problems that arise. To understand the normal behavior of the network, monitor the network over a long period of time. During this time you can see a pattern in the traffic flow, such as which devices users access most or when peak usage times occur.

To identify problems, you can use a baseline analysis, which is an important indicator of overall network status. A baseline serves as a useful reference of network traffic during normal operation, which you can then compare to captured network traffic while you troubleshoot network problems. A baseline analysis speeds the process of isolating network problems. By running tests on a properly functioning network, you compile normal data for your network. You can compare this normal data against the results that you get when the network experiences trouble.

For example, ping each node to discover how long it typically takes to receive a response from devices on your network. Capture and save each response time and you can use these baseline response times to help you troubleshoot. You can also use the **show tech/show fulltech** and **show khi performance {buffer-pool|cpu|memory|process|pthread|slabinfo}** commands to obtain baseline output for normal system behavior.

In the following example, the **show khi performance memory** command shows the average memory utilization at various time intervals. The **show khi performance memory history** command shows the VMSize utilization values in kilobytes for each process at various time intervals. After 1 hour elapses, the system stores this information in `/intflash/coreFiles/slot/khi_mem_log`.

```
Switch:1>show khi performance memory 1
Slot:1
  Used: 6259174 (KB)
  Free: 1933970 (KB)
  Current utilization: 76 %
  5-minute average utilization: 76 %
  5-minute high water mark: 80 (%)
  10-minute average utilization: 76 %
  10-minute high water mark: 80 (%)
  1-Hour average utilization: 76 %
  1-Hour high water mark: 79 (%)
  1-Day average utilization: 76 %
  1-Month average utilization: 0 %
  1-Year average utilization: 0 %
```

SMLT socket buffer memory usage 0 KB on 0 blocks

```
Switch:1>show khi performance memory history
```

Slot:1

Values indicate VMSize(VMRSS) in KB

Connectivity Problems

Use the following general tasks to isolate connectivity problems:

- Check physical connectivity. Verify if an alarm for link or port down exists.
- Check the link state by viewing the **show interfaces {gigabitEthernet|loopback|vlan}** command output.
- Use tools like ping or trace to verify if the connectivity issue is localized to an individual port or VLAN.
- Try to localize the affected range of ports and slot.

If you contact technical support staff to help troubleshoot connectivity problems, always provide source and destination IP pairs to facilitate in troubleshooting. Be sure to provide both working and non-working pairs for comparison.

```
Switch:1#show interfaces vlan
```

Vlan Basic									
VLAN ID	NAME	TYPE	MSTP INST_ID	PROTOCOLID	SUBNETADDR	SUBNETMASK	VRFLD	ORIGIN	ACCESS
1	Default	byPort	0	none	N/A	N/A	0	CONFIG	GlobalRouter

Routing Table Problems

Routing table problems include but are not limited to:

- inactive routes
- unnecessary routes
- discard routes

Note

Only discard routes that belong to the static type protocol are supported. An inter-VRF discard route is not installed in the routing table of the destination VRF on the same switch.

- flapping links (links that go up and come down) that cause the routes to flap
- incorrect route tables
- invalid Address Resolution Protocol (ARP) cache that causes incorrect IP to MAC assignment
- problems with administrative distance or other parameters

Important

Do not restart a device to clear a problem. In restarting the device, you also clear the logs. Logs are vital and can help determine many problems.

Cable Connection Problems

You can usually trace port connection problems to a poor cable connection or to an improper connection of the port cables at either end of the link. To remedy such problems, make sure that the cable connections are secure and that the cables

connect to the correct ports at both ends of the link. If you use homemade cables, ensure that the cables are wired correctly.

1000BASE-T cables

1 Gb/s ports operate using Category 5 UTP cabling only. Category 5 UTP cable is a two-pair cable. To minimize crosstalk noise, maintain the twist ratio of the cable up to the point of termination; untwist at termination cannot exceed 0.5 in. (1.27 cm).

Pluggable optic cables

Cables for the optical transceivers vary depending on the specific device type.

For more information about the cable requirements for optical transceivers, see [Extreme Optics](#) website.

Alarm Database

The switch contains a local alarms mechanism. Local alarms are raised and cleared by applications running on the switch. View active alarms by using the **show alarm database** command in the CLI. Local alarms are an automatic mechanism run by the system that do not require additional configuration.

Check local alarms regularly to ensure no alarms require additional attention. The raising and clearing of local alarms also creates a log entry for each event. For more information about viewing logs, see [View Logs](#) on page 2557.

View the alarm database regularly to monitor alarm conditions, even if you do not observe a performance problem. Review the alarm messages to determine if the system performs as expected.

Not all alarm conditions indicate a problem so you must be familiar with expected behavior.

The alarm database shows the following alarm text:

```
CP1 [01/01/70 00:03:06.796] 0x00010844 00000000 Global Router HW WARNING
USB found in slot 1 has VendorId 05dc ProductId a01a and Manufacturer
Lexar and did not match supported devices
```

This alarm means that you have tried to insert an unsupported USB device into the USB slot. Only the USB device provided with your system can be inserted into the USB slot.

LED Indications of Problems

For information on LEDs on the chassis, see the hardware installation documentation.

Failure to Read Failed Configuration File

The device can fail to read and load a saved configuration file after it starts. This situation occurs if you enable the `factorydefaults boot configuration` flag. Configure the flag to `false`: `no boot config flags factorydefaults`.

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# no boot config flags factorydefaults
```

No Web Management Interface Access to a Device

If the device and the PC that runs the web browser are in the same network, you can find that even though other applications, for example, Telnet, can access a particular switch, the web management interface cannot. This situation can occur if the web browser has a proxy server that resolves the `www` path and returns the reachable IP address to the browser. If no route exists from the proxy server to the device, the HTTP query does not reach the device, and does not receive a response.

To prevent this problem, ensure that if the web browser uses a proxy server, you specify a route from the proxy server to the device.

Configuration in EDM is not applied using CLI

In EDM, if you apply configuration that disrupts the connection to the web server, and you do not close the EDM session, you cannot apply the same configuration using CLI. This situation occurs if you, for example, delete the Segmented Management Instance, or the management IP address or the route used to access EDM, and you do not close the EDM session afterwards.

To prevent this issue, you must close the EDM session before you can apply the same configuration using CLI.

Connectivity Fault Management

Table 325: Connectivity Fault Management product support

Feature	Product	Release introduced
IEEE 802.1ag Connectivity Fault Management (CFM): <ul style="list-style-type: none"> • Layer 2 Ping • TraceRoute • TraceTree 	4220 Series	Fabric Engine 9.2

	VSP 7400 Series	VOSS 8.0

CFM Fundamentals

The Shortest Path Bridging MAC (SPBM) network needs a mechanism to debug connectivity issues and to isolate faults. This is performed at Layer 2, not Layer 3. Connectivity Fault Management (CFM) operates at Layer 2 and provides an equivalent of ping and traceroute. To support troubleshooting of the SPBM cloud, the switch supports a subset of CFM functionality. Configure CFM on all SPBM VLANs.

CFM is based on the IEEE 802.1ag standard.

IEEE 802.1ag Connectivity Fault Management (CFM) provides OAM tools for the service layer, which allows you to monitor and troubleshoot an end-to-end Ethernet service instance. CFM is the standard for Layer 2 ping, Layer 2 traceroute, and the end-to-end connectivity check of the Ethernet network.

The 802.1ag feature divides or separates a network into administrative domains called Maintenance Domains (MD). Each MD is further subdivided into logical groupings called Maintenance Associations (MA). A single MD can contain several MAs.

Each MA is defined by a set of Maintenance Points (MP). An MP is a demarcation point on an interface that participates in CFM within an MD. Two types of MP exist:

- Maintenance End Point (MEP)
- Maintenance Intermediate Point (MIP)

CFM supports three kinds of standard CFM messages: Continuity Check Message (CCM), Loopback Message (LBM), and Linktrace Message (LTM). Messages are sent between Maintenance Points (MP) in the system.

On the switch, CFM is implemented using the LBM and LTM features only to debug SPBM. CCM messages are not required or supported.

You can assign maintenance levels for each CFM SPBM MEP and MIP to each SPBM B-VLAN individually or you can assign maintenance levels and global MEPs for all SPBM VLANs.

Autogenerated CFM and Explicitly Configured CFM

The switch simplifies CFM configuration with autogenerated CFM. With autogenerated CFM, you use the **cfm spbm enable** command and the switch creates default MD, MA, MEPs, and MIPs for SPBM B-VLANs.

If you choose to configure CFM explicitly, you must configure an MD, MA, MEPs, and MIPs.

Autogenerated CFM

You can use autogenerated CFM at a global level to create a MEP and a MIP at a specified level for every SPBM B-VLAN on the chassis. If you use autogenerated CFM commands, you do not have to configure explicit MDs, MAs, MEPs, or MIPs, and associate them with multiple VLANs.

If you do not want to use autogenerated CFM commands, you can choose to configure explicit MDs, MAs, MEPs, and MIPs for SPBM B-VLANs. However, you cannot use both an autogenerated CFM configuration and an explicit CFM configuration together.

Note

Previous explicit CFM configurations of MDs, MAs, and MEPs on SPBM B-VLANs continue to be supported. However, if you want to enable the autogenerated commands you must first remove the existing MEP and MIP on the SPBM B-VLANs. The switch only supports one type of MEP or MIP for each SPBM B-VLAN.

For information on autogenerated CFM configuration using CLI see [Configuring Autogenerated CFM on SPBM B-VLANs](#) on page 3808. For information on autogenerated CFM configuration using EDM see [Configure Autogenerated CFM on SPBM B-VLANs](#) on page 3830.

Explicitly configured CFM

If you choose to explicitly configure CFM, you must configure an MD, MA, MEPs, and MIPs. You can configure explicit CFM only on SPBM B-VLANs.

For explicit configuration information for CLI see [Configure Connectivity Fault Management Explicit Mode](#) on page 3810.

For explicit configuration information for EDM see [Configure Explicit CFM](#) on page 3831.

Using CFM

For SPBM B-VLANs, the autogenerated MEPs and MIPs respond to **12 ping**, **12 traceroute**, and **12 tracetest** in the same manner as the MEPs and MIPs created explicitly. The CFM show commands that display MD, MA, and MEP information work for both autogenerated and explicitly configured CFM MEPs.

You can use CFM to troubleshoot networks and hosts that support the CFM protocol. After you configure CFM, CFM works in the network whether or not SPBM is in use.

You cannot use CFM to troubleshoot networks and hosts that do not support the CFM protocol, such as a customer domain that does not support CFM. Only devices that support the CFM protocol respond to **12 ping** and **12 traceroute** requests.

Maintenance Domain (MD)

A Maintenance Domain (MD) is the part of a network that is controlled by a single administrator. For example, a customer can engage the services of a service provider, who, in turn, can engage the services of several operators. In this scenario, there can be one MD associated with the customer, one MD associated with the service provider, and one MD associated with each of the operators.

You assign one of the following eight levels to the MD:

- 0–2 (operator levels)
- 3–4 (provider levels)
- 5–7 (customer levels)

The levels separate MDs from each other and provide different areas of functionality to different devices using the network. An MD is characterized by a level and an MD name (optional).

A single MD can contain several Maintenance Associations (MA).

Maintenance Association (MA)

An MA represents a logical grouping of monitored entities within its Domain. It can therefore represent a set of Maintenance association End Points (MEPs), each configured with the same Maintenance Association ID (MAID) and MD Level, established to verify the integrity of a single service instance.

The following figure shows MD level assignment in accordance with the 802.1ag standard. As shown in the figure, MIPs can be associated with MEPs. However, MIPs can also function independently of MEPs.

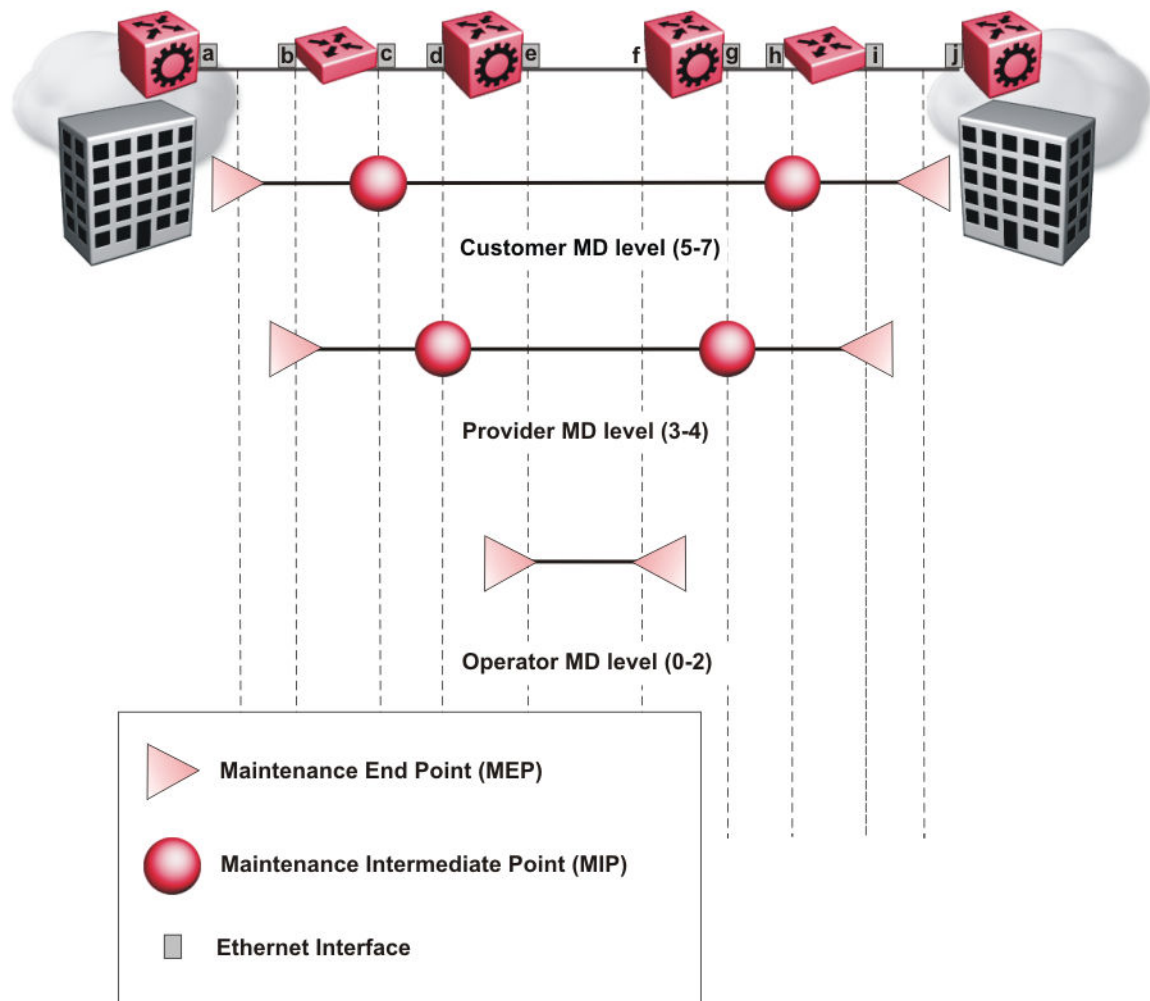

Figure 241: MD level assignment

Maintenance Association Endpoint (MEP)

A Maintenance Endpoint (MEP) represents a managed CFM entity, associated with a specific Domain Service Access Point (DoSAP) of a service instance, which can generate and receive CFM Protocol Data Units (PDU) and track any responses. A MEP is created by MEP ID under the context of an MA. MEP functionality can be divided into the following functions:

- Fault Detection
- Fault Verification
- Fault Isolation
- Fault Notification

Fault detection and notification are achieved through the use of Continuity Check Messages (CCM). CCM messages are not supported.

Fault Verification

Fault verification is achieved through the use of Loopback Messages (LBM). An LBM is a unicast message triggered by the operator issuing an operational command. LBM can be addressed to either a MEP or Maintenance Intermediate Point (MIP) but only a MEP can initiate an LBM. The destination MP can be addressed by its MAC address. The receiving MP responds with a Loopback Response (LBR). LBM can contain an arbitrary amount of data that can be used to diagnose faults as well as performance measurements. The receiving MP copies the data to the LBR.

LBM Message

The LBM packet is often compared to a ping. A MEP transmits the LBM packet. This packet can be addressed to another MEP or to the MAC address of the MP; in the case of SPBM, this is the SPBM system ID or its virtual SMLT MAC. Only the MP for which the packet is addressed responds with an LBR message.

- Provides “ICMP ping like” functionality natively at Layer-2.
- DA is the MAC address of the target.
- Includes a transaction identifier that allows the corresponding LBR to be identified when more than one LBM request is waiting for a response.
- Bridges forward the frame using the normal FDB rules.
- Only the target (MIP or MEP) responds.
- Initiator can choose the size and contents data portion of the LBM frame.
- Can be used to check the ability of the network to forward different sized frames.

L2 Ping

The **12 ping** command is a proprietary command that allows a user to trigger an LBM.

For B-VLANs, specify either the destination MAC address or node name.

You can specify an IP address as the destination address for the **12 ping** command.

You can test connectivity with Anycast IP Gateway I-SID.

Fault Isolation

Fault isolation is achieved through the use of Linktrace Messages (LTM). LTM is intercepted by all the MPs on the way to the destination MP. The switch supports two types of LTM.

The first type, the unicast LTM, can be addressed to either MEP or MIP MAC address. Each MP on the way decrements the TTL field in the LTM frame, sends Linktrace Reply (LTR), and forwards the original LTM to the destination. The LTM is forwarded until it reaches its destination or the TTL value is decremented to zero. LTR is a unicast message addressed to the originating MEP.

The second type, the proprietary LTM, is used to map the MAC addresses of the SPBM network; in this case the target MAC is not an MP, but rather a service instance identifier (I-SID).

Linktrace Message

Connectivity Fault Management offers linktrace messaging for fast fault detection. Use linktrace messages to verify the connectivity that you provide or use, and to debug systems.

Linktrace Message — Unicast

The linktrace message (LTM) is often compared to traceroute. A Maintenance Endpoint (MEP) transmits the LTM packet. This packet specifies the target MAC address of a Maintenance Point (MP), which is the SPBM system ID or the virtual SMLT MAC. MPs on the path to the target address respond with a linktrace reply (LTR).

- Trace the path to any given MAC address.
- DA is unicast
- The LTM contains:
 - Time to live (TTL)
 - Transaction Identifier
 - Originator MAC address
 - Target MAC address
- CFM unaware entities forward the frame as is like any other data frame.
- MIP or MEP that is not on the path to the target discards the LTM and does not reply.
- MIP that is on the path to the target
 - Forwards the LTM after decrementing the TTL and replacing the SA with its own address.
 - Sends a reply (LTR) to the originator.
 - Identifies itself in the forwarded LTM and LTR by modifying TLV information.
- If the MIP or MEP is a target
 - Sends an LTR to the originator.
 - Identifies itself in the forwarded LTM and LTR by modifying TLV information.
- A MEP that is not the target but is on the path to the target performs the following actions:
 - Generates a reply as described in previous bullets.
 - Configures one of the flag fields in the reply to indicate that it is the terminal MEP.

Linktrace Message — Multicast

Use the multicast LTM to trace the multicast tree from any node on any I- SID using the nickname MAC address and the I-SID multicast address.

Specifying a multicast target address for an LTM allows for the tracing of the multicast tree corresponding to that destination address (DA). With a multicast target every node that is in the active topology for that multicast address responds with a Linktrace reply and also forwards the LTM frame along the multicast path. Missing Linktrace replies (LTRs) from the nodes in the path indicate the point of first failure.

Use this functionality to better troubleshoot I-SID multicast paths in a SPBM network.

L2 Traceroute

The **12 traceroute** command is a proprietary command that allows you to trigger an LTM message.

For B-VLANs, specify either the destination MAC address or node name.

This command provides a simpler command syntax than the standard LTM commands, which require you to specify the MD, MA, and MEP ID information. The **12 traceroute** command provides a trace equivalent at Layer 2 for use with nodes on the SPBM B-VLAN in the customer domain.

You can use CFM to troubleshoot networks and hosts that support the CFM protocol. After you configure CFM, CFM works in the network whether or not SPBM is in use.

You cannot use CFM to troubleshoot networks and hosts that do not support the CFM protocol, such as a customer domain that does not support CFM. Only devices that support the CFM protocol respond to **12 ping** and **12 traceroute** requests.

Note

While performing CFM Layer 2 traceroute between two BEBs using a transit BCB, the transit BCB hop is not seen, if the transit BCB has IS-IS adjacencies over FE I3core with both source BEB and destination BEB.

12 traceroute with IP address

You can specify an IP address as the destination address for the **12 traceroute** command.

The **12 traceroute** command converts Layer 3 IP information to an appropriate Layer 2 VLAN and MAC combination. The system can also target IP addresses that are not SPBM derived routes.

If you enable ECMP, **12 traceroute** runs internally for each of the VLAN paths returned, and displays a summary of the results. If you disable ECMP, the results display only one path.

Note

If you use the **12 traceroute ip-address** command on a DvR Leaf node, the output only shows DvR Controller IP addresses if the IP address or host route specified is unknown in the DvR domain.

L2 traceroute with Anycast IP Gateway

You can test connectivity with Anycast IP Gateway I-SIDs.

L2 Tracetree

The **12 tracetree** command is a proprietary command that allows a user to trigger a multicast LTM message by specifying the B-VLAN and I-SID. This command allows the user to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID.

L2 Tracetree-fan

The **12 tracetree-fan** command allows a user to trigger an LTM on the internal Fabric Area Network I-SID. This command allows the user to trace the FAN tree.

Maintenance Domain Intermediate Point (MIP)

MIPs do not initialize any CFM messages. MIPs passively receive CFM messages, process the messages received and respond back to the originating MEP. By responding to received CFM messages, MIPs can support discovery of hop-by-hop path among MEPs, allow connection failures to be isolated to smaller segments of the network to help discover location of faults along the paths. MIPs can be created independent of MEPs. MIP functionality can be summarized as:

- Respond to Loopback (ping) messages at the same level as itself and addressed to it.
- Respond to Linktrace (traceroute) messages.
- Forward Linktrace messages after decrementing the TTL.

Layer 2 Tracemroute

The **12tracemroute** command is a proprietary command that allows the user to trace the multicast tree for a certain multicast flow. The user specifies source, group, and service context (either VLAN or VRF) for the multicast flow to trace.

CFM sends a multicast LTM using an internal calculation to map the source, group, and context to the corresponding target address. The LTR comes from all leaves of the multicast tree for that flow, as well as transit nodes. The target MAC used in the LTM is a combination of the data I-SID and the nickname and the packet is sent on the appropriate SPBM B-VLAN. The user can see the generated multicast tree for that flow, which includes the data I-SID and nickname.

Nodal MPs

Nodal MPs provide both MEP and MIP functionality for SPBM deployments. Nodal MPs are associated with a B-VLAN and are VLAN encapsulated packets. The Nodal MEP provides traceability and troubleshooting at the system level for a given B-VLAN. Each node (chassis) has a given MAC address and communicates with other nodes. The SPBM instance MAC address is used as the MAC address of the Nodal MP. The Nodal B-VLAN MPs supports eight levels of CFM and you configure the Nodal B-VLAN MPs on a per B-VLAN basis. Virtual SMLT 10 MAC addresses are also able to respond for LTM and LBM.

Nodal B-VLAN MEPs

The Nodal B-VLAN MEPs created on the CP and function as if they are connected to the virtual interface of the given B-VLAN. Because of this they are supported for both port and MLT based B-VLANs. To support this behavior a MAC Entry is added to the FDB and a new CFM data-path table containing the B-VLAN and MP level are added to direct CFM frames to the CP as required.

Nodal B-VLAN MIPs

The Nodal MIP is associated with a B-VLAN. VLAN and level are sufficient to specify the Nodal MIP entity. The Nodal MIP MAC address is the SPBM system ID for the node on

which it resides. If the fastpath sends a message to the CP, the MIP responds if it is not the target and the MEP responds if it is the target.

Nodal B-VLAN MIPs with SMLT

When Nodal MEPs or MIPs are on SPBM B-VLANs the LTM code uses a unicast MAC DA. The LTM DA is the same as the target MAC address, which is the SPBM MAC address or the SMLT MAC address of the target node.

The switch supports SMLT interaction with SPBM. This is accomplished by using two B-VIDs into the core from each pair of SMLT terminating nodes. Both nodes advertise the Nodal BMAC into the core on both B-VIDS. In addition each node advertises the SMLT virtual BMAC on one of the two B-VLANs.

The Nodal MEP and MIP are expanded to respond to both the Nodal MAC address as well as the Virtual SMLT MAC address if both MACs are being advertised on its B-VLAN. In addition a source mode is added to the LTM and LBM command to use either the Nodal MAC or the SMLT virtual MAC address as the source MAC in the packet.

Configuration Considerations

When you configure CFM, be aware of the following configuration considerations.

General CFM

- A single switch has a limit of one MEP and one MIP on B-VLAN.
- The maintenance level for MEPs and MIPs on a given B-VID (in a network) must be configured to the same level for them to respond to a given CFM command.
- You can configure global CFM at only one MD level for each switch.
- All nodal MEPs and MIPs are restricted to SPBM B-VIDs.

Autogenerated CFM

- Autogenerated MEPs are not unique across the entire network unless you configure the global MEP ID on each switch to a different value. You must configure a unique MEP ID at a global level, for CFM.
- A single switch can have only one autogenerated MEP or MIP for each B-VLAN.

Explicit CFM

- Previous explicit CFM configurations of MDs, MAs and MEPs on SPBM B-VLANs continue to be supported. However, if you want to enable autogenerated CFM you must first remove the existing MEP and MIP on the SPBM B-VLAN.
- You can assign maintenance levels for each CFM SPBM MEP and MIP to each SPBM B-VLAN individually or you can assign maintenance levels and global MEPs for all SPBM VLANs by following the appropriate procedure:
 - [Assign a MEP/MIP Level to an SPBM B-VLAN](#) on page 3814
 - [Assign MEP/MIP Levels to SPBM B-VLANs Globally](#) on page 3815
 - [Configure CFM Nodal MEP](#) on page 3834

CFM Configuration Using CLI

This section provides procedures to configure and use Connectivity Fault Management (CFM) using Command Line Interface (CLI). The Shortest Path Bridging MAC (SPBM) network needs a mechanism to debug connectivity issues and to isolate faults. This is performed at Layer 2, not Layer 3. To support troubleshooting of the SPBM cloud, the switch supports a subset of CFM functionality.

Note

When you enable CFM in an SBPM network, as a best practice, enable CFM on the Backbone Edge Bridges (BEB) and on all Backbone Core Bridges (BCB). If you do not enable CFM on a particular node, you cannot obtain CFM debug information from that node.

You can configure CFM using one of two modes: simplified or explicit. Both modes are described in the following sections, but the simplified mode should be used.

Note

If you enable the **cfm spbm enable** command, you cannot assign a MEP/MIP level to an individual SPBM B-VLAN or configure CFM MD maintenance levels individually.

Regardless of whether you have chosen to configure individually or globally, there is one MEP per SPBM B-VLAN and one MIP level per SPBM B-VLAN.

Autogenerated CFM

CFM provides two methods for configuration; autogenerated and explicit. You cannot use both. You must choose one or the other. Use the procedures in this section to configure autogenerated MEPs that eliminate the need to configure a MD, MA, and MEP ID to create a MEP.

For SPBM B-VLANs, you can use either autogenerated or explicitly configured CFM MEPs.

The CFM show commands that display MD, MA, and MEP information work for both autogenerated and explicitly configured CFM MEPs.

Previous explicit CFM configurations of MDs, MAs and MEPs on SPBM B-VLANs continue to function. However, if you want to enable the autogenerated commands you must first remove the existing MEP and MIP on the SPBM B-VLAN.

The switch only supports one MEP and one MIP, either autogenerated or explicitly configured, on the SPBM B-VLAN. This means that if you want to use these autogenerated MEPs, you cannot use your existing CFM configuration. You must first remove the existing MEP or MIP on the SPBM B-VLAN.

Configuring Autogenerated CFM on SPBM B-VLANs

Use this procedure to configure the autogenerated CFM MEP and MIP level for every SPBM B-VLAN on the chassis. This eliminates the need to explicitly configure an MD, MA, and MEP ID, and to associate the MEP and MIP level to the SPBM B-VLAN.

When you enable this feature, the device creates a global MD (named spbm) for all the SPBM Nodal MEPs. This MD has a default maintenance level of 4, which you can change with the level attribute. All the MEPs that the device creates use the MEP ID configured under the global context, which has a default value of 1.

The nodal MEPs are automatically associated with the SPBM B-VLANs configured. The MIP level maps to the global level. When you enable the feature, the device automatically associates the MIP level with the SPBM B-VLANs configured. The feature is disabled by default.

**Important**

CFM supports one MEP or MIP for each SPBM B-VLAN only. This means that if you want to use these autogenerated MEPs, you cannot use your existing CFM configuration. You must first remove the existing MEP or MIP on the SPBM B-VLAN. If you want to continue configuring MEPs manually, skip this procedure.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the maintenance level for every CFM SPBM MEP and MP level on all the SPBM B-VLANs:

```
cfm spbm level <0-7>
```

You can change this level from the default of 4 either before or after the feature is enabled.

Only configure global CFM at one MD level for each chassis for each VLAN type.

3. Assign a global CFM MEP ID for all CFM SPBM MEPs:

```
cfm spbm mepid <1-8191>
```

4. Enable the autogenerated CFM for SPBM B-VLANs globally:

```
cfm spbm enable
```

5. (Optional) Configure the maintenance level for every CFM SPBM MEP and MP level on all the SPBM B-VLANs to the default:

```
default cfm spbm level
```

6. (Optional) Assign a global CFM MEP ID for all CFM SPBM MEPs to the default:

```
default cfm spbm mepid
```

7. (Optional) Disable the global CFM MEPs and MIPs:

```
no cfm spbm enable
```

8. Display the global CFM MEP configuration:

```
show cfm spbm
```

Example

Configure autogenerated CFM MEPs and MIPs:

```
Switch>enable  
Switch#configure terminal
```

```
Switch(config)#cfm spbm level 6
Switch(config)#cfm spbm mepid 4
Switch(config)#cfm spbm enable
Switch(config)#show cfm spbm
```

LEVEL	ADMIN	MEPID	MAC
6	enable	4	00:15:e8:b8:a3:df

Variable Definitions

The following table defines parameters for the **cfm spbm** command.

Variable	Value
<i>level</i> <0-7>	Specifies the global SPBM CFM maintenance level for the chassis within the range of 0 to 7. The default is 4. Only configure global CFM at one MD level for each chassis for each VLAN type.
<i>mepid</i> <1-8191>	Specifies the global MEP ID within the range of 1-8191. Select a unique ID for each switch to ensure that the MEPs are unique across the network. The default is 1.
<i>enable</i>	Enables autogenerated CFM on all SPBM B-VLANs.

Configure Connectivity Fault Management Explicit Mode

In the explicit mode of configuring Connectivity Fault Management (CFM), you can manually configure a Maintenance Domain (MD), a Maintenance Association (MA), and a Maintenance Endpoint (MEP) and then associate the MEP to a B-VLAN and assign a MIP level to a B-VLAN.

Note

If you use autogenerated CFM, these steps are unnecessary.

Configure Connectivity Fault Management Maintenance Domain

Use this procedure to configure the Connectivity Fault Management (CFM) Maintenance Domain (MD). An MD is the part of a network that is controlled by a single administrator. A single MD can contain several Maintenance Associations (MA).

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Create the CFM MD:
cfm maintenance-domain WORD<0-22> [index <1-2147483647>] [maintenance-level <0-7>] [level <0-7>]
3. Display the CFM MD configuration:
show cfm maintenance-domain
4. Delete the CFM MD:
no cfm maintenance-domain WORD<0-22>

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#cfm maintenance-domain mdl index 99 maintenance-level 3
Switch:1(config)#show cfm maintenance-domain
=====
Maintenance Domain
=====
Domain Name          Domain Index    Level Domain Type
-----
mdl                  99              3      NODAL

Total number of Maintenance Domain entries: 1.
Switch:1(config)#no cfm maintenance-domain mdl
Switch:1(config)# show cfm maintenance-domain
=====
Maintenance Domain
=====
Domain Name          Domain Index    Level Domain Type
-----

Total number of Maintenance Domain entries: 0.
```

Variable Definitions

The following table defines parameters for the **cfm maintenance-domain** command.

Variable	Value
<i>WORD</i> <0-22>	Specifies the maintenance domain name.
<i>index</i> <1-2147483647>	Specifies a maintenance domain entry index.
<i>maintenance-level</i> <0-7>	Specifies the MD maintenance level when creating the MD. The default is 4.
<i>level</i> <0-7>	Modifies the MD maintenance level for an existing MD. The default is 4.

Configure Connectivity Fault Management Maintenance Association

Use this procedure to configure the Connectivity Fault Management (CFM) Maintenance Association (MA). An MA represents a logical grouping of monitored entities within its domain. It can therefore represent a set of Maintenance Association Endpoints (MEPs), each configured with the same Maintenance Association ID (MAID) and MD Level, established to verify the integrity of a single service instance.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Create the CFM MA:

```
cfm maintenance-association WORD<0-22> WORD<0-22> [index <1-2147483647>]
```

3. Display the CFM MA configuration:

```
show cfm maintenance-association
```

4. Use the following command, if you want to delete the CFM MA:

```
no cfm maintenance-association WORD<0-22> WORD<0-22>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#cfm maintenance-association mdl mal index 98
Switch:1(config)#show cfm maintenance-association
=====
Maintenance Association Status
=====
Domain Name      Assn Name      Domain Idx  Assn Idx
-----
mdl              mal            1           98

Total number of Maintenance Association entries: 1.

=====
Maintenance Association config
=====
Domain Name      Assn Name
-----
mdl              mal

Total number of MA entries: 1.
```

Variable Definitions

The following table defines parameters for the **cfm maintenance-association** command.

Variable	Value
<i>WORD<0-22> WORD<0-22></i>	Creates the CFM MA. The first parameter, specifies the MD name. The second parameter, specifies the MA short name.
<i>index <1-2147483647></i>	Specifies a maintenance association entry index.

Configure Connectivity Fault Management Maintenance Endpoint

Use this procedure to configure the Connectivity Fault Management (CFM) Maintenance Endpoint (MEP). A MEP represents a managed CFM entity, associated with a specific Domain Service Access Point (DoSAP) of a service instance, which can generate and receive CFM Protocol Data Units (PDU) and track any responses. A MEP is created by MEP ID under the context of an MA.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create the CFM MEP:

```
cfm maintenance-endpoint WORD<0-22> WORD<0-22> <1-8191> enable [state
<enable>]
```

3. Enable an existing CFM MEP:

```
cfm maintenance-endpoint WORD<0-22> WORD<0-22> <1-8191> enable
```

4. Disable an existing CFM MEP:

```
no cfm maintenance-endpoint WORD<0-22> WORD<0-22> <1-8191> enable
```

5. Display the CFM MEP configuration:

```
show cfm maintenance-endpoint
```

6. Delete an existing CFM MEP:

```
no cfm maintenance-endpoint WORD<0-22> WORD<0-22> <1-8191>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#cfm maintenance-endpoint md1 mal 1 state enable
Switch:1(config)#show cfm maintenance-endpoint
=====
Maintenance Endpoint Config
=====
DOMAIN          ASSOCIATION      MEP  ADMIN
NAME            NAME            ID
-----
md1             mal             1    enable

Total number of MEP entries: 1.

=====
Maintenance Endpoint Service
=====
DOMAIN_NAME      ASSN_NAME        MEP_ID TYPE    SERVICE_DESCRIPTION
-----
md1             mal             1      nodal    Vlan 1, Level 4

Total number of MEP entries: 1.
```

Variable Definitions

The following table defines parameters for the **cfm maintenance-endpoint** command.

Variable	Value
<i>WORD<0-22></i>	The first parameter, specifies the MD name.
<i>WORD<0-22></i>	The second parameter, specifies the MA short name.
<i><1-8191></i>	Specifies the MEP ID.
<i>enable</i>	Enables an existing MEP. Use this parameter with the no option to disable an existing MEP.
<i>state {enable disable}</i>	Enables or disables the MEP when creating the MEP. The default is disabled.

Assign a MEP/MIP Level to an SPBM B-VLAN

Use this procedure to assign a nodal MEP to an SPBM B-VLAN. The Nodal MEP provides traceability and troubleshooting at the system level for a given B-VLAN. The Nodal B-VLAN MEPs created on the CP and function as if they are connected to the virtual interface of the given B-VLAN. Because of this they are supported for both port and MLT based B-VLANs.

Nodal MPs provide both MEP and MIP functionality for SPBM deployments. Nodal MPs are associated with a B-VLAN and are VLAN encapsulated packets. Each node (chassis) has a given MAC address and communicates with other nodes. The SPBM instance MAC address is used as the MAC address of the Nodal MP.

Before You Begin

- You must configure a CFM MD, MA, and MEP.

Procedure

- Add nodal MEPs to the B-VLAN:

```
vlan nodal-mep <1-4059> WORD<0-22> WORD<0-22> <1-8191>
```
- Display the nodal MEP configuration:

```
show vlan nodal-mep <1-4059>
```
- Remove the nodal MEPs from the B-VLAN:

```
no vlan nodal-mep <1-4059> WORD<0-22> WORD<0-22> <1-8191>
```
- Add nodal MIP level to the B-VLAN:

```
vlan nodal-mip-level <1-4059> WORD<0-15>
```
- Display the nodal MIP level configuration:

```
show vlan nodal-mip-level [<1-4059>]
```
- Remove the nodal MIP level from the B-VLAN:

```
no vlan nodal-mip-level <1-4059> WORD<0-15>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#vlan nodal-mep 100 md1 ma1 2
Switch:1(config)#show vlan nodal-mep
=====
Vlan Nodal Mep
=====
VLAN_ID    DOMAIN_NAME.ASSOCIATION_NAME.MEP_ID
-----
100        spbm.100.6
200        spbm.200.6

Switch:1(config)#vlan nodal-mip 100 6
Switch:1(config)#show vlan nodal-mip
=====
Vlan Nodal Mip Level
=====
VLAN_ID    NODAL_MIP_LEVEL_LIST
-----
1
100        6
```

```
216
304
41000
1001
```

Variable Definitions

The following table defines parameters for the **vlan nodal-mep** command.

Variable	Value
<1-4059>	Specifies the VLAN ID.
WORD<0-22>	The first parameter, specifies the Maintenance Domain name.
WORD<0-22>	The second parameter, specifies the Maintenance Association name.
<1-8191>	Specifies the nodal MEPs to add to the VLAN.

The following table defines parameters for the **vlan nodal-mip-level** command.

Variable	Value
<1-4059>	Adds the nodal MIP level. Specifies the VLAN ID.
WORD<0-15>	Adds the nodal MIP level, which has up to eight levels, ranging from 0 to 7.

Assign MEP/MIP Levels to SPBM B-VLANs Globally

Note

If you enable the **cfm spbm enable** command, you cannot assign a MEP/MIP level to an individual SPBM B-VLAN or configure CFM MD maintenance levels individually.

About This Task

Enables the global CFM MEP and MIPs for all SPBM B-VLANs.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable simplified CFM configuration for SPBM VLANs:

```
cfm spbm enable
```
3. Enter the CFM SPBM level:

```
cfm spbm level <0-7>
```
4. Enter the CFM SPBM MEPID level:

```
cfm spbm mepid <1-8191>
```

Example

```
Switch:1(config)# cfm spbm level 7
Switch:1(config)# cfm spbm mepid 12
Switch:1(config)# cfm spbm enable
```

Variable Definitions

The following table defines parameters for the **simplified CFM** commands.

Variable	Value
<i>spbm level <0-7></i>	Configures the maintenance level for every CFM SPBM MEP and MIP level on all SPBM B-VLANs. The default is 4.
<i>mepid <1-8191></i>	Assigns a global MEP ID for all CFM SPBM MEPs. The default is 1.
<i>no cfm spbm enable</i>	Disables global configuration of CFM SPBM MEP and MIP levels on all SPBM B-VLANs.
<i>default cfm spbm level</i>	Returns maintenance level to default for all CFM SPBM MEP and MIP level on all SPBM B-VLANs.
<i>default cfm spbm mepid</i>	Returns MEP ID for all CFM SPBM MEPs to default.
<i>show cfm spbm</i>	Displays the global CFM MEP configuration for SPBM B-VLANs.

Trigger a Loopback Test (LBM)

Use this procedure to trigger a loopback test.

The LBM packet is often compared to ping. An MEP transmits the loopback message to an intermediate or endpoint within a domain for the purpose of fault verification. This can be used to check the ability of the network to forward different sized frames.

Before You Begin

- You must have a MEP that is associated with a B-VLAN.

Procedure

- To enter User EXEC mode, log on to the switch.
- Trigger the loopback test:

```
loopback WORD<0-22> WORD<0-22> <1-8191>
<0x00:0x00:0x00:0x00:0x00:0x00> [burst-count <1-200>] [data-tlv-
size <0-400>] [frame-size <64-1500>] [interframe-interval
<msecs>] [priority <0-7>] [source-mode {nodal| smltVirtual}]
[testfill-pattern <all-zero|all-zero-crc|pseudo-random-bit-sequence|
pseudo-random-bit-sequence-crc>] [time-out <1-10>]
```

Example

```
Switch:1# loopback mdl 4001 13 00:14:0D:A2:B3:DF burst-count 10 priority
3 time-out 5
```

```
Result of LBM from mep: spbm.bvlan1000.8 to MAC address: 00:66:00:66:00:66 :
Sequence number of the first LBM is 150404162
The total number of LBMs sent out is 1
The number of LBRs received is 1
The number of LBRs lost is 0
The percentage of LBMs lost is 0.00%
The RTT Min is 15071 microseconds, Max is 15071 microseconds, Average is 15071.00 microseconds
The Standard Deviation of RTT is 0.00 microseconds
```

Variable Definitions

The following table defines parameters for the **loopback** command.

Variable	Value
<i>WORD</i> <0-22>	The first parameter, specifies the MD name.
<i>WORD</i> <0-22>	The second parameter, specifies the MA name.
<1-8191>	Specifies the MEP ID.
<0x00:0x00:0x00:0x00:0x00:0x00>	Specifies the remote MAC address to reach the MEP/MIP.
<i>burst-count</i> <1-200>	Specifies the burst-count.
<i>data-tlv-size</i> <0-400>	Specifies the data TLV size.
<i>frame-size</i> <64-1500>	Specifies the frame-size. The default is 0.
<i>priority</i> <0-7>	Specifies the priority. The default is 7.
<i>source-mode</i> { <i>nodal</i> <i>smltVirtual</i> }} Note: Exception: <i>smltVirtual</i> is not supported on 4220 Series or 5320 Series.	Specifies the source mode: <ul style="list-style-type: none"> • <i>nodal</i> • <i>smltVirtual</i>—Use this value with B-VLANs only. The default is <i>nodal</i> .

Variable	Value
<code>testfill-pattern {all-zero all-zero-crc pseudo-random-bit-sequence pseudo-random-bit-sequence-crc}</code>	<p>Specifies the testfill pattern:</p> <ul style="list-style-type: none"> all-zero — null signal without cyclic redundancy check all-zero-crc — null signal with cyclic redundancy check with 32-bit polynomial pseudo-random-bit-sequence — pseudo-random-bit-sequence without cyclic redundancy check pseudo-random-bit-sequence-crc — pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial. <p>A cyclic redundancy check is a code that detects errors.</p> <p>The default is 1: all-zero.</p>
<code>time-out <1-10></code>	Specifies the time-out interval in seconds. The default is 3.

Trigger Linktrace (LTM)

Use the following procedure to trigger a linktrace.

The Linktrace Message is often compared to traceroute. An MEP transmits the Linktrace Message packet to a maintenance endpoint with intermediate points responding to indicate the path of the traffic within a domain for the purpose of fault isolation. The packet specifies the target MAC address of an MP, which is the SPBM system ID or the virtual SMLT MAC. MPs on the path to the target address respond with an LTR.

Before You Begin

- You must have a MEP that is associated with a VLAN.

Procedure

- To enter User EXEC mode, log on to the switch.
- Trigger the linktrace:

```
linktrace WORD<0-22> WORD<0-22> <1-8191>
<0x00:0x00:0x00:0x00:0x00:0x00> [detail] [priority <0-7>] [source-mode
<nodal|smltVirtual>] [ttl-value <1-255>]
```

Example

```
Switch:1# linktrace mdl 4001 13 00:bb:00:00:14:00 priority 7
```

```
Please wait for LTM to complete or press any key to abort
```

```
Received LTRs:
```

```
SeqNum: 10575 MD: mdl MA:4001 MepId: 13 Priority: 7
```

```
-----
TTL SRC MAC FWDYES TERMMEP RELAY ACTION
---
```

63	00:bb:00:00:10:00	true	false	Fdb
62	00:bb:00:00:14:00	false	true	Hit

Variable Definitions

The following table defines parameters for the **linktrace** command.

Variable	Value
<i>WORD</i> <0-22>	The first parameter, specifies the MD name.
<i>WORD</i> <0-22>	The second parameter, specifies the MA name.
<1-8191>	Specifies the MEP ID.
<0x00:0x00:0x00:0x00:0x00:0x00>	Specifies the target MAC address to reach the MEP.
<i>detail</i>	Displays linktrace result details.
<i>priority</i> <0-7>	Specifies the priority. The default is 7.
<i>source-mode</i> { <i>nodal</i> <i>smltVirtual</i> }} Note: Exception: <i>smltVirtual</i> is not supported on 4220 Series or 5320 Series.	Specifies the source mode: <ul style="list-style-type: none"> • <i>nodal</i> • <i>smltVirtual</i>—Use this value with B-VLANs only. The default is <i>nodal</i> .
<i>ttl-value</i> <1-255>	Specifies the Time-to-Live value. The default is 64.

Trigger a Layer 2 Ping

Before You Begin

- You must have a MEP that is associated with a VLAN.

About This Task

Use this procedure to trigger a Layer 2 ping, inside an SPBM cloud or network, which acts like native **ping**. This feature enables CFM to debug Layer 2. It can also help you debug IP shortcuts and the record for the shortcuts' ARP.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. Trigger a Layer 2 ping:

- `l2 ping {vlan <1-4059> routernodename WORD<0-255> | vlan <1-4059> mac <0x00:0x00:0x00:0x00:0x00:0x00>} [burst-count <1-200>] [data-tlv-size <0-400>] [frame-size <64-1500>] [priority <0-7>] [source-mode <nodal|smltVirtual>] [testfill-pattern <all-zero|all-zero-crc|pseudo-random-bit-sequence|pseudo-random-bit-sequence-crc>] [time-out <1-10>]`
- `l2 ping {ip-address WORD<0-255>} [burst-count <1-200>] [data-tlv-size <0-400>] [frame-size <64-1500>] [priority <0-7>] [source-mode <nodal|smltVirtual>] [testfill-pattern <all-zero|all-zero-crc|pseudo-random-bit-sequence|pseudo-random-bit-sequence-crc>] [time-out <1-10>] [vrf WORD<1-16>]`
- `l2 ping {anycast-gw <1-15999999>} [burst-count<1-200> | data-tlv-size <0-400>| frame-size <64-1500> | priority <0-7> | source-mode <nodal|smltVirtual| testfill-pattern <all-zero|all-zero-crc|pseudo-random-bit-sequence|pseudo-random-bit-sequence-crc>] [time-out <1-10>] [vrf WORD<1-16>]`

Example

```
Switch:1#l2 ping vlan 2 mac 00.14.0d.bf.a3.df
Please wait for l2ping to complete or press any key to abort
----00:14:0d:bf:a3:df  L2 PING Statistics----  0(68) bytes of data
1 packets transmitted, 0 packets received,   100.00% packet loss

Switch:1#l2 ping vlan 2 routernodename MONTIO
Please wait for l2ping to complete or press any key to abort

----00:14:0d:a2:b3:df  L2 PING Statistics----  0(68) bytes of data
1 packets transmitted, 1 packets received,   0.00% packet loss
  round-trip (us)          min/max/ave/stdv =  26895/26895/26895.00/  0.00

Switch:1#l2 ping ip-address 192.0.2.10
Please wait for l2ping to complete or press any key to abort

```

Variable Definitions

The following table defines parameters to configure the Layer 2 ping parameters.

Variable	Value
<pre>{vlan <1-4059> routernodename WORD<0-255> } (vlan <1-4059> mac <0x00:0x00:0x00:0x00:0x00:0x00> } {ip-address WORD<0-255> } {anycast-gw<1-15999999>}</pre>	<p>Specifies the destination for the Layer 2 ping:</p> <ul style="list-style-type: none"> • <1-4059> — Specifies the VLAN ID. • <1-15999999> — Specifies the Anycast IP Gateway service instance identifier (I-SID). • WORD<0-255> — Specifies the Router node name. • <XX:XX:XX:XX:XX:XX> — Specifies the MAC address. • <A.B.C.D> — Specifies the IP address.
<i>burst-count</i> <1-200>	Specifies the burst count.
<i>data-tlv-size</i> <0-400>	Specifies the data TLV size. The default is 0.
<i>frame-size</i> <64-1500>]	Specifies the frame size. The default is 0.
<pre>testfill-pattern <all-zero all-zero-crc pseudo-random- bit-sequence pseudo-random- bit-sequence-crc></pre>	<p>Specifies the testfill pattern:</p> <ul style="list-style-type: none"> • all-zero — null signal without cyclic redundancy check • all-zero-crc — null signal with cyclic redundancy check with 32-bit polynomial • pseudo-random-bit-sequence — pseudo-random-bit-sequence without cyclic redundancy check • pseudo-random-bit-sequence-crc — pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial. <p>A cyclic redundancy check is a code that detects errors. The default is all-zero.</p>
<i>priority</i> <0-7>	Specifies the priority. The default is 7.
<i>time-out</i> <1-10>	Specifies the interval in seconds. The default is 3.
<pre>source-mode{nodal smltVirtual}} </pre> <p>Note: Exception: smltVirtual is not supported on 4220 Series or 5320 Series.</p>	<p>Specifies the source mode:</p> <ul style="list-style-type: none"> • 1: nodal • 2: smltVirtual—Use this value with B-VLANs only. <p>The default is 1: nodal.</p>
<i>vrf</i> WORD<1-16>	Specifies the VRF name.

Trigger a Layer 2 Traceroute

Use this procedure to trigger a Layer 2 traceroute, which acts like native **traceroute**. This feature enables CFM to debug Layer 2 in an SPBM cloud or network. It can determine the path used by IS—IS to get from one MEP to another, by showing all

the hops between. Therefore, it can show where connectivity is lost. It can also work for IP shortcuts.

Important

To trace a route to a MAC address, the MAC address must be in the VLAN FDB table.

- For B-VLANs, you do not have to trigger an **l2ping** to learn the MAC address because IS-IS populates the MAC addresses in the FDB table.

linktrace traces the path up to the closest device to that MAC address that supports CFM.

Before You Begin

- You must have a MEP that is associated with a VLAN.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Trigger a Layer 2 traceroute:
 - `l2 traceroute {ip-address WORD<0-255>} [ttl <1-255>] [vrf WORD<1-16>]`
 - `l2 traceroute {<vlan <1-4059> routernodename WORD<0-255> | <vlan <1-4059> mac <0x00:0x00:0x00:0x00:0x00:0x00>} [priority <0-7>] [source-mode <nodal|smltVirtual>] [ttl <1-255>]`
 - `l2 traceroute {anycast-gw <1-15999999> [priority <0-7>] [source-mode <nodal|smltVirtual>] [ttl <1-255>]`

Examples

```
Switch:1#l2 traceroute vlan 2 routernodename Switch-MONTIO
Please wait for l2traceroute to complete or press any key to abort

l2traceroute to Switch-MONTIO (00:14:0d:a2:b3:df),  vlan 2
0   Switch-PETER4          (00:15:9b:11:33:df)
1   Switch-MONTIO          (00:14:0d:a2:b3:df)

Switch:1#l2 traceroute ip-address 192.0.2.10
Please wait for l2trace to complete or press any key to abort

L2 Trace  Statistics : IP 192.0.2.10, paths found 1
=====
Switch-SHAMIM (00:1a:8f:08:53:df),  vlan 2
0   Switch-PETER4          (00:15:9b:11:33:df)
1   Switch-MONTIO          (00:14:0d:a2:b3:df)
```

Variable Definitions

The following table defines parameters for the **l2 traceroute** command.

Variable	Value
<pre>{vlan <1-4059> routernodename WORD<0-255> } (vlan <1-4059> mac <0x00:0x00:0x00:0x00:0x00:0x00> } {ip-address WORD<0-255> } {anycast-gw<1-15999999>}</pre>	<p>Specifies the destination for the Layer 2 traceroute:</p> <ul style="list-style-type: none"> • <1-4059> — Specifies the VLAN ID • <1-15999999> — Specifies the Anycast IP Gateway service instance identifier (I-SID). • WORD<0-255> — Specifies the Router Node Name • <XX:XX:XX:XX:XX:XX> — Specifies the MAC address • WORD<0-255> — Specifies the IP address
<code>ttn-value <1-255></code>	Specifies the TTL value. The default is 64.
<code>priority <0-7></code>	Specifies the priority. The default is 7.
<pre>source-mode{nodal smltVirtual}} </pre> <p>Note: Exception: smltVirtual is not supported on 4220 Series or 5320 Series.</p>	<p>Specifies the source mode:</p> <ul style="list-style-type: none"> • nodal • smltVirtual—Use this value with B-VLANs only. <p>The default is nodal.</p>
<code>vrf WORD<1-16></code>	Specifies the VRF name.

Trigger a Layer 2 Tracetree

Use this procedure to trigger a Layer 2 tracetree. Layer 2 tracetree allows a user to trigger a multicast LTM message by specifying the B-VLAN and I-SID. The command allows the user to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID.

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP.
- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Trigger a Layer 2 tracetree:

```
12 tracetree {<1-4059> <1-16777215> [routernodename WORD<0-255>
| <1-4059> <1-16777215>] [mac <0x00:0x00:0x00:0x00:0x00:0x00>]}
[priority <0-7>] [source-mode <nodal|smltVirtual>] [ttn-value <1-255>]
```

Example

```
Switch:1#12 tracetree 500 1
Switch:1# 12 tracetree 500 1

Please wait for 12tracetree to complete or press any key to abort

12tracetree to 53:55:10:00:00:01, vlan 500 i-sid 1 nickname 5.55.10
```

```

hops 64
1   Switch-PETER4      00:15:9b:11:33:df -> Switch-MONTI0      00:14:0d:a2:b3:df
2   Switch-MONTI0      00:14:0d:a2:b3:df -> Switch-LEE2        00:15:e8:b8:a3:df

```

Variable Definitions

The following table defines parameters for the **12 tracetree** command.

Variable	Value
<pre>{ <1-4059><1-16777215> routernodename WORD<0-255> <1-4059><1-16777215> mac <0x00:0x00:0x00:0x00:0x00:0x00>}</pre>	<ul style="list-style-type: none"> • <1-4059> — Specifies the VLAN ID. • <1-16777215> — Specifies the I-SID. • WORD<0-255> — Specifies the Router Node Name. • <0x00:0x00:0x00:0x00:0x00:0x00> — Specifies the MAC address.
<code>ttl-value <1-255></code>	Specifies the TTL value. The default is 64.
<code>priority <0-7></code>	Specifies the priority value. The default is 7.
<pre>source-mode<nodal smltVirtual></pre> <p>Note: Exception: smltVirtual is not supported on 4220 Series or 5320 Series.</p>	Specifies the source mode. The default is nodal.

Trigger a Layer 2 Tracetree-fan

About This Task

Use this procedure to trigger a Layer 2 tracetree-fan from the nickname server to make sure that all the nodes towards the nickname client support the FAN protocol. Layer 2 tracetree-fan allows a user to trigger an LTM on the internal Fabric Area Network (FAN) I-SID. This command allows the user to trace the FAN tree.

Procedure

Trigger a Layer 2 tracetree-fan:

```
12 tracetree-fan [mac <0x00:0x00:0x00:0x00:0x00:0x00>] [priority <0-7>]
[routernodename WORD<0-255>] [ttl-value <1-255>]
```

Example

```

Switch:1# 12 tracetree-fan

Please wait for l2tracetree to complete or press any key to abort

l2tracetree to b1:ad:aa:41:b0:84, vlan 4051 i-sid 16777001 nickname 0.00.00 hops 64

1   Switch-PETER4      b0:ad:aa:41:b0:84 -> Switch-MONTI0      b0:ad:aa:41:48:84
1   Switch-PETER4      b0:ad:aa:41:b0:84 -> Switch-MONTI1      b0:ad:aa:42:88:84
2   Switch-MONTI0      b0:ad:aa:41:48:84 -> Switch-LEE2        b0:ad:aa:43:3c:84

```

Trigger a Layer 2 Tracemroute

Use this procedure to debug the IP Multicast over Fabric Connect stream path using **12 tracemroute** on the VLAN (Layer 2) or the VRF (Layer 3). This procedure queries the SPBM multicast module to determine the B-VLAN, I-SID and nickname for the S and G streams. The nickname and I-SID are used to create a multicast MAC address.

Note

The VLAN option is only valid for a VLAN that has an I-SID configured and IGMP snooping enabled.

Before You Begin

- On the source and destination nodes, you must configure an autogenerated or an explicit CFM MD, MA, and MEP.
- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Trigger a Layer 2 tracemroute on the VLAN:

```
12 tracemroute source <A.B.C.D> group <A.B.C.D> vlan <1-4059>[priority
<0-7>] [ttl-value <1-255>]
```

Note

For the preceding command, if you do not specify a VLAN, **12 tracemroute** uses the global default VRF.

Wait for the l2 tracemroute to complete or press any key to abort.

3. Trigger a Layer 2 tracemroute on the VRF:

```
12 tracemroute source <A.B.C.D> group <A.B.C.D> vrf WORD<1-16>
[priority <0-7>] [ttl-value <1-255>]
```

Note

For the preceding command, if you do not specify a VRF, **12 tracemroute** uses the global default VRF.

Wait for the l2 tracemroute to complete or press any key to abort.

Examples

The following is a sample output for a Layer 2 tracemroute on a VLAN:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#12 tracemroute source 192.0.2.81 233.252.0.1 vlan 201

Please wait for 12 tracemroute to complete or press any key to abort.

Source 192.0.2.81
```

```

Group: 233.252.0.1

VLAN:201

BMAC: 03:00:03:f4:24:01

B-VLAN: 10

I-SID: 16000001

=====
1 PETER4 00:03:00:00:00:00 -> LEE1 00:14:0d:bf:a3:df
2 LEE1 00:14:0d:bf:a3:df -> LEE2 00:15:e8:b8:a3:df

```

The following is a sample output for a Layer 2 tracemroute on a VRF:

```

Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#12 tracemroute source 192.0.2.10 group 233.252.0.1 vrf red

Please wait for l2 tracemroute to complete or press any key to abort.

Source 192.0.2.10

Group: 233.252.0.1

VRF: redID 1

BMAC: 03:00:04:f4:24:01

B-VLAN: 20

I-SID: 16000001

=====
1 PETER4 00:03:00:00:00:00 -> LEE1 00:14:0d:bf:a3:df
2 LEE1 00:14:0d:bf:a3:df -> LEE2 00:15:e8:b8:a3:df

```

Variable Definitions

The following table defines parameters for the **12 tracemroute** command.

Variable	Value
<i>source</i> <A.B.C.D>	Specifies the source IP address.
<i>group</i> <A.B.C.D>	Specifies the IP address of the multicast group.
<i>vlan</i> <1-4084>	Specifies the VLAN value.
<i>vrf</i> WORD<1-16>	Specifies the VRF name. If you do not specify a VRF name, then the results are shown for the flow in the Global Router (default) context.
<i>priority</i> <0-7>	Specifies the priority value.
<i>ttl</i> <1-255>	Specifies the time-to-live (TTL) for the trace packet, which is how many hops the trace packet takes before it is dropped.

Use Trace CFM to Diagnose Problems

Use the following procedure to display trace information for CFM.

About This Task

Use trace to observe the status of a software module at a certain time.

For example, if you notice a CPU utilization issue (generally a sustained spike above 90%) perform a trace of the control plane activity.

Use the **trace level 120 <0-4>** command to trace CFM module information, including CLI, instrumentation, show config, and platform dependent code. The CFM module ID is 120.

Use the **trace cfm level <0-4>** command to trace platform independent code and CFM protocol code.

Caution

Risk of traffic loss

Using the trace tool inappropriately can cause CPU lockup conditions, loss of access to the device, loss of protocols, and service degradation.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Clear the trace:

```
clear trace
```

3. Begin the trace operation:

```
trace cfm level <0-4>
```

Wait approximately 30 seconds, and then stop trace.

4. Stop tracing:

```
trace shutdown
```

5. View the trace results:

```
show trace cfm
```

6. Begin the trace operation for the CFM module:

```
trace level 120 <0-4>
```

Wait approximately 30 seconds, and then stop trace.

7. View trace results:

```
trace screen enable
```

Important

If you use trace level 3 (verbose) or trace level 4 (very verbose), do not use the screen to view commands due to the volume of information the system generates and the effect on the system.

8. Save the trace file to the Compact Flash card for retrieval.

```
save trace [file WORD<1-99>]
```

If you do not specify a file name, the file name is systrace.txt. By default, the system saves the file to the external flash.

9. Search trace results for a specific string value, for example, the word error:

```
trace grep [WORD<0-128>]
```

If you use this command and do not specify a string value, you clear the results of a previous search.

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)# clear trace
Switch:1(config)# trace cfm level 3
Switch:1(config)# trace shutdown
Switch:1(config)# show trace cfm
=====
                        CFM Tracing Info
=====
Status      : Enabled
Level       : VERBOSE
Switch:1(config)#trace level 120 3
Switch:1(config)# save trace
Switch:1(config)# trace grep error
Switch:1(config)#trace grep 00-1A-4B-8A-FB-6B
```

Variable Definitions

The following table defines parameters for the **trace** command.

Variable	Value
<i>cfm level</i> [<0-4>]	Starts the trace by specifying the level. <ul style="list-style-type: none"> <0-4> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.
<i>filter</i>	Configures a filter trace for a file or module.
<i>flags</i>	Configures trace flags for IS-IS or OSPF.
<i>grep</i> [WORD<0-128>]	Searches trace results for a specific string value, for example, the word error. Performs a comparison of trace messages.

Variable	Value
<code>level [<Module_ID>] [<0-4>]</code>	<p>Starts the trace by specifying the module ID and level.</p> <ul style="list-style-type: none"> • <code><Module_ID></code> specifies the module for the trace. Different hardware platforms support different IDs because of feature support differences. For feature support information, see <i>Fabric Engine and VOSS Feature Matrix</i>. To see the list of module IDs, use the show trace modid-list command or CLI command completion Help. • <code><0-4></code> specifies the trace level from 0–4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.
<code>route-map</code>	Enables or disables the trace route-map. The values are on and off.
<code>screen {disable enable}</code>	Enables the display of trace output to the screen.
<code>shutdown</code>	Stops the trace operation.
<code>spbm isis level [<0-4>]</code>	<p>Starts the trace by specifying the level.</p> <ul style="list-style-type: none"> • <code><0-4></code> specifies the trace level from 0–4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose. <p>The default is 1, very terse.</p>

The following table defines parameters for the **save trace** command.

Variable	Value
<code>file WORD<1-99></code>	<p>Specifies the file name in one of the following formats:</p> <ul style="list-style-type: none"> • <code>a.b.c.d:<file></code> • <code>x:x:x:x:x:x:x <file></code> • <code>/intflash/<file></code> • <code>/extflash/<file></code> • <code>/usb/<file></code> • <code>/mnt/intflash/ <file></code> • <code>/mnt/extflash/ <file></code> <p>/mnt/intflash is the internal flash of the CPU. /mnt/extflash is the external flash of the CPU.</p>

CFM Configuration Using EDM

This section provides procedures to configure Connectivity Fault Management (CFM) using Enterprise Device Manager (EDM).

Note

When you enable CFM in an SPBM network, as a best practice, enable CFM on the Backbone Edge Bridges (BEB) and on all Backbone Core Bridges (BCB). If you do not enable CFM on a particular node, you cannot obtain CFM debug information from that node.

Autogenerated CFM

CFM provides two methods for creating MEPs: autogenerated and explicit. You cannot use both. You must choose one or the other. Use the procedures in this section to configure autogenerated MEPs that eliminate the need to configure an MD, MA, and MEP ID to create a MEP.

Previous explicit CFM configurations of MDs, MAs and MEPs on SPBM B-VLANs continue to function. However, if you want to enable the autogenerated commands, you must first remove the existing MEP and MIP on the SPBM B-VLAN. The switch only supports one MEP or MIP on the SPBM B-VLAN, either explicitly configured or autogenerated.

Configure Autogenerated CFM on SPBM B-VLANs

Use this procedure to configure the autogenerated CFM MEP and MIP level for every SPBM B-VLAN on the chassis. This configuration eliminates the need to explicitly configure an MD, MA, and MEP ID and to associate the MEP and MIP level to the SPBM B-VLAN.

About This Task

When you enable this feature, the device creates a global MD (named `spbm`) for all the SPBM Nodal MEPs. This MD has a default maintenance level of 4, which you can change with the `level` attribute. All the MEPs that the device creates use the MEP ID configured under the global context, which has a default value of 1. The nodal MEPs are automatically associated with the SPBM B-VLANs configured. The MIP level maps to the global level. When you enable the feature, the device automatically associates the MIP level with the SPBM B-VLANs configured. The feature is disabled by default.

Important

CFM supports one MEP or MIP for each SPBM B-VLAN only. This means that if you want to use these autogenerated MEPs, you cannot use your existing CFM configuration. You must first remove the existing MEP or MIP on the SPBM B-VLAN. If you want to continue configuring MEPs manually, skip this procedure.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **CFM**.

3. Select the **Global** tab.
4. Select **enable** next to **SpbmAdminState**.
5. Select **Apply**.

Global Field Descriptions

Use the data in the following table to configure the global MEP and MIP parameters.

Name	Description
SpbmAdminState	Enables or disables autogenerated CFM for B-VLANs. The default is disable.
SpbmLevel	Specifies the global SPBM CFM maintenance level for the chassis within the range of 0 to 7. The default is 4. Only configure global CFM at one MD level for each chassis for each VLAN type.
SpbmMepld	Specifies the global MEP ID within the range of 1 to 8191. Select a unique ID for each switch to ensure that the MEPs are unique across the network. The default is 1.

Configure Explicit CFM

For SPBM B-VLANs, CFM provides two methods for creating MEPs: autogenerated and explicit. You cannot use both. Use the procedures in this section to configure MEPs explicitly.

If you want to create autogenerated CFM MEPs that eliminate the need to configure an MD, MA, and MEP ID, see the procedures in [Autogenerated CFM](#) on page 3830.

Note

The CFM show commands that display MD, MA, and MEP information work for both autogenerated and explicitly-configured CFM MEPs.

Configure CFM MD

About This Task

Use this procedure to configure a Connectivity Fault Management (CFM) Maintenance Domain (MD). An MD is the part of a network that is controlled by a single administrator. A single MD can contain several Maintenance Associations (MA).

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **CFM**.
3. Select the **MD** tab.
4. Select **Insert**.
5. In the fields provided, specify an index value, name, and level for the MD.
6. Select **Insert**.

MD Field Descriptions

Use the data in the following table to use the **MD** tab.

Name	Description
Index	Specifies a maintenance domain entry index.
Name	Specifies the MD name.
NumOfMa	Indicates the number of MAs that belong to this maintenance domain.
Level	Specifies the MD maintenance level. The default is 4.
NumOfMip	Indicates the number of MIPs that belong to this maintenance domain
Type	Indicates the type of domain.

Configure CFM MA

Before You Begin

- You must configure a CFM MD.

About This Task

Use this procedure to configure a CFM Maintenance Association (MA). An MA represents a logical grouping of monitored entities within its Domain. It can therefore represent a set of Maintenance Endpoints (MEPs), each configured with the same Maintenance Association ID (MAID) and MD Level, established to verify the integrity of a single service instance.

Procedure

- In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
- Select **CFM**.
- Select the **MD** tab.
- Highlight an existing MD, and then select **MaintenanceAssociation**.
- In the **MA** tab, select **Insert**.
- In the fields provided, specify an index value and name for the MA.
- Select **Insert**.

MA Field Descriptions

Use the data in the following table to use the **MA** tab.

Name	Description
DomainIndex	Specifies the maintenance domain entry index.
AssociationIndex	Specifies a maintenance association entry index.

Name	Description
DomainName	Specifies the MD name.
AssociationName	Specifies the MA name.
NumOfMep	Indicates the number of MEPs that belong to this maintenance association.

Configure CFM MEP

Use this procedure to configure the CFM Maintenance Endpoint (MEP). A MEP represents a managed CFM entity, associated with a specific Domain Service Access Point (DoSAP) of a service instance, which can generate and receive CFM Protocol Data Units (PDU) and track any responses. A MEP is created by MEP ID under the context of an MA.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **CFM**.
3. Select the **MD** tab.
4. Highlight an existing MD, and then select **MaintenanceAssociation**.
5. In the **MA** tab, highlight an existing MA, and then select **MaintenanceEndpoint**.
6. Select **Insert**.
7. In the fields provided, specify the ID and the administrative state of the MEP.
8. Select **Insert**.

MEP Field Descriptions

Use the data in the following table to use the **MEP** tab.

Name	Description
DomainIndex	Specifies the MD index.
AssociationIndex	Specifies the MA index.
Id	Specifies the MEP ID.
DomainName	Specifies the MD name.
AssociationName	Specifies the MA name.
AdminState	Specifies the administrative state of the MEP. The default is disable.

Name	Description
MepType	Specifies the MEP type: <ul style="list-style-type: none"> • trunk • sg • endpt • vlan • port • endptClient • nodal • remotetrunk • remotesg • remoteendpt • remoteVlan • remotePort • remoteEndptClient
ServiceDescription	Specifies the service to which this MEP is assigned.

Configure CFM Nodal MEP

Before You Begin

- You must configure a CFM MD, MA, and MEP.

About This Task

Use this procedure to configure the CFM nodal Maintenance Endpoint (MEP). The Nodal MEP provides traceability and troubleshooting at the system level for a given B-VLAN. The Nodal B-VLAN MEPs created on the CP and function as if they are connected to the virtual interface of the given B-VLAN. Because of this they are supported for both port and MLT based B-VLANs.

Nodal MPs provide both MEP and Maintenance Intermediate Point (MIP) functionality for SPBM deployments. Nodal MPs are associated with a B-VLAN and are VLAN encapsulated packets. Each node (chassis) has a given MAC address and communicates with other nodes. The SPBM instance MAC address is used as the MAC address of the Nodal MP.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Advanced** tab.
4. Select a VLAN with a type of spbm-bvlan.
5. Select **Nodal**.
6. In **NodalMepList**, specify the nodal MEPs to add to the VLAN.
7. Select **Apply**.

Nodal MEP/MIP Field Descriptions

Use the data in the following table to use the **Nodal MEP/MIP** tab.

Name	Description
NodalMepList	Specifies the nodal MEPs to add to the VLAN, in the format <mdName.maName.mepId>, for example md10.ma20.30.
NumOfNodalMep	Indicates the number of nodal MEPs assigned to this VLAN.
NodalMipLevelList	Specifies a MIP level list.
NumOfNodalMipLevel	Indicates the number of nodal MIP levels assigned to this VLAN that allows MIP functionality to be enabled on a per level per VLAN basis.

Configure Layer 2 Ping

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.

About This Task

Use this procedure to configure a Layer 2 ping inside an SPBM cloud or network. This feature enables CFM to debug Layer 2. It can also help you debug IP shortcuts and the record for the shortcuts' ARP.

Procedure

- In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
- Select **L2Ping/L2Trace Route**.
- From the **L2Ping** tab, configure the Layer 2 ping properties.
- To initiate a Layer 2 ping, highlight an entry, and then select **Start**.
- To update a Layer 2 ping, select **Refresh**.
- To stop the Layer 2 ping, select **Stop**.

L2Ping Field Descriptions

Use the data in the following table to use the **L2Ping** tab.

Name	Description
VlanId	Identifies the backbone VLAN.
DestMacAddress	Specifies the target MAC address.
HostName	Specifies the target host name.
DestIsHostName	Indicates whether the host name is (true) or is not (false) used for L2Ping transmission.

Name	Description
Messages	Specifies the number of L2Ping messages to be transmitted. The default is 1.
Status	<p>Specifies the status of the transmit loopback service:</p> <ul style="list-style-type: none"> • ready: the service is available. • transmit: the service is transmitting, or about to transmit, the L2Ping messages. • abort: the service aborted or is about to abort the L2Ping messages. <p>This field is also used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time.</p> <p>The default is ready.</p>
ResultOk	<p>Indicates the result of the operation:</p> <ul style="list-style-type: none"> • true: the L2Ping Messages will be (or have been) sent. • false: the L2Ping Messages will not be sent. <p>The default is true.</p>
Priority	<p>Specifies a 3-bit value to be used in the VLAN header, if present in the transmitted frame.</p> <p>The default is 7.</p>
TimeoutInt	Specifies the interval to wait for an L2Ping time-out. The default value is 3 seconds.
TestPattern	<p>Specifies the test pattern to use in the L2Ping PDU:</p> <ul style="list-style-type: none"> • allZero: null signal without cyclic redundancy check • allZeroCrc: null signal with cyclic redundancy check with 32-bit polynomial • pseudoRandomBitSequence: pseudo-random-bit-sequence without cyclic redundancy check • pseudoRandomBitSequenceCrc: pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial. <p>A cyclic redundancy check is a code that detects errors. The default value is allZero.</p>
DataSize	Specifies an arbitrary amount of data to be included in the data TLV, if the data size is selected to be sent. The default is 0.

Name	Description
FrameSize	Specifies the frame size. If the frame size is specified then the data size is internally calculated and the calculated data size is included in the data TLV. The default is 0.
SourceMode Note: Exception: smltVirtual is not supported on 4220 Series or 5320 Series.	Specifies the source mode of the transmit loopback service: <ul style="list-style-type: none"> • nodal • smltVirtual — Use the smltVirtual option with B-VLANs only. The default is nodal.
SeqNumber	The transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.
Result	Displays the Layer 2 Ping result.

Initiate a Layer 2 Traceroute

Use this procedure to trigger a Layer 2 traceroute. This feature enables CFM to debug Layer 2 in an SPBM cloud or network. It can determine the path used by IS—IS to get from one MEP to another, by showing all the hops between. Therefore, it can show where connectivity is lost. It can also work for IP shortcuts.

If you configure **IsTraceTree** to false then EDM performs Traceroute on the unicast path. If you configure **IsTraceTree** to true then EDM performs TraceTree on the multicast tree.

For more information on configuring tracetree, see [Configure a Layer 2 Tracetree](#) on page 3853.

Important

To trace a route to a MAC address, the MAC address must be in the VLAN FDB table.

For B-VLANs, you do not have to trigger an **L2Ping** to learn the MAC address because IS-IS populates the MAC addresses in the FDB table.

Linktrace traces the path up to the closest device to that MAC address that supports CFM.

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. Select the **L2 Traceroute/TraceTree** tab.
4. To start the traceroute, highlight an entry, and then select **Start**.
5. To update the traceroute, select **Refresh**.

6. To stop the traceroute, select **Stop**.

L2 Traceroute/TraceTree Field Descriptions

Use the data in the following table to use the **L2 Traceroute/TraceTree** tab.

Name	Description
VlanId	Specifies a value that uniquely identifies the Backbone VLAN (B-VLAN).
Priority	Specifies a 3-bit value to be used in the VLAN header, if present in the transmitted frame. The default is 7.
DestMacAddress	Specifies the target MAC address.
HostName	Specifies the target host name.
DestIsHostName	Specifies whether the host name is (true) or is not (false) used for the L2Trace transmission.
Isid	Specifies the Service Instance Identifier (I-SID).
IsTraceTree	<p>Specifies whether the multicast tree or unicast path is traced:</p> <ul style="list-style-type: none"> If you configure IsTraceTree to false then EDM performs Traceroute on the unicast path. If you configure IsTraceTree to true then EDM performs TraceTree on the multicast tree.
Status	<p>Indicates the status of the transmit loopback service:</p> <ul style="list-style-type: none"> ready: the service is available. transmit: the service is transmitting, or about to transmit, the L2Trace messages. abort: the service aborted or is about to abort the L2Trace messages. <p>This field is also used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time.</p> <p>The default is ready.</p>
ResultOk	<p>Indicates the result of the operation:</p> <ul style="list-style-type: none"> true: the L2Trace messages will be (or have been) sent. false: the L2Trace messages will not be sent. <p>The default is true.</p>

Name	Description
Ttl	<p>Specifies the number of hops remaining to this L2Trace.</p> <p>This value is decremented by 1 by each Bridge that handles the L2Trace. The decremented value is returned in the L2Trace. If 0 on output, the L2Trace is not transmitted to the next hop. The value of the time-to-live (TTL) field in the L2Trace is defined by the originating MEP.</p> <p>The default value is 64.</p>
SourceMode Note: Exception: smltVirtual is not supported on 4220 Series or 5320 Series.	<p>Specifies the source mode:</p> <p>The default is nodal.</p>
SeqNumber	<p>Specifies the transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.</p>
Flag	<p>L2Trace result flag that indicates L2Trace status or error code:</p> <ul style="list-style-type: none"> • none (1): No error • internalError (2): L2Trace internal error • invalidMac (3): Invalid MAC address • mepDisabled (4): MEP must be enabled in order to perform L2Trace • noL2TraceResponse (5): No L2Trace response received • l2TraceToOwnMepMac (6): L2Trace to own MEP MAC is not sent • l2TraceComplete (7): L2Trace completed • l2TraceLookupFailure (8): Lookup failure for L2Trace • l2TraceLeafNode (9): On a leaf node in the I-SID tree • l2TraceNotInTree (10): Not in the I-SID tree • l2TraceSmItNotPrimary (11): Requested SMLT source from non-primary node

View Layer 2 Traceroute Results

Use this procedure to view Layer 2 traceroute results. This feature enables CFM to debug Layer 2. It can also help you debug ARP problems by providing the ability to troubleshoot next hop ARP records.

About This Task

You can display Layer 2 tracetable results to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID. For more information, see [View Layer 2 Tracetable Results](#) on page 3856.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. Select the **L2Traceroute/TraceTree** tab.
4. Select **Refresh** to update the results.
5. To view the traceroute results, highlight an entry, and then select **Result**.

L2 Traceroute/Tracetable Result Field Descriptions

Use the data in the following table to use the **L2 Traceroute/Tracetable Result** tab.

Name	Description
VlanId	A value that uniquely identifies the Backbone VLAN (B-VLAN).
SeqNumber	The transaction identifier/sequence number returned by a previous transmit linktrace message command, indicating which L2Trace's response of the L2Trace is going to be returned. The default is 0.
Hop	The number of hops away from L2Trace initiator.
ReceiveOrder	An index to distinguish among multiple L2Trace responses with the same Transaction Identifier field value. This value is assigned sequentially from 1, in the order that the Linktrace Initiator received the responses.
Ttl	Time-to-Live (TTL) field value for a returned L2Trace response.
SrcMac	MAC address of the MP that responds to the L2Trace request for this L2TraceReply.
HostName	The host name of the replying node.
LastSrcMac	The MAC address of the node that forwarded the L2Trace to the responding node.
LastHostName	The host name of the node that forwarded the L2Trace to the responding node.

Configure Layer 2 IP Ping

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.

- If you want to run a Layer 2 IP Ping for a specific VRF, you must use EDM in the specific VRF context first. For more information, see the procedure for selecting and launching a VRF context view in [Select and Launch a VRF Context View](#) on page 4100.

About This Task

Use this procedure to configure Layer 2 IP ping

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. Select the **L2 IP Ping** tab.
4. To add a new entry:
 - a. Select **Insert**.
 - b. Specify the destination IP address.
 - c. Select **Insert**.
5. To start the Layer 2 IP ping, highlight an entry, and then select **Start**.
6. To stop the Layer 2 IP ping, select **Stop**.
7. To update the Layer 2 IP ping, select **Refresh**.

L2 IP Ping Field Descriptions

Use the data in the following table to use the **L2 IP Ping** tab.

Name	Description
IpAddrType	Specifies the address type of destination IP Address (only IPv4 is supported).
IpAddr	Specifies the destination IP Address.
VrfId	Specifies the VRF ID.
VrfName	Specifies the name of the virtual router.
Messages	Specifies the number of L2IpPing messages to be transmitted per MAC/VLAN pair. Range is 1–200. The default is 1.

Name	Description
Status	<p>Specifies the status of the transmit loopback service:</p> <ul style="list-style-type: none"> • ready: the service is available. • transmit: the service is transmitting, or about to transmit, the L2IpPing messages. • abort: the service is aborted or about to abort the L2IpPing messages. <p>This field is also used to avoid concurrency or race condition problems that could occur if two or more management entities try to use the service at the same time. The default is ready.</p>
ResultOk	<p>Indicates the result of the operation:</p> <ul style="list-style-type: none"> • true: L2IpPing Messages will be or have been sent. • false: L2IpPing Messages will not be sent. <p>The default is true.</p>
TimeoutInt	<p>Specifies the interval to wait for an L2IpPing time-out with a range of 1–10 seconds with a default value of 3 seconds.</p>
TestPattern	<p>Specifies the test pattern to use in the L2IPPing PDU:</p> <ul style="list-style-type: none"> • allZero — null signal without cyclic redundancy check • allZeroCrc — null signal with cyclic redundancy check with 32-bit polynomial • pseudoRandomBitSequence — pseudo-random-bit-sequence without cyclic redundancy check • pseudoRandomBitSequenceCrc — pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial. <p>A cyclic redundancy check is a code that detects errors. The default value is allZero.</p>
DataSize	<p>Specifies an arbitrary amount of data to be included in the data TLV, if the data size is selected to be sent. The range is 0–400. The default is 0.</p>
PathsFound	<p>Specifies the number of paths found to execute the command. The default is 0.</p>

*View Layer 2 IP Ping Results***About This Task**

Use this procedure to view Layer 2 IP ping results.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. Select the **L2 IP Ping** tab.
4. To view the Layer 2 IP ping results, highlight an entry, and then select **Result**.

L2 IP Ping Result Field Descriptions

Use the data in the following table to use the **L2 IP Ping Result** tab.

Name	Description
IpAddrType	The address type of the destination IP Address.
IpAddr	Destination IP Address.
SendOrder	Specifies the order that sessions were sent. It is an index to distinguish among multiple L2Ping sessions. This value is assigned sequentially from 1. It correlates to the number of paths found.
VrfId	Specifies the VRF ID.
VlanId	Specifies the VLAN ID found from the Layer 3 lookup and used for transmission.
DestMacAddress	An indication of the target MAC Address transmitted.
PortNum	Either the value '0', or the port number of the port used for the L2 IP ping.
DestHostName	The host name of the responding node.
Size	The number of bytes of data sent.
PktsTx	Number of Packets transmitted for this VLAN/MAC.
PktsRx	Number of Packets received for this VLAN/MAC.
PercentLossWhole	Percentage of packet loss for this VLAN/MAC.
PercentLossFract	Percentage of packet loss for this VLAN/MAC.
MinRoundTrip	Minimum time for round-trip for this VLAN/MAC in us.
MaxRoundTrip	Maximum time for round-trip for this VLAN/MAC in us.

Name	Description
RttAvgWhole	Average time for round-trip for this VLAN/MAC in us.
RttAvgFract	Fractional portion of average time for round-trip.
Flag	Result flag indicating status or error code: <ul style="list-style-type: none"> • 1 - No error • 2 - Internal error • 3 - Invalid IP • 4 - L2Trace completed • 5 - Lookup failure for IP (no VLAN/MAC entries)

Configure Layer 2 IP Traceroute

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN
- If you want to run a Layer 2 IP Traceroute for a specific VRF, you must use EDM in the specific VRF context first. For more information, see the procedure for selecting and launching a VRF context view in [Select and Launch a VRF Context View](#) on page 4100.

About This Task

Use this procedure to configure Layer 2 IP traceroute.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**
3. Select the **L2 IP Traceroute** tab.
4. To add a new entry:
 - a. Select **Insert**.
 - b. Specify the destination IP address.
 - c. (Optional) Specify the TTL value.
 - d. Select **Insert**.
5. To start the Layer 2 IP traceroute, highlight an entry, and then select **Start**.
6. To stop the Layer 2 IP traceroute, select **Stop**.
7. To update the Layer 2 IP traceroute, select **Refresh**.

L2 IP Traceroute Field Descriptions

Use the data in the following table to use the **L2 IP Traceroute** tab.

Name	Description
IpAddrType	Specifies the address type of destination IP address (only IPv4 is supported).
IPAddr	Specifies the destination IP Address.
VrfId	Specifies the VRF ID.
VrfName	Specifies the name of the virtual router.
Ttl	Specifies the number of hops remaining to this L2Trace. This value is decremented by 1 by each Bridge that handles the L2Trace. The decremented value is returned in the L2Trace. If 0 on output, the L2Trace is not transmitted to the next hop. The default value is 64
Status	<p>Indicates the status of the transmit loopback service:</p> <ul style="list-style-type: none"> • ready: the service is available. • transmit: the service is transmitting, or about to transmit, the L2Trace messages. • abort: the service is aborted or about to abort the L2Trace messages. <p>This field is also used to avoid concurrency or race condition problems that could occur if two or more management entities try to use the service at the same time. The default is ready.</p>
ResultOk	<p>Indicates the result of the operation:</p> <ul style="list-style-type: none"> • true: the Trace Messages will be or have been sent. • false: the Trace Messages will not be sent <p>The default is true.</p>
PathsFound	Specifies the number of paths found to execute the L2trace. The default is 0.

View Layer 2 IP Traceroute Results

About This Task

Use this procedure to view Layer 2 IP traceroute results.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. Select the **L2 IP Traceroute** tab.
4. To view the Layer 2 IP traceroute results, highlight an entry, and then select **Result**.

L2 IP Traceroute Result Field Descriptions

Use the data in the following table to use the **L2 IP Traceoute Result** tab.

Name	Description
IpAddrType	Specifies the address type of destination IP address.
IpAddr	Specifies the destination IP address.
SendOrder	Denotes the order that sessions are sent. It is an index to distinguish among multiple L2Trace sessions. It correlates to the number of paths found. This value is assigned sequentially from 1.
Hop	Specifies the number of Layer 2 hops away from L2Trace initiator.
ReceiveOrder	Specifies the order that sessions are sent. It is an index to distinguish among multiple L2Trace responses with the same Send Transaction Identifier field value. This value is assigned sequentially from 1, in the order that the Linktrace Initiator received the responses.
Ttl	Specifies the time-to-live (TTL) field value for a returned L2Trace response.
VrfId	Specifies the VRF ID.
VlanId	Specifies the VLAN found from Layer 3 lookup and used for transmission.
DestMacAddress	Indicates the target MAC address transmitted.
PortNum	Specifies either the value '0', or the port number of the port used for the l2trace.
SeqNumber	Specifies the transaction identifier/sequence number used in linktrace message packet. The default is 0.
SrcMac	Specifies the MAC address of the MP that responded to L2Trace request for this L2traceReply.
HostName	Specifies the host name of the replying node.
LastSrcMac	Specifies the MAC address of the node that forwarded the L2Trace to the responding node.

Name	Description
LastHostName	Specifies the host name of the node that forwarded the L2Trace to the responding node.
Flag	L2Trace result flag indicating status or error code: <ul style="list-style-type: none"> • none (1): No error • internalError (2): L2Trace internal error • invalidMac (3): Invalid MAC address • mepDisabled (4): MEP must be enabled in order to perform L2Trace • noL2TraceResponse (5): No L2Trace response received • l2TraceToOwnMepMac (6): L2Trace to own MEP MAC is not sent • l2TraceComplete (7): L2Trace completed • l2TraceLookupFailure (8): Lookup failure for L2Trace

Trigger a Loopback Test

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP.
- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

About This Task

Use this procedure to trigger a loopback test.

The LBM packet is often compared to ping. An MEP transmits the loopback message to an intermediate or endpoint within a domain for the purpose of fault verification. Use this function to check the ability of the network to forward different sized frames.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **CFM**.
3. Select the **LBM** tab.
4. Configure the loopback test properties as required.
5. Select **Apply**.
6. In **Status**, select **transmit**.
7. Select **Apply**.
8. Select **Refresh**.

LBM Field Descriptions

Use the data in the following table to use the **LBM** tab.

Name	Description
DomainIndex	Specifies the MD index value.
AssociationIndex	Specifies the MA index value.
Index	Specifies the Maintenance Endpoint index value.
DomainName	Specifies the MD name.
AssociationName	Specifies the MA name.
DestMacAddress	Specifies the remote MAC address to reach the MEP/MIP.
Messages	Specifies the number of loopback messages to be transmitted. The default is 1.
VlanPriority	Specifies the priority. The default is 7.
SeqNumber	Specifies the transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.
ResultOk	<p>Indicates the result of the operation:</p> <ul style="list-style-type: none"> • true: The Loopback Messages will be (or have been) sent. • false: The Loopback Messages will not be sent. <p>The default is true.</p>
Status	<p>Indicates the status of the transmit loopback service:</p> <ul style="list-style-type: none"> • ready: The service is available. • transmit: The service is transmitting, or about to transmit, the Loopback messages. • abort: The service is aborted or about to abort the Loopback messages. <p>The default is ready.</p>
Result	Displays the LBM result.
TimeoutInt	Specifies the timeout interval in seconds. The default value is 3 seconds.
InterFrameInt	Specifies the interval between LBM frames with a range of (0..1000) msec and a default value of 500 msec. The value of 0 msec indicates to send the frames as fast as possible. The default is 500.

Name	Description
TestPattern	<p>Specifies the testfill pattern:</p> <ul style="list-style-type: none"> • allZero — null signal without cyclic redundancy check • allZeroCrc — null signal with cyclic redundancy check with 32-bit polynomial • pseudoRandomBitSequence — pseudo-random-bit-sequence without cyclic redundancy check • pseudoRandomBitSequenceCrc — pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial. <p>A cyclic redundancy check is a code that detects errors. The default value is allZero.</p>
DataSize	Specifies the data type-length-value (TLV) size. The default is 0.
FrameSize	Specifies the frame-size. The default is 0.
Sourcemode Note: Exception: smltVirtual is not supported on 4220 Series or 5320 Series.	<p>Specifies the source mode of the transmit loopback service:</p> <ul style="list-style-type: none"> • nodal • smltVirtual — Use the smltVirtual option with B-VLANs only. <p>The default is nodal.</p>

Trigger Linktrace

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP.
- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

About This Task

Use the following procedure to trigger a linktrace. The linktrace message is often compared to traceroute. An MEP transmits the Linktrace Message packet to a maintenance endpoint with intermediate points responding to indicate the path of the traffic within a domain for the purpose of fault isolation. The packet specifies the target MAC address of an MP, which is the SPBM system ID or the virtual SMLT MAC. MPs on the path to the target address respond with an LTR.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **CFM**.
3. Select the **LTM** tab.
4. Configure the linktrace test properties as required.

5. Select **Apply**.
6. To trigger the linktrace test, perform one of the following actions:
 - In **Status**, select **transmit**, and then select **Apply**
 - Highlight an entry, and then select **Start**.
7. To update the linktrace, select the **Refresh** button.
8. To stop the linktrace, select **Stop**.

LTM Field Descriptions

Use the data in the following table to use the **LTM** tab.

Name	Description
DomainIndex	Specifies the MD index value.
AssociationIndex	Specifies the MA index value.
Index	Specifies the MEP index value.
DomainName	Specifies the MD name.
AssociationName	Specifies the MA name.
VlanPriority	Specifies the VLAN priority, a 3-bit value to be used in the VLAN tag, if present in the transmitted frame. The default is 7.
DestMacAddress	Specifies the remote MAC address to reach the MEP.
Ttl	Indicates the number of hops remaining to this LTM. This value is decremented by 1 by each bridge that handles the LTM. The decremented value is returned in the LTR. If the value is 0 on output, the LTM is not transmitted to the next hop. The value of the TTL field in the LTM is specified at the originating MEP. The default value is 64.
SeqNumber	Specifies the transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.
ResultOk	Indicates the result of the operation: <ul style="list-style-type: none"> • true: The Loopback Messages will be (or have been) sent. • false: The Loopback Messages will not be sent. The default is true.

Name	Description
Status	<p>Indicates the status of the transmit loopback service:</p> <ul style="list-style-type: none"> • ready: The service is available. • transmit: The service is transmitting, or about to transmit, the LTM messages. • abort: The service is aborted, or about to abort, the LTM message. <p>The default is ready.</p>
Flag	<p>Displays the LTM result flag indicating LTM status or error code. Each value represents a status or error case:</p> <ul style="list-style-type: none"> • 1 - No error • 2 - LTM internal error • 3 - Unknown Remote Maintenance Endpoint • 4 - Invalid Remote Maintenance Endpoint MAC Address • 5 - Unset Remote Maintenance Endpoint MAC address • 6 - MEP must be enabled in order to perform LTM • 7 - No LTR response received • 8 - Linktrace to own MEP MAC is not sent • 9 - Endpoint must be enabled in order to perform LTM • 10 - Pbt-trunk must be enabled in order to perform LTM • 11 - LTM completed • 12 - LTM leaf node
SourceMode Note: Exception: smltVirtual is not supported on 4220 Series or 5320 Series.	<p>Specifies the source mode of the transmit loopback service:</p> <ul style="list-style-type: none"> • nodal • smltVirtual — Use the smltVirtual option with B-VLANs only. <p>The default is nodal.</p>

View Linktrace Results

About This Task

Use this procedure to view linktrace results.

After you trigger linktrace, you must select **Refresh** to update the results.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **CFM**.

3. Select the **LTM** tab.
4. Highlight an entry, and then select **Result**.

Link Trace Replies Field Descriptions

Use the data in the following table to use the **Link Trace Replies** tab.

Name	Description
DomainIndex	Indicates the Maintenance Domain Index.
AssociationIndex	Indicates the Maintenance Association Index.
MepId	Indicates the Maintenance EndPoint ID.
SeqNumber	Indicates the transaction identifier/sequence number returned by a previous transmit linktrace message command, indicating which LTM response is going to be returned. The default is 0.
Hop	Indicates the number of hops away from the LTM initiator.
ReceiveOrder	Indicates the index value used to distinguish among multiple LTRs with the same LTR Transaction Identifier field value. This value is assigned sequentially from 1, in the order that the Linktrace Initiator received the LTRs.
Ttl	Indicates the TTL field value for a returned LTR.
DomainName	Indicates the Maintenance Domain Name.
AssociationName	Indicates the Maintenance Association Name.
Forwarded	Indicates if a LTM was forwarded by the responding MP, as returned in the FwdYes flag of the flags field.
TerminalMep	Displays a boolean value stating whether the forwarded LTM reached a MEP enclosing its MA, as returned in the Terminal MEP flag of the Flags field.
LastEgressIdentifier	Displays an octet field holding the Last Egress Identifier returned in the LTR Egress Identifier TLV of the LTR. The Last Egress Identifier identifies the MEP Linktrace Indicator that originated, or the Linktrace Responder that forwarded, the LTM to which this LTR is the response. This is the same value as the Egress Identifier TLV of that LTM.

Name	Description
NextEgressIdentifier	Displays an octet field holding the Next Egress Identifier returned in the LTR Egress Identifier TLV of the LTR. The Next Egress Identifier Identifies the Linktrace Responder that transmitted this LTR, and can forward the LTM to the next hop. This is the same value as the Egress Identifier TLV of the forwarded LTM, if any. If the FwdYes bit of the Flags field is false, the contents of this field are undefined, and the field is ignored by the receiver.
RelayAction	Indicates the value returned in the RelayAction field.
SrcMac	Displays the MAC address of the MP that responded to the LTM request for this LTR.
IngressAction	Displays the value returned in the IngressAction Field of the LTM. The value ingNoTlv indicates that no Reply Ingress TLV was returned in the LTM.
IngressMac	Displays the MAC address returned in the ingress MAC address field. If the rcCfmLtrReplyIngress object contains the value ingNoTlv(5), then the contents of this field are meaningless.
EgressAction	Displays the value returned in the Egress Action Field of the LTM. The value egrNoTlv(5) indicates that no Reply Egress TLV was returned in the LTM.
EgressMac	Displays the MAC address returned in the egress MAC address field. If the rcCfmLtrReplyEgress object contains the value egrNoTlv(5), then the contents of this field are meaningless.

Configure a Layer 2 Tracetree

Use this procedure to configure a Layer 2 Tracetree. This feature enables CFM to debug Layer 2. Layer 2 Tracetree allows a user to trigger a multicast LTM message by specifying the B-VLAN and I-SID. The command allows the user to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID.

Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see *Fabric Engine Release Notes*. As an alternative, use CLI.

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP.
- Enable the MEP.

- Assign a nodal MEP to the B-VLAN.

About This Task

If you configure **IsTraceTree** to false, then EDM performs Traceroute on the unicast path. If you configure **IsTraceTree** to true, then EDM performs TraceTree on the multicast tree.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. From the **L2 Traceroute/TraceTree** tab, configure the Layer 2 tracetree properties.
4. In the **IsTraceTree** field double-click and select **true** for EDM to perform Tracetree on the multicast tree.
5. Select **Apply**.
6. Select **Refresh** to update the results.

L2 Traceroute/TraceTree Field Descriptions

Use the data in the following table to use the **L2 Traceroute/TraceTree** tab.

Name	Description
VlanId	Specifies a value that uniquely identifies the Backbone VLAN (B-VLAN).
Priority	Specifies a 3-bit value to be used in the VLAN header, if present in the transmitted frame. The default is 7.
DestMacAddress	Specifies the target MAC address.
HostName	Specifies the target host name.
DestIsHostName	Specifies whether the host name is (true) or is not (false) used for the L2Trace transmission.
Isid	Specifies the Service Instance Identifier (I-SID).
IsTraceTree	Specifies whether the multicast tree or unicast path is traced: <ul style="list-style-type: none"> • If you configure IsTraceTree to false then EDM performs Traceroute on the unicast path. • If you configure IsTraceTree to true then EDM performs TraceTree on the multicast tree.

Name	Description
Status	<p>Indicates the status of the transmit loopback service:</p> <ul style="list-style-type: none"> • ready: the service is available. • transmit: the service is transmitting, or about to transmit, the L2Trace messages. • abort: the service aborted or is about to abort the L2Trace messages. <p>This field is also used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time.</p> <p>The default is ready.</p>
ResultOk	<p>Indicates the result of the operation:</p> <ul style="list-style-type: none"> • true: the L2Trace messages will be (or have been) sent. • false: the L2Trace messages will not be sent. <p>The default is true.</p>
Ttl	<p>Specifies the number of hops remaining to this L2Trace.</p> <p>This value is decremented by 1 by each Bridge that handles the L2Trace. The decremented value is returned in the L2Trace. If 0 on output, the L2Trace is not transmitted to the next hop. The value of the time-to-live (TTL) field in the L2Trace is defined by the originating MEP.</p> <p>The default value is 64.</p>
SourceMode Note: Exception: smltVirtual is not supported on 4220 Series or 5320 Series.	<p>Specifies the source mode:</p> <p>The default is nodal.</p>

Name	Description
SeqNumber	Specifies the transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.
Flag	<p>L2Trace result flag that indicates L2Trace status or error code:</p> <ul style="list-style-type: none"> • none (1): No error • internalError (2): L2Trace internal error • invalidMac (3): Invalid MAC address • mepDisabled (4): MEP must be enabled in order to perform L2Trace • noL2TraceResponse (5): No L2Trace response received • l2TraceToOwnMepMac (6): L2Trace to own MEP MAC is not sent • l2TraceComplete (7): L2Trace completed • l2TraceLookupFailure (8): Lookup failure for L2Trace • l2TraceLeafNode (9): On a leaf node in the I-SID tree • l2TraceNotInTree (10): Not in the I-SID tree • l2TraceSmltNotPrimary (11): Requested SMLT source from non-primary node

View Layer 2 Tracetree Results

Use this procedure to view Layer 2 Tracetree results. The Layer 2 Tracetree command is a proprietary command that allows a user to trigger a multicast LTM message by specifying the B-VLAN and I-SID. This command allows the user to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID.

Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see *Fabric Engine Release Notes*. As an alternative, use CLI.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. Select the **L2 Traceroute/TraceTree** tab.
4. In the **IsTraceTree** field double-click and select **true** for EDM to perform Tracetree on the multicast tree.
5. Select **Apply**.
6. Select **Refresh** to update the results.
7. To view the tracetre results, highlight an entry, and then select **Result**.

L2 Traceroute/Tracetree Result Field Descriptions

Use the data in the following table to use the **L2 Traceroute/Tracetree Result** tab.

Name	Description
VlanId	A value that uniquely identifies the Backbone VLAN (B-VLAN).
SeqNumber	The transaction identifier/sequence number returned by a previous transmit linktrace message command, indicating which L2Trace's response of the L2Trace is going to be returned. The default is 0.
Hop	The number of hops away from L2Trace initiator.
ReceiveOrder	An index to distinguish among multiple L2Trace responses with the same Transaction Identifier field value. This value is assigned sequentially from 1, in the order that the Linktrace Initiator received the responses.
Ttl	Time-to-Live (TTL) field value for a returned L2Trace response.
SrcMac	MAC address of the MP that responds to the L2Trace request for this L2TraceReply.
HostName	The host name of the replying node.
LastSrcMac	The MAC address of the node that forwarded the L2Trace to the responding node.
LastHostName	The host name of the node that forwarded the L2Trace to the responding node.

Configure Layer 2 Trace Multicast Route

Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.
- To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

About This Task

Use this procedure to configure the Layer 2 tracemroute on the VLAN (Layer 2) or VRF (Layer 3). This procedure queries the SPBM multicast module to determine the B-VLAN, I-SID, and nickname for the S and G streams. The nickname and I-SID are used to create a multicast MAC address.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > L2Ping/L2Trace Route**.
2. Select the **L2MCAST Traceroute** tab.
3. Select **Insert** to insert the Layer 2 MCAST Traceroute.
4. Type the **SrcIpAddr**.
5. Type the **GroupIpAddr**.
6. Select the **ServiceType**:
 - To perform a tracemroute on a VLAN, select **vlan**.
 - To perform a tracemroute on a VRF, select **vrfid**.
7. In **ServiceId**, type the VLAN ID.
8. Type the **Priority**.
9. Type the **Ttl** value.
10. Select **Insert**.
11. Select **Apply** to save your changes.
12. To start the Layer 2 tracemoute, configure the Status to transmit, and then select **Start**.
13. Update the Layer 2 tracemroute by selecting **Refresh**.
14. To stop the Layer 2 tracemroute, select **Stop**.
15. To see the result, select **Result**.

L2 MCAST Traceroute Field Descriptions

Use the data in the following table to use the **L2 MCAST Traceroute** tab.

Name	Description
SrcIpAddrType	Specifies the source IP address type as IPv4.
SrcIpAddr	Specifies the source IP address of the flow where the multicast trace tree originates.
GroupIpAddrType	Specifies the group IP address type as IPv4.
GroupIpAddr	Specifies the group IP address.
ServiceType	Specifies where you configure the Layer 2 tracemroute. This is either VLAN or VRF.
ServiceId	Specifies the VLAN ID.
VRFName	Specifies the VRF name.
Priority	Specifies the priority value. The value is between 0 and 7.
Ttl	Specifies the returned trace response. The TTL value is between 1 and 255.
SeqNumber	Specifies the transaction identifier/sequence number of the first message to be sent.

Name	Description
Status	<p>Specifies the status of the transmit loopback service:</p> <ul style="list-style-type: none"> ready: Specifies the service is available. transmit: Specifies the service is transmitting, or about to transmit the trace messages. abort: Specifies the services is aborted or about to abort the trace messages. <p>The column will also be used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time.</p>
ResultOK	<p>Specifies the result of the operation:</p> <ul style="list-style-type: none"> true: The trace messages will be or have been sent. false: The trace messages will not be sent.
Flag	<p>Specifies the result flag indicating that the Layer 2 trace status or error code. View Layer 2 Trace Multicast Route Results

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > L2Ping/L2Trace Route**.
2. Select the **L2 MCAST Traceroute** tab.
3. To view the CFMI2 trace multicast route results, highlight an entry and select **Result**.

L2tracemroute Result Field Descriptions

Use the data in the following table to use the **L2tracemroute Result** tab.

Name	Description
VlanId	Specifies a value that uniquely identifies the C-VLAN.
SeqNumber	Specifies the transaction identifier/sequence number returned by a previous transmit linktrace message command. Indicates which I2 tracemroute response is going to be returned.
Hop	Specifies the number of hops away from the I2 tracemroute initiator.
ReceiveOrder	Specifies an index to distinguish among multiple I2 tracemroute responses with the same transaction identifier field value. This value is assigned sequentially from 1, in the order that the linktrace initiator received the responses.
Ttl	Specifies the TTL value for a returned I2 tracemroute response.
SrcMac	Specifies the MAC address of the MP that responds to the I2 tracemroute request for this I2 tracemrouteReply.
HostName	Specifies the host name of the replying node.
LastSrcMac	Specifies the MAC address of the node that forwarded the I2 tracemroute to the responding node.
LastHostName	Specifies the host name of the node that forwarded the I2 tracemroute to the responding node.

CFM Configuration Examples

This section provides a configuration example for Connectivity Fault Management (CFM).

CFM Configuration Example

The following sections show the steps required to configure CFM.

Note

The following commands are not supported on all hardware platforms:

- cfm maintenance-domain
- cfm maintenance-association
- vlan nodal-mip-level

Switch A

```
MAINTENANCE-DOMAIN CONFIGURATION
```

```
cfm maintenance-domain "spbm" index 1 maintenance-level 6
```

```
MAINTENANCE-ASSOCIATION CONFIGURATION
```

```

cfm maintenance-association "spbm" "2" index 1
cfm maintenance-association "spbm" "3" index 2

MAINTENANCE-ENDPOINT CONFIGURATION

cfm maintenance-endpoint "spbm" "2" 1 state enable
cfm maintenance-endpoint "spbm" "3" 1 state enable

VLAN NODAL MEP/MIP CONFIGURATION

vlan nodal-mep 2 spbm 2 1
vlan nodal-mip-level 2 6
vlan nodal-mep 3 spbm 3 1
vlan nodal-mip-level 3 6

```

Switch B

```

MAINTENANCE-DOMAIN CONFIGURATION

cfm maintenance-domain spbm index 1 maintenance-level 6

MAINTENANCE-ASSOCIATION CONFIGURATION

cfm maintenance-association "spbm" "2" index 1
cfm maintenance-association "spbm" "3" index 2

MAINTENANCE-ENDPOINT CONFIGURATION

cfm maintenance-endpoint "spbm" "2" 2 state enable
cfm maintenance-endpoint "spbm" "3" 2 state enable

VLAN NODAL MEP/MIP CONFIGURATION

vlan nodal-mep 2 spbm 2 2
vlan nodal-mip-level 2 6
vlan nodal-mep 3 spbm 3 2
vlan nodal-mip-level 3 6

```

CFM Sample Output

The following sections show sample CFM output.

L2ping can use the system ID or the router name. The following example shows a case where the VLAN and MAC are given.

show isis adjacencies

```

Switch:1# show isis adjacencies

Software Troubleshooting Tool Configuration

This section provides troubleshooting information for common software problems.

Troubleshooting Tool Fundamentals

This section provides conceptual information about the methods and monitoring tools you can use for troubleshooting problems. This section also contains precautionary notices that you must read for the safe operation of the network.

Troubleshooting Overview

The types of problems that typically occur with networks involve connectivity and performance. This section also contains precautionary notices that you must read for the safe operation of the switch. The switch supports a diverse range of network architectures and protocols, some of which maintain and monitor connectivity and isolate connectivity faults.

In addition, the switch supports a wide range of diagnostic tools that you can use to monitor and analyze traffic, capture and analyze data packets, trace data flows, view statistics, and manage event messages.

Certain protocols and tools are tailored for troubleshooting specific switch network topologies. Other tools are more general in their application and you can use them to diagnose and monitor ingress and egress traffic on the switch.

If connectivity problems occur and the source of the problem is unknown, it is usually best to follow the Open Systems Interconnection (OSI) network architecture layers. Confirm that your physical environment, such as the cable and port connections, operates without failures before moving up to the network and application layers.

To gather information about a problem, consider the following information:

- Consider the OSI model when you troubleshoot. Start at Layer 1 and move upwards. The Address Resolution Protocol (ARP) can cause problems; ARP operates at Layer 2 to resolve MAC addresses to IP addresses (Layer 3).
- Device-specific tools and protocols can help you gather information. This document outlines switch-specific tools.

- You can use client- and server-based tools from Microsoft, Linux, and UNIX. For example, you can use Windows tools like `ifconfig`, `ipconfig`, `winipcfg`, and `route print` to obtain IP information and routing tables. Servers also maintain route tables.

The following command output shows example output of the `route print` command.

```

```

- Other network problems can give the impression that a device has a problem. For instance, problems with a Domain Name Service (DNS) server, another switch, firewall, or access point can appear to be routing problems.

Debug Files

The switch stores debug files in the `intflash` directory.

The debug file is in a zipped format and contains information to help debug the device, including:

- a memory snapshot
- logs
- traces

This best practice is to delete these files to ensure enough space exists in the internal flash. New files do not overwrite old files. You must remove the files; otherwise, the internal flash may not have enough free space for necessary activities, for example, to store a core dump file if the switch fails, or you may not have the space to transfer a new release to the internal flash to upgrade your switch.

The switch stores a maximum of 32 files for each debug file for each slot, depending on the file size of each debug file. The internal flash provides 2 GB of storage. The system displays a message on the console to inform you when less than 700 MB is available.

The **debug-file remove** command can delete the following types of debug files:

- core
- archive
- PMEM
- dmalloc
- flrec
- wd_stats

If you want to delete a specific file, you must use the **remove** command.

SNMP

The switch does not support SNMP for the **show debug-file** or the **debug-file remove** commands.

Flight Recorder

Table 326: Flight Recorder product support

Feature	Product	Release introduced
Flight Recorder for system monitoring	4220 Series	Fabric Engine 9.2
	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	7830 Series	Fabric Engine 9.3
	VSP 4900 Series	VOSS 8.1
	VSP 7400 Series	VOSS 8.0

The Flight Recorder is a high level term for the framework in place on the switch to store both history and current state information for various kernel, system, and application data with minimal overhead to execution. This data can later be accessed on-demand when debugging systems issues to give engineers the best

possible troubleshooting information. Functionally, the Flight Recorder consists of two elements; Persistent Memory and Always-on Trace.

The Persistent Memory feature stores information in volatile memory outside of any process. This feature provides information on crashes, errors, and outages that are not the result of a power failure. Persistent Memory data not saved to non-volatile storage before a power failure will be lost. Persistent Memory snapshots are taken when:

- a critical process stops functioning
- a process stops responding
- the hardware watchdog activates
- the user initiates a snapshot in the CLI

The Always-on Trace feature creates an ongoing, circular log of every trace call recently executed regardless of the trace level enabled by the user. The Always-On Trace feature uses circular logging, and therefore stores the most recent traces of the process.

Flight Recorder functionality is provided only through CLI. This feature uses the following commands:

- **flight-recorder all {slot[-slot]}[,...]**

The command creates a flight-recorder snapshot, trace and archive.

- **flight-recorder archive {slot[-slot]}[,...]**

This command creates a tarball of flight-recorder files, log files, and configuration files.

- **flight-recorder snapshot {slot[-slot]}[,...]**.

This command takes a snapshot of PMEM data.

- **flight-recorder trace {slot[-slot]}[,...]**

This command takes a snapshot of always-on-trace data.

Network Service Probe

	VSP 7400	VOSS 9.4

Create a Network Service Probe to troubleshoot network connectivity issues. A Network Service Probe interface supports the following configurations:

- Port-based VLAN with or without an attached I-SID
- Static IP address and static default gateway

**Note**

The default gateway must be non-local to the switch.

- Dynamic address resolution through DHCP

**Note**

The DHCP server and relay agent must be non-local to the switch.

- IPv4 only

A Network Service Probe interface supports the following functions:

- Provide feedback about its own IP and MAC address.
- Launch a ping request to any destination.
- Provide feedback about ping results and latency (CLI only).
- Respond to ARP and ping requests.

Dynamic DHCP and DNS Behavior

When you use dynamic IP configuration, the Service Probe interface receives and stores DNS servers from the DHCP server along with the IP address and default gateway.

The interface can store up to three dynamic DNS servers advertised by DHCP, designated as the following:

- primary-dynamic
- secondary-dynamic
- tertiary-dynamic

These DNS settings apply dynamically and they not saved in the configuration file. Additionally, you can query the state of any of the three dynamic DNS servers to determine whether they are functioning successfully or have failed.

Port Mirroring

Table 328: Port Mirroring product support

Feature	Product	Release introduced
Ingress mirroring (port and flow-based)	4220 Series	Fabric Engine 9.2
	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5

	7720 Series	Fabric Engine 8.10
	7830 Series	Fabric Engine 9.3 Note: Mirror destination MLT does not apply to 7830 Series.
	VSP 4900 Series	VOSS 8.1
	VSP 7400 Series	VOSS 8.0

Table 328: Port Mirroring product support (continued)

Feature	Product	Release introduced
Egress mirroring (port-based)	4220 Series	Fabric Engine 9.2
	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	7830 Series	Fabric Engine 9.3
	VSP 4900 Series	VOSS 8.1
	VSP 7400 Series	VOSS 8.0

True egress port-based mirroring that produces an identical copy of an outgoing packet is not supported. The mirrored copy does not reflect changes that occur in the switch to the outgoing packet (for example, packet fields that are updated during IP routing). As a result, the mirrored copy is not identical to the outgoing packet.

Use the port mirroring feature to monitor and analyze network traffic. Port mirroring supports both ingress (incoming traffic) and egress (outgoing traffic) port mirroring. When you enable port mirroring, the system forwards ingress or egress packets normally from the mirrored (source) port, and sends a copy of the packet to the mirroring (destination) port.

Port Mirroring Overview

Port mirroring causes the switch to make a copy of a traffic flow and send the copy to a device for analysis. Use port mirroring in diagnostic sniffing—use the mirror to view the packets in the flow without breaking the physical connection to place a packet sniffer inline. You can also use mirroring for security reasons.

You can use egress mirroring to monitor packets as they leave specified ports. Egress mirroring on the switch is done at the end of the ingress pipeline. Since packet modifications occur in the egress pipeline, some of the changes will not be reflected in the mirrored version of the packet. Changes that occur in the egress pipeline may be reflected in the mirrored packet due to the metadata that is carried with the packet. Metadata notifies the egress pipeline what to change.

Use a network analyzer to observe and analyze packet traffic at the mirroring port. Unlike other methods that analyze packet traffic, the packet traffic is uninterrupted and packets flow normally through the mirrored port.

You can mirror to a port or list of ports or a MultiLink Trunking (MLT) group. The switch supports one-to-many, many-to-one, and many-to-many mirroring configurations.

Ingress and Egress Mirrored Ports

You can use all ports in the system to function as an ingress port for mirroring (mirrored port), an egress port for mirroring (mirrored port), or as a mirroring port (where all the mirrored traffic is redirected). The number of mirroring ports (also called destination ports) that you can configure is limited by the hardware. The hardware limitation is four ports simultaneously (where each mirroring direction counts as one). For example, if two mirroring ports are designated to mirror both ingress and egress traffic then all four mirroring ports are consumed.

The following table describes ingress mirroring functionality. Only one type of mirroring destination is supported at a time. You cannot mirror the same port to multiple classes of destinations, for example, MLT. However, you can mirror to multiple physical destinations.

Important

Mirroring packets from one network-to-network interface (NNI) port to another NNI port is not supported. Mirror to access ports, not NNI ports.

Table 329: Ingress mirroring functionality

Function	Support information
Ingress port mirroring and ingress flow mirroring	Supported. Maximum of four mirror-to-ports per box.
One port to one port	Supported
One to MLT group [for threat protection system (TPS applications)]	Supported
One to many (multicast group ID/VLAN)	Not supported
One to one (remote mirrored destination)	Not supported
Many to one (multiple mirrored ports to one mirroring port)	Supported
Many to MLT group	Supported
Many to many (VLAN/multicast group ID) (multiple ports with several different destinations)	Not supported
Many to one (relation between Remote Mirror Source [RMS] and Remote Mirror Termination [RMT])	Not supported
VLAN and port combination as a mirroring destination	Not supported
Ingress flow mirroring	Supported
Allow filters to specify a separate destination for each access control entry	Supported

The following table describes egress mirroring functionality.

Table 330: Egress mirroring functionality

Function	Support information
Egress port mirroring	Supported
One port to one port	Supported
One to MLT groups (for TPS applications)	Supported
One to many (multicast group ID/VLAN)	Not supported
Many to one (multiple mirrored ports to one mirroring port)	Supported
Many to MLT group	Supported
Many to many (multicast group ID) (multiple ports with several different destinations)	Supported
Many to one (relation between Remote Mirror Source [RMS] and Remote Mirror Termination [RMT])	Not supported
VLAN and port combination as mirroring destination	Not supported
Egress flow mirroring	Supported
Allow filter to specify a separate destination for each access control entry	Supported

Port Configuration

You can specify a destination multilink trunking (MLT) group, a destination port or set of ports.

There are two port mirroring modes: rx (ingress, that is, inPort) and tx (egress, that is, outPort). In rx mode, when you configure the ACE mirror or ACL global options to mirror packets, use the ACE to configure the mirroring destination port.

To modify a port mirroring instance, first disable the instance. Also, to change a port or MLT entry, first remove whichever parameter is attached to the entry, and then add the required entry.

ACLs, ACEs, and Port Mirroring

You can use filters to reduce the amount of mirrored traffic. You can configure the mirroring action globally in an access control list (ACL), or for a specific access control entry (ACE) by using the ACE mirror actions. If you use the global action, mirroring applies to all ACEs that match in an ACL.

To use filters with port mirroring, apply an ACL to the mirrored port in the egress and ingress directions. Traffic patterns that match the ACL or ACE with an action of permit are forwarded to the destination and also to the mirroring port. Traffic patterns that match an ACE with an action of drop (deny) are not forwarded to the destination, but still reach the mirroring port. For example, for an ACL or ACE with a match action of permit, packets are mirrored to the specified mirroring destination on the ACE. If you enable a port or VLAN filter, then that filter is the mirroring filter.

You can specify more than one mirroring destination by using multiple ACEs. Use each ACE to specify a different destination.

You can configure a port-based and a flow-based mirroring filter on the same port. If such a case occurs, then the flow-based mirror takes precedence.

For information about how to configure ACLs and ACEs for port mirroring using CLI, see the following sections:

- [Configure Global Mirroring Actions with an ACL](#) on page 3897
- [Configure ACE Actions to Mirror](#) on page 3897

For information about how to configure ACLs and ACEs for port mirroring using EDM, see the following sections:

- [Configure ACLs for Mirroring](#) on page 3920
- [Configure ACEs for Mirroring](#) on page 3922

Port Mirroring Considerations and Restrictions

Although you can configure the switch to monitor both ingress and egress traffic, some restrictions apply:

- The software does not support true egress mirroring because packets are mirrored prior to the completion of packet processing, so egress mirrored packets can differ from the packets egressing the port.

Note

To mirror the egress traffic, you can use the NEXT-hop device ingress mirroring to capture the egress packets of the switch.

- Mirrored traffic shares ingress queue and fabric bandwidth with normal traffic and therefore can impact normal traffic. Therefore, use these features with this potential consequence in mind and enable them only for troubleshooting, debugging, or for security purposes such as packet sniffing, intrusion detection, or intrusion prevention.
- You can configure as many ingress mirroring flows as you have filters.
- To avoid VLAN members from seeing mirrored traffic, you must remove mirroring (destination) ports from all VLANs.
- The MAC drops an error packet, for example, packets that are too short or too long. Control packets consumed by the MAC (802.3x flow control) are also not mirrored.
- Certain control packets generated by the CP cannot be egress mirrored, such as those in the following list:
 - BPDU
 - EAPoL
 - IP Directed Broadcast
 - LACP
 - LLDP
 - Multicast routed packets
 - NAAP

- NLB
- Nodal CFM
- TDP
- VLACP
- The system displays ingress multicast packets in egress mirroring.
- For switches that support Extreme Integrated Application Hosting:
 - To use an Extreme Integrated Application Hosting port with a connect type as OVS or SR-IOV for Port Mirroring, associate VLAN 4091 to the virtual machine (VM) vport to send the mirrored packets to the VM.
- If incoming traffic from the same source port is simultaneously ingress mirrored on an incoming port into one I-SID and egress mirrored on another outgoing port into a different I-SID, the mirrored packet carries an I-SID associated with ingress mirroring.
- Incoming traffic that does not contain a VLAN tag is not mirrored into an I-SID if the offset ID is in the range 2 to 1000. It is mirrored to an I-SID only if the offset ID is 1.
- The original CVLAN tag on the mirrored packet is preserved for only one mirrored I-SID if the offset ID is 1. The original CVLAN tag is not preserved in a mirrored packet for all other remaining mirrored I-SIDs if the offset ID is in the range 2 to 1000.

Port Mirroring Resources

Port mirroring resources are limited to four ports simultaneously (where each mirroring direction counts as one). For example, if two mirroring ports are designated to mirror both ingress and egress traffic then all four mirroring ports are consumed.

Port mirroring shares these four resources with other applications such as port mirroring RSPAN, Fabric Extend, Application Telemetry, IPFIX, and ACL with mirror action. Each one of these applications consumes at least one port mirroring resource. (port mirroring RSPAN consumes two if you configure both Ingress and Egress modes.)

Important

To enable any one of the preceding applications, you must have at least one free mirroring resource. If all four port mirroring resources are already in use, the switch displays a `Resource not available` error message when you try to enable the application.

If you receive a `Resource not available` error message, you can use the **show mirror-resources** command to view information about mirror resource usage. For more information, see [Display Mirror Resource Usage](#) on page 3896.

General Diagnostic Tools

The switch has diagnostic features available with Enterprise Device Manager (EDM) and Command Line Interface (CLI). You can use these diagnostic tools to help you troubleshoot operational and configuration issues. You can perform such tasks as configuring and displaying log files, viewing and monitoring port statistics, tracing a route, running loopback and ping tests, and viewing the address resolution table.

Traceroute

Traceroute determines the path a packet takes to reach a destination by returning the sequence of hops (IP addresses) the packet traverses.

According to RFC1393, traceroute operates by: "sending out a packet with a time-to-live (TTL) of 1. The first hop then sends back an ICMP error message indicating that the packet could not be forwarded because the TTL expired. The packet is then resent with a TTL of 2, and the second hop returns the TTL expired. This process continues until the destination is reached. The purpose behind this is to record the source of each ICMP TTL exceeded message to provide a trace of the path the packet took to reach the destination."

Ping

Ping is a simple and useful diagnostic tool to determine reachability. When you use ping, the switch sends an ICMP echo request to a destination IP address. If the destination receives the packet, it responds with an ICMP echo response.

If a ping test is successful, the destination is alive and reachable. Even if a router is reachable, it could have improperly working interfaces or corrupted routing tables.

Trace

Use trace commands to provide detailed data collection about software modules on the switch. The trace toolset can be used to trace multiple modules simultaneously and provides options to specify the verbosity level of the output.

You can enable trace logging through the boot config trace-logging flag.

Caution

Risk of traffic loss

Using the trace tool inappropriately can cause a CPU lockup conditions, loss of access to the switch, loss of protocols, and service degradation.

**Tip**

While these occurrences are uncommon, when using the trace level tool, minimize this risk. The following actions are:

- In situations where trace data is required concurrently from multiple modules, consider troubleshooting during a maintenance window if feasible. Consider a maintenance window period if the switch is stable but CPU utilization is high and CPU traces (example trace levels 9 and 11) are required to diagnose the cause.
- Run trace commands from the console port when the CPU utilization is already high. While you can enable or disable tracing when directly connected to the console port.

Activate tracing on one software module at a time.

- Initially activate tracing at lower verbosity settings (that is, 2 rather than 3). Increase to verbosity level 3 or 4 only if required, and after level 2 runs safely.
- Avoid leaving traces active for extended periods of time. For high CPU utilizations, a few seconds (typically less than 5 seconds) is generally sufficient to identify the cause for sustained high CPU utilization.

Fabric RSPAN (Mirror to I-SID)

Table 331: Fabric RSPAN product support

Feature	Product	Release introduced
Fabric RSPAN (Mirror to I-SID)	4220 Series	Fabric Engine 9.2
	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	7830 Series	Not Supported
	VSP 4900 Series	VOSS 8.1
	VSP 7400 Series	VOSS 8.0

Remote mirroring is an important functionality that helps in:

- Intrusion Detection or Intrusion Prevention Systems
- Network Port debugging and packet capture
- Mirror and Monitor traffic to central collector or analyzers
- Mirror and Monitor traffic to distributed collectors or analyzers

With the Fabric RSPAN (Mirror to I-SID) feature, mirrored traffic captured from any switch in the network is sent to a remote switch over an SPB cloud for traffic analysis.

With this feature, you can monitor traffic on ports from different switches connected in the network, using just one network analyzer connected to a remote switch which acts as a collector. The source device where the traffic is mirrored to an I-SID, is known as Mirroring BEB (Backbone Edge Bridge), and the remote device where the traffic analyzer is connected for mirrored traffic analysis is known as Monitoring BEB.

The traffic source on the mirroring BEB is supported in the following ways:

- Port based mirroring — Any packet incoming or outgoing through a port is mirrored to a monitoring I-SID configured for that port.
- Flow based mirroring — Any particular packet flow configured in the system using filter based ACLs is mirrored to a monitoring I-SID configured for that flow.

Fabric RSPAN (Mirror to I-SID) Restrictions and Requirements

- Remote mirroring of traffic is not supported on network-to-network interface (NNI) ports or Fabric Extend Layer 2 core ports.
- Mirroring resources will be shared between Fabric RSPAN and regular port mirroring. Fabric RSPAN uses one out of four resources for mirroring if the mode is configured as Rx (Ingress) mirroring. In case of mode Tx (Egress) mirroring, it uses one more entry with same TX-LB port. Hence if mode Rx and Tx are configured for Fabric RSPAN, then only two unique destination ports can be used for regular port mirroring. For example, if you configure Fabric RSPAN on the switch, the regular port mirroring functionality can use only three unique destination ports. And, if all the four unique ports are used by the port mirroring functionality, you cannot configure Fabric RSPAN functionality on that node.
- When the monitor I-SID used for mirroring Fabric RSPAN traffic ingressing to I-SID is used to mirror regular traffic into SPB network, it will remove the customer tag in the mirrored packets. Hence, as a best practice, use different monitor I-SIDs for mirroring regular traffic and Fabric RSPAN traffic.
- Monitoring egress-ports and egress-mlt will not support regular production network traffic.
- The QoS value must be same for all mirror entries having common monitor I-SID, as the BMAC QoS is mapped to a monitor I-SID. QoS value configured for a specific monitor I-SID offset overrides the existing value for all mirroring entries sharing the same monitor I-SID.
- You cannot configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.
- Egress flow-based I-SID mirroring is not supported.
- **monitor-by-isid** works only for VLAN-tagged traffic.
- 5520 Series does not support the following combinations for I-SID mirroring:
 - Deny option for Filter ACL with monitor-isid-offset for Inport/Invlan/InVSN
 - Redirect-Next-Hop along with monitor-isid-offset when monitor-isid-offset is greater than 1

- Remove Tag option along with monitor-isid-offset
- For 5720 Series, 7520 Series, and 7720 Series:
 - To use an Extreme Integrated Application Hosting port as an analyzer port on a monitoring BEB for Fabric RSPAN (Mirror to I-SID), you must associate outer-tag 4091 to egress port 1/s1 or 1/s2 if the connect type is OVS or SR-IOV. Use the **monitor-by-isid <1-1000> map-to-vid <1-4093>** command to configure VLAN 4091 for Fabric RSPAN.

Software Troubleshooting Tool Configuration Using CLI

Use the tools described in this section to perform troubleshooting procedures using CLI.

Use CLI for Troubleshooting

You can use CLI to provide diagnostic information.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Disable scrolling of the output display:

```
terminal more disable
```

3. View configuration file information:

```
more WORD<1-99>
```

4. Capture the output for the following command after you observe a problem with the device:

```
show running-config [verbose] [module {app-telemetry | boot | cfm |
cli | diag | dvr | eap | endpoint-tracking | energy-saver | fa | fhs
| filter | ike | ip | ipfix | ipsec | ipv6 | iqagent | isis | i-sid |
lacp | license | lldp | lst | macsec | mlt | naap | nls | net-debug |
node-alias | ntp | openapi | ovssdb | port | qos | radius | rate-limit
| restconf | rmon | sflow | security | slpp | smtp | spbm | stg | sys
| tacacs | virtualservice | vlan | web | vxlan | vtp}]
```

5. Capture the output for the following command after you observe a problem with the device:

```
show tech
```

Note

`show tech` is an alias for `show fulltech`. Both commands provide the same output.

- Capture the output for the following commands after you observe a problem with the device:

Note

The **show interfaces gigabitEthernet statistics rmon** command displays information only if you previously configured **rmon stats** or **rmon history**.

- `show interfaces gigabitEthernet statistics <dhcp-relay [vrf WORD<1-16>][vrfids WORD<0-512>] [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]]}`
- `show interfaces gigabitEthernet statistics lacp [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]]}`
- `show interfaces gigabitEthernet statistics rate-limiting [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]]}`
- `show interfaces gigabitEthernet statistics rmon [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]]}`
- `show interfaces gigabitEthernet statistics verbose [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]]}`
- `show interfaces gigabitEthernet statistics vlacp [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]]}`

- Capture the output for the following command after you observe a problem with the device:

```
show interfaces gigabitEthernet error [collision|ospf|verbose] [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]]}
```

Examples

Due to the length of command output, the following examples are truncated.

Capture the output for the following commands after you observe a problem with the device:

```
Switch:1>enable
Switch:1#show running-config module cli

Variable Definitions

The following table defines parameters for the **more** command.

Variable	Value
<code>WORD<1-99></code>	Specifies the file name to view. Provide the file name in one of the following formats: a.b.c.d:<file> or /intflash/<file>.

The following table defines parameters for the **show running-config** command.

Variable	Value
<code>[module {app-telemetry boot cfm cli diag dvr eap endpoint-tracking energy-saver fa fhs filter ike ip ipfix ipsec ipv6 iqagent isis i-sid lacp license lldp lst macsec mlt naap nls net-debug node-alias ntp openapi ovsdb port qos radius rate-limit restconf rmon sflow security slpp smtp spbm stg sys tacacs virtualservice vlan web vxlan ptp}]</code>	Specifies the command group for which you request configuration settings. Note: All configuration modules are not supported on all hardware platforms. For information about feature support, see <i>Fabric Engine and VOSS Feature Matrix</i> .
<code>verbose</code>	Specifies a complete list of all configuration information about the switch.

The following table defines parameters for the **show interfaces gigabitEthernet statistics** command.

Variable	Value
<code>dhcp-relay [vrf WORD<1-16>] [vrfids WORD<0-512> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...] [slot/all] [all]]}</code>	Displays port Dynamic Host Configuration Protocol (DHCP) statistics.
<code>lacp {slot/port[/sub-port] [-slot/port[/sub-port]] [,...] [slot/all] [all]}</code>	Displays Link Aggregation Control Protocol (LACP) statistics.
<code>rate-limiting {slot/port[/sub-port] [-slot/port[/sub-port]] [,...] [slot/all] [all]}</code>	Displays port ingress rate-limiting statistics.
<code>rmon {slot/port[/sub-port] [-slot/port[/sub-port]] [,...] [slot/all] [all]} [history]</code>	Displays Remote Network Monitoring (RMON) statistics.

Variable	Value
<i>verbose</i>	Displays a complete list of all statistics.
<i>vlacp</i> [<i>history</i>] { <i>slot/port[/sub-port]</i> [<i>-slot/port[/sub-port]</i>] [,...] [<i>slot/all</i>] [<i>all</i>] }	<p>Displays port Virtual Link Aggregation Control Protocol (VLACP) statistics.</p> <ul style="list-style-type: none"> <i>history</i>—Displays the VLACP port counter profile. {<i>slot/port[/sub-port]</i> [<i>-slot/port[/sub-port]</i>] [,...] [<i>slot/all</i>] [<i>all</i>] } <p>Identifies the slot and port in one of the following formats:</p> <ul style="list-style-type: none"> ◦ a single slot and port (<i>slot/port</i>) ◦ a range of slots and ports (<i>slot/port-slot/port</i>) ◦ a series of slots and ports (<i>slot/port,slot/port,slot/port</i>) ◦ all ports on the same slot (<i>slot/all</i>) ◦ all ports on the switch (<i>all</i>) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format <i>slot/port/sub-port</i>.</p>

The following table defines parameters for the **show interfaces gigabitEthernet error** command.

Variable	Value
<i>collision</i>	Displays port collision error information.
<i>ospf</i>	Displays ports Open Shortest Path First (OSPF) error information.
{ <i>slot/port[/sub-port]</i> [<i>-slot/port[/sub-port]</i>] [,...] [<i>slot/all</i>] [<i>all</i>] }	<p>Identifies the slot and port in one of the following formats:</p> <ul style="list-style-type: none"> ◦ a single slot and port (<i>slot/port</i>) ◦ a range of slots and ports (<i>slot/port-slot/port</i>) ◦ a series of slots and ports (<i>slot/port,slot/port,slot/port</i>) ◦ all ports on the same slot (<i>slot/all</i>) ◦ all ports on the switch (<i>all</i>) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format <i>slot/port/sub-port</i>.</p>
<i>verbose</i>	Displays all port error information.

Use Software Record Dumps

About This Task

Capture a dump of the software records from ingress traffic to help troubleshoot performance problems. Generally, a verbosity level of 1 suffices.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Dump software record information:
`dump ar <1-12> WORD<1-1536> <0-3>`

Example

```
Switch:1>enable
Switch:1#dump ar 1 vlan 1
```

Variable Definitions

The following table defines parameters for the **dump ar** command.

Variable	Value
<1>	Specifies the slot number.
WORD<1-1536>	Specifies a record type in the AR table. Options include vlan, ip_subnet, mac_vlan, mac, arp, ip, ipmc, protocol, all.
<0-3>	Specifies the verbosity from 0–3. Higher numbers specify more verbosity.

Use Trace to Diagnose Problems

Use trace to observe the status of a software module at a given time.

About This Task

For example, if you notice a CPU utilization issue (generally a sustained spike above 90%) perform a trace of the control plane activity.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Clear the trace:
`clear trace`
3. Identify the module ID for which you want to use the trace tool:
`show trace modid-list`
4. Begin the trace operation:
`trace level [<Module_ID>] [<0-4>]`

5. Wait approximately 30 seconds.

The default trace settings for CPU utilization are:

- High CPU Utilization: 90%
- High Track Duration: 5 seconds
- Low CPU Utilization: 75%
- Low Track Duration: 5 seconds

6. Stop tracing:

```
trace shutdown
```

7. View the trace results:

```
show trace file [tail]
```

8. Search trace results for a specific string value, for example, the word error:

```
trace grep [WORD<0-128>]
```

If you use this command and do not specify a string value, you clear the results of a previous search.

9. Stop tracing:

```
trace shutdown
```

Example

```
Switch:1> enable
```

Clear the trace:

```
Switch:1# clear trace
```

Identify the module ID for which you want to use the trace tool:

```
Switch:1# show trace modid-list
```

```
0  - COMMON
1  - SNMP
2  - RMON
3  - PORT_MGR
4  - CHAS_MGR
5  - BRIDGE
6  - HWIF
7  - SIM
8  - CPP
9  - NETDRV
10 - VLAN_MGR
11 - CLI
12 - MAIN
12 - P2IP
12 - RCIP
15 - WEBSRV
16 - ACIF
17 - GBIF
18 - WDT
19 - TDP
20 - MAN_DIAG
21 - MAN_TEST

--More-- (q = quit)
```

Begin the trace operation:

```
Switch:1# trace level 2 3
```

Stop tracing:

```
Switch:1# trace shutdown
```

Save the trace file to the internal flash card for retrieval:

```
Switch:1# save trace
```

Search trace results for a specific string value, for example, the word error:

```
Switch:1# trace grep error
```

Search trace results for a specific string value, for example, MAC address 00-1A-4B-8A-FB-6B:

```
Switch:1# trace grep 00-1A-4B-8A-FB-6B
```

Variable Definitions

The following table defines parameters for the **trace** command.

Variable	Value
<code>grep [WORD<0-128>]</code>	Search trace results for a specific string value, for example, the word error. Performs a comparison of trace messages.
<code>level [<Module_ID>] [<0-4>]</code>	Starts the trace by specifying the module ID and level. <ul style="list-style-type: none"> <code><Module_ID></code> specifies the module for the trace. Different hardware platforms support different IDs because of feature support differences. For feature support information, see <i>Fabric Engine and VOSS Feature Matrix</i>. To see the list of module IDs, use the show trace modid-list command or CLI command completion Help. <code><0-4></code> specifies the trace level from 0–4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.
<code>shutdown</code>	Stops the trace operation.
<code>screen {disable enable}</code>	Enables the display of trace output to the screen.

The following table defines parameters for the **save trace** command.

Variable	Value
<code>file WORD<1-99></code>	Specifies the file name in one of the following formats: <ul style="list-style-type: none"> a.b.c.d:<file>

Use Trace to Diagnose IPv6 Problems

Use trace to observe the status of IPv6 at a certain time.

Before You Begin

- Confirm that trace level 99 is set to a value of 1 before you use trace to diagnose IPv6 problems. Trace level 1 is very terse.

**Caution****Risk of traffic loss**

Using the trace tool inappropriately can cause CPU lockup conditions, loss of access to the device, loss of protocols, and service degradation.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Activate or deactivate the trace for the IPv6 base:

```
trace ipv6 base <disable|enable> <all|debug|error|icmp|info|ipclient|
nbr|pkt|warn> [vrf WORD <1-16>]
```

3. Activate or deactivate the trace for IPv6 forwarding:

```
trace ipv6 forwarding <disable|enable> <all|debug|error|info|pkt|warn>
[vrf WORD <1-16>]
```

4. Activate or deactivate the trace for IPv6 neighbor discovery:

```
trace ipv6 nd <disable|enable> <all|debug|error|info|nbr|pkt|redirect|
warn> [vrf WORD <1-16>]
```

5. Activate or deactivate the trace for IPv6 OSPF:

```
trace ipv6 ospf <disable|enable> <adj|all|config|error|import|info|
lsa|pkt|spf|warn> [vrf WORD <1-16>]
```

6. Activate or deactivate the trace for the IPv6 routing table manager:

```
trace ipv6 rtm <disable|enable> <all|change-list|debug|error|fib|info|
redist|update|warn> [vrf WORD <1-16>]
```

7. Activate or deactivate the trace for IPv6 transport:

```
trace ipv6 transport <disable|enable> <all|common|tcp|udp> [vrf WORD
<1-16>]
```

8. Deactivate the trace to prevent service degradation:

```
trace shutdown
```

```
clear trace
```

Examples

Activate the trace for all the IPv6 forwarding categories:

```
Switch:1>enable
Switch:1#trace ipv6 forwarding enable all
```

Activate the trace for all the IPv6 neighbor discovery categories:

```
Switch:1#trace ipv6 nd enable all
```

Activate the trace for the all IPv6 routing table manager categories:

```
Switch:1#trace ipv6 rtm enable all
```

Activate the trace for all the IPv6 transport categories:

```
Switch:1#trace ipv6 transport enable all
```

Deactivate the trace:

```
Switch:1#trace shutdown
Switch:1#clear trace
Removed 5 files.
```

Variable Definitions

The following table defines parameters for the **trace ipv6** command.

Variable	Value
<i>base</i> <disable enable> <all debug error icmp info ipclient nbr pkt warn>	Enables or disables a specific trace category for IPv6 base.
<i>forwarding</i> <disable enable> <all debug error info pkt warn>	Enables or disables a specific trace category for IPv6 forwarding.
<i>nd</i> <disable enable> <all debug error info nbr pkt redirect warn>	Enables or disables a specific trace category for IPv6 neighbor discovery.
<i>ospf</i> <disable enable> <adj all config error import info lsa pkt spf warn>	Enables or disables a specific trace category for IPv6 OSPF.
<i>rtm</i> <disable enable> <all change-list debug error fib info redist update warn>	Enables or disables a specific trace category for IPv6 routing table manager.
<i>transport</i> <disable enable> <all common tcp udp>	Enables or disables a specific trace category for IPv6 transport.
<i>vrf</i> WORD<1-16>	Specifies the VRF name.

View and Delete Debug Files

Use this procedure to view and delete debug files.

Delete debug files to free space in the internal flash. As a best practice, delete these files to ensure enough space exists in intflash. New debug files do not overwrite old debug files. You must remove the file; otherwise, enough free space might not exist in the intflash to store the core dump if the switch fails or enough space might not exist for you to transfer a new release to the intflash of the switch to upgrade your switch.

The **debug-file remove** command can delete the following types of files:

- core
- archive
- PMEM
- dmalloc
- flrec
- wd_stats

If you want to delete a specific file, you must use the **remove** command. For more information, see *Fabric Engine Command References*.

Procedure

1. To enter User EXEC mode, log on to the switch.

2. View debug files:

```
show debug-file [all][{slot[-slot]}[,...]]
```

3. Delete debug files:

```
debug-file remove [all]
```

4. Enter Privileged EXEC mode:

```
enable
```

5. View core files:

```
show core-files {slot[-slot]}[,...]]
```

Example

The following example shows how you view all debug files for all slots.

```
Switch>show debug-file
```

```

Variable Definitions

The following table defines parameters for the **show core-files** command.

Variable	Value
<code>{slot[-slot][,...]}</code>	Displays the core files for the slot that you select.

The following table defines parameters for the **show debug-file** command.

Variable	Value
<code>all</code>	Displays all types of debug files
<code>{slot[-slot][,...]}</code>	Displays debug files for the slot that you select. If you do not select a slot number, the device displays all types of the archived debug files present in a slot by slot basis. If you select a slot number, the device only displays archived files for the slot you select.

The following table defines parameters for the **debug-file remove** command.

Variable	Value
<code>all</code>	Removes debug files in all slots. If you use the <code>all</code> parameter with the remove debug-file command, the device deletes all types of debug files, including the latest debug files. If you do not use the <code>all</code> parameter, the device retains the latest file of each type.

Configure Port Mirroring

Use port mirroring to aid in diagnostic and security operations.

About This Task

Use port mirroring to make a copy of a traffic flow and send that copy to a device for analysis, for example, for diagnostic sniffing. Use the mirror to see the packets in the flow without breaking into the physical connection to place a packet onto the sniffer inline. You can also use port mirroring for security. You can send flows to inspection engines for post processing.

Connect the sniffer (or other traffic analyzer) to the output port you specify in this procedure.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Create a port mirroring instance:

```
mirror-by-port <1-479> in-port {slot/port[/sub-port][-slot/port[/sub-port]][,...][slot/all][all]} {monitor-mlt <1-512>| out-port {slot/port[/sub-port][-slot/port[/sub-port]][,...][slot/all][all]}}
```

3. Create an I-SID mirroring instance:

```
mirror-by-port <1-479> [in-port {slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]} monitor-isid-offset <1-1000> [mode <rx|tx|both>][qos <qos-level>]]
```

4. Configure the mode:

```
mirror-by-port <1-479> mode <both|rx|tx>
```

**Note**

- When you configure `tx` mode port mirroring on T-UNI and SPBM network-to-network interface (NNI) ports, unknown unicast, broadcast and multicast traffic packets that ingress these ports and the system displays it on the mirror destination port, although they do not egress the mirror source port. This is because `tx` mode port mirroring happens on the mirror source port before the source port squelching logic drops the packets at the egress port.
- The available four mirroring resources are shared between Fabric RSPAN and regular port mirroring, and are allocated based on the mode configured, Ingress (`rx`) or Egress (`tx`). Each configured mode occupies one mirroring resource, but when you configure the mode as `both`, it occupies two mirroring resources (one for Rx and one for Tx).
- You cannot configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.

5. Enable the mirroring instance:

```
mirror-by-port <1-479> enable
```

6. Modify existing mirroring entries as required:

```
mirror-by-port mirror-port <1-479> {slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]}
```

OR

```
mirror-by-port monitor-mlt <1-479> <1-512>
```

OR

```
mirror-by-port monitor-port <1-479> {slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]}
```

**Note**

Before you can modify an existing entry, you must disable the entry: no
 mirror-by-port <1-479> enable.

7. Modify QoS value for Fabric RSPAN mirroring session:

```
mirror-by-port <1-479> qos <0-5>
```

8. Verify the configuration:

```
show mirror-by-port
```

Example

Port mirroring configuration:

```
Switch:1> enable
Switch:1# configure terminal
```

Create the port mirroring instance:

```
Switch:1(config)# mirror-by-port 8 in-port 1/15 out-port 1/1
```

The analyzer connects to port 1/1.

Disable the entry:

```
Switch:1(config)# no mirror-by-port 8 enable
```

Mirror both ingress and egress traffic passing through port 1/16:

```
Switch:1(config)# mirror-by-port 8 mode both
```

Enable mirroring for the instance:

```
Switch:1(config)# mirror-by-port 8 enable
```

Fabric RSPAN configuration:

```
Switch:1> enable
Switch:1# configure terminal
```

Create the Fabric RSPAN mirroring instance:

```
Switch:1(config)#mirror-by-port 3 in-port 1/3 monitor-isid-offset 3 mode both qos 3
```

Disable the entry:

```
Switch:1(config)# no mirror-by-port 3 enable
```

Mirror the egress traffic passing through port 1/3:

```
Switch:1(config)# mirror-by-port 3 mode tx
```

Enable Fabric RSPAN for the instance:

```
Switch:1(config)# mirror-by-port 3 enable
```

The sample command output in the following example does not necessarily reflect the preceding examples.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#show mirror-by-port
```

```
=====
Diag Mirror-By-Port
```

ID	MIRRORED_PORT	MIRRORING_DEST	ENABLE	MODE	REMOTE-MIRROR VLAN-ID	DSCP	TTL
1	1/1	2/1	true	both	0 0		64
2	1/2	2/2	true	rx	0 0		64
3	1/3	2/3	true	tx	0 0		64
4	1/4	2/4	true	both	0 0		64

Variable Definitions

The following table defines parameters for the **mirror-by-port** command.

Variable	Value
<1-479>	Specifies the entry ID.
<i>enable</i>	Enables or disables a mirroring instance already created in the mirror-by-port table.
<i>in-port</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...] [slot/all][all]} {monitor-mlt <1-512> <i>out-port</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...] [slot/all][all]}	<p>Creates a new mirror-by-port table entry.</p> <ul style="list-style-type: none"> <i>in-port</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...] [slot/all][all]} specifies the mirrored port. <i>monitor-mlt</i> <1-512> specifies the mirroring MLT ID from 1-512. <p>Note: Exception: This parameter does not apply to 7830 Series.</p> <ul style="list-style-type: none"> <i>out-port</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...] [slot/all][all]} specifies the mirroring port.
<i>mirror-port</i> <1-479> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...] [slot/all][all]}	<p>Modifies the mirrored port.</p> <p>Before you can modify an existing entry, you must disable the entry: no mirror-by-port <1-479> enable.</p>
<i>monitor-ip</i> <1-479> {A.B.C.D} [dscp <0-63>] [ttl <2-255>]	Creates a mirroring instance for Layer 3 mirroring. The destination must be an IP address {A.B.C.D}. The default DSCP is 0 and the default TTL is 255.
<i>monitor-mlt</i> <1-479> <1-512> Note: Exception: This parameter does not apply to 7830 Series.	<p>Modifies the monitoring MLT. <1-512> specifies the mirroring MLT ID.</p> <p>Before you can modify an existing entry, you must disable the entry: no mirror-by-port <1-479> enable.</p>
<i>monitor-port</i> <1-479> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...] [slot/all][all]}	<p>Modifies the monitoring ports.</p> <p>Before you can modify an existing entry, you must disable the entry: no mirror-by-port <1-479> enable.</p>

Variable	Value
<code>monitor-vlan <1-479> <1-4059></code>	<p>Modifies the monitoring VLAN.</p> <p>Before you can modify an existing entry, you must disable the entry: <code>no mirror-by-port <1-479> enable</code>.</p> <p>Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.</p>
<code>mode <both rx tx></code>	<p>Configures the mirroring mode. The default is rx.</p> <ul style="list-style-type: none"> • <i>both</i> mirrors both egress and ingress packets. • <i>rx</i> mirrors ingress packets. • <i>tx</i> mirrors egress packets.
<code>monitor-isid-offset <1-1000></code> Note: Exception: This parameter does not apply to 7830 Series.	<p>Specifies the offset ID that is mapped to the actual monitor I-SID where packets are mirrored.</p> <p>Monitor I-SID = base monitor I-SID + offset ID. The base monitor I-SID is 16776000.</p>
<code>qos <0-5></code>	<p>Specifies the Quality of Service (QoS) profiles for the system. Monitoring I-SID supports six different QoS levels, each QoS level can be configured individually. Default value is 1.</p>

Display Mirror Resource Usage

About This Task

Mirror resources can be consumed by internal processes that are not easily identified, which can lead to unexpected resource shortages. Use the following procedure to display mirror resource usage.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display mirror resource usage:

```
show mirror-resources
```

Example

```
Switch:1#show mirror-resources
<Switch> Mirror Resource Manager stats:
      2 unique mirror destinations allocated, system max is 4
```

```
-----
Mirror      | Mirror      | Total | Mirror
```

Destination	Direction	Refs	Users
Port 1/2	Egress	1	MBP ID 1
Port 1/2	Ingress	1	MBP ID 1

Function execution completed successfully

Configure Global Mirroring Actions with an ACL

Configure the global action to mirror packets that match an access control list (ACL).

Before You Begin

- The ACL exists.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Configure the global action for an ACL:

```
filter acl set <1-2048> global-action {monitor-dst-mlt <1-512>|
monitor-dst-ports {slot/port[-slot/port][,...][slot/all][all]}
```

Example

Configure the global action for an ACL:

```
Switch:1> enable
Switch:1#configure terminal
Switch:1(config)#filter acl set 200 global-action monitor-dst-mlt 20
```

Variable Definitions

The following table defines parameters for the **filter acl set** command.

Variable	Value
<1-2048>	Specifies an ACL ID from 1–2048.
<i>default-action</i> <deny permit>	Specifies the global action to take for packets that do not match an ACL.
<i>global-action</i> { <i>monitor-dst-mlt</i> <i>PT MLT</i> <1-512> <i>monitor-dst-ports</i> { <i>slot/port</i> [/ <i>sub-port</i>][- <i>slot/port</i> [/ <i>sub-port</i>]][,...][<i>slot/all</i>][<i>all</i>]}	Specifies the global action to take for matching ACLs: <ul style="list-style-type: none"> monitor destination MLT—Configures mirroring to a destination MultiLink Trunking (MLT) group. monitor destination ports—Configures mirroring to a destination port or ports.

Configure ACE Actions to Mirror

Configure actions to use filters for flow-based mirroring.

Before You Begin

- The access control entry (ACE) exists.

About This Task

If you use the mirror action, ensure that you specify the mirroring destination: MLTs or ports.

Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Configure actions for an ACE:

```
filter acl ace action <1-2048> <1-2000> {permit|deny} monitor-dst-mlt  
<1-512>
```

OR

```
filter acl ace action <1-2048> <1-2000> {permit|deny} monitor-dst-  
ports {slot/port[-slot/port][,...][slot/all][all]}
```

- Ensure the configuration is correct:

```
show filter acl action [<1-2048>] [<1-2000>]
```

Example

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#filter acl ace action 901 1 permit monitor-dst-mlt 5
```

Variable Definitions

The following table defines parameters for the **filter acl ace action** command.

Variable	Value
<i>1-2048</i>	Specifies the ACL ID from 1-2048
<i>1-2000</i>	Specifies the ACE ID from 1-2000.
<i>monitor-dst-mlt <1-512></i>	Configures mirroring to a destination MLT group.
<i>monitor-dst-ports {slot/ port[/sub-port][-slot/ port[/sub-port]][,...] [slot/all][all]}</i>	Configures mirroring to a destination port or ports.
<i>{permit deny}</i>	Configures the action mode for security ACEs. The default value is permit.

Clear ARP Information for an Interface

Clear the Address Resolution Protocol (ARP) cache as part of ARP problem resolution procedures.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Clear ARP information:

```
clear ip arp interface gigabitethernet {slot/port[/sub-port] [-slot/
port[/sub-port]][,...][slot/all][all]}
```

OR

```
clear ip arp interface vlan <1-4059>
```

Example

```
Switch:1>enable
Switch:1#clear ip arp interface gigabitethernet 1/1
```

Variable Definitions

The following table defines parameters for the **clear ip arp interface** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
{slot/port[/sub-port] [-slot/port[/sub-port]][,...][slot/all][all]}	<p>Identifies the slot and port in one of the following formats:</p> <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>

Flush Routing, MAC, and ARP Tables for a Port

Flush or clear the routing tables for administrative and troubleshooting purposes. The clear and flush commands perform the same function; they remove the contents of the table.

Procedure

- 1. Enter GigabitEthernet Interface Configuration mode:
`enable`

`configure terminal`

`interface GigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...][slot/all][all]}`

Note If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- 2. Flush IP routing tables by port:
`action flushIp`
- 3. Flush the MAC address tables by port:
`action flushMacFdb`
- 4. Flush ARP tables by port:
`action flushArp`
- 5. Flush all tables with one command:
`action flushAll`
- 6. Exit to Global Configuration mode:
`exit`
- 7. Clear a routing table for a port:
`clear ip route gigabitethernet {slot/port[sub-port]}`

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config-if)#action flushAll
Switch:1(config-if)#exit
Switch:1(config)#clear ip route gigabitethernet 1/1
```

Variable Definitions

The following table defines parameters for the `clear ip route gigabitethernet` command.

Variable	Value
<code>{slot/port[/sub-port]}</code>	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Flush Routing, MAC, and ARP Tables for a VLAN

Flush or clear the routing tables for administrative and troubleshooting purposes. The clear and flush commands perform the same function; they remove the contents of the table.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Flush IP routing tables by VLAN:
vlan action <1-4059> flushIp
3. Flush the MAC address tables by VLAN:
vlan action <1-4059> flushMacFdb
4. Flush ARP tables by VLAN:
vlan action <1-4059> flushArp
5. Flush all tables with one command:
vlan action <1-4059> all
6. Clear a routing table for a VLAN:
clear ip route vlan <1-4059>

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config-if)#vlan action 123 all
Switch:1(config)#clear ip route vlan 123
```

Variable Definitions

The following table defines parameters for the **vlan action** and **clear ip route vlan** commands.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

*Ping an IP Device***About This Task**

Ping a device to test the connection between the switch and another network device. After you ping a device, the switch sends an Internet Control Message Protocol (ICMP)

packet to the target device. If the device receives the packet, it sends a ping reply. After the switch receives the reply, a message displays that indicates traffic can reach the specified IP address. If the switch does not receive a reply, the message indicates the address does not respond.

If you originate the **ping** or **traceroute** operation from a device other than the switch to a routing IP interface associated with a VRF, the operation can fail if you use large packet sizes. For these situations, do not use packet sizes larger than the following:

- Ping for VRF routes: 1472 bytes
- Traceroute for VRF routes: 1444 bytes

Note

Exceptions:

- The CLIP Segmented Management Instance can support large packets for VRF routes.
- If you originate the **ping** or **traceroute** operation from the switch, you can configure large datasizes and the operation functions properly.

You can specify a management instance ID to use the correct source for the outgoing ICMP ECHO request packet.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Ping an IP network connection:

```
ping WORD<0-256> [-d] [-I <1-60>] [-s] [-t <1-120>] [count <1-9999>]
[datasize <28-9216|28-51200>] [grt] [interface gigabitEthernet {slot/
port[sub-port]}| tunnel <1-2000> | vlan <1-4059>] [scopeid <1-9999>]
[source WORD<1-256>] [vrf WORD<1-16>]
```

3. Ping an IP network connection using a Global Routing Table (GRT):

```
ping WORD<0-256> [-d] [-I <1-60>] [-s] [-t <1-120>] [count <1-9999>]
[datasize <28-9216|28-51200>] grt [interface gigabitEthernet {slot/
port[sub-port]}| tunnel <1-2000> | vlan <1-4059>] [source WORD<1-246>]
```

4. Ping a network connection using a Segmented Management Instance:

```
ping WORD<0-256> [-s] [-t <1-120>] [count <1-9999>] [datasize
<28-9216|28-51200>] mgmt [clip | oob | vlan]
```

Note

If you do not use the *mgmt* parameter, the **ping** command uses the IP routing stack to initiate the ping request.

If you ping a device using a management CLIP, the ping source IP address is configured as the management CLIP IP address. If you ping a device using a management VLAN, the ping source IP address is configured as the management VLAN IP address.

5. (Optional) Ping a network connection using a Network Service Probe interface:

```
ping WORD<0-256> service-probe
```

Examples

Ping an IP device from a GRT VLAN IP interface:

```
Switch:1#ping 192.0.2.16 grt interface vlan 1
192.0.2.16 is alive
```

Ping a device using the management routing table:

```
Switch:1#ping 192.0.2.12 mgmt
```

Ping a device using a management CLIP:

```
Switch:1#ping 192.0.2.12 mgmt clip
```

Ping an IP device using a management VLAN:

```
Switch:1#ping 192.0.2.12 mgmt vlan
```

Ping an IP device using the configured Network Service Probe interface:

```
Switch:1#ping 192.0.2.6 service-probe
Sending ping in context grt
PING 192.0.2.6 (192.0.2.6) from 192.0.2.1 : 64(92) bytes of data.
72 bytes from 192.0.2.6: icmp_seq=1 ttl=255 time=1.11 ms

--- 192.0.2.6 ping statistics ---
1 packets transmitted, 1 received, 0% packet loss, time 0ms
rtt min/avg/max/mdev = 1.111/1.111/1.111/0.000 ms
```

Variable Definitions

The following table defines parameters for the **ping** command.

Variable	Value
<i>count</i> <1-9999>	Specifies the number of times to ping. The default is 1.
<i>-d</i>	Configures the ping debug mode. This variable detects local software failures (ping related threads creation or write to sending socket) and receiving issues (icmp packet too short or wrong icmp packet type). This parameter does not apply if you use the mgmt [clip oob vlan] parameter.
<i>datasize</i> <28-9216 28-51200>	Specifies the size of ping data sent in bytes. The datasize for IPv4 addresses is 28-9216. The datasize for IPv6 addresses is 28-51200. The default is 64.
<i>grt</i>	Specifies the ping in Global Routing Table context.
<i>-I</i> <1-60>	Specifies the interval between transmissions in seconds.

Variable	Value
<code>interface gigabitEthernet {slot/port[sub-port]} tunnel <1-2000> vlan <1-4059></code>	<p>Specifies the outgoing interface.</p> <p>Additional ping interface parameters:</p> <ul style="list-style-type: none"> • <code>gigabitEthernet {slot/port[sub-port]}</code>: <code>gigabitEthernet port</code> • <code>tunnel</code>: tunnel ID as a value from 1 to 2000 • <code>vlan</code>: Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. <p>This parameter does not apply if you use the <code>mgmt [clip oob vlan]</code> parameter.</p>
<code>mgmt [clip oob vlan]</code> Note: Exception: <code>oob</code> only applies to hardware with a dedicated physical management interface.	<p>Specifies the Segmented Management Instance as the source for the outgoing ICMP ECHO packet. The packet goes out this specific interface only.</p> <p>If you do not specify the management interface type, the ping command uses the management routing table to determine the best management interface and selects the source IP based on the egress management interface. This also includes the <code>Mgmt-sdwan</code> interface if you need to use the ping command for the SD-WAN Appliance. For more information, see Fabric Extend (FE) States on page 32.</p>
<code>-s</code>	Configures the continuous ping at the interval rate defined by the <code>[-I]</code> parameter or until you enter a Ctrl + C keystroke.
<code>scopeid <1-9999></code>	<p>Specifies the circuit ID for IPv6.</p> <p>This parameter does not apply if you use the <code>mgmt [clip oob vlan]</code> parameter.</p>
<code>service-probe</code>	Launches a ping request from the configured Network Service Probe interface.
<code>source WORD<1-256></code>	<p>Specifies the source IP address for the ping command.</p> <p>This parameter does not apply if you use the <code>mgmt [clip oob vlan]</code> parameter.</p>

Variable	Value
<code>-t <1-120></code>	Specifies the no-answer timeout value in seconds. The default is 5.
<code>WORD<0-256></code>	Specifies the host name or IPv4 (a.b.c.d) or IPv6 (x:x:x:x:x:x:x) address.
<code>vrf WORD<1-16></code>	Specifies the virtual router and forwarder (VRF) name. This parameter does not apply if you use the <code>mgmt [clip oob vlan]</code> parameter.

Run a Traceroute Test

Use traceroute to determine the route packets take through a network to a destination.

About This Task

If you originate the **ping** or **traceroute** operation from a device other than the switch to a routing IP interface associated with a VRF, the operation can fail if you use large packet sizes. For these situations, do not use packet sizes larger than the following:

- Ping for VRF routes: 1472 bytes
- Traceroute for VRF routes: 1444 bytes

Note

Exceptions:

- The CLIP Segmented Management Instance can support large packets for VRF routes.
- If you originate the **ping** or **traceroute** operation from the switch, you can configure large datasizes and the operation functions properly.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Run a traceroute test:

```
traceroute WORD<0-256> [<1-1176>] [-m <1-255>] [-p <1-65535>] [-q  
<1-255>] [-v] [-w <1-255>] [grt [source]] [mgmt [clip | oob | vlan]]  
[source <WORD 1-256>] [vrf <WORD 1-16>]
```

3. Run a traceroute test using a Segmented Management Instance:

```
traceroute WORD<0-256> [<1-1176>] [-m <1-255>] [-p <1-65535>] [-q  
<1-255>] [-w <1-255>] [grt [source]] mgmt [<clip | oob | vlan>]
```

Note

If you do not use the `mgmt` parameter, the **traceroute** command uses the IP routing stack to initiate the traceroute request.

Examples

Run a traceroute test with a probe packet size of 200 and a max time to live of 60:

```
Switch:1>enable
Switch:1#traceroute 192.0.2.33 200 -m 60
```

Run a traceroute test for an IPv6 address:

```
Switch:1#traceroute 2001:db8::1
```

Run a traceroute test using the management routing table:

```
Switch:1#traceroute 192.0.2.12 mgmt
```

Run a traceroute test using a management CLIP:

```
Switch:1#traceroute 192.0.2.12 mgmt clip
```

Run a traceroute test using a management VLAN:

```
Switch:1#traceroute 192.0.2.12 mgmt vlan
```

Variable Definitions

The following table defines parameters for the **traceroute** command.

Variable	Value
<code>-m <1-255></code>	Specifies the maximum time-to-live (TTL).
<code>-p <1-65535></code>	<p>Specifies the base UDP port number. The default is 33434.</p> <p>Note: If the traceroute action is directed to an IPv6 host address, Linux increments the UDP port on a per-TTL basis. For an IPv4 host address, Linux increments the UDP port on a per-probe basis. Because the traceroute command sends a default of three probes, three incrementing ports will be sent for an IPv4 host address. If you use the <code>-p</code> parameter with a value greater than 65533, the traceroute command fails for an IPv4 host address because the maximum port number, 65535, is exceeded.</p> <p>If you send a traceroute probe into the device through the Segmented Management Instance or any routing interface, you must use the default UDP port range of 33434 to 33534. Using other ports will fail.</p>
<code>-q <1-255></code>	Specifies the number of probes per TTL.
<code>-v</code>	<p>Specifies verbose mode (detailed output).</p> <p>This parameter does not apply if you use the <code>mgmt [clip oob vlan]</code> parameter.</p>
<code>-w <1-255></code>	Specifies the wait time for each probe.

Variable	Value
<1-1176>	Specifies the size of the probe packet.
<i>grt</i>	Specifies the traceroute command is executed in grt context.
<i>mgmt</i> [<clip oob vlan>]	Specifies the Segmented Management Instance as the source for the outgoing packet. The packet goes out this specific interface only. If you do not specify the management interface type, the traceroute command uses the management routing table to determine the best management interface and selects the source IP based on the egress management interface.
<i>source</i> <WORD 1-256>	Specifies the source IP address. This parameter does not apply if you use the mgmt [clip oob vlan] parameter.
<i>WORD</i> <0-256>	Specifies the destination IPv4 or IPv6 address, or hostname.
<i>vrf</i> <WORD 1-16>	Specifies the VRF instance by VRF name. This parameter does not apply if you use the mgmt [clip oob vlan] parameter.

Show SNMP Logs

Show the full SNMP logs. SNMP logs display the alarms and events that have been registered on the device.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Show the logs:
show fulltech file *WORD*<1-99>

Variable Definitions

The following table defines parameters for the **show fulltech** command.

Variable	Value
<i>file</i> <i>WORD</i> <1-99>	This variable represents the log file to be opened and displayed. It is displayed in the following format: • /intflash/<file>

Use Trace to Examine IS-IS Control Packets

Use trace as a debug tool to examine the code flow and Intermediate-System-to-Intermediate-System (IS-IS) control packets.

About This Task

The default trace settings for CPU utilization are:

- High CPU Utilization: 90%
- High Track Duration: 5 seconds
- Low CPU Utilization: 75%
- Low Track Duration: 5 seconds

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Identify the module ID for which you want to use the trace tool:
`show trace modid-list`
3. Clear any previous trace:
`clear trace`
4. Begin the trace operation:
`trace level [<Module_ID>] [<0-4>]`
5. Wait approximately 30 seconds.
6. Stop tracing:
`trace shutdown`
7. View the trace results:
`trace screen enable`

Important

If you use trace level 3 (verbose) or trace level 4 (very verbose), do not use the screen to view commands due to the volume of information the system generates and the effect on the system.

8. (Optional) Save the trace file.
`save trace [file WORD<1-99>]`

If you do not specify a file name, the file name is systrace.txt.

9. (Optional) Display trace lines saved to a file:
`show trace file [tail]`
10. (Optional) Search trace results for a specific string value:
`trace grep [WORD<0-128>]`

If you use this command and do not specify a string value, you clear the results of a previous search.

Example

Clear prior trace information, and then enable the display of trace output to the screen. Begin the trace operation for received IS-IS hello packets:

```
Switch:1#clear trace
Switch:1>enable
```

```
Switch:1#trace screen enable
Switch:1#Screen tracing is on
Switch:1#trace level 267 2
```

Variable Definitions

The following table defines parameters for the **show trace** command.

Variable	Value
<i>auto</i>	Displays the current configuration for the automatic trace function.
<i>file [tail]</i>	Displays the trace results saved to a file.
<i>level</i>	Displays the current trace level for all modules.
<i>modid-list</i>	Specifies the module ID list.

The following table defines parameters for the **trace** command.

Variable	Value
<i>grep [WORD<0-128>]</i>	Specifies the search keyword. You can use a specific MAC address. You can search for errors, using the command, trace grep error .
<i>level [<Module_ID>] [<0-4>]</i>	<p>Starts the trace by specifying the module ID and level.</p> <p><i><Module_ID></i> specifies the module for the trace. Different hardware platforms support different IDs because of feature support differences. For feature support information, see <i>Fabric Engine and VOSS Feature Matrix</i>. To see the list of module IDs, use the show trace modid-list command or CLI command completion Help.</p> <p>0-4 specifies the trace level:</p> <ul style="list-style-type: none"> • 0 — Disabled • 1 — Very terse • 2 — Terse • 3 — Verbose • 4 — Very verbose
<i>shutdown</i>	Stops the trace operation.
<i>screen {disable enable}</i>	<p>Enables or disables the display of trace output to the screen.</p> <p>Important:</p> <p>Avoid using the screen to view commands if you use trace level 3 (verbose) or trace level 4 (very verbose) due to the volume of information generated and the effect on the system.</p>

The following table defines parameters for the **save trace** command.

Variable	Value
<i>file</i> WORD<1-99>	<p>Specifies the file name in one of the following formats:</p> <ul style="list-style-type: none"> a.b.c.d: <file> <p>WORD<1-99> is a string of 1-99 characters.</p> <p>Note: If you do not specify a file name, the file name is systrace.txt.</p>

View Detailed TLV Information for IS-IS

About This Task

Use the following procedure to view the detailed information about metric type of IS-IS routes in TLVs in Link State Packets (LSP).

Procedure

1. Display the detail view of TLV 135:
show isis lsdb tlv 135 detail
2. Display the detail view of TLV 184:
show isis lsdb tlv 184 detail

Examples

Viewing the metric type of IS-IS route in TLV 135:

```
Switch:1#show isis lsdb tlv 135 detail

=====
                        ISIS LSDB (DETAIL)
=====
-----

View Summarized TLV Information for IS-IS

About This Task

Use the following procedure to view the summarized information about the metric type of IS-IS routes in TLVs. You can also view the metric type of the prefix.

Procedure

Display the summarized view of TLVs 135 and 184:

```
show isis lsdb ip-unicast
```

Example

Display the summarized view of TLVs:

```

evp4k:1#show isis lsdb ip-unicast
=====
                        ISIS IP-UNICAST-ROUTE SUMMARY

Configure I-SID Monitoring

Use the following procedure to configure Fabric RSPAN (Mirror to I-SID) on the Backbone Edge Bridge (BEB) connected to the monitor station.

**Note**

You cannot configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.

**Note**

If you change the egress port or egress MLT for a particular session using a separate CLI command, it overwrites the existing egress port list or egress MLT.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a monitor by I-SID entry:

**Note**

If you use the Extreme Integrated Application Hosting (IAH) port 1/s1 as the analyzer port on the monitoring BEB for remote mirroring, you must associate it to VLAN ID 4091.

```
monitor-by-isid <1-1000> [monitor-isid-offset <1-1000> {egress-mlt
<1-512> | egress-ports {slot/port[-slot/port][,...][slot/all][all]} }
[map-to-vid <1-4093>]]
```

3. Configure map to VLAN ID:

```
monitor-by-isid <1-1000> map-to-vid <1-4093>
```

4. Configure egress MLT:

```
monitor-by-isid <1-1000> egress-mlt <1-512>
```

5. Configure egress port:

```
monitor-by-isid <1-1000> egress-ports {slot/port[-slot/port][,...]
[slot/all][all]}
```

6. Enable monitoring by I-SID entry:

```
monitor-by-isid <1-1000> enable
```

**Note**

Disable the entries (egress ports, MLT, and VLAN ID) to modify or remove parameters in the existing configuration.

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# monitor-by-isid 1 monitor-isid-offset 1 egress-port 1/6
Switch:1(config)# monitor-by-isid 2 monitor-isid-offset 2 egress-port 1/7 map-to-vid 200
Switch:1(config)# monitor-by-isid 3 monitor-isid-offset 3 egress-port 1/7 map-to-vid 201
Switch:1(config)# monitor-by-isid 2 egress-port 1/8
Switch:1(config)# monitor-by-isid 1 monitor-isid-offset 1000 egress-ports 1/1 egress-mlt
16 map-to-vid 1000
Switch:1(config)# monitor-by-isid 7 monitor-isid-offset 7 egress-mlt 2 map-to-vid 203
Switch:1(config)# monitor-by-isid 2 egress-mlt 3
```

Variable Definitions

The following table defines parameters for the **monitor-by-isid** command.

Variable	Value
<1-1000>	Specifies the monitoring session.
<i>monitor-isid-offset</i> <1-1000> Note: Exception: This parameter does not apply to 7830 Series.	Specifies the offset ID that is mapped to the actual monitor I-SID where packets are mirrored. Monitor I-SID = Base monitor I-SID + Offset ID. The base monitor I-SID is 16776000.
<i>egress-ports</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...] [slot/all] [all]}	Specifies the port to which the analyzers connect.
<i>egress-mlt</i> <1-512>	Specifies the MLT to which the analyzers connect.
<i>map-to-vid</i> <1-4093>	Maps the mirrored packet to a specified VLAN ID for analysis. This parameter is optional. Note: If you use the Extreme Integrated Application Hosting (IAH) port 1/s1 as the analyzer port on the monitoring BEB for remote mirroring, you must associate it to VLAN ID 4091.

Display I-SID Monitoring Diagnostics

Use the following procedure to display the **monitor-by-isid** entries on the monitoring BEB.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Enter the following command:

```
show monitor-by-isid WORD<1-1024>
```

Example

```
Switch:1>show monitor-by-isid 3
=====
                Diag Monitor-By-ISID
=====
ID MONITOR_ISID ISID_OFFSET  EGRESS_PORTS  EGRESS_MLT  MAP_TO_VLAN  ENABLE
-----
3      16776000      1           1/4, 1/5         1           999         true
-----
```

Variable Definitions

The following table defines parameters for the **show monitor-by-isid** command.

Variable	Value
<i>WORD<1-1024></i>	Specifies the session ID list ranging from 1 to 1000.

Display I-SID Mirroring Statistics

Use the following procedure to display the statistics of the number of packets mirrored into I-SID on the mirroring BEB.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enter the following command:

```
show isid-mirroring stats [monitor-isid-offset WORD<1-1024>]
```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# show isid-mirroring stats monitor-isid-offset 1
=====
                Mirror Statistics Info
=====
ISID          ISID_OFFSET  PACKETS
-----
16776000      1            100
-----
```

Variable Definitions

The following table defines parameters for the **show isid-mirroring stats** command.

Variable	Value
<i>monitor-isid-offset WORD<1-1024></i>	Specifies the offset ID mapped to monitor the I-SID.
Note: Exception: This parameter does not apply to 7830 Series.	The offset ID ranges from 1 to 1000.

Clear Fabric RSPAN (Mirror to I-SID) Statistics

Use the following procedure to clear Fabric RSPAN (Mirror to I-SID) statistics of packets mirrored into the specified mirroring I-SID or all mirroring I-SIDs on the BEB.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enter the following command:

```
clear isid-mirroring stats monitor-isid-offset WORD<1-1024>
```

Note

You must use this command on the Mirroring BEB to clear the statistics of packets mirrored into I-SID.

Example

```
Switch:1>enable
Switch:1#configure terminal
```

Clear all Fabric RSPAN statistics:

```
Switch:1(config)# clear isid-mirroring stats
```

Clear all Fabric RSPAN (Mirror to I-SID) statistics of packets mirrored into the specified mirroring I-SID

```
Switch:1(config)# clear isid-mirroring stats monitor-isid-offset 1
```

Variable Definitions

The following table defines parameters for the **clear isid-mirroring stats** command.

Variable	Value
<i>monitor-isid-offset WORD<1-1024></i>	Specifies the offset ID that is mapped to the actual monitor I-SID where packets are mirrored.
Note: Exception: This parameter does not apply to 7830 Series.	Monitor I-SID = base monitor I-SID + offset ID.
	The range of the <i>monitor-isid-offset</i> is 1 to 1000.
	The base monitor I-SID is 16776000.

Configure a Network Service Probe

Configure a Network Service Probe to troubleshoot network connectivity issues.

Before You Begin

- Ensure that the port-based VLAN exists on the switch.

About This Task

You can create only one service probe on the switch. If you delete the VLAN, the Network Service Probe configuration is also removed.

If you do not configure a static IP address for the Network Service Probe or assign a static default gateway, the switch uses DHCP to acquire an IP address or dynamically learn the gateway address. The DHCP Server and relay agent must be non-local to the switch. The gateway must be non-local to the switch.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Create the Network Service Probe and associate it with a VLAN ID:

```
service-probe vlan <1-4059>
```
3. (Optional) Create a static IP address and subnet mask for the Network Service Probe:

```
service-probe ip static {<A.B.C.D/X> | (A.B.C.D) (A.B.C.D) }
```
4. (Optional) Create a static IP association with the default gateway:

```
service-probe default-gateway {A.B.C.D}
```
5. Enable the Network Service Probe:

```
service-probe enable
```
6. View the Network Service Probe configuration:

```
show service-probe
```

Example

Create, and enable, a Network Service Probe with a static IP configuration, and then view the configuration:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#service-probe vlan 15
Switch:1(config)#service-probe ip static 15.0.0.1 255.255.255.0
Switch:1(config)#service-probe enable
Switch:1>show service-probe
```

Service Probe Info

```
=====
Vlan: 15
Administrative State: enabled
MAC Address: 4e:bf:2d:0c:1f:bd
IP Address: 192.0.2.11
IP Mask: 255.255.255.0
IP Address Config: dynamic
Default Gateway: 192.0.2.1
Default Gateway State: ACTIVE
Primary dynamic DNS server
=====
IP address: 198.51.100.2
```

```

Query status: Fail

Secondary dynamic DNS server
=====
IP address:    203.0.113.3
Query status: Success

```

NEW! Query Domain Name Server using Service Probe

About This Task

Perform this procedure to query the DNS servers that the switch receives and stores from the DHCP server.

Note

This only applies for dynamic IP configuration on Service Probe.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Query the DNS servers to perform domain resolution tests:

```
service-probe query dns [primary-dynamic | secondary-dynamic | tertiary-dynamic]
```

NEW! Variable Definitions

The following table defines parameters for the **service-probe query dns** command.

<i>primary-dynamic</i>	Specifies the primary DNS server learned through DHCP. If you do not specify a DNS server parameter, the switch uses primary-dynamic by default.
<i>secondary-dynamic</i>	Specifies the secondary DNS server learned through DHCP. This option sends the DNS query to the second DHCP-assigned DNS server.
<i>tertiary-dynamic</i>	Specifies the tertiary DNS server learned through DHCP. This option sends the DNS query to the third DHCP-assigned DNS server.

Software Troubleshooting Tool Configuration Using EDM

Use the tools described in this section to perform troubleshooting procedures using Enterprise Device Manager (EDM).

Flush Routing Tables by VLAN

About This Task

For administrative and troubleshooting purposes, sometimes you must flush the routing tables. You can use EDM to flush the routing tables by VLAN or flush them by port. Perform this procedure to flush the IP routing table for a VLAN.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Advanced** tab.
4. In the **Vlan Operation Action** column, select a flush option.
In a VLAN context, all entries associated with the VLAN are flushed. You can also flush the Address Resolution Protocol (ARP) entries and IP routes for the VLAN.
5. Select **Apply**.

Flush Routing Tables by Port

About This Task

For administrative and troubleshooting purposes, sometimes you must flush the routing tables. You can use EDM to flush the routing tables by VLAN or flush them by port. Perform this procedure to flush the IP routing table for a port.

Procedure

1. On the Device Physical View, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **Interface** tab.
5. In the **Action** section, select **flushAll**.
In a port context, all entries associated with the port are flushed. You can flush the ARP entries and IP routes for a port. After you flush a routing table, it is not automatically repopulated. The repopulation time delay depends on the routing protocols in use.
6. Select **Apply**.

Configure Port Mirroring

Before You Begin

- To change a port mirroring configuration, first disable mirroring.

About This Task

Use port mirroring to aid in diagnostic and security operations.

Use port mirroring to make a copy of a traffic flow and send that copy to a device for analysis, for example, for diagnostic sniffing. Use the mirror to see the packets in the flow without breaking into the physical connection to place a packet onto the sniffer inline. You can also use port mirroring for security. You can send flows to inspection engines for post processing.

Connect the sniffer (or other traffic analyzer) to the output port you specify in this procedure.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **General**.
3. Select the **Port Mirrors** tab.
4. Select **Insert**.
5. To enable port mirroring for the instance, select the **Enable** check box.
6. Configure mirroring as required.

Note

- When you configure `tx` mode port mirroring on T-UNI and SPBM NNI ports, unknown unicast, broadcast and multicast traffic packets that ingress these ports and the system displays on the mirror destination port, although they do not egress the mirror source port. This is because `tx` mode port mirroring happens on the mirror source port before the source port squelching logic drops the packets at the egress port.
- The available four mirroring resources are shared between Fabric RSPAN and regular port mirroring, and are allocated based on the mode configured, Ingress (`rx`) or Egress (`tx`). Each configured mode occupies one mirroring resource, but when you configure the mode as `both`, it occupies two mirroring resources (one for Rx and one for Tx).
- You cannot configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.

7. Select **Insert**.

Port Mirrors Field Descriptions

Use the data in the following table to use the **Port Mirrors** tab.

Name	Description
Id	Specifies an assigned identifier for the configured port mirroring instance.
MirroredPortList	Specifies a port to be mirrored (the source port).
Enable	Enables or disables this port mirroring instance. The default value is Enable.
Mode	Specifies the traffic direction of the packet being mirrored: <ul style="list-style-type: none"> • <code>tx</code> mirrors egress packets. • <code>rx</code> mirrors ingress packets. • <code>both</code> mirrors both egress and ingress packets. The default is <code>rx</code> .

Name	Description
MirroringPortList	Specifies a destination port (the port to which the mirrored packets are forwarded). Configures the mirroring port.
MirroringMltId	Specifies the destination MultiLink trunking ID.
MonitoringIsidOffset	Used to configure the monitoring I-SID offset value. The offset ID is mapped to the actual monitor I-SID value to which the packets are mirrored.
MonitoringIsid	Specifies the actual monitor I-SID value to which the packets are mirrored.
MirroringQos	Used to define the Quality of Service (QoS) profiles for the mirrored packet into monitoring I-SID.

Configure ACLs for Mirroring

Before You Begin

- The ACL exists.

About This Task

Configure the access control list (ACL) to mirror packets for an access control entry (ACE) that matches a particular packet.

You cannot change a parameter that the system displays it dimmed; in this case, delete the ACL, and then configure a new one.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Double-click the parameter **MirrorMltId** to configure mirroring to a destination MLT group.
5. Double-click the parameter **MirrorDstPortList** to configure mirroring to a destination port or ports.
6. Select **Apply**.

ACL Field Descriptions

Use the data in the following table to use the **ACL** tab.

Name	Description
AcId	Specifies a unique identifier for the ACL.
Type	<p>Specifies the ACL type. Valid options are</p> <ul style="list-style-type: none"> • inVlan • inPort • outPort • inVsn <p>Important: The inVlan ACLs drop packets if you add a VLAN after ACE creation.</p> <p>Important: You can insert an inVsn ACL type for a Switched UNI only if the Switched UNI I-SID is associated with a platform VLAN.</p>
Name	Specifies a descriptive user-defined name for the ACL.
VlanList	For inVlan ACL types, specifies all VLANs to associate with the ACL.
PortList	For inPort and outPort ACL types, specifies the ports to associate with the ACL.
DefaultAction	Specifies the action taken when no ACEs in the ACL match. Valid options are deny and permit, with permit as the default. Deny means the system drops the packets; permit means the system forwards packets.
ControlPktAction	Specifies the action taken for control packets. Valid options are deny and permit.
State	Enables or disables all of the ACEs in the ACL. The default value is enable.
PktType	Indicates the packet type to which this ACL applies.
MirrorMltId	Configures mirroring to a destination MLT.
MirrorDstPortList	Configures mirroring to a destination port or ports.
MatchType	<p>For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are:</p> <ul style="list-style-type: none"> • <i>both</i> for traffic ingressing on both UNI ports and network-to-network interface (NNI) ports terminating on this node • <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node • <i>uniOnly</i> for traffic ingressing on UNI ports only <p>The default value is <i>both</i></p>

Name	Description
Isid	<p>For inVsn ACL types, specifies the I-SID associated with the customer VLAN (Layer 2 VSN) or the customer VRF (Layer 3 VSN). This I-SID should already be configured on the fabric node.</p> <p>The InVSN Filter supports IP Shortcut traffic if the inVsn ACL match type is <i>both</i>. In this case, the I-SID is zero (0).</p> <p>Important: You can specify a Switched UNI I-SID if the I-SID is associated with a platform VLAN.</p>
Origin	<p>Indicates the origin of the ACL:</p> <ul style="list-style-type: none">• config - ACL created by the user.• eap - ACL created by Extensible Authentication Protocol (EAP) through Remote Authentication Dial-In User Service (RADIUS) response.
DefaultSvcRate	<p>Specifies the service rate limit in kbps {8-4000000000}.The granularity is 8 kbps.</p>
DefaultPeakRate	<p>Specifies the value when exceeded causes packets to drop on ingress. Peak rate limit in kbps {8-4000000000}.The granularity is 8 kbps.</p>

Configure ACEs for Mirroring

Before You Begin

- The ACL exists.
- The ACE exists.

About This Task

Configure actions to use filters for flow mirroring. Use an ACE to define the mirroring actions the filter performs.

If you use the mirror action, ensure that you specify the mirroring destination: IP address, MLTs, ports, or VLANs.

Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the ACL for which to modify an ACE.
5. Select **ACE**.
6. Select an ACE, and then select **Action**.
7. Configure one of: **DstPortList**, **DstMltId**, or **DstIp**.
8. Select **Apply**.

Action Field Descriptions

Use the data in the following table to use the **Action** tab.

Note

The table lists the options for both Security ACEs and QoS ACEs. Dependent upon the ACE, the system displays different options on the EDM interface.

Name	Description
AcId	Specifies the ACL ID.
AcId	Specifies the ACE ID.
Mode	Configures the action mode for security ACEs. The default value is deny.
RemarkDscp	Specifies the new Per-Hop Behavior (PHB) for matching packets: phbcs0, phbcs1, phbaf11, phbaf12, phbaf13, phbcs2, phbaf21, phbaf22, phbaf23, phbcs3, phbaf31, phbaf32, phbaf33, phbcs4, phbaf41, phbaf42, phbaf43, phbcs5, phbef, phbcs6, phbcs7. This action is a QoS action.
RemarkDot1Priority	Specifies the new 802.1 priority bit for matching packets: zero, one, two, three, four, five, six, or seven. This action is a QoS action. Note: This does not apply to IPv6 filtering.
InternalQoS	This variable is a QoS action. The default value is 1. Note: This does not apply to IPv6 filtering.
RedirectNextHop	Specifies the next-hop IPv4 address (a.b.c.d) or IPv6 address (aaaa:bbbb:cccc:dddd:eeee:ffff:gggg:hhhh) for redirect mode. Applies to ingress ACLs (routed and Layer 2 packets).
Count	Enables the ability to count matching packets. Use this parameter with either a security or QoS ACE. The default is disabled.
DstPortList	Configures mirroring to a destination port or ports. This action is a security action.
DstMltId	Configures mirroring to a destination MLT. This action is a security action.

Name	Description
MonitoringIsidOffset	Configures the monitoring I-SID offset value. The offset ID is mapped to the actual monitor I-SID value to which the packets are mirrored.
MirroringQoS	Defines the Quality of Service (QoS) profiles for the mirrored packet into monitoring I-SID.

Run a Ping Test

About This Task

Use ping to determine if an entity is reachable.

Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see *Fabric Engine Release Notes*. As an alternative, use CLI.

Procedure

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **Ping/Trace Route**.
3. Select the **Ping Control** tab.
4. Select **Insert**.
5. In **OwnerIndex**, type the owner index.
6. In **TestName**, type the name of the test.
7. In **TargetAddress**, type the host IP address.
8. From **AdminStatus**, select **enabled**.
9. In the remainder of the options, type the desired values.
10. Select **Insert**.
11. Select an entry, and then select **Start**.
Let the test run for several seconds.
12. Select an entry, and then select **Stop**.
13. View the Ping results.

Ping Control Field Descriptions

Use the data in the following table to use the **Ping Control** tab.

Name	Description
OwnerIndex	Provides access control by a security administrator using the View-Based Access Control Model (VACM) for tables in which multiple users need to independently create or modify entries. This is a string of up to 32 characters.
TestName	Specifies the name of the ping test.

Name	Description
TargetAddress	Specifies the host address to use at a remote host to perform a ping operation.
DataSize	Specifies the size of the data portion (in octets) to transmit in a ping operation. The default is 16.
TimeOut	Specifies the timeout value, in seconds, for a remote ping operation. The default is 3 seconds.
ProbeCount	Specifies the number of times to perform a ping operation at a remote host. The default is 1.
AdminStatus	Specifies the state of the ping control entry: enabled or disabled. The default is disabled.
DataFill	Determines the data portion of a probe packet.
Frequency	Specifies the number of seconds to wait before repeating a ping test. The default is 0.
MaxRows	Specifies the maximum number of entries allowed in the PingProbeHistory table. The default is 50.
TrapGeneration	<p>Specifies when to generate a notification. The options are:</p> <ul style="list-style-type: none"> ProbeFailure—Generates a PingProbeFailed notification subject to the value of TrapProbeFailureFilter. The object TrapProbeFailureFilter can specify the number of successive probe failures that are required before a pingProbeFailed notification is generated. TestFailure—Generates a PingTestFailed notification. The object TrapTestFailureFilter can determine the number of probe failures that signal when a test fails. TestCompletion—Generates a PingTestCompleted notification. <p>The value of this object defaults to zero, indicating that none of the options have been selected.</p>
TrapProbeFailureFilter	Specifies the number of successive probe failures that are required before a pingProbeFailed notification is generated. The default is 1.
TrapTestFailureFilter	Determines the number of probe failures that signal when a test fails. The default is 1.
Descr	Describes the remote ping test. The default is 0x00.
SourceAddress	Specifies the IP address (a.b.c.d) as the source address in outgoing probe packets.
ByPassRouteTable	Enables (optionally) the bypassing of the route table. The default is disabled.

View Ping Results

About This Task

View ping results to view performance-related data.

Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see *Fabric Engine Release Notes*. As an alternative, use CLI.

Procedure

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **Ping/Trace Route**.
3. Select the **Ping Control** tab.
4. Select a ping test entry.
5. Select **Ping Result**.

Ping Result Field Descriptions

Use the data in the following table to use the **Ping Result** tab.

Name	Description
OwnerIndex	Specifies the ping test owner.
TestName	Specifies the test name.
OperStatus	Indicates the operational status of the test. The default is disabled.
IpTargetAddressType	Specifies the IP address type of the target. The default is unknown.
IpTargetAddress	Specifies the IP address of the target.
MinRtt	Specifies the minimum ping round-trip-time (RTT) received. A value of 0 means that no RTT is received.
MaxRtt	Specifies the maximum ping RTT received. A value of 0 means that no RTT is received.
AverageRtt	Specifies the current average ping RTT.
ProbeResponses	Specifies the number of responses to probes.
SentProbes	Specifies the number of sent probes.
RttSumOfSquares	Specifies the sum of squares of RTT for all probes received.
LastGoodProbe	Specifies the date and time when the last response is received for a probe.

View Ping Probe History

About This Task

View the ping probe history to view the history of ping tests performed by the switch.

Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see *Fabric Engine Release Notes*. As an alternative, use CLI.

Procedure

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **Ping/Trace Route**.
3. Select a ping entry.
4. Select **Ping Probe History**.

Ping Probe History Field Descriptions

Use the data in the following table to use the **Ping Probe History** tab.

Name	Description
OwnerIndex	Specifies the owner index
TestName	Indicates the name given to the test.
Index	Specifies the index number.
Response	Indicates the amount of time, measured in milliseconds, between request (probe) and response, or when the request timed out. Response is reported as 0 when it is not possible to transmit a probe.
Status	Indicates the status of the response; the result of a particular probe done by a remote host.
LastRC	Indicates the last implementation-method-specific reply code (RC) received. If ICMP Echo is used, then a successful probe ends when an ICMP response is received that contains the code ICMP_ECHOREPLY(0).
Time	Indicates the timestamp for this probe result.

Run a Traceroute Test

About This Task

Run a traceroute test to determine the route packets take through a network to a destination.

Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see *Fabric Engine Release Notes*. As an alternative, use CLI.

Procedure

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **Ping/Trace Route**.
3. Select the **Trace Route Control** tab.
4. Select **Insert**.
5. Configure the instance as required.
6. Select **Insert**.
7. Select an entry, and then select **Start**.
Let the test run for several seconds.
8. Select an entry, and then select **Stop**.
9. View the traceroute test results.

Trace Route Control Field Descriptions

Use the data in the following table to use the **Trace Route Control** tab.

Name	Description
OwnerIndex	Provides access control by a security administrator using the VACM for tables in which multiple users need to independently create or modify entries.
TestName	Specifies the name of the traceroute test.
TargetAddressType	Specifies the type of host address to use on the traceroute request at the remote host. The default is IPv4.
TargetAddress	Specifies the host address used on the traceroute request at the remote host.
ByPassRouteTable	Enables bypassing of the route table. If you enable this variable, the remote host bypasses the normal routing tables and sends directly to a host on an attached network. If the host is not on a directly-attached network, an error is returned. You can use this variable to perform the traceroute operation to a local host through an interface that has no route defined. The default is disabled.
DataSize	Specifies the size of the data portion of a traceroute request in octets. The default is 1.
TimeOut	Specifies the timeout value, in seconds, for a traceroute request. The default is 3.
ProbesPerHop	Specifies the number of times to reissue a traceroute request with the same time-to-live (TTL) value. The default is 3.

Name	Description
Port	<p>Specifies the UDP port to which to send the traceroute request. Specify a port that is not in use at the destination (target) host. The default is the IANA assigned port 33434.</p> <p>Note: If the traceroute action is directed to an IPv6 host address, Linux increments the UDP port on a per-TTL basis. For an IPv4 host address, Linux increments the UDP port on a per-probe basis. Because the traceroute command sends a default of three probes, three incrementing ports will be sent for an IPv4 host address. If you use the -p parameter with a value greater than 65533, the traceroute command fails for an IPv4 host address because the maximum port number, 65535, is exceeded.</p>
MaxTtl	Specifies the maximum time-to-live from 1–255. The default is 30.
DSField	Specifies the value to store in the Differentiated Services (DS) field in the IP packet used to encapsulate the traceroute probe. The default is 0.
SourceAddressType	Specifies the type of the source address to use at a remote host.
SourceAddress	Uses the specified IP address (which must be an IP number, not a hostname) as the source address in outgoing probe packets.
IfIndex	Directs the traceroute probes to be transmitted over the specified interface. The default is 0.
MiscOptions	Enables an application to specify implementation-dependent options.
MaxFailures	Indicates the maximum number of consecutive timeouts allowed before terminating a remote traceroute request. The default is 5.
DontFragment	Enables setting of the do not fragment (DF) flag in the IP header for a probe. The default is disabled.
InitialTtl	Specifies the initial time-to-live (TTL) value to use. The default is 1.
Frequency	Specifies the number of seconds to wait before repeating a traceroute test as defined by the value of the various objects in the corresponding row. The default is 0.
StorageType	Specifies the storage type for this row.
AdminStatus	Specifies the desired state for TraceRouteCtlEntry. The options are enabled or disabled. The default is disabled.

Name	Description
MaxRows	Specifies the maximum number of entries allowed in the TraceRouteProbeHistoryTable. The default is 50.
TrapGeneration	Determines when to generate a notification for this entry. The options are <ul style="list-style-type: none">• pathChange —Generates a TraceRoutePathChange notification after the current path varies from a previously determined path.• testFailure —Generates a TraceRouteTestFailed notification after the full path to a target cannot be determined.• testCompletion —Generates a TraceRouteTestCompleted notification after the path to a target has been determined.
Descr	Describes the remote traceroute test.
CreateHopsEntries	Stores the current path for a traceroute test in the TraceRouteHopsTable on an individual hop basis when the value of this object is true. The default is false.
Type	Reports or selects the implementation method to use for performing a traceroute operation.

View Traceroute Results

About This Task

View traceroute results to view performance-related data.

Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see *Fabric Engine Release Notes*. As an alternative, use CLI.

Procedure

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **Ping/Trace Route**.
3. Select the **Trace Route Control** tab.
4. Select a traceroute entry.
5. Select **Trace Route Result**.

Trace Route Result Field Descriptions

Use the data in the following table to use the **Trace Route Result** tab.

Name	Description
OwnerIndex	Specifies the index of the owner.
TestName	Specifies the name of the test.

Name	Description
OperStatus	Specifies the operational status of the test. The default is disabled.
CurHopCount	Specifies the current count of hops.
CurProbeCount	Specifies the current count of probes.
IpTgtAddressType	Specifies the IP target address type
IpTgtAddr	Specifies the IP target address.
TestAttempts	Specifies the number of test attempts.
TestSuccesses	Specifies the number of successful test attempts.
LastGoodPath	Specifies the date and time when the last response is received for a probe.

View the Traceroute History

About This Task

View the traceroute history to view the history of traceroute tests performed by the switch.

The traceroute probe history contains probe information for the hops in the routing path.

Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see *Fabric Engine Release Notes*. As an alternative, use CLI.

Procedure

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **Ping/Trace Route**.
3. Select the **Trace Route Control** tab.
4. Select an entry.
5. Select **Trace Route Probe History**.

Route Probe History Field Descriptions

Use the data in the following table to use the **Trace Route Probe History** tab.

Name	Description
OwnerIndex	Identifies the Trace Route entry to which a probe result belongs.
TestName	Specifies the test name.
Index	Specifies the Index.
HopIndex	Indicates for which hop in a traceroute path the probe results are intended.

Name	Description
ProbeIndex	Specifies the index of a probe for a particular hop in a traceroute path.
HAddrType	Specifies the IP address type of the hop to which this probe belongs.
HAddr	Specifies the IP address of the hop to which this probe belongs.
Response	Specifies the cumulative results at any time.
Status	Specifies the status of the probe.
LastRC	When a new entry is added, the old entry is purged if the total number of entries exceeds the specified maximum number of entries in the Control Table Entry.
Time	Specifies the response time of the probe.

Configure I-SID Monitoring

Use the following procedure to configure Fabric RSPAN on the Backbone Edge Bridge (BEB) connected to the monitor station.

About This Task

You cannot configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.

Note

If you change the egress port or egress MLT for a particular session using a CLI command, it overwrites the existing egress port list or egress MLT.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **General**.
3. Select the **Monitor-By-ISID** tab.
4. Select **Insert**.
5. Configure the parameters as required.
6. Select **Insert**.
7. To modify mappings, double-click a parameter to view a list of options.
8. Select **Apply**.

Monitor-By-ISID Field Descriptions

Use the data in the following table to use the **Monitor-By-ISID** tab.

Name	Description
Index	Specifies the entry that contains monitor by I-SID information.
MonitorIsidOffset	Configures the monitoring I-SID offset value. The offset ID is mapped to the actual monitor I-SID value to which the packets are mirrored.
MonitorIsid	Specifies the actual monitor I-SID value to which packets are mirrored.
EgressPortList	Specifies the egress ports to which traffic analyzers connect.
EgressMltId	Specifies the egress MLT ID to which traffic analyzers connect.
MapToVlanId	Specifies the VLAN ID to map with mirrored traffic on the monitoring node.
Enable	Enables or disables monitoring by I-SID.

View Fabric RSPAN (Mirror to I-SID) Statistics

About This Task

Use the following procedure to view or clear statistics of the number of packets mirrored into I-SID on the mirroring BEB.

Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **General**.
3. Select the **Isid-Mirroring Stats** tab.

Isid-Mirroring Stats Field Descriptions

Use the data in the following table to use the **Isid-Mirroring Stats** tab.

Name	Description
Index	Specifies the entry that contains Fabric RSPAN statistics information.
MonitorIsid	Specifies the actual monitor I-SID value to which the packets are mirrored.
MirroredPackets	Specifies the number of packets mirrored into I-SID on the mirroring BEB.
ClearStats	Clears the Fabric RSPAN statistics.

Hardware Troubleshooting

The following sections provide troubleshooting information for common hardware problems.

Time Domain Reflectometer (TDR)

Table 332: Time Domain Reflectometer product support

Feature	Product	Release introduced
Time Domain Reflectometer (Cable Diagnostic)	4220 Series	Fabric Engine 9.2
	5320 Series	Fabric Engine 9.0.2
	5420 Series	Fabric Engine 8.10 Not supported on 5420F-24S-4XE
	5520 Series	Fabric Engine 9.0.2 Not supported on 5520-24X or 5520-48SE
	5720 Series	Fabric Engine 9.0.2
	7520 Series	Fabric Engine 9.0.2 Supported on 7520-48XT-6C
	7720 Series	Not Supported
	7830 Series	Not Applicable
	VSP 4900 Series	Not Supported
	VSP 7400 Series	Not Supported

With Time Domain Reflectometer (TDR) cable diagnostic, you can test Ethernet cables connected to a switch port, or ports, for defects. Use this functionality to diagnose a link with poor connectivity. The cable diagnostic detects the state of the port or ports, the status of the cable pairs, and the length of the cable.

Note

You can perform TDR cable diagnostic on copper ports.

The following table lists the states of the cables connected to a port or ports.

State	Description
Ok	No cable fault is detected.
Open	Detects lack of continuity between the pins at each end of the cable.
Short	Detects a short circuit in the cable.
Open/Short	Detects either a short circuit on the cable or a lack of continuity between the pins at each end of the cable.
Crosstalk	Detects interference and degradation between two pairs in the cable.
Unknown	Detects an unknown issue.

Troubleshoot Fiber Optic Links

About This Task

You can troubleshoot fiber optic links to ensure that the optical transmitters and receivers operate correctly, and to determine if a receiver is saturated, or does not receive enough power.

To troubleshoot optical links and devices, you can use Digital Diagnostic Monitoring (DDM), as well as published optical specifications.

For more information about transceivers, see [Extreme Optics](#) website.

Important

As a best practice, use transceivers documented in [Extreme Optics](#) website, as they have been through extensive qualification and testing. Extreme Networks is not responsible for issues related to third party transceivers.

Procedure

1. Measure the transmit power.
2. Compare the measured transmit power with the specified launch power.
The values are similar. If the measured power is far below the specified value, a faulty transmitter is a possible cause.
3. Compare the measured transmit power for the near-end optical device to the measured transmit power for the far-end device.
Large differences can mean that the optical devices are mismatched (that is, -SX versus -LX).
4. Measure the receive power at each end of the link.
5. Compare the receive power to the transmit power.
 - For short fiber links, the transmit and received power are similar (after taking into consideration connection losses).
 - For long fiber links, the transmit and received power are similar (after taking into consideration connection losses and fiber attenuation).

Large differences can mean a damaged fiber or dirty or faulty connectors. Large differences can also mean that the link does not use the right type of fiber (single mode or multimode). If the receiver power is measured to be zero, and the link worked previously, it is probable that the far-end transmitter is not operating or the fiber is broken.

6. Compare the measured receive power for the near-end optical device to the measured receive power for the far-end device.

Large differences could mean that the optical devices are mismatched (that is, -SX versus -LX). If optical devices are mismatched, the receiver can be saturated (overdriven).

7. If a receiver is saturated but still operable, install a suitable attenuator.

For long-haul optical devices, the receive power must be significantly less than the transmit power.

8. To help debug the link, loop back the local transmit and receive ports, and use the DDM parameters to help determine the fault.

Hardware Troubleshooting using CLI

This section provides procedures to troubleshoot common hardware problems using the command line interface (CLI).

Use Trace to Diagnose Hardware Problems

Use trace to observe the status of a hardware module at a given time.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Begin the trace operation:
line-card 1 trace level [*<Module_ID>*]{*<0-4>*}
3. Search the trace for a specific string value:
line-card 1 trace grep {*WORD<0-1024>*}

Example

```
Switch:1>enable
```

Begin the trace operation:

```
Switch:1#line-card 1 trace level 67 1
```

Search the trace for a specific string value:

```
Switch:1#line-card 1 trace grep 00-1A-4B-8A-FB-6B
```

Variable Definitions

The following table defines parameters for the **line-card 1** command.

Variable	Value
<i><Module_ID></i> { <i><0-4></i> }	<p>Starts the trace by specifying the module ID and level.</p> <p><i><Module_ID></i> specifies the module for the trace. Different hardware platforms support different IDs because of feature support differences. For feature support information, see <i>Fabric Engine and VOSS Feature Matrix</i>. To see the list of module IDs, use the show trace modid-list command or CLI command completion Help.</p> <p><i><0-4></i> specifies the trace level from 0–4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.</p>
<i>WORD<0-1024></i>	Performs a string search in the trace.

Troubleshoot USB Viewing Problems

After you insert a USB device in the USB slot, the Linux system automatically detects and mounts the device. If you cannot view files on the device, perform this procedure.

Note

Not all hardware platforms can use the USB device for additional file storage. Some platforms use the USB as part of the system operation and must never be removed. For more information, see your hardware documentation.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Check the file system:

```
ls /usb/
```

3. Remove a USB device:

- a. Unmount the USB device:

```
usb-stop
```

- b. Wait for the response that indicates it is safe to remove the device.

- c. Physically remove the device.

4. Remove and then reinsert the device.

5. Check the device for errors:

```
dos-chkdsk /usb
```

Run the **dos-chkdsk /usb repair** command, if at the end of the **dos-chkdsk /usb** command output you see:

1) Correct

2) Don't correct

6. If errors are detected, then you can reformat the device:

```
dos-format /usb
```

Caution

If you format the device, you erase all data on the device.

Example

Check the file system:

```
Switch:1>enable
Switch:1#ls /usb/
Listing Directory /usb/:
drwxr-xr-x 4 0 0 4096 Jan 1 1970 ./
drwxrwxr-x
22 0 0 0 Sep 9 20:22 ../
drwxr-xr-x 2 0 0 4096 Mar 17 16:03 Photos-of-Flash-
drwxr-xr-x 2 0 0 4096 Jun 13 20:56 intflash/
```

Check the device for errors:

```
Switch:1#usb-stop
It is now safe to remove the USB device.
Switch:1#dos-chkdsk /usb
/usr/sbin/fsck.vfat /dev/usb1 -v >& /dev/console dosfsck 2.11a
(05 Mar 2010)
dosfsck 2.11a, 05 Mar 2010, FAT32, LFN
Checking we can access the last sector of the filesystem
Boot sector contents:
System ID "mkdosfs"
Media byte 0xf8 (hard disk)
512 bytes per logical sector
4096 bytes per cluster
32 reserved sectors
First FAT starts at byte 16384 (sector 32)
2 FATs, 32 bit entries
3897344 bytes per FAT (= 7612 sectors)
Root directory start at cluster 2 (arbitrary size)
Data area starts at byte 7811072 (sector 15256)
974240 data clusters (3990487040 bytes)
62 sectors/track, 124 heads
0 hidden sectors
7809178 sectors total
Checking for unused clusters.
Checking free cluster summary.
/dev/usb1: 17 files, 174804/974240 clusters
```

If errors are detected, reformat the disk:

```
Switch:1#dos-format /usb
```

Reset a Transceiver

Reset a transceiver to simulate removal and reinsertion of the transceiver, which can be helpful in troubleshooting. For example, if authentication of the transceiver fails but you believe the transceiver is a qualified Extreme Networks part, you can reset the transceiver to begin the authentication process again.

Before You Begin

- Before you use the **pluggable-optical-module reset** command, ensure the port is administratively down to avoid link flaps.

About This Task

Resetting the transceiver stops traffic and triggers log messages similar to the removal and insertion of the transceiver.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```

2. Reset the transceiver:

```
pluggable-optical-module reset {slot/port[/sub-port]}
```

**Important**

Not all hardware platforms support these port types. For more information, see your hardware documentation.

Examples

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#pluggable-optical-module reset 1/41
Switch:1(config)#
CP1 [06/25/14 22:15:09.644] 0x0000c5e7 00300001.232 DYNAMIC SET GlobalRouter HW INFO Link

```

Variable Definitions

The following table defines parameters for the **pluggable-optical-module reset** command.

Variable	Value
{slot/port[/sub-port]}	Specifies location of the transceiver to reset. Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Initiate a Time Domain Reflectometer Diagnostic Test

About This Task**Note**

This procedure does not apply to 7720 Series. For model support, see *Fabric Engine and VOSS Feature Matrix*.

Perform this procedure to initiate a Time Domain Reflectometer (TDR) diagnostic test to detect defects on Ethernet cables or to determine the status and length of the cable pairs attached to copper ports on the switch. Use this functionality to diagnose a link with poor connectivity.

TDR cable diagnostic operates on administratively enabled ports only. You cannot initiate a TDR test on a port with Auto-Negotiation disabled.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Initiate the diagnostic test on a port:

```
tdr-test [port {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]  
[slot/all][all]]
```

Note

The following warning message displays to inform you that the TDR test impacts the traffic flow, if you continue. %WARNING: TDR test will impact the traffic flow. Do you want to continue (y/n) ?

3. Display the results of the TDR diagnostic test:

```
show tdr-test [port ]{slot/port[/sub-port]}[-slot/port[/sub-port]]  
[,...][slot/all][all]]
```

Example

Initiate the cable diagnostic test on port 1/1:

```
Switch:1#tdr-test port 1/1  
%WARNING: TDR test will impact the traffic flow.  
Do you want to continue (y/n)? y  
Test Started for port 1/1
```

Display the results of the cable diagnostic test on port 1/1:

```
Switch:1>show tdr-test port 1/1  
Port          1/1 (cable length accuracy +/- 10 meters)  
Port Status   Ok  
Pair1 Status   Ok  
Pair1 Length   4M  
Pair2 Status   Ok  
Pair2 Length   9M  
Pair3 Status   Ok  
Pair3 Length   9M  
Pair4 Status   Crosstalk  
Pair4 Length   4M
```

Initiate the cable diagnostic test on ports 1/1-1/2:

```
Switch:1#tdr-test port 1/1-1/2  
%WARNING: TDR test will impact the traffic flow.  
Do you want to continue (y/n)? y  
Test Started for port 1/1  
Test Started for port 1/2
```

Display the results of the cable diagnostic test on ports 1/1-1/3

```
Switch:1#show tdr-test port 1/1-1/3
Port                               1/1 (cable length accuracy +/- 10 meters)
Port Status                        Ok
Pair1 Status                       Ok
Pair1 Length                       4M
Pair2 Status                       Ok
Pair2 Length                       9M
Pair3 Status                       Ok
Pair3 Length                       9M
Pair4 Status                       Crosstalk
Pair4 Length                       4M

Port                               1/2 (cable length accuracy +/- 10 meters)
Port Status                        Ok
Pair1 Status                       Ok
Pair1 Length                       5M
Pair2 Status                       Ok
Pair2 Length                       2M
Pair3 Status                       Ok
Pair3 Length                       124M
Pair4 Status                       Ok
Pair4 Length                       4M

Port                               1/3 Cable diagnosis has not been performed on the specified port 1/3
```

Variable Definitions

The following table defines parameters for the **tdr-test** command.

Variable	Value
<code>port {slot/port[-slot/port][,...] [slot/all][all]}</code>	<p>Identifies the slot and port in one of the following formats:</p> <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all)

Hardware Troubleshooting using EDM

This section provides procedures to troubleshoot common hardware problems using Enterprise Device Manager (EDM).

Initiate a Time Domain Reflectometer Diagnostic Test

About This Task

Note

This procedure does not apply to 7720 Series. For model support, see *Fabric Engine and VOSS Feature Matrix*.

Perform this procedure to initiate a Time Domain Reflectometer (TDR) test to detect defects on Ethernet cables or to determine the status and length of the cable pairs attached to copper ports on the switch. Use this functionality to diagnose a link with poor connectivity.

TDR cable diagnostic operates on administratively enabled ports only. You cannot initiate a TDR test on a port with Auto-Negotiation disabled.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **TDR** tab.
5. Select **StartTest**.
6. Select **Apply**.
7. Select **Yes** to continue.
8. Select **Refresh** to display the results.

TDR Field Descriptions

Use data from the following table in the **TDR** tab.

Name	Description
StartTest	Enables the cable diagnostic test on the current port.
TestDone	Specifies whether the test is complete.
NormalCableLength	Specifies the cable length in meters.
CableLength	Specifies the length of the cable in meters based on the average electrical length of 4 pairs.
CableStatus	<p>Specifies the status of the cable as a summation of the status of the cable conductor pairs.</p> <ul style="list-style-type: none">• 1—Fail: the cable experiences any combination of open and shorted pairs.• 2—Normal: the cable operates without any faults

Name	Description
Pair#Status where # is the number of the pair. For example, Pair1Status .	Specifies the status of the pair. The following lists the states of the cables connected to a port or ports: <ul style="list-style-type: none"> • pairFail • pairNormal • pairOpen • pairShorted • pairNotApplicable • pairNotTested • pairForce • pinShort • pairUnknown • pairOpenShorted • pairCrossTalk
Pair#ErrLength where # is the number of the pair. For example, Pair1ErrLength .	Specifies the approximate distance to the break, measured in meters on the first pair.

Upper Layer Troubleshooting

Use the information in this section to troubleshoot upper layer problems.

Troubleshooting SNMP

About This Task

Troubleshoot Simple Network Management Protocol (SNMP) if the network management station (NMS) does not receive traps.

Verify the management configurations for the management station. Also verify the management station setup. If the management station can reach a device but not receive traps, verify the trap configurations (that is, the trap destination address and the traps to be sent).

If you enable enhanced secure mode, the switch does not support the default SNMPv1 and default SNMPv2 community strings, and default SNMPv3 user name. The individual in the administrator access level role can configure a non-default value for the community strings, and the switch can continue to support SNMPv1 and SNMPv2. The individual in the administrator access level role can also configure a non-default value for the SNMPv3 user name and the switch can continue to support SNMPv3. If you disable enhanced secure mode, the SNMPv1 and SNMPv2 support for community strings remains the same, and the default SNMPv3 user name remains the same. Enhanced secure mode is disabled by default.

Procedure

1. From the NMS, ping the IP address for the switch. If you can ping successfully, the IP address is valid and you may have a problem with the SNMP setup.
If you cannot ping the switch, you have a problem with either the path or the IP address.
2. Telnet to the switch.
If you can Telnet, the switch IP address is correct.
3. If Telnet does not work, connect to the console port using a serial line connection and ensure that the IP address configuration is correct.
4. If the management station is on a separate subnet, make sure that the gateway address and subnet mask are correct.
5. Using a management application, perform an SNMP Get request and an SNMP Set request (that is, try to poll the device or change a configuration using management software).
6. If you cannot reach the device using SNMP, access the console port, and then ensure that the SNMP community strings and traps are correct.
7. Use sniffer traces to verify that the switch receives the poll.
8. Use sniffer traces to verify that the NMS receives the response.
9. Verify that the data in the response is the data that was requested.

SNMP Trap not Received

Perform the following procedure to troubleshoot issues in which an SNMP trap is not received.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Show the BPDU Guard status for the port:
show spanning-tree bpduguard {slot/port[-slot/port][,...][slot/all]
[all]}
3. Configure the correct SNMP target information:
snmp-server host WORD<1-256> [port <1-65535>] v3 {noAuthNoPriv|
authNoPriv|authPriv WORD<1-32> [inform [timeout <1-2147483647>]
[retries <0-255>]] [filter WORD<1-32>]}

Example

In the following example, BPDU guard is enabled on port 1/8, BPDU packets are received, port 1/8 is disabled, and the TimerCount is incrementing, but no SNMP trap is ever received.

```
Switch:1>enable
Switch:1#show spanning-tree bpduguard 1/8
```

```
=====
Bpdu Guard
```

Port NUM	PORT MLTID	PORT ADMIN_STATE	PORT OPER_STATE	TIMEOUT	TIMER COUNT	BPDUGUARD ADMIN_STATE	BPDUGUARD ORIGIN
1/8		Down	Down	120	0	Disabled	CONFIG

Variable Definitions

The following table defines parameters for the **show spanning-tree** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...] [slot/all] [all]}</code>	<p>Identifies the slot and port in one of the following formats:</p> <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>

The following table defines parameters for the **snmp-server host** command.

Variable	Value
<code>filter WORD<1-32></code>	Specifies a filter profile name.
<code>host WORD<1-256></code>	Specifies the IPv4 or IPv6 host address
<code>inform [timeout <1-2147483647>]</code>	Specifies the notify type. The optional timeout parameter configures the timeout value, which specifies the time to wait for a reply before resending the inform message. Time is specified in centiseconds
<code>noAuthNoPriv authNoPriv authPriv WORD<1-32></code>	Specifies the security level.
<code>port <1-65535></code>	Specifies the port number that will be set as the destination port at the UDP level in the trap packet.
<code>retries <0-255></code>	Specifies the number of packets to be sent if no reply is received.
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...] [slot/all] [all]}</code>	<p>Identifies the slot and port in one of the following formats:</p> <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>

Troubleshooting DHCP

About This Task

Perform this procedure to troubleshoot the following Dynamic Host Configuration Protocol (DHCP) scenarios:

- The client cannot obtain a DHCP address when in the same subnet.
- The client cannot obtain a DHCP address when in a different subnet.

When the DHCP server and client are on the different subnets or VLANs, you must configure the device as a DHCP relay agent. The device must forward DHCP requests to the DHCP server. You must perform extra troubleshooting steps to troubleshoot the DHCP relay agent.

Procedure

1. Check the physical connectivity between the DHCP client and server.
2. Verify network connectivity by configuring a static IP address on a client workstation.
If the workstation still cannot reach the network, the problem is not DHCP. Start troubleshooting network connectivity.
3. Attempt to obtain an IP address from the DHCP server by manually forcing the client to send a DHCP request.
If the client obtains an IP address after the PC startup is complete, the issue is not the DHCP server.
4. Obtain an IP address on the same subnet or VLAN as the DHCP server.
If the issue persists, the problem may be with the DHCP server. If DHCP is working on the same subnet or VLAN as the DHCP server, the DHCP issue can be with the DHCP relay agent.
5. Confirm the DHCP relay agent configuration is correct.
6. Obtain sniffer traces where the traffic ingresses and egresses the switch and also on the client side of the network.
7. Check the logs on the switch for errors such as size exceeded or incorrect packet format.

Troubleshooting DHCP Relay

Before You Begin

- Configure the server to reply to the client subnet. Check the server configuration file to verify the configuration.
- Configure a route on the server for the client subnet to create a path on which to send replies.

About This Task

Perform this procedure to troubleshoot the DHCP relay agent.

Procedure

1. Verify that the interfaces that link the client and server are up, and that the ports are in the forwarding state.

- a. To verify client availability, you can configure a temporary static IP address on the client, and then use the ping command.

```
ping WORD<0-256>
```

- b. To verify the port is in the forwarding state, use the following command for the slot and port number:

```
show spanning-tree [rstp|mstp] port role [{slot/port[-slot/port]}
[,...][slot/all][all]]
```

If STP detects loops in the configuration, it blocks ports to avoid flooding in the network. In this situation, the port is not in the forwarding state.

2. Ensure that DHCP is enabled on the client interface and that a valid forwarding path exists and is enabled. Ensure the server is reachable.
3. View the statistics counters for the relay.
4. If request or reply counters do not increase, use a sniffer tool to ensure that the client sends the packets, and that the interface module receives the packets.

You can configure mirroring for the ingress port to verify if the packets reach the module.

- a. If the client sends the packets, check that the packets reach the CPP and search the trace results for the ingress port:

```
trace level 9 3
```

```
trace grep WORD<0-128>
```

- b. If the packets reach the CPP, check that they reach the DHCP protocol; check for errors or packet drop messages:

```
trace level 170 3
```

```
trace grep WORD<0-128>
```

5. If Option 82 is enabled, check the statistic counters for dropped packets, and perform a trace for the DHCP protocol:

```
trace level 170 3
```

Example

```
Switch:1#ping 192.0.2.31
```

```
Switch:1:#show spanning-tree mstp port role
```

CIST Port Roles and States				
Port-Index	Port-Role	Port-State	PortSTPStatus	PortOperStatus

--More-- (q = quit)
Switch:1:#trace level 9 3
Switch:1:#trace grep 00-1A-4B-8A-FB-6B

```

Variable Definitions

Use the data in the following table to use the troubleshooting commands in this procedure.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...][slot/all][all]}</code>	<p>Identifies the slot and port in one of the following formats:</p> <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>
<code>WORD<0-128></code>	Specifies the text string to use as the search criterion.
<code>WORD<0-256></code>	Specifies the IP address.

Troubleshoot Client Connection to the DHCP Server

About This Task

Perform this procedure if the client cannot reach the DHCP server.

Procedure

1. Check that the DHCP relay agent in the network switch is correctly configured.
2. Check that the DHCP server configuration is correct.
3. Check for routing issues.

The routing in the network may not be configured so that DHCP request and reply packets are propagated. You can use ping and traceroute.

4. Check that the DHCP pools are correctly configured.
5. If the client cannot reach the server because the link is down, enable auto-negotiation on the link.

Troubleshooting IPv6 DHCP Relay

The following sections provide troubleshooting information for IPv6 DHCP Relay.

IPv6 DHCP Relay Switch Side Troubleshooting

With DHCP Relay, the switch only participates in forwarding the requests and replies to and from the client and the DHCP server. The switch always acts as the relay agent, on which you configure the forward path to the server.

To troubleshoot DHCP Relay issues on the switch, use the following procedure.

Procedure

1. Verify that the DHCP server is reachable using ping. If ping is working and the DHCP server is reachable, DHCP should work.
2. Verify that the relay agents and the forward path configured are reachable. Ping the server and the gateway to the server.
3. Check that the relay agent configurations are correct. Also verify that DHCP is enabled on the switch:

```
show ipv6 dhcp-relay interface {gigabitEthernet {slot/port[/sub-port]}
[-slot/port[/sub-port]][,...][slot/all][all]}|vlan <1-4059>
```

4. Verify that IPv6 forwarding is enabled globally:
5. Verify that the IPv6 based VLAN where the DHCP relay agent is configured is enabled:
6. In a scenario with VRRP and SMLT, configure VRRP IP as the DHCP relay agent.
7. When using the VRRP VRID as the relay agent, make sure the VRRP configurations are proper.
8. To verify that relay forward and relay receive are working, enable trace for DHCP with IPv6, and grep trace for relay:

```
trace level 66 3
```

```
trace grep relay
```

```
trace screen enable
```

9. Display the count of DHCP Relay requests and replies to verify the system received requests and replies:

```
show ipv6 dhcp-relay counters
```

IPv6 DHCP Relay Server Side Troubleshooting

Use the following procedure to troubleshoot IPv6 DHCP Relay on the server side.

Procedure

1. Enable the services on the server side, and then create an IP pool.
The IP pool must contain the range of addresses that you want to assign to the clients.

Configure the IP pool with the same network subnet as that of the relay agent.

2. When the configuration is complete, initiate a DHCP request from a client.
3. Check the log file available on the server to verify the reason for packet drop.

4. Capture the packets on the server side using Ethereal.
5. From the server side, use ping to verify that the relay agent address is reachable.
Ensure that a route to the relay is configured.
6. For more configuration aspects, see the Microsoft webpage for troubleshooting and configuration issues.

**Note**

You can receive some log messages that indicate the system cannot forward packets. However, certain situations are not DHCP failures.

Example 1: if you receive the message `0x00108796 (relayMsgSend)`: cannot find route entry for destination on the console, you must ping the server. If the server is not reachable, the system cannot forward the packet. This is not a DHCP issue.

Example 2: if you receive the message `0x00108705` this indicates a problem at the transmission level. Check the server reachability and ensure that MAC learning is correct before you pursue DHCP issues.

IPv6 DHCP Relay Client Side Troubleshooting

You can collect a client console dump, which can be used to analyze why the received packet cannot be processed and the allocated address cannot be used by the client.

In addition, restarting the client can also fix the issue in some cases.

Make sure the client supports IPv6 requests.

Connect the server directly to the client. If the IP is assigned, then the problem is with the relay.

Enable Trace Messages for IPv6 DHCP Relay

Use this procedure to enable trace for IPv6 DHCP Relay and enable IPv6 forwarding trace.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. To troubleshoot IPv6 DHCP Relay, you can enable rcip6 trace messages using the following command:
`trace level 66 3`
3. You can also enable IPv6 forwarding trace using the following command:
`trace ipv6 forwarding enable <all|debug|error|info|pkt|warn>`

Example

Enable rcip6 trace messages and enable IPv6 forwarding trace:

```
Switch:1>enable
Switch:1#trace level 66 3
Switch:1#trace ipv6 forwarding
```

Troubleshooting TACACS+

The switch supports the Terminal Access Controller Access Control System plus (TACACS+) client. TACACS+ is a remote authentication protocol that provides centralized validation of users who attempt to gain access to a router or network access server (NAS). The TACACS+ feature is disabled by default.

The switch implementation of TACACS+ does not support:

- Earlier versions of TACACS
- Point-to-Point Protocol (PPP) authentication and accounting
- IPv6 addresses

See the following sections to troubleshoot TACACS+.

Unable to Log On Using Telnet

If you cannot log on using Telnet, perform the following steps.

Procedure

1. Check whether the TACACS+ server is available or unreachable.
2. On the TACACS+ server, check whether you configured the privilege level correctly. On successful authorization, the TACACS+ server returns an access level to the switch for the current user, which determines the user access privileges. The switch supports access levels 1 to 6 and access level 15.

The following table maps user accounts to TACACS+ privilege level.

Switch access level	TACACS+ privilege level	Description
NONE	0	If the TACACS+ server returns an access level of 0, the user is denied access. You cannot log into the device if you have an access level of 0.
READ ONLY	1	Permits you to view only configuration and status information.
LAYER 1 READ WRITE	2	Permits you to view most of the switch configuration and status information and change physical port settings.
LAYER 2 READ WRITE	3	Permits you to view and change configuration and status information for Layer 2 (bridging and switching) functions.
LAYER 3 READ WRITE	4	Permits you to view and change configuration and status information for Layer 2 and Layer 3 (routing) functions.

Switch access level	TACACS+ privilege level	Description
READ WRITE	5	Permits you to view and change configuration and status information across the switch. This level does not allow you to change security and password settings.
READ WRITE ALL	6	Permits you to have all the rights of read-write access and the ability to change security settings, including command line interface (CLI) and web-based management user names and passwords, and the SNMP community strings.
NONE	7 to 14	If the TACACS+ server returns an access level of 7 to 14, the user is denied access. You cannot log into the device if you have an access level of 7 to 14.
READ WRITE ALL	15	<p>Permits you to have all the rights of read-write access and the ability to change security settings, including command line interface (CLI) and web-based management user names and passwords, and the SNMP community strings.</p> <p>Note: Access level 15 is internally mapped to access level 6, which ensures consistency with other vendor implementations. The switch does not differentiate between an access level of 6 and an access level of 15.</p>

After you enable TACACS+ authorization, the current privilege-level to command mapping on the switch is no longer relevant because the TACACS+ server has

complete responsibility for command authorization. TACACS+ authorization provides access to the system based on user name, not based on privilege level.

Note

If you want to switch to a privilege level 'X' using **tacacs switch level <1-15>** command, you must create a user "\$enabX\$" on the TACACS+ server. X is the privilege level that you want to change.

3. On the TACACS+ server, check whether you configured the password and user name correctly.
4. On the TACACS+ server, check whether you configured the switch IP address in the trust list.
5. Check whether you configured the encryption key, connection mode (single connection or per-session connection), and TCP port number the same on the TACACS+ server and switch.
6. If you can log on to the switch, check whether the TACACS+ server configured on the platform has the correct IP address:

```
show tacacs
```

7. Use the output from the **show tacacs** command to verify whether you configured the single connection option on the platform, and whether the TACACS+ server supports the single connection.

Example

Check whether the TACACS+ server configured on the platform has the correct IP address:

```
Switch:1>enable
Switch:1(config)#show tacacs

Global Status:

    global enable : false

    authentication enabled for : cli

    accounting enabled for : none

    authorization : disabled

    User privilege levels set for command authorization : None

Server:

    create :

Backup  NotConn ***** 47   198.51.100.1  10    false 0.0.0.0   false
```

Unable to Log On Using SSH

If you cannot log on using Secure Shell (SSH), perform the following steps.

Procedure

1. Verify that the network, the switch, and the TACACS+ server is reachable.
2. Verify whether you configured the SSH client correctly.
3. Verify whether you enabled and configured the SSH function correctly on the switch:

```
show ssh global
```

Example

Verify whether you enabled and configured SSH function correctly on the switch:

```
Switch:1(config)#show ssh global
Total Active Sessions      : 1
version                   : v2only

                           diffie-hellman-group18-sha512
```

Unable to Log On by any Means

If you cannot log on by any means, perform the following steps.

Procedure

1. Check whether the TACACS+ server runs properly and try to restart the TACACS+ server.
2. Check whether you enabled both TACACS+ and RADIUS on the switch.

```
show radius
```

```
show tacacs
```

If TACACS+ fails, RADIUS can take over the authentication, authorization, and accounting (AAA) process.

3. Check whether you configured the TACACS+ server to unencrypted mode, as the switch always sends encrypted TACACS+ messages.

4. Check whether you configured the switch properly.

Note

In particular, check the IP address and key.

```
show tacacs
```

5. Check whether you configured the encryption key, connection mode (single connection or per-session connection), and TCP port number the same on the TACACS+ server and switch.
6. If the server connects directly, check whether the administrative and operation status of the port is up:

```
show interfaces gigabitethernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]
```

7. If the server is connected in a network, check whether the switch has a route configured to the server network:

```
show ip route
```

8. If the server is connected in a network, check whether the switch has a route configured to the server network:

```
show ip route
```

```
show ipv6 route
```

9. For the Out-of-Band (OOB) or VLAN Segmented Management Instance, check whether the switch has a route configured to the server network:

```
show mgmt ip route
```

```
show mgmt ipv6 route
```

```
show mgmt ip route static
```

10. For Segmented Management Instance troubleshooting, check the management network statistics:

```
show mgmt ip arp
```

```
show khi mgmt statistics
```

```
show mgmt ip ip-statistics
```

```
show mgmt ip icmp-statistics
```

Examples

Check if you enabled both TACACS+ and RADIUS on the switch:

```
Switch:1>enable
Switch:1(config)#show tacacs

Global Status:

  global enable : false

  authentication enabled for : cli

  accounting enabled for : none
```

```

authorization : disabled

User privilege levels set for command authorization : None

Server:

                create :

Prio   Status  Key      Port  IP address  Timeout Single Source SourceEnabled
Primary NotConn ***** 3    192.0.2.254    30   true 5.5.5.5   true
Backup  NotConn ***** 47   198.51.100.1   10  false 0.0.0.0   false

Switch:1>show radius
      acct-attribute-value : 193
      acct-enable : false
      acct-include-cli-commands : false
      access-priority-attribute : 192
      auth-info-attr-value : 91
      command-access-attribute : 194
      cli-commands-attribute : 195
      cli-cmd-count : 40
      cli-profile-enable : false
      enable : false
      igap-passwd-attr : standard
      igap-timeout-log-fsize : 512
      maxserver : 10
      mcast-addr-attr-value : 90
      supported-vendor-ids : 1584, 562, 1916
      secure-flag : false

```

Check if the administrative and operation status of the port is up:

```

Switch:1#show interfaces gigabitethernet 1/2

Administrator Unable to Obtain Accounting Information from the TACACS+ Server

If the administrator is unable to obtain accounting information from the TACACS+ server, perform the following steps.

Procedure

1. Check whether you enabled accounting on the switch:

```
show tacacs
```
2. Check whether you enabled accounting on the TACACS+ server.

Example

Check whether accounting is enabled on the switch:

```
Switch:1>enable
Switch:1(config)#show tacacs

Global Status:

global enable : false
```

```

authentication enabled for : cli

accounting enabled for : none

authorization : disabled

User privilege levels set for command authorization : None

Server:

                create :

```

Trap Server Cannot Receive Trap Packets from the Switch

If the trap server cannot receive trap packets from the switch, perform the following steps.

Procedure

1. Check whether you configured the trap server correctly on the switch:

```
show snmp-server host
```
2. Check whether a firewall exists between the switch and the trap server.

Example

Check whether you configured the trap server correctly on the switch:

```

Switch:1>enable
Switch:1#show snmp-server host

Troubleshoot TACACS+ Problems

Use the **trace level** command to check traps and log files to see any TACACS+ failure. If TACACS+ experiences failure conditions, the TACACS+ module sends SNMP traps to notify the user. The TACACS+ module also logs the failure information into the system log file.

About This Task

Caution

Using the trace tool inappropriately can cause CPU lockup conditions, loss of access to the device, loss of protocols, and service degradation. If you use trace level 3 (verbose) or trace level 4 (very verbose), do not use the screen to view commands due to the volume of information the system generates and the effect on the system.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Configure the trace level for the TACACS+ module:
trace level 109 <1-4>

The TACACS+ module ID is 109.

3. Stop trace:

```
trace shutdown
```

4. View the trace results on screen:

```
trace screen enable
```

5. View trace saved to a file:

```
show trace file [tail]
```

6. Save the trace file to the Compact Flash card for retrieval:

```
save trace [file WORD<1-99>]
```

If you do not specify a file name, the file name is systrace.txt. By default, the system saves the file to the external flash.

7. Save the trace file for retrieval:

```
save trace [file WORD<1-99>]
```

If you do not specify a file name, the file name is systrace.txt.

Variable Definitions

The following table defines parameters for the **trace** command.

Variable	Value
<i>level</i> [<Module_ID>] [<1-4>]	Starts the trace by specifying the module ID and level. Module ID 23 represents the IGMP module <Module_ID> specifies the module for the trace. Different hardware platforms support different IDs because of feature support differences. For feature support information, see <i>Fabric Engine and VOSS Feature Matrix</i> . To see the list of module IDs, use the show trace modid-list command or CLI command completion Help. <0-4> specifies the trace level: <ul style="list-style-type: none"> • 0 — Disabled • 1 — Very terse • 2 — Terse • 3 — Verbose • 4 — Very verbose
<i>shutdown</i>	Stops the trace operation.
<i>screen</i> {disable enable}	Enables or disables the display of trace output to the screen. Important: As a best practice, avoid using the screen to view commands if you use trace level 3 (verbose) or trace level 4 (very verbose) due to the volume of information generated and the effect on the system.

The following table defines parameters for the **show trace** command.

Variable	Value
<i>file [tail]</i>	Displays the trace results saved to a file.
<i>level</i>	Displays the current trace level for all modules.
<i>modid-list</i>	Specifies the module ID list.

Use BGP Debugging Commands

Use global and peer debug commands to display specific debug messages for the global and peer Border Gateway Protocol (BGP) configuration, including the BGP neighbors.

You can use these commands to troubleshoot the BGP configuration.

Procedure

1. Enter BGP Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router bgp
```
2. Show specific debug messages for the global BGP configuration:

```
global-debug mask WORD<1-100>
```
3. Display specific debug messages for the global BGP neighbors:

```
neighbor-debug-all mask WORD<1-100>
```
4. Display specific debug messages for BGP peers or peer groups:

```
neighbor <nbr_ipaddr|peer-group-name> neighbor-debug-mask WORD<1-100>
```
5. Display debug messages on the console:

```
debug-screen <on|off>
```

Example

Display the global debug messages for error and packet:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router bgp
Switch:1(router-bgp)#global-debug mask error,packet
```

End (disable) the display of global debug messages:

```
Switch:1(router-bgp)#global-debug mask none
```

Display specific debug messages for the global BGP neighbors:

```
Switch:1(router-bgp)#neighbor-debug-all mask packet,event
```

Display specific debug messages for BGP peers or peer groups:

```
Switch:1(router-bgp)#neighbor 192.0.2.10 neighbor-debug-mask event,trace
```

Display debug messages on the console:

```
Switch:1(router-bgp)#debug-screen on
```

Variable Definitions

The following table defines parameters for the **global-debug mask** and **neighbor-debug-all mask** commands.

Variable	Value
<i>WORD<1-100></i>	Specifies one or more mask choices that you enter, separated by commas with no space between choices. For example: [<mask>,<mask>,<mask>...]. Options include: none, all, error, packet, event, trace, warning, state, init, filter, update.

The following table defines parameters for the **neighbor** command.

Variable	Value
<i><nbr_ipaddr peer-group-name></i>	Specifies the IP address or the group name of the peer.
<i>WORD<1-100></i>	Specifies one or more mask choices that you enter, separated by commas with no space between choices. For example: [<mask>,<mask>,<mask>...]. Options include: none, all, error, packet, event, trace, warning, state, init, filter, update.

Job Aid

Use debug command values to control debug messages for global BGP message types, and for message types associated with a specified BGP peer or peer group. The following table identifies mask categories and messages.

Table 333: Mask categories and messages

Mask category	Message
none	None disables the display of all debug messages.
all	All configures the device to show all categories of debug messages.
error	Error configures the device to show error debug messages.
packet	Packet configures the device to show packet debug messages.
event	Event configures the device to show event debug messages.
warning	Warning configures the device to show warning debug messages.

Table 333: Mask categories and messages (continued)

Mask category	Message
init	Init configures the device to show initialization debug messages.
filter	Filter configures the device to show filter-related debug messages.
update	Update configures the device to show update-related debug messages.

Virtual Link Aggregation Control Protocol

Virtual Link Aggregation Control Protocol

Use Virtual Link Aggregation Control Protocol (VLACP) as an extension to LACP for end-to-end failure detection. VLACP is not a link aggregation protocol, it is a mechanism to periodically check the end-to-end status of a point-to-point connection. VLACP uses the Hello mechanism of LACP to periodically send Hello packets to ensure end-to-end communication. After Hello packets are not received, VLACP transitions to a failure state, which indicates a service provider failure and that the port is disabled.

The VLACP only works for port-to-port communications where there is a guarantee for a logical port-to-port match through the service provider. VLACP does not work for port-to-multiport communications where there is no guarantee for a point-to-point match through the service provider. You can configure VLACP on a port.

You can also use VLACP with MLT to complement its capabilities and provide quick failure detection.

VLACP trap messages are sent to the management stations if the VLACP state changes. If the failure is local, the only traps that are generated are port linkdown or port linkup.

The Ethernet cannot detect end-to-end failures. Functions such as remote fault indication or far-end fault indication extend the Ethernet to detect remote link failures. A major limitation of these functions is that they terminate at the next Ethernet hop. They cannot determine failures on an end-to-end basis.

For example, in [Figure 242](#), after the Enterprise networks connect the aggregated Ethernet trunk groups through a service provider network connection (for example, through a VPN), far-end failures cannot be signaled with Ethernet-based functions that operate end-to-end through the service provider network. The multilink trunk (between Enterprise switches S1 and S2) extends through the Service Provider (SP) network.

The following illustration shows an MLT running with VLACP. VLACP can operate end-to-end, but you can also use it as a point-to-point link.

Figure 242: Problem description (1 of 2)

In the following illustration, if the Layer 2 link on S1 (S1/L2) fails, the link-down failure is not propagated over the SP network to S2 and S2 continues to send traffic over the failed S2/L2 link.

Figure 243: Problem description (2 of 2)

Use VLACP to detect far-end failures, which causes MLT to failover if end-to-end connectivity is not guaranteed for links in an aggregation group. VLACP prevents the failure scenario.

The switch software uses the following VLACP timers:

- fast periodic timer—100 to 20 000 ms; default 200 ms
- slow periodic timer—10 000 to 30 000 ms; default 30 000 ms

VLACP Considerations

Use the information in this section to understand the considerations while configuring VLACP into your network.

- If a VLACP-enabled port does not receive a VLACP Data Unit (VLACPDU), it must enter the disabled state. There are occasions where a VLACP-enabled port does not receive a VLACPDU but remains in the forwarding state. To avoid this situation, ensure that the VLACP configuration at the port level is consistent. You must either enable or disable both sides of the point-to-point connection.
- If VLACP is enabled on a MACsec Key Agreement-enabled link, it takes approximately 30 seconds for the VLACP session to begin.

You can configure VLACP on each port. The port can be either an individual port or an MLT member. VLACPDUs can be sent periodically on each port where VLACP is enabled to exchange VLACPDUs from an end-to-end perspective. If VLACPDUs are not received on a particular link, that link is taken down after the expiry timeout occurs (timeout scale x periodic time).

VLACP Flap Detect and Damping

When there is instability or packet loss in a connection, the Virtual Link Aggregation Control Protocol (VLACP) state of the port flaps, causing services such as IP multicast to stop and start rapidly. This behavior causes system-wide instability, including high CPU utilization. In such cases, VLACP Flap Detect and Damping provides link flap detection capability, by configuring a specific time interval and frequency to count the number of VLACP flaps. After the system detects excessive VLACP flaps, it disables the specific VLACP port until the root cause is resolved.

For example, VLACP Flap Detect and Damping detects 3 VLACP flaps within 60 seconds, by default. After the system detects the first VLACP flap, the flap timer starts to count the number of VLACP flaps occurring within 60 seconds. If the flap count reaches 3 before the timer ends, the system disables the specific VLACP port, and generates a Simple Network Management Protocol (SNMP) trap. For more information about SNMP traps, see [Logs and Traps Fundamentals](#) on page 2536.

If you view the port state information, the port displays as operationally down and the reason provided is VLACP_FLAP. The following example shows a port that is disabled because of VLACP flapping; only the relevant sections of the show command output is included.

```
Switch:1#show interfaces gigabitethernet 1/1
```

Port Interface									
PORT NUM	INDEX	DESCRIPTION	LINK TRAP	PORT LOCK	MTU	PHYSICAL ADDRESS	STATUS		
							ADMIN	OPERATE	
1/1	192	1000BaseTX	true	false	1950	e4:5d:52:3c:64:00	up		down

Port State					
PORT NUM	ADMINSTATUS	PORTSTATE	REASON	DATE	
1/1	up	down	VLACP_FLAP	09/19/19 02:22:58	

Note

VLACP Flap Detect and Damping does not support auto-recovery of VLACP ports; you must reenab the ports manually.

VLACP Flap Detect and Damping Considerations

Use the following information when configuring VLACP Flap Detect and Damping.

- Do not enable VLACP Flap Detect and Damping on Link Aggregation Control Protocol (LACP) enabled ports.

Note

Link flap detection takes priority if you enable both VLACP Flap Detect and Damping and link flap detection on the same port.

VLACP Configuration using CLI

Configure Virtual LACP (VLACP) to implement link status control protocol at the port level. VLACP detects end-to-end failures in the switch. Virtual LACP cannot interoperate with Link Aggregation Control Protocol (LACP).

Configure VLACP on a Port

Configure VLACP on a port to ensure there is end-to-end reachability. VLACP uses the Hello mechanism of LACP to periodically send Hello packets to ensure there is

an end-to-end approach. After Hello packets are not received, VLACP transitions to a failure state and disables the port.

Important

Changes made at the global level override and reset all port level settings.

About This Task

Use the following information to prevent flooding VLACP packets across a defaulted switch:

- Use the default MAC address, 01:80:c2:00:11:00, for end-to-end connections that traverse an intermediate network.
- Use the reserved multicast MAC address 01-80-c2-00-00-0f for directly-connected, peer-to-peer links.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...][slot/all][all]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure optional parameters for the port. If you do not configure these parameters, the system uses the default values.

- a. Configure the protocol identification for the port:

```
vlacp ethertype <1536-65535 | 0x600-0xffff> [funcmac-addr  
0x00:0x00:0x00:0x00:0x00:0x00]
```

- b. Configure the fast or slow periodic times:

```
vlacp fast-periodic-time <100-20000> | slow-periodic-time  
<10000-30000>
```

You can configure both parameters in the same command entry.

- c. Configure the timeout parameters:

```
vlacp timeout <long|short> timeout-scale <2-10>
```

You can configure both parameters in the same command entry.

3. Enable VLACP on a port:

```
vlacp enable
```

Example

Configure VLACP on port 1/1:

```
Switch:1#configure terminal
Switch:1#interface GigabitEthernet 1/2
Switch:1#vlacp fast-periodic-time 400 timeout short
Switch:1#vlacp enable
```

Variable Definitions

Use the data in the following table to help you use the **vlacp** command.

Variable	Value
<i>enable</i>	Enables VLACP for this port. The default is disabled.
<i>ethertype</i> <1536-65535 0x600-0xffff>	Configures the VLACP protocol identification for this port. Enter the type in decimal or hexadecimal format. The default is 0x8103.
<i>fast-periodic-time</i> <100-20000>	Configures the fast periodic time (in milliseconds) for this port. The default is 200.
<i>funcmac-addr</i> <0x00:0x00:0x00:0x00:0x00:0x00>	Configures the multicast MAC address used for the VLACPDU. Specify a MAC address in the format 0x00:0x00:0x00:0x00:0x00:0x00. The default is 01:80:c2:00:11:00.
<i>slow-periodic-time</i> <10000-30000>	Configures the slow periodic time (in milliseconds) for a specific port type. The default is 30,000.
<i>timeout</i> {long short}	Configures the port to use the long or short timeout: <ul style="list-style-type: none"> <i>long</i> sets the port to use the timeout-scale value multiplied by the slow periodic time. <i>short</i> sets the port to use the timeout-scale value multiplied by the fast periodic time. <p>For example, if you specify a short timeout, set the timeout-scale value to 3, and the fast periodic time to 400 ms, the timer expires within 1000 to 1200 ms. The default is long.</p>
<i>timeout-scale</i> <2-10>	Configures a timeout scale for this port used to calculate the timeout. The default value is 3.

View the VLACP Port Configuration

View the VLACP port configuration to show the port VLACP configuration.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the VLACP port configuration for all interfaces:

```
show vlacp interface gigabitethernet [vid <1-4059>] [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]]
```

Example

```
Switch:1>show vlacp interface gigabitethernet

Variable definitions

Use the data in the following table to use the **show vlacp interface gigabitethernet** command.

Variable	Value
<code>vid <1-4059></code>	<p>Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.</p> <p>The VLAN ID is in one of the following formats: A single VLAN ID (vlan-id), a range of VLAN IDs [(vlan-id)-(vlan-id)] or a series of VLAN IDs (vlan-id, vlan-id, vlan-id).</p>
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...] [slot/all] [all]}</code>	<p>Specifies a port or list of ports to show only the VLACP information for those ports. Identifies the slot and port in one of the following formats:</p> <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>

Display VLACP Statistics for Specific Ports

Display VLACP statistics for specific ports to manage network performance.

About This Task

You can enable sequence numbers for each VLACPDU to assist in monitoring performance. The switch counts mismatched PDU sequence numbers to determine packet loss information. By default, sequence numbers are enabled.

You can use the show commands from Privileged EXEC mode but must enter Global Configuration mode to enable or disable the sequence numbers.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Confirm sequence numbers are enabled:

```
show vlacp
```
3. (Optional) Enable sequence numbers for VLACPDUs:

```
vlacp sequence-num
```
4. View VLACP statistics:

```
show interfaces gigabitEthernet statistics vlacp [{slot/port[/sub-port]
[-slot/port[/sub-port]][,...]} ]
```
5. (Optional) View VLACP statistics history:

```
show interfaces gigabitEthernet statistics vlacp history [{slot/port[-slot/port]
[,...][slot/all][all]]}
```
6. (Optional) Clear VLACP statistics:

```
clear vlacp stats [port {slot/port[-slot/port][,...][slot/all][all]]}
```
7. (Optional) Disable sequence numbers for VLACPDUs:

```
no vlacp sequence-num
```

Example

Determine if sequence numbers are enabled, and then view port statistics. Port numbering may differ depending on your product and configuration.

```
Switch:1(config)#show vlacp
```

```
=====
```

```
                        Vlacp Global Information
```

```

```
=====
```

Variable Definitions

Use the data in the following table to use the commands in this procedure.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...] [slot/all] [all]}</code>	<p>Identifies the slot and port in one of the following formats:</p> <ul style="list-style-type: none">• a single slot and port (slot/port)• a range of slots and ports (slot/port-slot/port)• a series of slots and ports (slot/port,slot/port,slot/port)• all ports on the same slot (slot/all)• all ports on the switch (all) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>

Configure VLACP Globally

Use VLACP as an extension to LACP for end-to-end failure detection. Enable or disable VLACP globally to reset the port level configuration. The default is disabled.

About This Task

Important

Changes you make at the global level override and reset all port level settings.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable VLACP globally:

```
vlACP enable
```

Configure VLACP Flap Detect and Damping on a Port

Before You Begin

- To configure VLACP Flap Detect and Damping on sub-ports, enable channelization. For more information about channelization, see [Channelization](#) on page 704.
- As a best practice, to modify an existing VLACP Flap Detect and Damping configuration, first disable VLACP on the interface.

About This Task

Perform the following procedure to control link state changes on VLACP ports. By default, VLACP Flap Detect and Damping is disabled on all VLACP ports.

Important

Do not enable VLACP Flap Detect and Damping on Link Aggregation Control Protocol (LACP) enabled ports.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port]}[-slot/port[/sub-port]]
[,...][slot/all][all]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable VLACP Flap Detect and Damping on the specified port:

```
vlACP flap-detect enable
```

3. Configure the time interval (in seconds) to record VLACP flaps:

```
vlACP flap-interval <10-600>
```

4. Configure the VLACP flap frequency:

```
vlACP flap-frequency <3-30>
```

5. View VLACP Flap Detect and Damping configuration on the specific port:

```
show vlACP interface gigabitEthernet {slot/port[/sub-port]}[-slot/
port[/sub-port]][,...][slot/all][all]}
```

Example

Configure VLACP Flap Detect and Damping on port 1/3:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/3
Switch:1(config-if)#vlACP flap-detect enable
Switch:1(config-if)#vlACP flap-interval 120
Switch:1(config-if)#vlACP flap-frequency 6
Switch:1(config-if)#show vlACP interface gigabitEthernet 1/3
```

VLACP Information									
INDEX	ADMIN ENABLED	OPER ENABLED	PORT STATE	FAST TIME	SLOW TIME	TIMEOUT TIME	TIMEOUT SCALE	ETHER TYPE	MAC ADDR
1/3	false	false	DOWN	200	30000	long	3	0x8103	01:80:c2:00:11:00
VLACP Flap Detect Information									

INDEX	FLAP DETECT	FLAP FREQ	FLAP INTERVAL	TOTAL FLAP	FIRST-FLAP TIME	LAST-FLAP TIME
1/3	enable	6	120	6	01/03/19 15:11:52	01/03/19 15:12:12

Variable Definitions

Use data in the following table to use the **vlacp** command.

Variable	Value
<i>flap-detect enable</i>	Enables VLACP Flap Detect and Damping on the specified port. By default, VLACP Flap Detect and Damping is disabled on all ports.
<i>flap-interval<10-600></i>	Configures VLACP Flap Detect and Damping time interval in seconds. The default value is 60 seconds.
<i>flap-frequency<3-30></i>	Configures the VLACP Flap count permitted during the configured time interval. The default value is 3.

Clear VLACP Flap Detect and Damping Statistics for a Port

Perform the following procedure to clear the VLACP Flap Detect and Damping statistics for a specific VLACP port or all VLACP ports on the switch.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Clear VLACP Flap Detect and Damping statistics:
clear vlapc flap-stats port [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]]

Example

```
Switch:1>enable
Switch:1#clear vlapc flap-stats port 2/1
```

Variable Definitions

Use data in the following table to use the **clear vlacp flap-stats** command.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...] [slot/all] [all]}</code>	<p>Identifies the slot and port in one of the following formats:</p> <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>

VLACP Configuration using EDM

Configure Virtual LACP (VLACP) to implement link status control protocol at the port level. VLACP cannot interoperate with Link Aggregation Control Protocol (LACP).

Enable VLACP Globally

About This Task

Enable VLACP globally to detect for end-to-end failure. VLACP uses the Hello mechanism of LACP to periodically send Hello packets to ensure there is an end-to-end approach. After Hello packets are not received, the VLACP transitions to a failure state and the port is disabled.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **MLT/LACP**.
3. Select the **VLACP Global** tab.
4. Select **VlacpEnable**.
5. Select **Apply**.

VLACP Global Field Descriptions

Use the data in the following table to use the **VLACP Global** tab.

Name	Description
VlacpEnable	Enables VLACP globally. The default is disabled.

Configure VLACP on a Port

Perform the following procedure to enable VLACP on a port. VLACP periodically checks the end-to-end condition of a point-to-point connection. You can also configure VLACP Flap Detect and Damping to control link state changes on VLACP ports. By default, VLACP Flap Detect and Damping is disabled on all VLACP ports.

Important

Changes made at the global level override and reset all port level settings.

Before You Begin

- To configure VLACP Flap Detect and Damping on sub-ports, enable channelization.
- As a best practice, to modify an existing VLACP or VLACP Flap Detect and Damping configuration, first disable VLACP on the interface.

About This Task

Use the following information to prevent flooding VLACP packets across a defaulted switch:

- Use the default MAC address, 01:80:c2:00:11:00, for end-to-end connections that traverse an intermediate network.
- Use the reserved multicast MAC address 01-80-c2-00-00-0f for directly-connected, peer-to-peer links.

Procedure

1. On the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **VLACP** tab.
5. Configure the parameters, as required.
6. Select **Apply**.

VLACP Field Descriptions

Use data in the following table to use the **VLACP** tab.

Name	Description
AdminEnable	Enables VLACP for the port. The default is disabled.
OperEnable	Specifies the VLACP operational status for the port. The default is false.
FastPeriodicTimer	Specifies the number of milliseconds between periodic transmissions using short timeouts. Use the same value for all LACP-enabled ports. The default value is 200.

Name	Description
SlowPeriodicTimer	Specifies the number of milliseconds between periodic transmissions using long timeouts. Use the same value for all LACP-enabled ports. The default value is 30000.
Timeout	Specifies the timeout control value. Specify long or short timeout. The default value is long.
TimeoutScale	Assigns the value used to calculate timeout from the periodic time for all VLACP-enabled ports. $\text{Timeout} = \text{PeriodicTime} \times \text{TimeoutScale}$. The default value is 3.
EtherType	Specifies the VLACP identification. The ID is in hexadecimal format. The default value is 0x8103.
EtherMacAddress	Specifies the multicast MAC address exclusively used for VLACPDUs. The default is 01:80:c2:00:11:00.
PortState	Specifies the VLACP port state.
FlapDetectEnable	Enables VLACP Flap Detect and Damping on the port. By default, VLACP Flap Detect and Damping is disabled on all ports.
FlapFrequency	Specifies the number of VLACP flaps detected on the port. The port is shut down if the recorded flaps are within the configured time interval. The default value is 3.
FlapInterval	Specifies the time interval (in seconds) during which the VLACP flaps on the port are monitored. The default value is 60 seconds.
TotalFlapCount	Shows the total number of VLACP flaps detected on the port since you enabled VLACP Flap Detect and Damping or cleared the counters and timers.
FirstFlapTimeStamp	Shows the timestamp of the first VLACP flap detected on the port since you enabled VLACP Flap Detect and Damping or cleared the counters and timers.
LastFlapTimeStamp	Shows the timestamp of the latest VLACP flap detected on the port since you enabled VLACP Flap Detect and Damping or cleared the counters and timers.
FlapClearStats	Clears all VLACP Flap Detect and Damping counters and timers.

Configure VLACP on an Extreme Integrated Application Hosting Port

Note

This procedure only applies to 5720-24MXW, 5720-48MXW, 7520 Series, and 7720 Series.

About This Task

Perform this procedure to enable Virtual Link Aggregation Control Protocol (VLACP) on an Extreme Integrated Application Hosting (IAH) port. VLACP periodically checks the end-to-end status of a point-to-point connection.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **VLACP** tab.
4. Select **AdminEnable**.
5. Configure the other parameters as required.
6. Select **Apply**.

VLACP Field Descriptions

Use data in the following table to configure the **VLACP** tab.

Name	Description
AdminEnable	Enables VLACP on the Extreme Integrated Application Hosting (IAH) port. The default is disabled.
OperEnable	Specifies the VLACP operational status for the IAH port. The default is false.
FastPeriodicTimer	Specifies the number of milliseconds between periodic transmissions using short timeouts. Set the same value for all LACP enabled IAH ports. The default value is 200.
SlowPeriodicTimer	Specifies the number of milliseconds between periodic transmissions using long timeouts. Set the same value for all LACP enabled IAH ports. The default value is 30000.
Timeout	Specifies the timeout control value. The default value is long.
TimeoutScale	Specifies the value used to calculate timeout duration from the periodic time for all VLACP enabled IAH ports. Timeout = PeriodicTime x TimeoutScale. The default value is 3.

Name	Description
EtherType	Specifies the VLACP protocol identification. The ID is in hexadecimal format. The default value is 0x8103.
EtherMacAddress	Specifies the multicast MAC address exclusively used for VLACPDUs.
PortState	Specifies the VLACP port state.

VLAN Configuration

[VLAN Fundamentals](#) on page 3981

[VLAN Configuration Using CLI](#) on page 4007

[VLAN Configuration using EDM](#) on page 4043

A VLAN is a switched network that is logically segmented by functions, project teams, or applications without regard to the physical location of users. By using a VLAN, you can divide the Local Area Network into smaller groups without interfering with the physical network.

The following topics provide necessary concepts and procedures to configure VLANs. For information about SPBM B-VLANs, see [SPBM B-VLAN](#) on page 1201.

For information about how to enable IGMP Layer 2 querier on a switch in a VLAN, see [IGMP Layer 2 Querier](#) on page 1712.

VLAN Fundamentals

The practical applications of a VLAN include the following:

- You can create VLANs, or workgroups, for common interest groups.
- You can create VLANs, or workgroups, for specific types of network traffic.
- You can add, move, or delete members from these workgroups without making physical changes to the network.

By dividing the network into separate VLANs, you can create separate broadcast domains. This arrangement conserves bandwidth, especially in networks supporting broadcast and multicast applications that flood the network with traffic. A VLAN workgroup can include members from a number of dispersed physical segments on the network, improving traffic flow between them.

The switch performs the Layer 2 switching functions necessary to transmit information within VLANs, as well as the Layer 3 routing functions necessary for VLANs to communicate with one another. You can define a VLAN for a single switch or spanning multiple switches. A port can be a member of multiple VLANs. A VLAN is associated with a spanning tree group.

A VLAN packet is classified before it is forwarded. If the packet matches a classification rule, the port membership is checked. If the port is not an allowed member (potential, static, or active), the system drops the packet.

Port-Based VLANs

A port-based VLAN is a VLAN in which you explicitly configure the ports to be in the VLAN. When you create a port-based VLAN on a device, you assign a VLAN identification number (VLAN ID) and specify the ports that belong to the VLAN. These port members are always active port members. The VLAN ID is used to coordinate VLANs across multiple switches. Any type of frame can be classified to a port-based VLAN.

The example in the following figure shows two port-based VLANs: one for the marketing department, and one for the sales department. Ports are assigned to each port-based VLAN. A change in the sales area can move the sales representative at port 1/1 to the marketing department without moving cables. With a port-based VLAN, you only need to indicate in the Command Line Interface (CLI) that port 1/1 in the sales VLAN now is a member of the marketing VLAN.

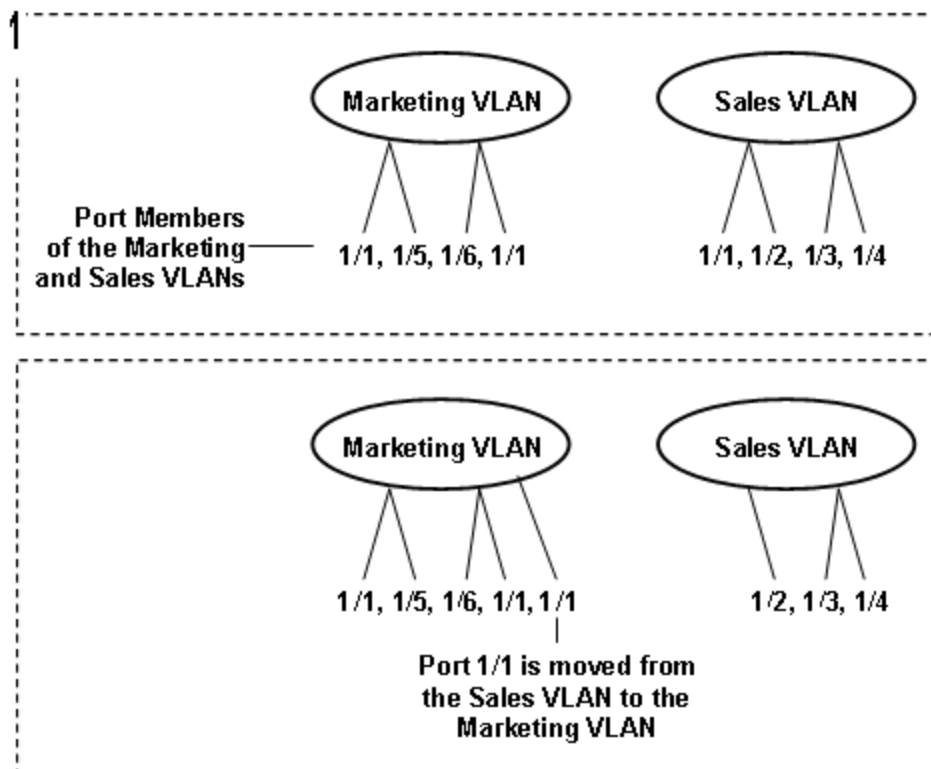

Figure 244: Port-based VLAN

Private VLANs

Table 335: E-Tree and Private VLANs product support

Feature	Product	Release introduced
E-Tree and Private VLANs	4220 Series	Fabric Engine 9.2

Routing on Private VLANs	4220 Series	Not Supported
	5320 Series	Fabric Engine 8.6 Not supported on 5320-24T-4X-XT
	5420 Series	VOSS 8.5
	5520 Series	VOSS 8.5
	5720 Series	Fabric Engine 8.7
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	7830 Series	Fabric Engine 9.4
	VSP 4900 Series	VOSS 8.5
	VSP 7400 Series	VOSS 8.5

Private VLANs provide isolation between ports within a Layer-2 service.

The primary and secondary VLAN make the private VLAN. Standard VLAN configuration takes place on the primary VLAN. The secondary VLAN is used to label traffic ingressing isolated ports.

Ports in the private VLAN are configured as isolated, promiscuous, or trunk. The default value is None.

Port Types**Note**

Layer 2 and Layer 3 services based on port types also apply in any routing scenario between two private VLANs or E-trees.

Table 336: Layer 2 services based on port types

Port type	Description
Promiscuous (tagged or untagged ports)	Promiscuous ports communicate with all other ports within the private VLAN. Uses the primary VLAN.
Isolated (tagged or untagged ports)	Isolated ports communicate with the promiscuous ports, but not with any other isolated port. Uses the secondary VLAN.
Trunk (tagged ports)	Trunk ports carry traffic between other port members within the private VLANs. Accepts either primary or secondary VLAN.

Table 337: Layer 3 services based on port types

Port type	Description
Promiscuous (tagged or untagged ports)	Promiscuous ports communicate with all other ports of any Layer 3 VLAN.
Isolated (tagged or untagged ports)	Isolated ports communicate with any promiscuous or regular VLAN ports but not with other isolated ports.
Trunk (tagged ports)	Trunk ports carry traffic between other port members within the private VLANs.

Trunk ports must have VLAN encapsulation enabled. A port can be a single port or can belong to an MLT.

The following figure shows a basic private VLAN topology with private VLAN configured on five switches. All ports connecting to other switches are trunk type ports and all other ports are either promiscuous or isolated ports. On the secondary VLAN, spokes can communicate with hubs, and hubs can communicate with all spokes in the same private VLAN using the primary VLAN, however, spokes cannot communicate with other spokes.

Figure 245: Private VLAN Topology

E-Tree

The E-Tree allows private VLANs to traverse the Shortest Path Bridging MAC (SPBM) network.

For more information about E-Tree and SPBM configuration, see [E-Tree and Private VLAN Topology](#) on page 1187.

Routing on Private VLANs

You can route traffic out of a private VLAN (PVLAN) by applying an IP address to a PVLAN. IP routing is supported on private VLANs for edge switches. With PVLAN packet routing, two hosts located in different private VLANs can communicate over the network.

Packets can be routed over the network between the following:

- regular VLAN and a private VLAN
- different private VLANs

- different I-SIDs (E-tree)

**Note**

Routed private VLANs support Secondary IP Interfaces. For more information, see [Secondary IP Interfaces](#) on page 3992.

The number of private VLANs that you configure with an IP address influences the IPv4 Egress ACE count. For information about scaling information, see *Fabric Engine Release Notes*. Limits are not enforced; either number of private VLANs or number of private VLAN trunk ports can go beyond the recommended values. As a best practice, use the **show io resources filter** command to monitor allocated resources.

**Note**

You cannot enable IP Multicast on a private VLAN interface. **ip spb-multicast enable** and **ip pim enable** commands are not available on a private VLAN.

Private VLAN Configuration Rules

The following are private VLAN rules for the switch:

- Use private VLANs for Layer 2 and Layer 3 services.
- You cannot configure IP Source Guard (IPSG) on ports that are members of private VLANs.
- Do not use the *untag-port default vlan* parameter on private VLAN interfaces that are operating as trunk ports, because it impacts the private VLAN functionality.

Policy-Based VLANs

Received frames are classified into a policy-based VLAN based on certain fields of the frame that matches the associated VLAN policy.

Port Membership Types

In a policy-based VLAN, a port can be designated as a potential member, a static member, or one not allowed to be a member of the VLAN.

If a port is designated as a potential member of the VLAN, and the incoming traffic matches the policy, the system dynamically adds the port to the active port list of the VLAN, making the port an active member of the VLAN. After the system adds a port to the active list, it can remove the port from the active list due to time-out. Potential member ports that join the VLAN are removed (timed out) from the active port list of the VLAN after the timeout (aging time) period expires.

All members of the Spanning Tree Group associated with a protocol-based VLAN are automatically considered potential members of the VLAN. In addition, all tagged ports (trunk ports) become static ports. If you do not want all the tagged ports to be static members of a protocol-based VLAN, put the port in the disallowed list.

Static port members are always members of the VLAN. Static port members are not aged out due to inactivity and they are not removed from the active list. If a server

or router connects to a port, designate that port as a static member of a VLAN. If a server connects to a port that is only a potential member and the server sends very little traffic, a client fails to reach the server if the server port is timed out of the VLAN. As a best practice, make these ports static members of the VLAN.

A disallowed port can never become a member of the VLAN until you add it as a port-member. After you remove a port from the VLAN, the system adds the port to the disallowed list.

On any single spanning-tree instance, an access (untagged) port can belong to one port-based VLAN and many policy-based VLANs. A trunk (tagged) port can belong to many port-based and policy-based VLANs.

The following table describes port membership types for policy-based VLANs.

Table 338: Port membership types for policy-based VLANs

Membership type	Description
Potential	Potential members of a VLAN become active members upon receiving data matching the policy defined for the VLAN (a packet tagged with that VLAN, or an untagged packet matching the policy).
Static (always a member)	Static members are always active members of the VLAN after you configure them as belonging to that VLAN.
Not allowed to join (never a member)	Ports of this type cannot join the VLAN.

The following table lists supported policy-based VLANs.

Table 339: Supported policy-based VLAN types

VLAN type	Support
Protocol-based	supported

Protocol-Based VLANs

Protocol-based VLANs are an effective way to segment your network into broadcast domains according to the network protocols in use.

A port member of a port-based VLAN can belong to multiple protocol-based VLANs. Port tagging is not required for a port to be a member of multiple protocol-based VLANs.

The switch supports IPv6 protocol-based VLAN only.

VLAN Tagging and Port Types

The switch supports the IEEE 802.1Q specification for tagging frames and coordinating VLANs across multiple switches.

Figure 246 shows how an additional four octet (tag) header is inserted in a frame after the source address and before the frame type. The tag contains the VLAN ID associated with the frame.

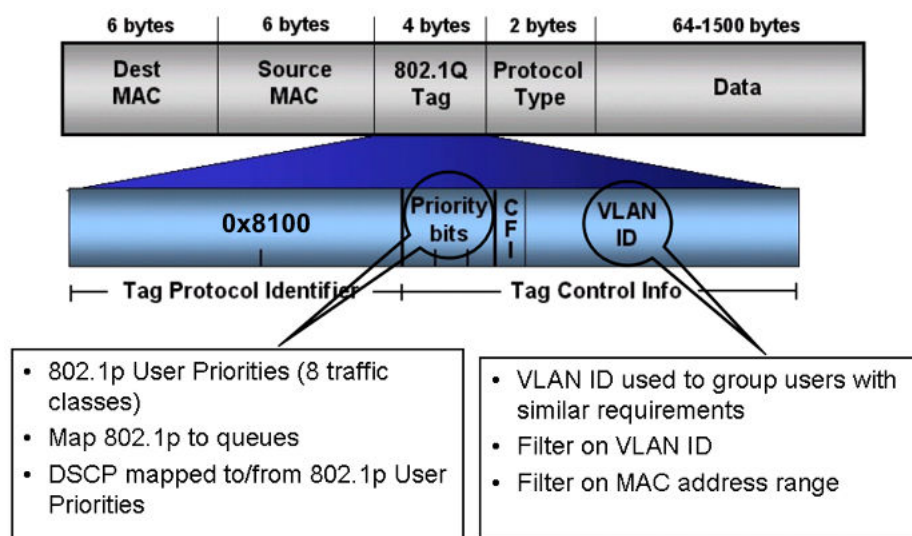

Figure 246: VLAN tag insertion

802.1Q Tagged Ports

Tagging a frame adds four octets to a frame, possibly making it bigger than the traditional maximum frame size. If a device does not support IEEE 802.1Q tagging, it can have problems interpreting tagged frames that it receives.

Whether tagged frames are sent depends on what you configure at the port level. Tagging is configured as true or false for the port, and is applied to all VLANs on that port.

A port with tagging enabled applies the VLAN ID tag to all packets sent on the port. Tagged ports are typically used to multiplex traffic belonging to multiple VLANs to other IEEE 802.1Q-compliant devices.

If you disable tagging on a port, it does not send tagged frames. A nontagged port connects a switch to devices that do not support IEEE 802.1Q tagging. If a tagged frame is forwarded to a port with tagging configured to false, the switch removes the tag from the frame before sending it to the port.

Treatment of Tagged and Untagged Frames

The switch associates a frame with a VLAN based on the data content of the frame and the configuration of the receiving port. The treatment of the frame depends on whether the frame is tagged or untagged.

If a tagged frame is received on a port, if the port is a static or potential member of the VLAN ID specified in the tag, the switch directs it to that VLAN. If the port is not a member of the VLAN that is identified by the tag in the packet, the switch discards the packet. If a port is untagged, you can configure it to discard tagged frames received on the port. In this case the tagged frame is discarded.

For untagged frames, VLAN membership is implied from the content of the frame itself. You can configure a tagged port to accept or discard untagged frames received on the port.

The default VLAN of a port is the VLAN to which untagged frames are classified if they do not match the criteria of any policy-based VLAN of which the port is a member. The default VLAN of the port can be any port-based VLAN a port belongs to, or the unassigned VLAN (1). Frames classified to the unassigned VLAN are discarded.

The frame is forwarded based on the VLAN on which the frame is received, and on the forwarding options available for that VLAN. The switch tries to associate untagged frames with a VLAN in the following order:

- Does the frame belong to a protocol-based VLAN?
- What is the default VLAN for the receiving port?
- Is the default VLAN for the port not the unassigned VLAN?

If the frame meets none of these criteria, it is discarded.

Untagging Default VLAN on a Tagged Port Feature

This feature provides the ability to connect two devices such as an IP phone and a PC to a single port of the switch. Most IP phones ship with an embedded three port switch, and traffic coming from the phone is generally tagged (VLAN ID configured statically or remotely). However, the traffic originating from a PC is usually untagged traffic and must be separated from the IP phone traffic. This separation ensures that broadcast traffic from the PC does not impact voice quality.

After an IP phone is attached to an untagged port, it can fail to register with a remote Internet Telephony Gateway (or equivalent device) dependent on the netmask of the destination IP address (Call Server subnet).

For more information about the Network with IP phone and PC, see the following figure.

Figure 247: Network with IP phone and PC

IP phones and PCs coexist on the same port due to the use of an embedded IP Phone Layer 2 switch. In this scenario if you configure the port as untagged, the egress traffic on this port is untagged and no separation exists between the traffic to the IP phone and the PC. To avoid this condition, the port that connects to the IP phone must be tagged. If the port is tagged, the traffic for the PC is tagged with the default VLAN ID for the port. This configuration creates a problem because the PC does not expect tagged packets. Untag the default VLAN on a tagged port (in this example, port 1/1 that connects to the IP phone) to ensure that the traffic to the PC is sent untagged.

VLAN Router Interfaces

When you configure routing on a VLAN, you assign an IP address to the VLAN, which acts as a virtual router interface address for the VLAN. This IP address is not associated with a physical port. You can reach the VLAN IP address through any of the VLAN port members. Frames are routed to another VLAN IP address within the device. A port can belong to multiple VLANs; some, all, or none can perform routing.

IP routing and VLANs

The switch supports IP routing on the following types of VLANs:

- Port-based VLANs
- IP protocol-based VLANs

VLAN Implementation

This section describes how to implement VLANs and describes default VLANs, the unassigned (NULL) VLAN, and brouter ports. This section also summarizes the defaults and rules regarding VLAN creation on the switch.

- [Default VLAN](#) on page 3991
- [NULL VLAN](#) on page 3991
- [Brouter Ports](#) on page 3991

Default VLAN

Devices are factory-configured so that all ports are in a port-based VLAN called the default VLAN. Because all ports are in the default VLAN, the device functions like a Layer 2 device. The VLAN ID of this default VLAN is always 1, and it is always a port-based VLAN. You cannot delete the default VLAN.

NULL VLAN

Internally, the switch creates a special port-based VLAN called NULL VLAN or unassigned VLAN. This is a place holder VLAN for ports that are not members of any port-based VLAN. When a port is removed from all port-based VLANs, it is added to the NULL VLAN as a port member. Ports can belong to policy-based VLANs as well as to the NULL VLAN. If a frame does not meet the policy criteria and no underlying port-based VLAN exists, the port belongs to the NULL VLAN and the frame is dropped.

Because it is an internal construct, the NULL VLAN cannot be deleted.

Brouter Ports

A brouter port is actually a one-port VLAN with an IP interface. The difference between a brouter port and a standard IP protocol-based VLAN configured to perform routing is that the routing interface of the brouter port is not subject to the spanning tree state of the port. A brouter port can be in the blocking state for nonroutable traffic and still route IP traffic. Because a brouter port is a single-port VLAN, it uses one VLAN ID. Each brouter port decreases the number of available VLANs by one.

Secondary IP Interfaces

Table 340: Secondary IP Interfaces product support

Feature	Product	Release introduced
Secondary IP Interfaces	4220 Series	Not Applicable
	5320 Series	Fabric Engine 8.10 For the 5320 Series, only the following models support more than one VRF with IP configuration: <ul style="list-style-type: none"> • 5320-16P-2MXT-2X • 5320-24T-4X-XT • 5320-24T-24S-4XE-XT • 5320-48P-8XE • 5320-48T-8XE
	5420 Series	Fabric Engine 8.10
	5520 Series	Fabric Engine 8.10
	5720 Series	Fabric Engine 8.10
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	7830 Series	Fabric Engine 9.3
	VSP 4900 Series	VOSS 8.10
	VSP 7400 Series	VOSS 8.10

The ability to add Secondary IP Interfaces on a Layer 2 VLAN means that you can have both primary and secondary IP subnets as local routes and increase the number of connected hosts. This feature is useful for subnets that have used all available host IP addresses.

You can configure Secondary IP Interfaces on VLAN interfaces only; you cannot configure a Secondary IP Interface for a brouter port or CLIP interface. Both the Global Router (VRF 0) and user-defined VRFs support Secondary IP Interfaces on associated VLANs. The secondary addresses share the same routeable MAC with the primary IP address.

A VLAN interface can support up to 32 secondary IP addresses. The total number of secondary IP addresses you can create on the same switch depends on available resources. For scaling information, see *Fabric Engine Release Notes*.

DHCP Smart Relay makes DHCP Relay aware of Secondary IP Interfaces. DHCP Smart Relay can also work with a subset of VRRP addresses. For more information, see [DHCP Smart Relay for Secondary IP Interfaces](#) on page 830.

Configuration Rules

- You must configure a primary IP address on the VLAN before you can add secondary addresses.
- You cannot remove a primary IP address if a secondary address exists.
- Primary and secondary subnets must be unique across all VLANs, including within the same VLAN. Subnets cannot overlap, meaning you cannot configure a subnet range that would be included within another subnet range.
- When the command originates on the switch, the **ping** and **traceroute** commands both support secondary IP addresses as the source IP address. If you do not specify a source address as part of the command, the switch automatically uses the a secondary address in the subnet.
- Protocol exchange, both unicast and multicast, occurs only on the primary subnet. Control packets use the primary IP address, including neighbor or peer relationships, and election processes.

Note

IGMP interfaces accept and process all IGMP reports received for subnets that belong to that interface, either primary or secondary.

- Routing protocols do not advertise secondary subnets; you must configure redistribution of direct routes to announce secondary subnets.
- The switch sends all broadcast packets within the VLAN to all hosts regardless of subnet.
- You cannot configure the following features on a secondary subnet:
 - BFD
 - IP security features
 - LLDP
 - Proxy ARP
 - UDP
 - Virtual Inter-Switch Trunk (vIST) peers
- The following feature restrictions exist for Secondary IP Interfaces:
 - You cannot configure a MAC offset for secondary IP addresses.
 - You cannot configure RSMLT on a VLAN with secondary IP addresses.
 - You cannot configure a DvR Gateway IP address that exists in a secondary subnet. DvR-One-IP always selects the primary IP address.
 - You cannot configure a secondary IP address as the source IP for a Fabric Extend tunnel.
 - Enabling Directed Broadcast on a VLAN only applies to the primary IP address on the VLAN and not to Secondary IP Interfaces on the VLAN.

For more information, see the following tasks:

- [Assign an IP Address to a VLAN](#) on page 4013 (CLI)
- [Configure a Secondary IP Interface for a VLAN](#) on page 4053 (EDM)

Network Load Balancing

Table 341: Network Load Balancing product support

Microsoft Network Load Balancing (NLB) is a clustering technology available with the Microsoft Windows 2000, Microsoft Windows 2003, Microsoft Windows 2008, and Microsoft Windows 2012 Server family of operating systems. You can use NLB to share the workload among multiple clustering servers. NLB uses a distributed algorithm to load balance TCP/IP network traffic across a number of hosts, enhancing the scalability and availability of the following mission critical, IP-based services:

- web
- VPN
- Streaming media
- Firewalls

NLB also provides high availability by detecting host failures and automatically redistributing traffic to remaining operational hosts.

NLB Considerations and Restrictions

Although the switch interoperates with NLB clusters that operate in Unicast mode and Multicast mode, the following restrictions apply:

- The software does not support true egress mirroring because packets are mirrored prior to the completion of packet processing, so egress mirrored packets can differ from the packets egressing the port.

Note

To mirror the egress traffic, you can use the NEXT-hop device ingress mirroring to capture the egress packets of the switch.

- Inter-VRF routing is not supported between an NLB client and an NLB cluster VLAN in Unicast mode or Multicast mode.
- You must configure NLB to use the same mode as the NLB Server.
- Static ARP entries are not supported for NLB Unicast or NLB Multicast.
- For interoperability with NLB, the switch provides configuration options at the VLAN level.
- ARP entries for NLB server IP addresses do not age out when there is still client traffic coming to the NLB servers, even after the NLB servers are no longer reachable.

NLB Clustering in Unicast Mode

When the cluster is running in NLB unicast mode, all servers in the cluster share a common virtual MAC address, which is 02-bf-x-x-x-x (where x-x-x-x is the cluster IP address in hexadecimal form). All traffic destined to this MAC address is sent to all the servers in the cluster. The virtual MAC address is specified in the Sender MAC Address field of the Address Resolution Protocol (ARP) reply from the cluster to the switch. ARP responses from the switch are sent to the virtual MAC address (rather than to the hardware MAC address).

You can configure the switch for NLB unicast mode support. After you enable the NLB unicast option, the switch floods traffic destined to the cluster IP address to all ports on the VLAN. Unicast mode supports connectivity to a secondary virtual IP address. For information about software scaling capabilities in unicast mode, see *Fabric Engine Release Notes*.

NLB Clustering in Multicast Mode

When the cluster is running in NLB multicast mode, a multicast virtual MAC address with the format 03-bf-x-x-x-x (where x-x-x-x is the cluster IP address in hexadecimal form) is bound to all cluster hosts but the real MAC address of the network adapter is retained. The multicast MAC address is used for client-to-cluster traffic, and the real MAC address of the adapter is used for network traffic specific to the host server.

You can configure the switch for NLB multicast mode support. When you enable NLB multicast mode on a VLAN, the routed traffic destined to the NLB cluster is flooded by default on all ports of the VLAN. All VLANs support multiple cluster IPs by default. You

can connect up to 200 NLB clusters to a single VLAN. For information about software scaling capabilities, see .

Note

Shortest Path Bridging MAC (SPBM) supports NLB Unicast and Multicast modes. For more information on SPBM, see [Fabric Basics and Layer 2 Services](#) on page 1178.

Supported NLB Topologies

The switch supports Network Load Balancing (NLB) in the following topologies.

Supported NLB Topology–Example 1

The switch supports NLB when the NLB Cluster connections use a different physical port on the switch than the NLB clients.

The following figure illustrates this configuration where the NLB Server and the NLB Client workstations connect to different aggregation switches, which connect to the switch using different VLANs and different ports.

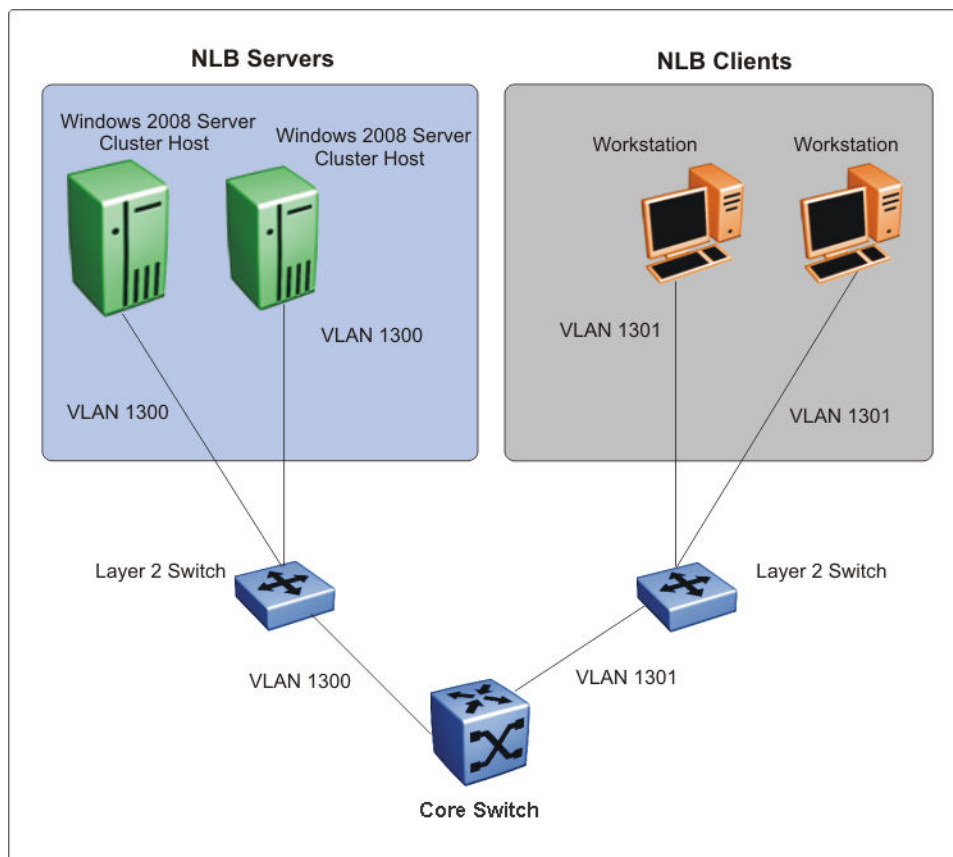

Figure 248: Supported NLB topology–example 1

Supported NLB Topology–Example 2

The switch also supports the following topology where the NLB Server and the NLB Client workstations connect to the same aggregation switch and then connect to the switch using the same port.

Note

The switch supports Layer 3 routing between an NLB-enabled VLAN and another VLAN on the same port.

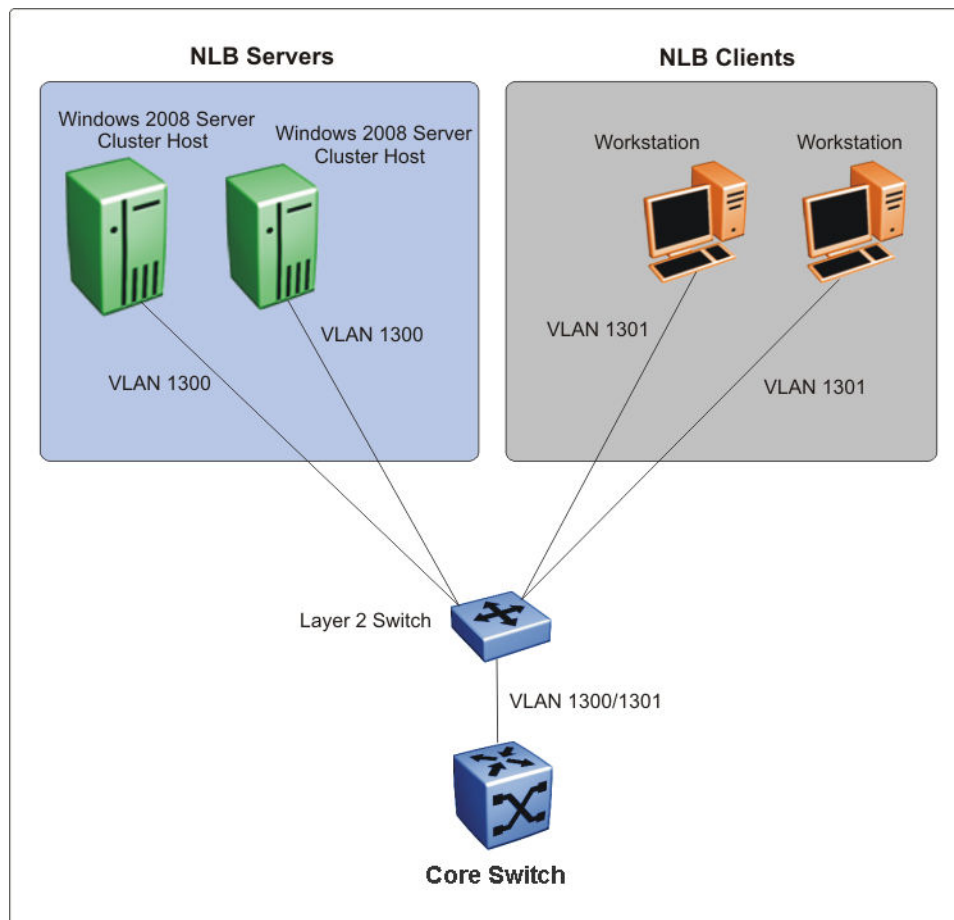

Figure 249: Supported NLB topology–example 2

Other Supported NLB Topologies

The switch supports NLB in the following other topologies:

- NLB cluster hosts and clients are connected to Layer 2 Ethernet switches that are SMLT connected to the SMLT cluster.
- NLB cluster hosts are directly connected and distributed between the switches and the clients are connected to Layer 2 Ethernet switch that is SMLT connected to the SMLT cluster.

- NLB cluster hosts and clients are directly connected and distributed between the switches in the SMLT cluster.
- NLB cluster hosts and clients are connected to Layer 2 Ethernet switches that are SMLT connected to the SMLT cluster core.

**Note**

For more information on these topologies, see *Technical Configuration Guide for Microsoft Network Load Balancing*.

NLB and Directed Broadcast Resource Limits

NLB and Directed Broadcast consume resources from the same pool of 200 resources. When you configure either NLB or Directed Broadcast, the switch uses one resource. If you configure both NLB and Directed Broadcast, the switch uses two resources.

To avoid a situation where there is a lack of resources, adhere to the following limits:

- The number of NLB cluster IP interfaces multiplied by the number of configured clusters must be equal to, or less than, 200. The number of NLB cluster IP interfaces is the key, not the number of VLANs. You can configure 1 VLAN with up to 200 NLB cluster IP interfaces or configure up to 200 VLANs with 1 NLB cluster IP interface per VLAN.

For example: 1 NLB cluster IP interface x 200 clusters = 200 or 2 NLB cluster IP interfaces x 100 clusters = 200

- If you configure VLANs with Directed Broadcast only, you can scale up to 200 VLANs.
- If you configure VLANs with both NLB and Directed Broadcast, you can only scale up to 100 VLANs assuming there is only 1 NLB cluster IP interface per VLAN.

For information on Directed Broadcast, see [Denial-of-Service Attack Prevention](#) on page 3372.

VLAN MAC-layer Filtering Database and MAC Security

Table 342: FDB Protected by Port product support

Feature	Product	Release introduced
FDB protected by port (MAC security limit-learning)	4220 Series	Not Supported
	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.3
	5720 Series	Fabric Engine 8.7
	7520 Series	Not Supported
	7720 Series	Not Supported
	7830 Series	Not Supported
	VSP 4900 Series	VOSS 8.3
	VSP 7400 Series	Not Supported

To perform MAC-layer bridging, the device must know the destination MAC-layer address of each device on each attached network to forward packets to the appropriate destination. The system stores MAC-layer addresses in the bridge forwarding database (FDB) table, and can forward packet traffic based on the destination MAC-layer address information.

MAC Security

Use MAC security to control traffic from specific number of MAC addresses. You can also limit the number of allowed MAC addresses. You can enable this feature at the port level.

Port-level security applies to traffic for all VLANs received on that port.

Port-level MAC security provides limit—learning option:

- **limit-learning:** This option protects the FDB from traffic from too many MAC addresses, which fill the FDB table.

This option limits the number of MAC addresses a port learns. You can specify a maximum number of addresses. After the number of addresses reaches the maximum, learning stops. The port disables packet forwarding and drops packets from new source MAC address. MAC address learning resumes after enough existing addresses age out and there is room to learn new MAC addresses.

Note

If you configure a limit on a port that has already learned more than the new limit, packet forwarding for those additional MAC addresses continues to work until the port flaps, you flush the MAC address, or the MAC address disappears.

Restrictions

The following list identifies restrictions to MAC security limit-learning:

- This feature is not supported on:
 - MLT ports members
 - NNI ports
 - Transparent Port UNI or Switched UNI
- The switch supports MAC learning only in the VLAN domain; it is not supported in the I-SID domain.
- The port MAC limit does not count static MAC addresses.
- The switch supports the maximum number of MAC addresses a port can learn for non-SPBM configurations.

Prevention of IP Spoofing within a VLAN

VLAN IP as the default gateway

You can prevent VLAN logical IP spoofing by blocking the external use of the device IP address. A configurable option is provided, for each port, which detects a duplicate IP address (that is, an address that is the same as the device VLAN IP address) and blocks all packets with a source or destination address equal to that address.

If an ARP packet is received that has the same source IP address as the logical VLAN IP address of the receiving port, all traffic coming to that port (with this MAC address as source/destination address) is discarded by the hardware. After detecting a duplicate IP address, the device sends a gratuitous ARP packet to inform devices on the VLAN about the correct MAC address for that IP address. You can specify a time on a configurable global timer after which the MAC discard record is deleted, and the device resumes accepting packets from that MAC address.

VRRP IP as the default gateway

Similarly, you can prevent VRRP IP spoofing by blocking the external use of the virtual IP address. A configurable option is provided, for each port, which detects a duplicate IP address (that is, an address that is the same as the device virtual IP address) and blocks all packets with a source or destination address equal to that address.

If an ARP packet is received that has the same source IP address as the virtual IP address of the receiving port, all traffic coming to that port (with this MAC address as source/destination address) is discarded by the hardware. After detecting a duplicate IP address, the device sends a gratuitous ARP packet to inform devices on the VRRP subnet about the correct virtual router MAC address for that IP address. You can specify a time on a configurable global timer after which the MAC discard record is deleted, and the device resumes accepting packets from that MAC address.

Packet spoofing

You can stop spoofed IP packets by configuring the switch to forward only IP packets that contain the correct source IP address of your network. By denying all invalid source

IP addresses, you minimize the chance that your network is the source of a spoofed DoS attack.

A spoofed packet is one that comes from the Internet into your network with a source address equal to one of the subnet addresses on your network. The source address belongs to one of the address blocks or subnets on your network. To provide spoofing protection, you can use a filter that examines the source address of all outside packets. If that address belongs to an internal network or a firewall, the packet is dropped.

To prevent DoS attack packets that come from your network with valid source addresses, you need to know the IP network blocks in use. You can create a generic filter that:

- Permits valid source addresses
- Denies all other source addresses

To do so, configure an ingress filter that drops all traffic based on the source address that belongs to your network.

If you do not know the address space completely, it is important that you at least deny private (see RFC1918) and reserved source IP addresses. The following table lists the source addresses to filter.

Table 343: Source addresses to filter

Address	Description
0.0.0.0/8	Historical broadcast. High Secure mode blocks addresses 0.0.0.0/8 and 255.255.255.255/16. If you enable this mode, you do not need to filter these addresses.
10.0.0.0/8	RFC1918 private network
127.0.0.0/8	Loopback
169.254.0.0/16	Link-local networks
172.16.0.0/12	RFC1918 private network
192.0.2.0/24	TEST-NET
192.168.0.0/16	RFC1918 private network
224.0.0.0/4	Class D multicast
240.0.0.0/5	Class E reserved
248.0.0.0/5	Unallocated
255.255.255.255/32	Broadcast ¹

You can also enable the spoof-detect feature on a port.

VLAN loop prevention

Table 344: Simple Loop Prevention Protocol product support

Feature	Product	Release introduced
Simple Loop Prevention Protocol (SLPP)	4220 Series	Fabric Engine 9.2
	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	7830 Series	Fabric Engine 9.3
	VSP 4900 Series	VOSS 8.1
	VSP 7400 Series	VOSS 8.0

Loop Prevention

Under certain conditions, such as incorrect configurations or cabling, loops can form. This is true mainly for Layer 2 bridged domains, such as VLANs.

Simple Loop Prevention Protocol (SLPP) provides active protection against Layer 2 network loops on a per-VLAN basis. SLPP uses a lightweight hello packet mechanism to detect network loops. Sending hello packets on a per VLAN basis allows SLPP to detect VLAN based network loops for untagged as well as tagged IEEE 802.1Q VLAN link configurations. After SLPP detects a loop, the port is shutdown.

Note

If you use SLPP in a vIST environment, you must enable it on both vIST peers. When an SLPP packet of a vIST peer is looped through UNI ports to the other device, that device will shut down its UNI port due to receiving SLPP packets from its peer. A device's own SLPP packets will go over a vIST connection but will not be forwarded by its vIST peer back onto its UNI ports.

Configure the SLPP functionality with the following criteria:

- **SLPP TX Process** – You decide on which VLANs a switch can send SLPP hello packets. The packets are then replicated out all ports which are members of the SLPP-enabled VLAN. As a best practice, enable SLPP on all VLANs.
- **SLPP RX Process** – You decide on which ports the switch can act when receiving an SLPP packet that is sent by the same switch or by its SMLT peer. You must enable this process only on Access SMLT ports. You can enable this process only when the design permits on SMLT CORE ports in the case of a square/full mesh core design.
- **SLPP Action** – The action operationally disables the ports receiving the SLPP packet. You can also tune the network failure behavior. You can choose how many SLPP packets a port needs to receives before a switch takes an action. You need to stagger these values to avoid edge switch isolation.

Instead of manually recovering a port that is shutdown by SLPP, you can configure an automatic recovery delay per port. The **auto-recover-delay** command specifies the minimum amount of time after which the port is brought back up. The maximum amount of time that can pass until the port is brought back up is two times the configured **auto-recover-delay** value.

Loops can be introduced into the network in many ways. One way is through the loss of an MLT/link aggregation configuration caused by user error or malfunctioning equipment. This scenario does not always introduce a broadcast storm, but because all MAC addresses are learned through the looping ports, does significantly impact Layer 2 MAC learning. Spanning Tree cannot, in all cases, detect such a configuration issue, whereas SLPP reacts and disables the malfunctioning links and limits network impact to a minimum.

The desire is to prevent a loop from causing network problems, while also attempting not to totally isolate the edge where the loop was detected. Total edge closet isolation is the last resort to protect the rest of the network from the loop. With this in mind, some administrators adopt the concept of an SLPP primary switch and SLPP secondary switch. These are strictly design terms and are not configuration parameters. The Rx thresholds are staggered between the primary and secondary switch. Therefore, the primary switch disables an uplink immediately upon a loop occurring. If this resolves the loop issue, then the edge closet still has connectivity back through the SLPP secondary switch. If the loop is not resolved, then the SLPP secondary switch disables the uplink and isolates the closet to protect the rest of the network from the loop.

As the number of VLANs running SLPP scale off of a specific uplink port, increase the Rx-threshold value to prevent complete isolation of the offending edge. The primary goal of SLPP is to protect the core at all costs. In certain loop conditions, what can occur is the secondary switch also detects the loop and SLPP Rx-threshold of the secondary switch is reached before the primary can stop the loop by taking its port down. Therefore, both switches eventually take their ports down and the edge is isolated. The larger the number of VLANs associated with the port, the more likely this can occur, especially for loop conditions that affect all VLANs.

Important

The loop detection functionality of the device must not be used under normal operating conditions. Only use it if directed by technical support personnel.

You cannot configure the EtherType for SLPP. The switch uses an EtherType of 0x8102 .

Spanning Tree and Protection against Isolated VLANs

Virtual Local Area Network (VLAN) isolation disrupts packet forwarding. The following figure illustrates the problem. Two VLANs (V1 and V2) connect four devices, and both VLANs are in the same spanning tree group. V2 includes three of the four devices, whereas V1 includes all four devices. After a spanning tree protocol detects a loop, it blocks the link with the highest link cost. In this case, the 100 Mbps link is blocked, which isolates a device in V2. To avoid this problem, either configure V2 on all four

devices or use MSTP with a different Multiple Spanning Tree Instance (MSTI) for each VLAN.

Figure 250: VLAN isolation

Switched UNI Layer 3

Create a platform VLAN using the command **vlan create <vlan-id> type port-mstprsp <msti-instance>**. Enable Layer 3 services on the platform VLAN and is associated with the Switched UNI (S-UNI) Service Instance Identifier (I-SID). All S-UNI ports are added to the platform VLAN.

You must associate the S-UNI I-SID to the platform VLAN. After you associate the platform VLAN with the I-SID, it becomes a CVLAN.

The switch performs MAC and ARP learning on the platform VLAN.

Note

You cannot add S-UNI ports or MLT to the S-UNI platform VLANs directly. Add the ports to the I-SID and assign the I-SID to the platform VLAN.
You can associate only port based VLAN with S-UNI I-SID.

VLAN Feature Support

The following table summarizes supported features.

For the latest scalability information, see *Fabric Engine Release Notes*.

Table 345: VLAN support

Feature	Description
Number of VLANs	4059
Port-based VLANs	Supported
Policy-based VLANs <ul style="list-style-type: none"> Protocol-based SPBM-based 	Supported
IEEE 802.1Q tagging	Supported
IP routing and VLANs	Supported
Special VLANs <ul style="list-style-type: none"> Default VLAN Null VLAN Router ports Private VLAN 	Supported

NEW! VLAN IDs

The following table provides information on VLAN ID availability.

Table 346: VLAN ID allocation

VLAN ID	Purpose
1	Default VLAN
2-4059	User-configurable VLANs
3500-3998	Reserved range on switches that enable the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags. Note: <i>vrf-scaling</i> does not apply to switch models that support a single active VRF with IP configuration, or to 5320-16P-2MXT-2X and 5320-24T-4X-XT.
4047	SD-WAN-associated VLAN

Table 346: VLAN ID allocation (continued)

VLAN ID	Purpose
4048-4049	Onboarding Private VLAN pair (primary/secondary)
4051-4052	SPBM B-VLANs
4060-4094	System-reserved VLANs

VLAN Configuration Rules

The following are VLAN rules for the switch:

- A tagged port can belong to multiple VLANs in multiple Spanning Tree Groups.
- Under the default configuration, the default Spanning Tree Group is number 1 if the chassis configuration permits multiple STGs.
- An untagged port can belong to only one port-based VLAN.
- You can configure only one protocol-based VLAN for a given protocol.
- The VLAN membership of a frame is determined by the following order of precedence, if applicable:
 1. IEEE 802.1Q tagged VLAN ID
 2. protocol-based VLAN
 3. port-based VLAN default VLAN of the receiving port
- You cannot configure a VLAN name that uses all numbers, for example, 222.

Interaction Between Anycast IP Gateway, Distributed Virtual Routing and SLPP Guard

On VLANs that use Anycast IP Gateway or Distributed Virtual Routing (DvR), the switch sends a small control packet every five seconds on UNI ports. Similar to VRRP hello packets, these packets ensure that the Anycast IP Gateway or DvR MAC address remains active on Layer 2 switches that connect to the SPB Fabric, such as those using Fabric Attach (FA).

Although these packets share the same EtherType as Simple Loop Prevention Protocol (SLPP), they differ in how the MAC addresses are constructed:

- Standard SLPP packets:
 - Source MAC: Chassis MAC address
 - Destination MAC: Chassis MAC address with the multicast bit set
- Anycast IP Gateway/DvR keep-alive packets:
 - Source MAC: Anycast IP Gateway or DvR MAC address
 - Destination MAC: Same Anycast IP Gateway or DvR MAC address (with multicast bit applied)

SLPP-RX does not use these packets but SLPP Guard does recognize them. When you enable SLPP Guard on a port, it can detect these packets, and take the necessary

action to prevent unwanted loops, and thus does not require you to configure SLPP-TX on the VXLAN.

SLPP-TX/RX can operate in parallel with these packets without restrictions, and the two mechanisms do not interfere with each other.

VLAN Configuration Using CLI

This section provides procedures to configure and to manage Virtual Local Area Networks (VLANs) using the command line interface (CLI).

Create a VLAN

Create a VLAN by port, protocol, or an SPBM B-VLAN. Optionally, you can choose to assign the VLAN a name and color.

Assign an IP address to the VLAN. You can also assign a MAC-offset value that allows you to manually change the default MAC address.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Create a VLAN by specifying one of the following VLAN types:
 - a. Create a VLAN by port:

```
vlan create <2-4059> [name WORD<0-64>] type port-mstprstp <0-63> [color <0-32>]
```
 - b. Create a VLAN using a user-defined protocol and specify the frame encapsulation header type:

```
vlan create <2-4059> [name WORD<0-64>] type protocol-mstprstp <0-63> ipv6 [color <0-32>]
```
 - c. Create an SPBM B-VLAN:

```
vlan create <2-4059> [name WORD<0-64>] type spbm-bvlan [color <0-32>]
```
3. (Optional) Associate a CVLAN I-SID to the platform VLAN.

```
vlan i-sid <1-4059> <1-16777215> [force]
```
4. Log on to the VLAN Interface Configuration mode for the VLAN ID:

```
interface VLAN <1-4059>
```
5. Assign an IP address to a VLAN:

```
ip address {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>} [dvr-one-ip] [state-disabled]
```
6. (Optional) Assign a Secondary IP Interface to a VLAN:

```
ip address {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>} secondary
```
7. (Optional) Specify the MAC-offset value:

```
ip address <A.B.C.D/X>|<A.B.C.D> <A.B.C.D> dvr-one-ip <0-511>
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#vlan create 2 type port-mstprstp 0 color 4
Switch:1(config)#vlan i-sid 2 100
Switch:1(config)#interface vlan 2
Switch:1(config-if)#ip address 192.0.2.0/24 dvr-one-ip
```

Variable Definitions

The following table defines parameters for the **vlan create** command.

Variable	Value
<code><2-4059></code>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
<code>name WORD<0-64></code>	Specifies the VLAN name. The name attribute is optional.
<code>type port-mstprstp <0-63> [color <0-32>]</code>	Creates a VLAN by port: <ul style="list-style-type: none"> <code><0-63></code> is the STP instance ID from 0 to 63. <code>color <0-32></code> is the color of the VLAN in the range of 0 to 32. Note: MSTI instance 62 is reserved for SPBM if SPBM is enabled on the switch.
<code>type pvlan-mstprstp <0-63> [color <0-32>]</code>	Creates a private VLAN by port: <ul style="list-style-type: none"> <code><0-63></code> is the STP instance ID from 0 to 63. <code>color <0-32></code> is the color of the VLAN in the range of 0 to 32.
<code>type protocol-mstprstp <0-63> ipv6</code>	Creates a VLAN by protocol: <ul style="list-style-type: none"> <code><0-63></code> is the STP instance ID. <code>color <0-32></code> is the color of the VLAN in the range of 0 to 32.
<code>type spbm-bvlan</code>	Creates a SPBM B-VLAN.

The following table defines parameters for the **ip address** command.

Variable	Value
<code><A.B.C.D/X> <A.B.C.D> <A.B.C.D></code>	Specifies the IP address and subnet mask in the format A.B.C.D/X or A.B.C.D A.B.C.D.
<code>dvr-one-ip</code>	Specifies that the IP address will be used as the DvR gateway IP address and will be used by all other DvR Controllers for the DvR VLAN subnet.
<code><0-511></code>	Specifies a number by which to offset the MAC address from the chassis MAC address. This ensures that each IP address has a different MAC address. If you omit this variable, a unique MAC offset is automatically generated. Note: You cannot specify the mac-offset for a given secondary IP.
<code>secondary</code>	Identifies the IP address as a Secondary IP Interface.
<code>state-disabled</code>	Creates the IP interface in an administratively disabled state. This parameter is useful if you want to preconfigure an IP interface, including the routing protocol configuration for that interface, and enable it later during a maintenance window. This parameter applies only to the primary IP address. By default, the switch enables an IP interface after you configure the primary IP address.

The following table defines parameters for the **vlan i-sid** command.

Variable	Value
<code><1-4059></code>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<code><0-16777215></code>	Specifies the service instance identifier (I-SID). You cannot use I-SID 0x00ffffff. The system reserves this I-SID to advertise the virtual BMAC in an SMLT dual-homing environment. This value is the same for the primary and secondary VLANs.
<code>force</code>	Specifies the software must replace the existing VLAN-to-I-SID mapping, if one exists.

Create a Private VLAN

About This Task

You can create a private VLAN and set the port type. The primary and secondary VLAN IDs are associated with the same MTSI, the secondary VLAN inherits the primary VLAN configuration. You cannot create another VLAN with the same VLAN ID as the secondary VLAN. The secondary VLAN cannot be any other type of VLAN other than a secondary VLAN.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Create a private VLAN:

```
vlan create <2-4059> type pvlan-mstprstp secondary <2-4059>
```
3. Specify a name for the VLAN:

```
vlan create <2-4059> name
```

4. Enter GigabitEthernet Interface Configuration mode:

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...][slot/all][all]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

5. Set the port type:

```
private-vlan <isolated|promiscuous|trunk>
```

**Note**

If the port is a member of an MLT, the port inherits the private VLAN port type of the MLT.

6. Exit to Global Configuration mode:

```
exit
```

7. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

8. Add ports to the primary VLAN:

```
vlan members add <1-4059> {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...][slot/all][all]}
```

Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#vlan create 2 type pvlan-mstprstp 6 secondary 5
Switch:1(config)#interface gigabitethernet 1/36
Switch:1(config-if)#private-vlan isolated
Switch:1(config-if)#exit
Switch:1(config)#interface vlan 2
Switch:1(config-if)#vlan members add 2 1/36
```

Variable Definitions

Use the data in the following table to use the **vlan create** command.

Variable	Value
<code><2-4059></code>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
<code>name WORD<0-64></code>	Specifies the VLAN name. The name attribute is optional.
<code>type pvlan-mstp <0-63></code>	Creates a private VLAN by port. The variable <code><0-63></code> is the STP instance ID from 0 to 63. Note: MSTI instance 62 is reserved for SPBM if SPBM is enabled on the switch.
<code>secondary<2-4059></code>	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.

Use the data in the following table to use the `private vlan port type` command.

Variable	Value
<code><isolated promiscuous trunk></code>	Specifies the port type. If not specified, the port type defaults to None. <ul style="list-style-type: none"> Isolated: An Isolated port can belong only to one private VLAN Promiscuous: A Promiscuous port can belong to many private VLANs Trunk: A Trunk port can belong to many private VLANs, is tagged, and can also belong to non-private VLANs
<code>no private-vlan</code>	Port defaults to type None.
<code>default private-vlan</code>	Port defaults to type None.

Note

If there are other non-private VLANs using the defined port, the following message is displayed: All non private VLANs using this interface will be removed once this port becomes a member of a private VLAN. Ports with private-vlan type of isolated or promiscuous may only contain private VLANs. Do you wish to continue (y/n) ?

Use the data in the following table to use the `interface vlan` and `vlan members add` commands.

Variable	Value
<code><1-4059></code>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Assign an IP Address to a VLAN

Assign an IP address to a VLAN so that it supports routing operations.

Before You Begin

- You must create the VLAN.
- Activate IP forwarding globally.
- If you use this procedure to create a Secondary IP Interface, you must first create the primary IP address.

About This Task

If an IP interface is configured without specifying the VRF instance, it maps to VRF 0 by default.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Assign a primary IP address to a VLAN:

```
ip address {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>} [dvr-one-ip] [name WORD  
<0-64>] [state-disabled]
```

3. (Optional) Assign a Secondary IP Interface to a VLAN:

```
ip address {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>} secondary
```

4. (Optional) If required, associate the VLAN with a VRF:

```
vrf WORD<1-16>
```

Example

Add a primary IP address to the VLAN and configure it as the DvR-One-IP interface. Give the address a name.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface vlan 2
Switch:1(config-if)#ip address 192.0.2.5 255.255.255.0 dvr-one-ip name Boston
```

Variable Definitions

The following table defines parameters for the **ip address** command.

Variable	Value
<A.B.C.D/X> <A.B.C.D> <A.B.C.D>	Specifies the IP address and subnet mask in the format A.B.C.D/X or A.B.C.D A.B.C.D.
dvr-one-ip	Specifies that the IP address will be used as the DvR gateway IP address and will be used by all other DvR Controllers for the DvR VLAN subnet.
name WORD <0-64>	Specifies the name associated with the IP address on a VLAN.

Variable	Value
<i>secondary</i>	Identifies the IP address as a Secondary IP Interface.
<i>state-disabled</i>	Creates the IP interface in an administratively disabled state. This parameter is useful if you want to preconfigure an IP interface, including the routing protocol configuration for that interface, and enable it later during a maintenance window. This parameter applies only to the primary IP address. By default, the switch enables an IP interface after you configure the primary IP address. Note: This parameter is not saved in the configuration file.

The following table defines parameters for the **vrf** command.

Variable	Value
<i>WORD<0-16></i>	Specifies the VRF of the VLAN.

Display All Configured IP Addresses

About This Task

Use this procedure to verify the configuration of all IP addresses, including Secondary IP Interfaces on VLANs. You cannot create Secondary IP Interfaces on brouter ports.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all configured IP addresses:
`show ip address`
3. Display all primary IP addresses:
`show ip address primary`
4. Display all secondary IP addresses:
`show ip address secondary`
5. Display IP addresses associated with a VLAN:
`show ip address vlan [vlan-id[-vlan-id] [, ...]]<1-4059>`
6. Display IP addresses associated with a VRF name:
`show ip address vrf WORD<1-16>`
7. Display IP addresses associated with a VRF ID:
`show ip address vrfids WORD<0-512>`

View the IPv4 and IPv6 Interface Configuration on a VLAN

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Verify the interface configuration on the VLAN:

For IPv4, enter: `show interfaces vlan ip`

For IPv6, enter: `show ipv6 interface vlan`

Example

Verify the IPv4 interface configuration on the VLAN:

```
Switch:1(config-if)# show interfaces vlan ip
```

Vlan Ip										
VLAN ID	VRF NAME	IP ADDRESS	NET MASK	ADMIN STATUS	OPER STATUS	ADVERTISE WHEN_DOWN	DIRECTED BROADCAST	RPC	RPCMODE	RMON

Remove All Secondary IP Interfaces From a VLAN

Perform this procedure to remove all secondary IP addresses on a VLAN simultaneously.

About This Task

To remove specific secondary IP addresses from a VLAN, use the **no** operator with the **ip address {A.B.C.D} secondary** command on the VLAN.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Remove all Secondary IP Interfaces from a VLAN:
clear secondary-ips vlan <1-4059>

Perform a General VLAN Action

Perform a general VLAN action to initiate a specific function on a VLAN, such as clearing learned MAC addresses or ARP entries from the forwarding database by performing this procedure.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Perform a general VLAN action:
vlan action <1-4059> {none|flushMacFdb|flushArp|flushIp|flushDynMemb|triggerRipUpdate|all}

Example

Perform a general VLAN action:

```

Switch(config)#vlan action 1 none
Switch(config)#vlan action 1 flushMacFdb
Switch(config)#vlan action 1 flushIp
Switch(config)#vlan action 1 flushDynMemb

```

Variable Definitions

Use the data in the following table to use the **vlan action** command.

Variable	Value
<i>none</i>	Configures action to none. This action performs no updates.
<i>flushMacFdb</i>	Configures action to flushMacFdb. This action removes the learned MAC addresses from the forwarding database for the selected VLAN.
<i>flushArp</i>	Configures action to flushArp. This action removes the ARP entries from the address table for the selected VLAN.
<i>flushIp</i>	Configures action to flushIp. This action removes the learned IP addresses from the forwarding table for the selected VLAN.
<i>flushDynMemb</i>	Configures action to flushDynMemb. This action removes port members not configured as static from the list of active port members of a policy-based VLAN, and removes MAC addresses learned on those ports for this VLAN.
<i>flushDynMemb</i>	Configures action to flushDynMemb. This action removes port members not configured as static from the list of active port members of a policy-based VLAN, and removes MAC addresses learned on those ports for this VLAN.
<i>triggerRipUpdate</i>	Configures action to triggerRipUpdate.
<i>all</i>	Configures action to all and performs all preceding actions.

Configure Static MAC Addresses for a VLAN

Configure the static MAC address parameters.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure a static MAC address of a VLAN:

```
vlan mac-address-static <1-4059> <0x00:0x00:0x00:0x00:0x00:0x00>
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...] [slot/all] [all]}
```

Example

Configure a static MAC address of a VLAN:

```
Switch(config)#vlan mac-address-static 1 0x00:0x00:0x00:0x00:0x00:0x01 1/1
```

Variable Definitions

Use the data in the following table to use the **vlan mac-address-static** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<0x00:0x00:0x00:0x00:0x00:0x00>	Indicates the MAC address.
{slot/port[/sub-port] [-slot/port[/sub-port]][, ...] [slot/all] [all]}	Identifies the slot and port in one of the following formats: <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>

Limit MAC Address Learning

Configure the MAC security feature to control traffic from specific number of MAC addresses. The total number of MAC addresses that you can configure are fixed. The switch help text shows the maximum MAC addresses a port can learn in non-SPBM configurations. In an SPBM configuration, the maximum value is reduced by half.

About This Task

This feature limits the number of forwarding database (FDB) entries learned on a particular port to a user-specified value. After the number of learned forwarding database entries reaches the maximum limit, MAC learning stops on that port.

Note

This procedure does not apply to 7830 Series.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...][slot/all][all]} or interface mlt <1-512>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Protect the FDB from hits by too many MAC addresses:

```
mac-security [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...][slot/all][all]] limit-learning enable [max-addr <1-64000>]
```

Example

Protect the FDB from hits by too many MAC addresses:

```
Switch:1(config)#interface gigabitethernet 1/1
Switch:1(config-if)#mac-security limit-learning enable
Switch:1(config-if)#mac-security limit-learning max-addr 5000
```

Variable Definitions

Use the data in the following table to use the **mac-security limit-learning** command.

Variable	Value
<i>enable</i>	Limits the MAC learning for the port. After the number of addresses reaches the maximum, the port disables packet forwarding and drops packets. If you enable <i>limit-learning</i> , the FDB entry for each port is limited to the number you specify in <i>max-addr</i> .
<i>max-addr</i> <1-64000>	Specifies the maximum number of MAC addresses to learn. After the number of addresses reaches the maximum, the port disables packet forwarding and drops packets. The default is 1024.
<i>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...][slot/all][all]}</i>	Identifies the slot and port in one of the following formats: <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p> <p>Use this parameter to apply the change to multiple ports without changing CLI modes.</p>

Configure the Forwarding Database Timeout Globally

Use the following procedure to configure the aging time globally for the forwarding database.

Procedure

1. Enter Global Configuration mode:
enable

configure terminal
2. Enter the following command:
mac-address-table aging-time <10-1000000>

Variable Definitions

Use the data in the following table to use the **mac-address-table** command.

Variable	Value
<i>aging-time</i>	Specifies the timeout period for dynamically learned mac addresses on the vlan. The default value is 300.
<i><10-1000000></i>	Specifies the range for the aging time.

Add or Remove Ports in a VLAN

Procedure

1. Enter Interface Configuration mode:
enable

configure terminal

interface GigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...][slot/all][all]} or interface vlan <1-4059>

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Add ports in a VLAN:
vlan members add <1-4059> {slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...][slot/all][all]} [{portmember|static|notallowed}]
3. Remove ports in a VLAN:
vlan members remove <1-4059> {slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...][slot/all][all]} [{portmember|static|notallowed}]

Example

The following example illustrates the use of optional parameters with both commands:

```
Switch:1>enable
Switch:1#configure terminal
```

```

Enter configuration commands, one per line.  End with CNTL/Z.
Switch:1<config>#interface vlan 21
Switch(config-if)#vlan members add 21 1/2 static
Switch(config-if)#vlan members remove 21 1/3 notallowed

```

Variable Definitions

Use the data in the following table to use the **vlan members add** and **vlan members remove** commands.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...] [slot/all] [all]}	Identifies the slot and port in one of the following formats: <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
portmember	Configures the port type as port member.

Configure NLB support

Use Microsoft Network Load Balancing (NLB) to share the workload among multiple clustering servers. For information about software scaling capabilities, see *Fabric Engine Release Notes*.

Before You Begin

- For all modes, configure an IP address on the VLAN enabled with NLB.
- To switch between Unicast NLB and Multicast NLB, you must first disable the NLB support.

About This Task

Use the following procedure to configure NLB support on an IP interface to enable or disable NLB support.

The default value is NLB support disabled.

**Note**

SPBM supports Network Load Balancing (NLB) Unicast and Multicast modes.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Enable NLB support on an interface:

```
nlb-mode unicast
```

Or

```
nlb-mode multicast
```

To switch from one nlb-mode to another, you must first disable the NLB support, and then enter the new nlb-mode.

3. (Optional) Disable NLB support on an interface:

```
no nlb-mode
```

Example

Configure unicast mode for VLAN 2, and then switch to multicast mode.

```
Switch:1(config)#interface vlan 2
Switch:1(config-if)#nlb-mode unicast
Switch:1(config-if)#no nlb-mode
Switch:1(config-if)#nlb-mode multicast
```

Configure a Tagged Port to Discard Untagged Frames

Configure a tagged port to discard all untagged packets so that the frame is not classified into the default VLAN for the port.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...][slot/all][all]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure a tagged port to discard untagged frames:

```
untagged-frames-discard [port {slot/port[/sub-port] [-slot/port[/sub-  
port]][,...]]
```

3. Discard a tagged frame on an untagged port:

```
tagged-frames-discard [port {slot/port[/sub-port] [-slot/port[/sub-  
port]][,...]] enable
```

4. Untag the default VLAN on a tagged port:

```
untag-port-default-vlan [port {slot/port[/sub-port] [-slot/port[/sub-  
port]][,...]] enable
```

Example

Configure a tagged port to discard untagged frames:

```
Switch:1(config-if)#untagged-frames-discard port 1/1
```

Discard a tagged frame on an untagged port:

```
Switch:1(config-if)#tagged-frames-discard port 1/1 enable
```

Untag the default VLAN on a tagged port:

```
Switch:1(config-if)#untag-port-default-vlan port 1/2 enable
```

Variable Definitions

Use the data in the following table to use optional parameters with the **untagged-frames-discard** command.

Variable	Value
<code>{slot/port[/sub-port][-slot/port[/sub-port]][,...][slot/all][all]}</code>	<p>Identifies the slot and port in one of the following formats:</p> <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>

Configuring SLPP

Enable the Simple Loop Prevention Protocol (SLPP) globally and for a VLAN to detect a loop and automatically stop it. The VLAN configuration controls the boundary of SLPP-PDU transmission.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Enable SLPP:

```
slpp enable
```
3. Configure the transmission interval:

```
slpp tx-interval <500-5000>
```
4. Add a VLAN to the transmission list:

```
slpp vid <1-4059>
```

Example

Enable SLPP:

```
Switch:1(config)#slpp enable
```

Configure the transmission interval to 5000 milliseconds:

```
Switch:1(config)#slpp tx-interval 5000
```

Add a VLAN, with the VLAN ID 2, to the transmission list:

```
Switch:1(config)#slpp vid 1
```

Variable Definitions

Use the data in the following table to use the **slpp** command.

Variable	Value
<i>enable</i>	Enables or disables the SLPP operation. You must enable the SLPP operation to enable the SLPP packet transmit and receive process. If you disable the SLPP operation, the system sends no SLPP packets and discards received SLPP packets. The default is disabled.
<i>500–5000</i>	Configures the SLPP packet transmit interval, expressed in milliseconds in a range from 500–5000. The default value is 500.
<i><1–4059></i>	Adds a VLAN, by VLAN ID, to a SLPP transmission list.

Job aid

The following table provides the SLPP values.

Table 347: SLPP values

Enable SLPP	Setting
Access SMLT	Yes
Core SMLT	No
Primary switch	
Packet Rx threshold	5
Transmission interval	500 milliseconds (ms) (default)
Secondary switch	
Packet Rx threshold	50
Transmission interval	500 ms (default)

Configure SLPP packet-rx on a Port

Enable SLPP by port to detect a loop and automatically stop it.

Important

To provide protection against broadcast and multicast storms, as a best practice, enable Rate Limiting for broadcast traffic and multicast traffic.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...][slot/all][all]}
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure SLPP on a port:

```
slpp port {slot/port[-slot/port][,...][slot/all][all]} packet-rx  
[packet-rx-threshold <1-500>]
```

Example

```
Switch(config-if)#slpp port 1/1 packet-rx-threshold 5
```

Variable Definitions

Use the data in the following table to use the **slpp port** command.

Variable	Value
<1-500>	<p>Specifies the SLPP reception threshold on the ports, expressed as an integer. The packet reception threshold specifies how many SLPP packets the port receives before it is administratively disabled. The default value is 1.</p> <p>Note: As a best practice, configure the rx-threshold above 50 slpp packets only on lightly loaded switches. If you configure the rx-threshold to a value greater than 50 on a heavily loaded switch and a loop occurs, the system can experience high CPU utilization.</p>
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...] [slot/all] [all]}	<p>Identifies the slot and port in one of the following formats:</p> <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>

Job aid

The following table provides the SLPP values.

Table 348: SLPP values

Enable SLPP	Setting
Access SMLT	Yes
Core SMLT	No
Primary switch	
Packet Rx threshold	5
Transmission interval	500 milliseconds (ms) (default)
Secondary switch	
Packet Rx threshold	50
Transmission interval	500 ms (default)

Configure SLPP packet-tx on a VLAN

Enable SLPP by VLAN to detect a loop and automatically stop it. This configuration controls the boundary of SLPP-PDU transmission.

Important

To provide protection against broadcast and multicast storms, as a best practice, enable Rate Limiting for broadcast traffic and multicast traffic.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port]}[-slot/port[/sub-port]]  
[,...][slot/all][all]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable SLPP:

```
slpp enable
```

3. Configure the transmission interval:

```
slpp tx-interval <500-5000>
```

4. Add a VLAN to the transmission list:

```
slpp vid <1-4059>
```

Example

Enable SLPP:

```
Switch:1(config)#interface vlan 2  
Switch(config-if)#slpp enable
```

Configure the transmission interval to 500 milliseconds:

```
Switch:1(config-if)#slpp tx-interval 500
```

Add a VLAN, with the VLAN ID of 2, to the transmission list:

```
Switch:1(config-if)#slpp vid 2
```

Variable Definitions

Use the data in the following table to use the **slpp** command.

Variable	Value
<i>enable</i>	Activates or disables the SLPP operation. You must enable the SLPP operation to enable the SLPP packet transmit and receive process. If you disable the SLPP operation, the system sends no SLPP packets and discards received SLPP packets. The default is disabled.
<i>500–5000</i>	Configures the SLPP packet transmit interval, expressed in milliseconds in a range from 500–5000. The default value is 500.
<i><1–4059></i>	Adds a VLAN, by VLAN ID, to a SLPP transmission list.

View SLPP Information

Use SLPP information to view loop information.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. View SLPP information:
`show slpp`

Example

```
Switch:1#show slpp
=====
                        SLPP Info
=====
      operation : enabled
    tx-interval : 500
         vlan : 2
```

View SLPP Information for a Port

Show SLPP information for a port so that you can view the loop information for a port.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. View SLPP information for a port:
`show slpp interface GigabitEthernet [{slot/port[-slot/port]}[,...]
[slot/all][all]]`

3. Clear SLPP packet RX counters:

```
clear slpp stats port [{slot/port[-slot/port]][,...][slot/all][all]}
```

Example

```
Switch:1>enable
Switch:1#show slpp interface GigabitEthernet 1/7
=====
Port Interface
=====
PORT      PKT-RX      PKT-RX      INCOMING      SLPP PDU
NUM       THRESHOLD   VLAN ID      ORIGINATOR
-----
1/7       enabled     5
PORT      PKT-RX      TIME LEFT
NUM       COUNT      TO CLEAR RX COUNT
-----
1/7       29         300
```

Variable Definitions

Use the data in the following table to use the **show slpp interface GigabitEthernet** command.

Variable	Value
{slot/port[/sub-port][-slot/port[/sub-port]][,...][slot/all][all]}	Identifies the slot and port in one of the following formats: <ul style="list-style-type: none">• a single slot and port (slot/port)• a range of slots and ports (slot/port-slot/port)• a series of slots and ports (slot/port,slot/port,slot/port)• all ports on the same slot (slot/all)• all ports on the switch (all) If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configure Automatic Port Recovery

About This Task

Instead of manually recovering a port that is shutdown by SLPP, you can configure an automatic recovery delay per port. The **auto-recover-delay** command specifies the minimum amount of time after which the port is brought back up. The maximum amount of time that can pass until the port is brought back up is two times the configured **auto-recover-delay** value.

By default, automatic recovery is disabled on a port. When enabled, the default delay is 30 seconds.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Configure the automatic recovery delay, in seconds:
`auto-recover-delay <5-3600>`
3. Enable automatic recovery on a port:
`interface gigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...][slot/all][all]}`
`auto-recover-port enable`

Configure Spoof Detection

Configure spoof detection to prevent IP spoofing.

For more information about this feature, see [Prevention of IP Spoofing within a VLAN](#) on page 4000.

Important

If you use SMLT, configure spoof detection on both SMLT aggregation devices to avoid connectivity issues.

Procedure

1. Enter GigabitEthernet Interface Configuration mode:
`enable`
`configure terminal`
`interface GigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...][slot/all][all]}`
-  **Note**
If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
2. Enable or disable spoof detection:
`spoof-detect [port {slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]
[slot/all][all]}] [enable]`
`no spoof-detect [port {slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...][slot/all][all]}} [enable]`

3. Enable or disable auto-recovery on a port:

```
auto-recover-port [port {slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...][slot/all][all]}

no auto-recover-port [port {slot/port[/sub-port]} [-slot/port[/sub-
port]][,...][slot/all][all]] [enable]
```

Example

Enable spoof detection:

```
Switch(config-if)#spoof-detect port 1/1 enable
```

Enable autorecovery on a port:

```
Switch(config-if)#auto-recover-port port 1/1 enable
```

View VLAN Information

View the VLAN information to display the basic configuration for all VLANs or a specified VLAN.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View VLAN information:

```
show vlan basic <1-4059>
```
3. View advanced parameters:

```
show vlan advance <1-4059>
```

Example

View VLAN information for VLAN 2:

```
Switch:1>show vlan basic 2
=====
Vlan Basic
=====
VLAN      INST
ID  NAME      TYPE      ID  PROTOCOLID  SUBNETADDR  SUBNETMASK  VRFID  ORIGIN
-----
2    VLAN-2    byPort    0   none        N/A         N/A         0      CONFIG
```

View VLAN information:

```
Switch:1>show vlan basic
=====
Vlan Basic
=====
VLAN      INST
ID  NAME      TYPE      ID  PROTOCOLID  SUBNETADDR  SUBNETMASK  VRFID  ORIGIN
-----
1    Default    byPort    0   none        N/A         N/A         0      CONFIG
2    abc        byPort    0   none        N/A         N/A         0      CONFIG
```

3	VLAN-VRRP	byPort	0	none	N/A	N/A	0	CONFIG
4	VLAN-6	byPort	0	none	N/A	N/A	1	CONFIG
5	VLAN-7	byPort	0	none	N/A	N/A	1	CONFIG
6	VLAN-8	byPort	0	none	N/A	N/A	1	CONFIG
19	VLAN-9	byPort	0	none	N/A	N/A	0	CONFIG
10	VLAN-10	byPort	0	none	N/A	N/A	0	CONFIG
11	VLAN-11	byPort	0	none	N/A	N/A	0	CONFIG
12	VLAN-12	byPort	0	none	N/A	N/A	0	CONFIG
13	VLAN-13	spbm-bvlan	62	none	N/A	N/A	0	CONFIG
14	VLAN-14	spbm-bvlan	62	none	N/A	N/A	0	CONFIG
15	VLAN-15	byPort	1	none	N/A	N/A	0	CONFIG
--More-- (q = quit)								

View advanced parameters. The following example displays a VLAN that is not associated with a Segmented VRF, as seen in the L3 ACCESS of GlobalRouter:

```
Switch:1>show vlan advance
=====
                        Vlan Advance
=====
VLAN      IF      AGING  MAC      USER      L3
ID  NAME      INDEX TIME  ADDRESS  DEFINEPID ACCESS  ENCAP  DSAP/SSAP
-----
2    Default  2050  0    00:24:7f:9f:6a:03  0x0000  GlobalRouter
```

Variable Definitions

Use the data in the following table to use optional parameters with the **show vlan basic** and **show vlan advance** commands.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

View Private VLAN Information

You can view the private VLAN information to display the primary and secondary VLANs and I-SIDs, and also view the private VLAN port types.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View private VLAN information:
show vlan private-vlan <1-4059>
3. View private VLAN port information:
show interfaces gigabitethernet private-vlan

Example

View VLAN information for private VLAN:

```
Switch:1(config)#show vlan private-vlan
=====
PRIVATE VLAN
=====
Primary      Primary      Secondary      Secondary
VLAN         ISID         VLAN           ISID
-----
3            75           5              75
10           22           15             22

All 2 out of 2 Total Num of Private Vlans displayed
```

View port information for private VLAN:

```
Switch:1(config)#show interfaces gigabitethernet private-vlan
=====
Port Private Vlans
=====
PORT      TAGGING  ORIGIN  PVLAN  PVLAN TYPE  VID  VID
NUM              TYPE              TYPE      TYPE
-----
2/2       enable   CONFIG  enable  promiscuous -     -

All 1 out of 1 Total Num displayed
```

View Brouter Port Information

View the brouter port information to display the brouter port VLAN information for all VLANs on the device or for the specified VLAN.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View brouter port information:
show vlan brouter-port

Example

View brouter port information:

```
Switch:1>show vlan brouter-port
Vlan Id      Port      VrfId
=====
2202         1/11      0
```

All 1 out of 1 Total Num of Vlan Brouter Port Entries displayed

View VLAN Port Member Status

View the VLAN port member status to display the port member status for all VLANs on the device or for the specified VLAN.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View VLAN port member status:

```
show vlan members [<1-4059>][null-vlan][port {slot/port[-slot/port]}
[,...][slot/all][all]]
```

Example

View VLAN port member status:

```
Switch:1>show vlan members port 1/2
=====
Vlan Port
=====
VLAN PORT      ACTIVE      STATIC      NOT_ALLOW
ID  MEMBER      MEMBER      MEMBER      MEMBER
-----
2    1/2,1/5-1/8,1/11,  1/2,1/5-1/8,1/11,
    1/14,1/26,1/38    1/14,1/26,1/38

3    1/2,1/5-1/8,1/14,  1/2,1/5-1/8,1/14,
    1/26,1/38          1/26,1/38

4    1/1-1/2,1/5-1/8,  1/1-1/2,1/5-1/8,
    1/13-1/14,1/25-    1/13-1/14,1/25-
    1/26,1/37-1/38    1/26,1/37-1/38

100  1/2,1/14,1/23-    1/2,1/14,1/23-
    1/24,1/26-1/28,    1/24,1/26-1/28,
    1/38                1/38

300  1/2,1/5-1/8,1/14,  1/2,1/5-1/8,1/14,
    1/26,1/38          1/26,1/38
```

Variable definitions

Use the data in the following table to use optional parameters with the **show vlan members** command.

Variable	Value
<code>null-vlan</code>	Displays port members of the NULL VLAN. This is a place holder VLAN for ports that are not members of any port-based VLAN. When a port is removed from all port-based VLANs, it is added to the NULL VLAN as a port member. The NULL VLAN is an internal construct and cannot be deleted.
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...] [slot/all] [all]}</code>	<p>Identifies the slot and port in one of the following formats:</p> <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p> <p>If you do not specify a port, the command shows information for all the ports.</p>
<code><1-4059></code>	<p>Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.</p> <p>Note: Entering a VLAN ID is optional. If you enter a VLAN ID the command shows information for the specified VLAN or port. Without the VLAN ID the command shows information for all the configured VLANs.</p>

View VLAN Source MAC Addresses

View the VLAN source MAC addresses to display the source MAC address for a source MAC-based VLAN on the device or for the specified VLAN.

Procedure

View VLAN source MAC addresses:

```
show vlan src-mac [<1-4059>]
```

Example

View VLAN source MAC addresses:

```
Switch(config)#show vlan src-mac
=====
                        Vlan Srcmac
=====
VLAN_ID    MAC_ADDRESS
-----
10         00:00:00:00:00:11

All 1 out of 1 Total Num of Vlan Srcmac Entries displayed
```

View VLAN Forwarding Database Information

Use this procedure to display the MAC addresses that are learned or statically configured for a VLAN. In order to learn you have to be connected to another switch or host and receive some traffic.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View VLAN forwarding database information:

```
show vlan mac-address-entry [<1-4059>]
```

Example

View VLAN forwarding database information:

```
Switch:1>show vlan mac-address-entry
=====
                        Vlan Fdb
=====
VLAN      MAC              SMLT
ID  STATUS  ADDRESS          INTERFACE  REMOTE TUNNEL
-----
1    learned  f8:15:47:e1:80:0c Port-1/2   false  -
2    learned  32:20:d3:81:00:77 Port-1/9   false  -
4    learned  b4:a9:5a:2b:78:31 Port-2/1   false  -

3 out of 3 entries in all fdb(s) displayed.
```

View where entries are learned. The TUNNEL column indicates where in the SPBM network an entry is learned.

```
Switch:1>show vlan mac-address-entry spbm-tunnel-as-mac
=====
                        Vlan Fdb
=====
VLAN      MAC              SMLT
ID  STATUS  ADDRESS          INTERFACE  REMOTE TUNNEL
-----
1    learned  f8:15:47:e1:80:0c Port-1/2   false  -
2    learned  32:20:d3:81:00:77 Port-1/9   false  -
```

```

4      learned      b4:a9:5a:2b:78:31  Port-2/1      false  -
3 out of 3 entries in all fdb(s) displayed.

```

Variable Definitions

Use the data in the following table to use optional parameters with the **show vlan mac-address-entry** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
mac <0x00:0x00:0x00:0x00:0x00:0x00>	Specifies the MAC address.
port {slot/port[-slot/port][,...]}	Specifies the port or port list.
spbm-tunnel-as-mac	Displays where entries are learned. The TUNNEL column indicates where in the SPBM network an entry is learned.

View Manual Edit MAC Addresses

Use the procedure to view the list of manual edit MAC addresses and the associated ports configured as allow-mac for MAC security.

Procedure

View manual edit MAC addresses:

```
show vlan manual-edit-mac
```

Example

View manual edit MAC addresses:

```

Switch(config)#show vlan manual-edit-mac
=====
Manual Edit Mac
=====
MAC ADDRESS      PORTS
-----
00:00:00:00:00:55  1/3
00:00:00:00:00:66  1/3

All 2 out of 2 Total Num of Manual Edit Mac Entries displayed

```

View Port-Level MAC Security

View port-level MAC security to review the configuration.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View port-level MAC security for limit-learning:
show interfaces gigabitethernet limit-fdb-learning [{slot/port[-slot/port]}[,...]]

Example

View port-level MAC security for limit-learning:

```
Switch:1#show interfaces gigabitethernet limit-fdb-learning 1/4-1/5
=====
Port limit-fdb-learning
=====
```

PORT NUM	FDB PROTECT	MAXMAC COUNT	MINMAC COUNT	PORT DOWN	CURMAC COUNT	MAC LEARN
1/4	dis	1024	512	dis	0	true
1/5	ena	5000	3000	dis	0	true

View NLB-Mode Information

View Network Load Balancing-mode (NLB-mode) information.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View NLB port information:
show interfaces vlan nlb-mode [<1-4059>]

Example

View NLB-mode information.

```
Switch:1#show interfaces vlan nlb-mode
=====
Vlan Nlb
=====
```

VLAN_ID	NLB_ADMIN_MODE	NLB_OPER_MODE	PORT_LIST	MLT_GROUPS
2	unicast	disable		
22	multicast	multicast	1/19-1/21	2 3

Total Entries: 2

Enable DvR on a Layer 2 VSN (VLAN)

Before You Begin

- Ensure that the VLAN on which to enable DvR exists and is associated with an I-SID.

About This Task

On a Controller, DvR must be manually enabled at the Layer 2 VSN (VLAN) level.

Use this procedure to configure a gateway IPv4 address for a Layer 2 VSN (VLAN) subnet and then enable DvR on it. This address is pushed, along with other Layer 3 configuration information, from the Controllers to the Leaf nodes within the domain, so that the Leaf nodes can create a gateway IP service for each DvR-enabled Layer 2 VSN.

Note

Optionally, you can now use a single IP address in the subnet for every Controller by configuring the DvR VLAN IP to be the same as the DvR GW IP.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```

2. Configure a gateway IPv4 address for the VLAN.

```
dvr gw-ipv4 {A.B.C.D}
```

Important

Ensure that you configure the same gateway IPv4 address on all Controllers in the domain that belong to a Layer 2 VSN (VLAN).

3. Enable DvR.

```
dvr enable
```

By default, DvR is disabled.

Example

Enable DvR on the Global Router VLAN.

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config-if)#vlan create 200 type port-mstprstp 0
Switch:1(config-if)#vlan i-sid 200 20200
Switch:1(config-if)#interface vlan 200
Switch:1(config-if)#dvr gw-ipv4 192.0.2.1
Switch:1(config-if)#dvr enable
Switch:1(config-if)#ip address 192.0.2.2 255.255.0.0
```

Enable DvR on a VLAN associated to a VRF:

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config-if)#vlan create 400 type port-mstprstp 0
Switch:1(config-if)#vlan i-sid 400 20200
```

```
Switch:1(config-if)#interface vlan 400
Switch:1(config-if)#vrf vrf500
Switch:1(config-if)#dvr gw-ipv4 198.51.100.1
Switch:1(config-if)#dvr enable
Switch:1(config-if)#ip address 198.51.100.2 255.255.0.0
```

Variable definitions

Use the data in the following table to use the **dvr gw-ipv4** command.

Variable	Value
{A.B.C.D}	Specifies the gateway IPv4 address for the VLAN.

Configure a Single IP Address for All DvR Controllers on a VLAN Subnet

Before You Begin

- Ensure that the VLAN on which to enable DvR exists and is associated with an I-SID.

About This Task

On a Controller, DvR must be manually enabled at the Layer 2 VSN (VLAN) level.

Use this procedure to configure a single IP address to be used for both the DvR GW IP and the VLAN IP in the DvR VLAN. This IP address represents the DvR GW IP address used by all DvR Controllers for the same DvR VLAN. When you configure a DvR VLAN in this way, the Controllers no longer have a unique VLAN IP address.

Note

Optionally, you can use two different IP address for the DvR VLAN and the DvR GW IP.

Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Configure a single IP address for both the DvR GW IP and the VLAN IP in the DvR VLAN.

```
ip address {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>} dvr-one-ip [state-  
disabled]
```

3. Enable DvR.

```
dvr enable
```

By default, DvR is disabled.

Example

Enable DvR.

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config-if)#vlan create 200 type port-mstprstp 0
Switch:1(config-if)#vlan i-sid 200 20200
Switch:1(config-if)#interface vlan 200
Switch:1(config-if)#ip address 192.0.2.1 255.255.0.0 dvr-one-ip
Switch:1(config-if)#dvr enable
```

Variable Definitions

The following table defines parameters for the **ip address** command.

Variable	Value
<A.B.C.D/X> <A.B.C.D> <A.B.C.D>	Specifies the IP address and subnet mask in the format A.B.C.D/X or A.B.C.D A.B.C.D.
<i>dvr-one-ip</i>	Specifies the IP address used for the DvR gateway IP address and the VLAN IP in the DvR VLAN.
<i>state-disabled</i>	Creates the IP interface in an administratively disabled state. This parameter is useful if you want to preconfigure an IP interface, for example, to prepare for DvR migration, and enable it later during a maintenance window. By default, the switch enables an IP interface after you configure the primary IP address.

VLAN Configuration using EDM

This section describes how to configure and manage Virtual Local Area Networks (VLAN) using Enterprise Device Manager (EDM).

Configure a VLAN on a Port

Configure a VLAN on a port.

Procedure

1. In the Device Physical View tab, select a port or multiple ports.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **VLAN** tab.
5. To perform tagging, select **PerformTagging**.
6. To discard tagged frames, select **DiscardTaggedFrames**.
7. To discard untagged frames, select **DiscardUntaggedFrames**.

8. To use the Untag Default VLAN feature, select **UntagDefaultVlan**.

Important

Enable tagging on the port before you configure UntagDefaultVlans.

9. Enter a default VLAN ID.
 10. To enable spoof detect, select **SpoofDetect**.
 11. In the Classification area, select the types of VLAN to enable.
 12. In the **Classification** area, select the Private VLAN port type.
 See [Create a Private VLAN](#) on page 4049 for more information.
 13. Select **Apply**.
 14. Select **Close**.

VLAN Field Descriptions

Use the data in the following table to use the **VLAN** tab.

Name	Description
PerformTagging	If checked, this port is a tagged (Trunk) Port. It can belong to multiple port-based VLANs and a VLAN tag is inserted in every frame it transmits. If it is not checked, the port is an untagged (Access) port. The default is disabled.
VlanIdList	Identifies which VLANs this port is assigned.
DiscardTaggedFrames	If selected, and the port is untagged (an access port), tagged frames received on the port are discarded by the forwarding process. If clear, tagged frames are processed normally. The default is disabled.
DiscardUntaggedFrames	If selected and the port is tagged (a trunk port), untagged frames received on the port are discarded by the forwarding process. If clear, untagged frames are processed normally. The default is disabled.
UntagDefaultVLAN	If selected, even if the port is tagged (a trunk port), frames forwarded to the default VLAN for the port are not tagged. The default is disabled.
UntaggedVlanIds	Identifies which VLANs this port is associated with as untagged.
DefaultVlanId	Specifies the VLAN ID assigned to untagged frames received on this trunk port that match no policy-based VLAN to which the port belongs.
SpoofDetect	Enables or disables spoof detection on the specified port.

Name	Description
PrivateVlanPortType	Specifies the port type for a Private VLAN. If not specified, the port type defaults to None. <ul style="list-style-type: none">• Isolated: An Isolated port can belong only to one private VLAN• Promiscuous: A Promiscuous port can belong to many private VLANs.• Trunk: A Trunk port can belong to many private VLANs, is tagged, and can also belong to non-private VLANs.
Origin	Specifies the origin of VLAN configuration on the port, either manually configured through CLI or EDM, or dynamically configured through Auto-sense.

Configure the VLAN Feature on an Extreme Integrated Application Hosting Port

About This Task

Note

This procedure only applies to 5720-24MXW, 5720-48MXW, 7520 Series, and 7720 Series.

Perform this procedure to configure the VLAN feature on an Extreme Integrated Application Hosting (IAH) port.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **VLAN** tab.
4. Select **PerformTagging** to enable tagging.
5. Select **DiscardTaggedFrames** to discard tagged frames.
6. Select **DiscardUntaggedFrames** to discard untagged frames.
7. Select **UntagDefaultVlan** to enable the Untag Default VLAN feature.

Important

You must enable tagging on the IAH port before you enable the Untagging Default VLANs feature.

8. In **DefaultVlanId**, enter a default VLAN ID.
9. Select **SpoofDetect** to enable spoof detection.
10. In **PrivateVlanPortType**, select a type.
11. Select **Apply**.

VLAN Field Descriptions

Use data in the following table to use the **VLAN** tab.

Name	Description
PerformTagging	Enables tagging (trunking) on the Extreme Integrated Application Hosting (IAH) port. It can belong to multiple port-based VLANs and a VLAN tag is inserted in every frame it transmits. If it is not checked, the IAH port is an untagged (Access) IAH port. The default value is different for each IAH port.
VlanIdList	Shows the VLAN ID to which the IAH port is assigned to.
DiscardTaggedFrames	Enables the functionality to discard tagged frames received on the IAH port by the forwarding process, for untagged (access) IAH port. The default is disabled.
DiscardUntaggedFrames	Enables the functionality to discard untagged frames received on the IAH port by the forwarding process, for tagged (trunk) IAH port. The default is disabled.
UntagDefaultVLAN	Enables the functionality to untag the frames forwarded to the default VLAN, even if the IAH port is tagged (trunk port). The default is disabled.
UntaggedVlanIds	Shows the untagged VLAN IDs associated with the IAH port.
DefaultVlanId	Specifies the VLAN ID assigned to untagged frames received on the IAH port that match no policy-based VLAN to which the EIAH port belongs.
SpoofDetect	Enables spoof detection on the specified IAH port.
PrivateVlanPortType	Specifies the following: <ul style="list-style-type: none"> • trunk: tagged IAH port. • isolated: Only private VLANs are permitted on isolated IAH ports. • promiscuous: Only private VLANs are permitted on promiscuous IAH ports. • none: default value.

View existing VLANs

View the configuration and current status of all defined VLANs.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.

2. Select **VLANs**.
3. View the configured VLANs in the **Basic** tab.
4. View the configured private VLANs in the **Private VLAN** tab.

Create a Port-Based VLAN

Create a port-based VLAN. To create a different type of VLAN, see one of the following procedures:

- [Create a Protocol-Based VLAN](#) on page 4054
- [Create an SPBM B-VLAN](#) on page 4055

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. In the **Basic** tab, select **Insert**.
4. In the **Id** box, enter an unused VLAN ID, or use the ID provided.
5. In the **Name** box, type the VLAN name, or use the name provided.
6. In the **Color Identifier** box, select the down arrow and choose a color from the list, or use the color provided.
7. In the **MstpInstance** box, select the down arrow and choose an msti instance from the list.
8. In the **Type** box, select **byPort**.
9. In the **PortMembers** box, select the ellipsis (...).
10. Select the ports to add as member ports.
The ports that are selected are recessed. Nonselected ports are not recessed. You cannot select a Port number that is dimmed as a VLAN port members.
11. Select **OK**.
12. Select **Insert**.

Basic Field Descriptions

Use the data in the following table to use the **Basic** tab.

Name	Description
Id	Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
Name	Specifies the name of the VLAN.
IfIndex	Specifies the logical interface index assigned to the VLAN.

Name	Description
Color Identifier	Specifies a proprietary color scheme to associate a color with the VLAN. Color does not affect how frames are forwarded.
Type	Specifies the type of VLAN: <ul style="list-style-type: none"> • byPort • byProtocolId • spbm-bvlan • private
MstpInstance	Identifies the MSTP instance.
VrfId	Indicates the VRF ID to which the VLAN belongs.
VrfName	Indicates the name of the VRF to which the VLAN belongs.
PortMembers	Specifies the slot/port of each VLAN member. The system displays the sub-port only for channelized ports.
ActiveMembers	Specifies the slot/port of each VLAN member. The system displays the sub-port only for channelized ports.
StaticMembers	Specifies the slot/port of each static member of a policy-based VLAN. The system displays the sub-port only for channelized ports.
NotAllowToJoin	Specifies the slot/ports that are never allowed to become a member of the policy-based VLAN. The system displays the sub-port only for channelized ports.
ProtocolId	Specifies the network protocol for protocol-based VLANs. This value is taken from the Assigned Numbers of remote function call (RFC). If the VLAN type is port-based, none is displayed in the Basic tab ProtocolId field.

Name	Description
AgingTime	Specifies the timeout period, in seconds, to age out dynamic members of this VLAN. This parameter only applies to policy-based VLANs. The default is 600.
Clear Secondary IPs	Removes all secondary IP addresses on a VLAN simultaneously. To remove specific secondary IP addresses from a VLAN, use the Secondary IP Addresses tab (Configuration > VLAN > VLANs > Basic > IP). For more information, see Secondary IP Addresses Field Descriptions on page 4053.

Note

If you or another user changes the name of an existing VLAN using the VLAN **Basic** tab (or using CLI), the system does not display the new name initially in EDM. To display the updated name, perform one of the following actions:

- Refresh your browser to reload EDM.
- Log out of EDM and log in again to restart EDM.
- Select **Refresh** in the VLAN **Basic** tab toolbar. If the system displays the old VLAN name in other tabs, select **Refresh** on those tabs as well.

Create a Private VLAN

Before You Begin

- To create a private VLAN, you must configure the VLAN type to private and configure the private VLAN port type.
- The ports you add to a private VLAN must have a port type of isolated, promiscuous, or trunk.

About This Task

For additional information about the tabs referenced in this procedure, see the following sections:

- **VLAN > VLANs > Basic** tab: [Basic Field Descriptions](#) on page 4047
- **Edit > Port > General > VLAN** tab: [VLAN Field Descriptions](#) on page 4044

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select **Insert**.
5. For **Id**, type an unused VLAN ID, or use the ID provided.

6. (Optional) For **Name**, type the VLAN name, or use the name provided.
7. (Optional) For **Color Identifier**, select a color from the list, or use the color provided.
8. (Optional) For **MstpInstance**, select an msti instance from the list.
9. For **Type**, select **private**.
10. For **PortMembers**, select the ellipsis (...).
11. Select the ports to add as member ports.
The ports that are selected are recessed, while the non-selected ports are not recessed. Port numbers that are dimmed cannot be selected as VLAN port members.
12. Select **OK**.
13. For **Secondary Vlan**, type an unused VLAN ID.
14. Select **Insert**.
15. In the Device Physical View, select the Private VLAN port members.
16. In the navigation pane, expand **Configuration > Edit > Port**.
17. Select **General**.
18. Select the **VLAN** tab.
19. For **PrivateVlanPortType**, select the port type.
20. Select **Apply**.

View Private VLAN Information

You can view the private VLAN information for the primary and secondary VLANs, I-SIDs, and private VLAN port types.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select **Private VLAN**.

Private VLAN Field Descriptions

Use the data in the following table to use the **Private VLAN** tab.

Name	Description
Primary Vlan	Shows the VLAN ID for the primary VLAN.
Secondary Vlan	Shows the VLAN ID for the secondary VLAN.
Primary / Secondary I-sid	Shows the I-SID for the VLAN.

Configure a Primary IP Address for a VLAN

Assign an IP address to a VLAN to enable routing on the VLAN.

About This Task

The ability to create an IP interface in a disabled state in one step is available only using CLI.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. On the **Basic** tab, select the VLAN to configure.
4. Select **IP**.
5. On the **Primary IP Address** tab, select **Insert**.
6. Configure the required parameters.
7. Select **Insert**.

Primary IP Address Field Descriptions

Use the data in the following table to use the **Primary IP Address** tab.

Name	Description
Interface	Shows the interface to which this entry applies.
Ip Address	Specifies the IP address to associate with the VLAN.
Net Mask	Specifies the subnet mask associated with the IP address of this entry. The value of the mask is an IP address with all the network bits configured to 1 and all the hosts bits configured to 0.
Name	Specifies a name for the interface.
BcastAddrFormat	Shows the IP broadcast address format on this interface.
ReasmMaxSize	Shows the size of the largest IP datagram which this entity can reassemble from incoming IP fragmented datagrams received on this interface.
VlanId	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
BrouterPort	Indicates whether this entry corresponds to a brouter port, as oppose to a routable VLAN.

Name	Description
MacOffset	Specifies the MAC offset value. Routable VLANs are assigned MAC addresses arbitrarily or by offset. Their MAC addresses are: <ul style="list-style-type: none"> • 24 bits: Vendor ID • 12 bits: Chassis ID • 12 bits: 0xA00-0xFFFF If you enter the MAC offset, the lowest 12 bits are 0xA00 plus the offset. If not, they are arbitrary.
IfType	Identifies the type of interface.
VrfId	Associates the VLAN with a VRF. VRF ID 0 is reserved for the administrative VRF.

Modify the Administrative State of an IP Interface on a VLAN

By default, the switch enables an IP interface after you configure the primary IP address. You can administratively disable, and then reenables, an IPv4 interface after you create it. For example, if you want to change the routing protocol configuration on the interface.

About This Task

This procedure applies to the IP Layer and functionality for the VLAN.

The ability to create an IP interface in a disabled state in one step is available only using CLI.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. On the **Basic** tab, select the VLAN you need to modify.
4. Select **IP**.
5. Select the **IP Interface** tab.
6. Change the **AdminStatus** value to change the administrative state.
7. Select **Apply**.

IP Interface Field Descriptions

Use the data in the following table to help use the **IP Interface** tab.

Name	Description
AdminStatus	Modifies the administrative state of the IP Interface. By default, the switch enables an IP interface after you configure the primary IP address.
OperState	Displays the operational state of the IP Interface.

Configure a Secondary IP Interface for a VLAN

Assign a secondary IP address to a VLAN to increase the number of connected hosts the VLAN can support.

Before You Begin

You must configure a primary IP address before you can add a Secondary IP Interface.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. On the **Basic** tab, select the VLAN to configure.
4. Select **IP**.
5. On the **Secondary IP Addresses** tab, select **Insert**.
6. Type the IP address.
7. Type the subnet mask.
8. Select **Insert**.

Secondary IP Addresses Field Descriptions

Use the data in the following table to use the **Secondary IP Addresses** tab.

Name	Description
Interface	Identifies the IP interface.
Ip Address	Specifies the secondary IP address.
Net Mask	Specifies the subnet mask for the address.
Vlan ID	Identifies the VLAN ID.
Vrf ID	Identifies the associated VRF ID, if applicable.

Change VLAN Port Membership

Modify VLAN port members to control access to the VLAN.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
 2. Select **VLANs**.
 3. Select the **PortMembers** number for the VLAN for which you want to modify port membership.
 4. Select the port members you want to add or remove.
 5. Select **Ok**.
 6. Select **Apply**.
- The VLAN port membership is changed.

Create a Protocol-Based VLAN

Use a protocol-based VLAN so that the VLAN only carries certain traffic types.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. In the **Basic** tab, select **Insert**.
4. In the **Id** box, type the unique VLAN ID or use the ID provided.
5. In the **Name** box, type the VLAN name or use the name provided.
6. In the **Color Identifier** box, select the color or use the color provided.
This color is used to visually distinguish the VLANs in a network.
7. In the **MstpInstance** box, select the down arrow and choose an MSTI instance from the list.
8. In the **Type** box, select **byProtocolId**.
This activates additional fields needed to configure protocol-based VLANs.
9. To specify the VLAN port membership, select the ellipsis (...) for one of the following fields:

Port Members

OR

StaticMembers

OR

NotAllowToJoin

10. Select each port button to choose the desired membership color.
Yellow: Potential members—dynamic (potential members are treated as always members)

OR

Green: Always members—static

OR

Red: Never members—not allowed to join

Important

In a protocol-based VLAN, a potential member becomes an active member of the VLAN after a frame of the specified protocol is received.

11. Select **Insert**.

Create an SPBM B-VLAN

Create a Shortest Path Bridging MAC (SPBM) Backbone VLAN (B-VLAN). Each SPBM network instance is associated with at least one backbone VLAN (B-VLAN) in the core SPBM network. This VLAN is used for both control plane traffic and dataplane traffic.

Note

As a best practice, configure two B-VLANs in an SPBM dual-homing environment.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. In the **Basic** tab, Select **Insert**.
4. In the **Id** box, enter an unused VLAN ID, or use the ID provided.
5. In the **Name** box, type the VLAN name, or use the name provided.
6. In the **Color Identifier** box, select the down arrow and choose a color from the list, or use the color provided.
7. In the **Type** box, select **spbm-bvlan**.
8. Select **Insert**.
9. Collapse the **VLANs** tab.

The VLAN is added to the **Basic** tab.

Configure Advanced VLAN Features

Use advanced VLAN features to configure the VLAN name, aging time, VLAN operation action, and QoS level. The VLAN Operation Action parameter can be useful for troubleshooting.

You can also configure a DvR Gateway IPv4 address on a VLAN, and enable DvR on it.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Advanced** tab.
4. Configure the parameters as required by double-clicking fields to make changes.
You cannot make changes to fields that are dim.
5. Select **Apply**.

Advanced Field Descriptions

Use the data in the following table to use the **Advanced** tab.

Name	Description
Id	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
Name	Specifies the name of the VLAN.
IfIndex	Specifies the logical interface index assigned to the VLAN.
Type	Specifies the type of VLAN: <ul style="list-style-type: none"> • byPort • byProtocolId • spbm-bvlan • private
Isid	Specifies the Service Instance Identifier (I-SID) number assigned to a customer VLAN (C-VLAN). The default value is 0, which indicates that no I-SID is assigned. <p>Note: When you add or remove an I-SID on a VLAN IP interface for 5520 Series or 5720 Series, the switch disables and enables routing on the VLAN interface.</p>
Isid Name	Specifies the name of the I-SID.
Origin	Specifies the origin of the VLAN configuration, either manually configured through CLI or SNMP, or dynamically configured through RADIUS VSA or Zero Touch Fabric Configuration.
ProtocolId	Specifies the network protocol for protocol-based VLANs. If the VLAN type is not protocol-based, the switch displays a value of None.
AgingTime	Specifies the timeout period for dynamic VLAN membership. A potential VLAN port is made ACTIVE after it receives a packet that matches the VLAN; if no such packet is received for AgingTime seconds, the port is no longer active. The default is 600.

Name	Description
MacAddress	Specifies the MAC address assigned to the virtual router interface for this VLAN, which is relevant only after the VLAN is configured for routing. This MAC address is used as the Source MAC in routed frames and ARP replies.
Vlan Operation Action	<p>Performs an operation on the VLAN. The values are:</p> <ul style="list-style-type: none"> • none • flushMacFdb: Configures action to flushMacFdb. This action removes the learned MAC addresses from the forwarding database for the selected VLAN. • flushArp: Configures action to flushArp. This action removes the ARP entries from the address table for the selected VLAN. • flushIp: Configures action to flushIp. This action removes the learned IP addresses from the forwarding table for the selected VLAN. • flushDynMemb: Configures action to flushDynMemb. This action removes port members not configured as static from the list of active port members of a policy-based VLAN and removes MAC addresses learned on those ports. • all: Configures action to all. This action performs all the supported actions; it does not perform the Snoop-related actions. <p>The default is none.</p>
Result	Specifies the result code after you perform an action.
NlbMode	Enables or disables Microsoft Network Load Balancing (NLB) operations on the VLAN. The default is disabled.
SpbMulticast	Enables or disables IP Multicast over Fabric Connect. The default is disabled.
SpbPimGatewayMulticast	Enables or disables SPB-PIM Gateway Multicast on a VLAN. The default is disabled.
RmonEnable	Enables or disables Remote Monitoring (RMON) on the interface. The default is disabled.
Ipv6FhsSnoopDhcpEnable	Enables or disables IPv6 dhcp snooping on a VLAN. The default is disabled.

Name	Description
Ipv6FhsNDInspectionEnable	Enables or disables neighbor discovery (ND) inspection on a VLAN. The default is disabled.
DvrEnable Note: Exception: not supported on 4220 Series.	Enables or disables Distributed Virtual Routing (DvR) on a VLAN that is configured on the DvR Controller. The default is disabled. Note: You must enable DvR on every VLAN that is configured on a DvR Controller.
DvrGwIpv4Addr Note: Exception: not supported on 4220 Series.	Specifies the DvR gateway IPv4 address for a VLAN. Important: Ensure that you configure the same gateway IPv4 address on all Controllers in the DvR domain that belong to a VLAN.
DvrGwIpv4Onelp Note: Exception: not supported on 4220 Series.	Enables or disables the DvR One IP for a VLAN. The default is disabled (false).
DvrVrrpElection Note: Exception: not supported on 4220 Series, 5320 Series, or 5420 Series.	Identifies the DvR VLAN, and associated I-SID, to become the primary Virtual Router Redundancy Protocol (VRRP) router through the election process. You can identify only one VLAN for election per DvR Controller. By default, no VLAN is configured as the DvR VRRP election VLAN.
MvpnIsidValue	Configures the MVPN I-SID value for the VLAN.
MvpnIsidStatus	Identifies the MVPN I-SID status. <ul style="list-style-type: none"> static—VRF was created by configuring an MVPN I-SID on a VLAN through CLI and EDM dynamic—VRF was created by configuring an MVPN I-SID on a VLAN through RADIUS notConfigured—MVPN I-SID is not configured on a VLAN.
MvpnIsidOffset	Allows you to add an offset parameter to the MVPN I-SID. This is an optional value and the range is 0-511.

Configure NLB Support

Use Microsoft Network Load Balancing (NLB) to share the workload among multiple clustering servers. For more information about software scaling capabilities, see *Fabric Engine Release Notes*.

Before You Begin

Ensure that the VLAN exists and has an associated IP address.

About This Task

Use the following procedure to configure NLB support on an IP interface to enable or disable NLB support. The default value is NLB support disabled.

Note

- SPBM supports Network Load Balancing (NLB) Unicast and Multicast modes.
- Static multicast ARP entries are not supported for NLB Unicast or NLB Multicast.
- Multicast MAC flooding is not supported for NLB.
- ARP entries for NLB server IP addresses do not age out when there is still client traffic coming to the NLB servers, even after the NLB servers are no longer reachable.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Advanced** tab.
4. In the row for the VLAN, double-click the value in the **NlbMode** column.
5. Select the appropriate value.
6. Select **Apply**.

Configure a Port to Accept Tagged or Untagged Frames

Configure a port to accept tagged or untagged frames.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **VLAN** tab.

5. To configure tagging on the port, select the **PerformTagging** check box.

This setting applies to all VLANs associated with the port.

**Note**

If the check box is selected, tagging is enabled. All frames sent from this port are tagged.

If the check box is cleared, tagging is disabled. The port does not send tagged frames. The switch removes the tag before sending the frame out of the port.

6. To discard tagged frames on a port for which tagging is disabled, select **DiscardTaggedFrames**.
7. To discard untagged frames on a port for which tagging is enabled, select **DiscardUntaggedFrames**.
8. To designate a default VLAN to associate with a packet that does not match a policy-based VLAN, enter a VLAN ID in the **DefaultVlanId** box or use the default VLAN 1.
9. Select **Apply**.
10. Select **Close**.

Configure Untagging Default VLAN on a Tagged Port

Configure an untagged default VLAN on a tagged port to separate untagged packets originating from a PC from the tagged packets originating from an IP phone.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **VLAN** tab.
5. Select **UntagDefaultVlan**.
6. In the **DefaultVlanId**, enter a default VLAN ID.
7. Select **Apply**.
8. Select **Close**.

Configure SLPP Globally

About This Task

Enable the Simple Loop Prevention Protocol (SLPP) to detect a loop and automatically stop it.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **SLPP**.
3. Select the **Global** tab.
4. Select **GlobalEnable**.

5. In **TransmissionInterval**, type a value for the time interval for loop detection.
6. Select **Apply**.

Global Field Descriptions

Use the data in the following table to use the **Global** tab.

Name	Description
GlobalEnable	Activates or disables SLPP globally. The default is disabled.
TransmissionInterval	Configures the interval for which loop detection occurs. The interval is expressed in milliseconds in a range from 500–5000. The default value is 500.

Job aid

The following table provides the SLPP values.

Table 349: SLPP values

Enable SLPP	Setting
Access SMLT	Yes
Core SMLT	No
Primary switch	
Packet Rx threshold	5
Transmission interval	500 milliseconds (ms) (default)
Secondary switch	
Packet Rx threshold	50
Transmission interval	500 ms (default)

Configure the SLPP by VLAN

Before You Begin

- Enable SLPP globally before you configure it on a VLAN.

About This Task

Activate SLPP on a VLAN to enable forwarding of the SLPP packet over the VLAN. This configuration controls the boundary of SLPP-PDU transmission.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **SLPP**.
3. Select the **VLANS** tab.
4. Select **Insert**.

5. Select the **VlanId** ellipses (...).
6. Select the desired VLAN ID.
7. Select **Ok**.
8. Select **SlppEnable**.
9. Select **Insert**.

VLANS Field Descriptions

Use the data in the following table to use the **VLANS** tab.

Name	Description
VlanId	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
SlppEnable	Activates SLPP on the selected VLAN. The SLPP packet transmission and reception process is active only if you enable the SLPP operation. If you disable the SLPP operation, the following occurs: <ul style="list-style-type: none">• the system sends no SLPP packets• the system discards received SLPP packets The default is enabled.

Configure the SLPP by Port

Before You Begin

- Enable SLPP globally before you configure it on a port.

About This Task

Use SLPP on a port to avoid traffic loops on the port.

Note

To provide protection against broadcast and multicast storms, as a best practice, enable Rate Limiting for broadcast traffic and multicast traffic.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **SLPP**.
3. Select the **Ports** tab.

4. Double-click **PktRxThreshold** for the desired port to edit the threshold value for packet reception.
5. Double-click **SlppEnable** for the desired port.
6. Select **true** to enable SLPP.
7. Select **Apply**.

Ports Field Descriptions

Use the data in the following table to use the **Ports** tab.

Name	Description
IfIndex	Specifies the interface index number for a port.
PktRxThreshold	Specifies the threshold for packet reception. Configure the SLPP packet receive threshold to a value (1- 500) that represents the number of received SLPP-PDUs to shut down the port. This variable is a port-level parameter, therefore if the port is tagged, SLPP-PDUs from the various VLANs increment this single threshold counter. The default is 1.
SlppEnable	Activates SLPP on the selected interface. The default is disabled.
IncomingVlanId	Shows the VLAN ID of the classified packet on a port disabled by SLPP.
SrcNodeType	Specifies the source node type of the received SLPP packet.
PktRxCount	Shows the total number of SLPP packets the port received.
TimeToClrPktRxCount	Specifies the timer to clear the SLPP receive counter. After you enable SLPP and the port receives SLPP PDUs, the timer starts. After the timer exceeds the configured value, the system resets the count to zero. The default is 21,600 seconds.
RemainingTimeToClrPktRxCount	Shows the time remaining before the SLPP receive counter is reset to zero.

Job aid

The following table provides the SLPP values.

Table 350: SLPP values

Enable SLPP	Setting
Access SMLT	Yes
Core SMLT	No

Table 350: SLPP values (continued)

Enable SLPP	Setting
Primary switch	
Packet Rx threshold	5
Transmission interval	500 milliseconds (ms) (default)
Secondary switch	
Packet Rx threshold	50
Transmission interval	500 ms (default)

Configure the Global Forwarding Database Timeout

Configure the forwarding database global timeout to age out dynamically learned forwarding information.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANS**.
3. Select the **FdbAging** tab.
4. Type an interval, in seconds, for aging out dynamically learned forwarding information.
5. Select **Apply**.

FDB Aging *Field Descriptions*

Use the data in the following table to use the **FDB Aging** tab.

Name	Description
FdbAging	Specifies the timeout period for dynamically learned mac addresses on the vlan. The default value is 300.

View VLAN Forwarding Database Information

About This Task

Perform this procedure to view forwarding database entries for all VLANs on the device.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANS**.
3. Select the **Forwarding** tab.

Forwarding Field Descriptions

Use the data in the following table to use the **Forwarding** tab.

Name	Description
VlanId	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
Address	Specifies a unicast MAC address for which the VLAN has forwarding or filtering information.
Status	Specifies the status of the VLAN.
Port	Specifies either a value of zero (0) or the port number of the port on which a frame having the specified MAC address was seen. A value of cpp indicates a self-assigned MAC address.
BMac	Shows the backbone MAC address if the entry is learned from a Shortest Path Bridging MAC (SPBM) network.
Cvid	Specifies the customer VID.

View the Forwarding Database for a Specific VLAN

Use the forwarding database for VLANs to determine how the system forwards a received frame.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**
2. Select **VLANs**.
3. Select a VLAN.
4. Select **Bridge**.
5. Select the **Forwarding** tab and the VLAN forwarding database information is displayed.

Forwarding Field Descriptions

Use the data in the following table to use the **Forwarding** tab.

Name	Description
VlanId	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
Address	Specifies a unicast MAC address for which the bridge has forwarding or filtering information.
Status	Specifies the status of this entry.
Port	Specifies either a value of zero (0) or the port number of the port on which a frame having the specified MAC address was seen. A value of cpp indicates a self-assigned MAC address.
Cvid	Identifies the customer VID for this interface.

Clear Learned MAC Addresses by VLAN

About This Task

Use the clear learned MAC addresses feature to flush the bridge forwarding database.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Advanced** tab.
4. Double-click **VLAN Operation Action**.
5. Select **FlushMacFdb** from the list.
6. Select **Apply**.

Clear Learned MAC Addresses for all VLANs by Port

About This Task

Use the following procedure to clear all the forwarding database (FDB) for VLANs associated with this port.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **Interface** tab.
5. For **Action**, select **FlushMacFdb**.
6. Select **Apply**.

All learned MAC addresses are cleared from the forwarding database (FDB) for VLANs associated with this port.

7. Select **Close**.

Configure Static Forwarding

Configure static forwarding to specify the group of ports that are allowed to forward frames.

Important

Entries are valid for unicast and for group/broadcast addresses.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select a VLAN.
5. Select **Bridge**.
6. Select the **Static** tab.
7. Select **Insert**.
8. In **MacAddress**, type a forwarding destination MAC address.
9. In **Port**, select the ellipsis (...).
10. Select the port on which the frame is received.
11. Select **Ok**.
12. Select **Insert**.

Static Field Descriptions

Use the data in the following table to use the **Static** tab.

Name	Description
MacAddress	Specifies the destination MAC address in a frame to which the forwarding information for this entry applies. This object can take the value of a unicast address.
Port	Specifies the port number of the port on which the frame is received.

Name	Description
VlanId	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
Status	Specifies the status of the VLAN.

Configure Limit Learning

Limit MAC address learning to limit the number of forwarding database (FDB) entries learned on a particular port to a user-specified value. After the number of learned forwarding database entries reaches the maximum limit, MAC learning stops at that port.

Procedure

1. On the Device Physical View tab, select one or more ports.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **Limit-Learning** tab.
5. Configure the parameters as required.
6. Select **Apply**.

Limit Learning Field Descriptions

Use the data in the following table to use the **Limit-Learning** tab.

Name	Description
PortNum	Shows the slot and port number to configure.
MaxMacCount	Configures the number of entries in the MAC table for the port that causes learning to stop. The default is 1024.
CurrentMacCount	Shows the number of entries currently in the MAC table for the port.
Enable	Enables or disables limit learning for the port. The default is disable.
MacLearning	Shows if MAC learning is enabled or disabled for the port.

VRF Lite provides secure customer data isolation.

VRF Lite Fundamentals

The switch supports what is termed as VRF Lite. Lite conveys the fact that the switch does not use Multiprotocol Label Switching (MPLS) for VRF; VRF Lite is a device virtualization feature, not a network-wide virtualization feature.

Use VRF Lite to offer networking capabilities and traffic isolation to customers that operate over the same node (router). Each virtual router emulates the behavior of a dedicated hardware router; the network treats each virtual router as a separate physical router. In effect, you can perform the functions of many routers using a single platform that runs VRF Lite. The result is a substantial reduction in the cost associated with providing routing and traffic isolation for multiple clients.

With multicast virtualization for IPv4, the switch can function as multiple virtual multicast routers.

The following figure shows one platform acting as multiple virtual routers, each serving a different customer network.

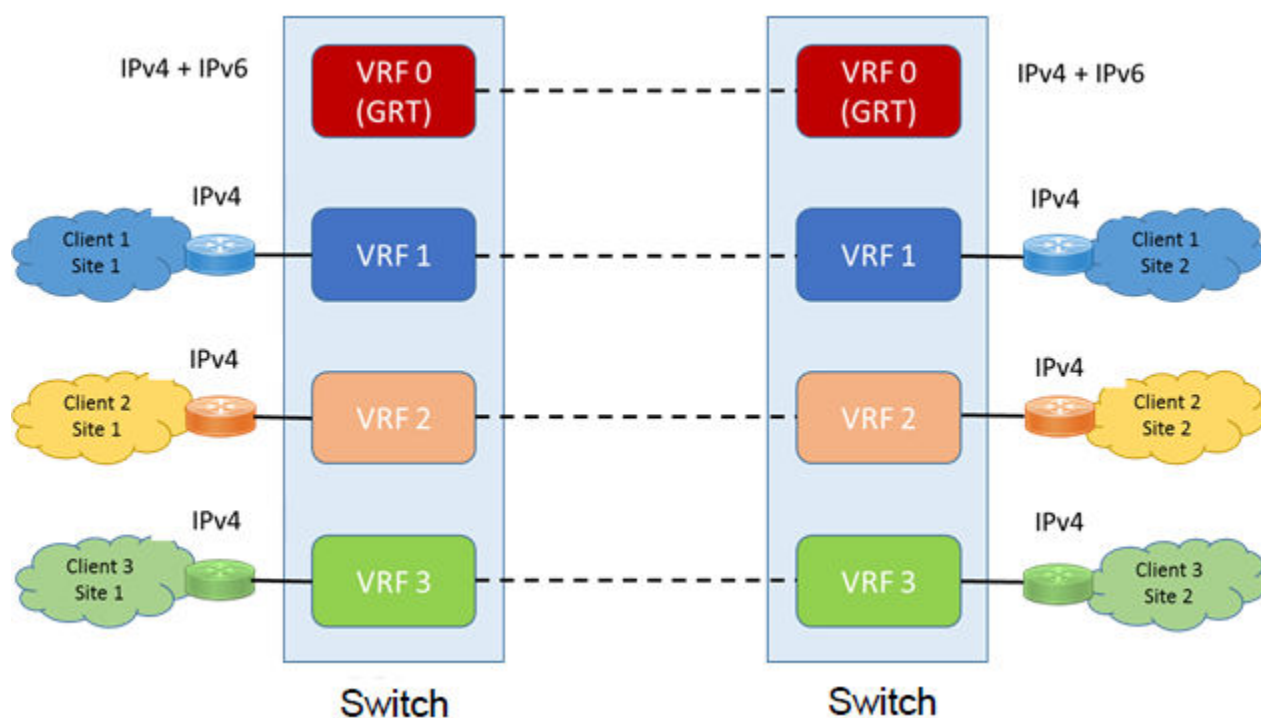

Figure 251: Multiple virtual routers in one system

A switch can support many virtual routers. Each virtual router instance is called a VRF instance. A VRF represents a single instance of a virtual router. Each instance maintains its own routing table. The term Multiple Virtual Router (MVR) is sometimes used to represent a router that contains many VRF instances.

The IPv6 Virtualization functionality adds IPv6 support on VRFs and Layer 3 VSNs. Each VRF instance has its own IPv6 interfaces, IPv6 address space, IPv6 routing table,

and IPv6 global parameters. For more information on Layer 3 VSN, see [Layer 3 VSN Configuration](#) on page 1654.

The Global Router, VRF 0, is the first instance of the router. When the system starts, it creates VRF 0 by default. VRF 0 provides all non-virtual and traditional routing services. You cannot delete this instance. You can create and configure other VRF instances, if required.

VRF 0 is the only VRF that you can log into through CLI. CLI requires you to specify the VRF when you enter commands.

You can associate one VRF instance with many IPv4 or IPv6 interfaces. These interfaces are unique for each VRF instance. An interface is an entity with an IPv4 or IPv6 address that has the following characteristics:

- A unique association with a VLAN.
- A unique association with a brouter, if not associated with a VLAN
- A unique association with a circuit

A VLAN can only be associated with a single VRF instance.

Note

- You cannot associate a VLAN or port and a VRF instance if the VLAN or port has an IPv4 or IPv6 address. You must first associate the port and VRF instance and then you can configure the IPv4 or IPv6 address.
- Use the **boot config flag vrf-scaling** command, on supported switches, to increase the total number of supported VRFs. For more information on route scaling, see *Fabric Engine Release Notes*.

VRF Lite Capability and Functionality

VRF Lite supports virtualization of IPv4 and IPv6 protocols and features. Use the VRF Router Configuration Mode in the CLI or the **Configuration > VRF** navigation pane in Enterprise Device Manager (EDM) to view the specific capabilities supported on your switch.

The switch uses VRF Lite to perform the following actions:

- Partition traffic and data and represent an independent router in the network
- Provide virtual routers that are transparent to end-users
- Support addresses that are not restricted to the assigned address space provided by host Internet Service Providers (ISP)
- Support overlapping IP address spaces in separate VRF instances

Note

If you enable multicast route redistribution between two VRFs, the switch does not support IP addresses that overlap within the two VRFs. The device does not generate an error if addresses overlap. You must avoid this situation.

VRF Lite interoperates with RFC 4364, Layer 3 VPNs. Split MultiLink Trunking (SMLT) and Routed SMLT (RSMLT) are also supported for VRF instances.

Although customer data separation into Layer 3 virtual routing domains is usually a requirement, sometimes customers must access a common network infrastructure. For example, they want to access the Internet, data storage, Voice over IP (VoIP)-public switched telephone network (PSTN), or call signaling services. To interconnect VRF instances, you can use an external firewall that supports virtualization, or use inter-VRF forwarding for specific services. With the inter-VRF solution, you can use routing policies and static routes to inject IP subnets from one VRF instance to another, and you can use filters to restrict access to certain protocols. The following figure depicts inter-VRF forwarding by the switch.

Figure 252: Inter-VRF forwarding

For more information about the latest VRF Lite scalability, see *Fabric Engine Release Notes*.

For configuration information about multicast virtualization, see [IP Multicast](#) on page 1696.

VRF Lite and inter-VRF route redistribution

Note

Some switches do not support Inter-VRF Routing because they support only a single active VRF. For more information about these models, see [VRF Lite Configuration Rules](#) on page 4078.

The switch supports three route redistribution functions:

- Intra-VRF inter-protocol route redistribution (redistribution within the same VRF instance), for example, redistribute RIP to OSPF.

- Inter-VRF inter-protocol redistribution (redistribution between two VRF instances), for example, redistribute RIP in VRF 2 to OSPF in VRF 4.
- Inter-VRF static routes (for example, a static route in a given VRF instance) configured as a typical static route but with the added parameter of a next-hop-vrf (the next-hop IP address is found in the next-hop-vrf instance).

With inter-VRF route redistribution, a user in one VRF instance can access route data in other VRF instances. You can redistribute routes within a VRF instance or between VRF instances; for example, one VRF instance can redistribute routes to all other VRF instances. You can redistribute Local, static, OSPF, RIP, and BGP routes and both dynamic (OSPF, BGP, and RIP) and static route redistribution is supported.

More than one routing protocol can be present in each VRF instance. Route redistribution can occur either between different protocol types, or between the same protocol types on different VRF instances.

An interface uses redistribution to announce routes that are learned by other protocols (OSPF or BGP, for example). Control route redistribution by using route policies. When you associate routing policies with route redistribution, the policy is checked before the target protocol is updated. Across VRF instances, the policy is checked at the source VRF instance, so only qualified routes are added to the routing table.

You can use static route commands to inject one specific route (including a default route) from one VRF instance to another. The route is added to the target VRF instance, while the next hop is resolved by the next-hop VRF instance.

Static routes are used to direct packets from a given source using a next-hop IP address. The next-hop-vrf option in a static route permits this path to proceed from one VRF to another. Overlapping IP addresses are supported within VRFs, thus it is possible for two VRFs to have identical IP addresses.

The following list describes interVRF route redistribution:

- Redistributed routes are added to the target VRF instance, and their next hop remains in the source VRF instance.
- If either the source or destination VRF instance is deleted, the redistribution configuration is automatically deleted.
- Redistributed routes are not further redistributed to another VRF instance.
- Route redistribution is unidirectional. You must configure route redistribution for the reverse direction if you require it. You can configure different route policies for each direction.
- After you configure interVRF route redistribution between two VRF instances, you must avoid using overlapping IP addresses between these two VRF instances.

Avoid overlapping addresses; the device does not generate an error if addresses overlap.

- Intra-VRF routes take precedence over inter-VRF routes.
- You can physically connect two VRF instances to distribute route across VRF instances (in this case, you do not need to configure route redistribution).

Route Redistribution Operation

To perform redistribution, the device maintains a route change list. The change list contains all the best routes that are either added to or deleted from the forwarding table. When a best route is added to or deleted from the forwarding table, the change list is updated to reflect the change and notify registered protocols. The registered protocols pick up the change from the change list when it becomes available.

An example scenario of interVRF redistribution follows. To redistribute OSPF routes in VRF 1 to RIP in VRF 0:

- Create, enable, and apply a RIP redistribution instance. The source protocol is OSPF and the VRF source is VRF 1.
- When an OSPF route is added in VRF 1, the Routing Table Manager (RTM) in VRF 1 puts the new route into the change list.
- The device notifies RIP in VRF 0, because RIP is registered with the RTM of VRF 1 for OSPF route changes.
- To send OSPF routes from VRF 1 through the RIP interface in VRF 0, the interface uses a route policy with match VRF criterion of VRF 1.

The switch also supports inter-domain multicast routing. For more information, see [IP Multicast](#) on page 1696.

Port parameters and VRF Lite management

You can configure each VRF instance as a separate router, this means that you can configure different routing protocols and associated parameters for each instance. You can associate non0 VRF instances with ports.

The port parameters that you can edit for a VRF instance depend on whether the port belongs to only one, or more than one, VRF instance. For example, if a port belongs to only one VRF, you can edit the port parameters of the VRF. If a port belongs to more than one VRF instance, you cannot edit the port parameters of that port unless you are accessing the port through the Global Router with read-write-all access. If you do not have read-write-all access, you can only edit the GlobalRouter port parameters. If a port belongs to a single non0 VRF, the port parameters can be changed by this VRF. If a port belongs to multiple VRF instances, only a user with read-write-all access who is accessing the port through the Global Router can change this port configuration.

Virtualized Management Applications

Virtualized management applications, such as **ping** and **tracert**, operate using the specified user-created VRF context. If you do not specify the VRF context in the command syntax, **ping** defaults to the Global Router VRF.

Ping test for IPv4:

```
Switch:1(config)#ping 192.0.2.1 vrf vrfRED
192.0.2.1 is alive
```

Ping test for IPv6:

```
Switch:1(config)#ping 2001:db8::1 vrf vrfRED
2001:db8::1 is alive
```

Traceroute test for IPv4:

```
Switch:1#traceroute 192.0.2.1 vrf vrfRED
```

Traceroute test for IPv6:

```
Switch:1#traceroute 2001:db8::1 vrf vrfRED
```

If you want to ping a device through the out-of-band management port, you must include the *mgmt oob* command parameters to specify the Segmented Management Instance as the source for the outgoing ICMP ECHO packet. The packet goes out this specific interface only.

If you do not specify the management interface type, the **ping** command uses the management routing table to determine the best management interface, and selects the source IP based on the egress management interface.

For more information about how to use a Segmented Management Instance with these commands, see [Ping an IP Device](#) on page 3901 and [Run a Traceroute Test](#) on page 3905.

VRF Lite Configuration Rules

You must select the VRF for global IPv4 or IPv6 options before entering commands; not all Global Router parameters are configurable on other VRF instances.

Layer 1 and Layer 2 information (including VLAN information) is global and is not maintained for each VRF instance. However, you can associate a set of VLANs with a VRF instance.

A VLAN cannot belong to more than one VRF instance at a time. When you create a VLAN, more than one physical port can belong to it. You can associate a VRF instance with more than one IPv4 or IPv6 interface (a physical Ethernet port or a VLAN).

Perform physical port assignment at the VLAN and brouter port level. A VRF instance inherits all the ports assigned to its VLANs and brouter ports. You cannot directly assign a physical port to a VRF instance, but it is implicitly assigned when you associate the VRF with VLANs or brouter ports.

For IPv4, after you configure interVRF route redistribution between two VRF instances, avoid overlapping IP addresses between these two VRF instances.

When you configure VRF Lite, remember the following rules:

- You can connect two VRFs from the same system with an external cable.
- An IPv4 or IPv6 routable VLAN can become a member of a VRF.
- An IPv4 or IPv6 interface can belong to only one VRF.
- A VRF can exist even if no interfaces are assigned to it.
- Routing policies apply to VRFs on an individual basis.
- Multiple VRFs on the same node can function in different autonomous systems.

Following rules apply to IPv4 interfaces specifically:

- If you configure an IPv4 interface without specifying the VRF instance, it is mapped to VRF 0 by default.
- VRF Lite supports SMLT and RSMLT.
- VRF Lite supports RIP in and out policies.
- VRF Lite supports OSPF in and out (accept and redistribute) policies.
- Before you delete a VRF instance, disable OSPF. Deleting a VRF instance deletes the OSPF instance if OSPF is disabled.
- When you create a VRF instance, an OSPF instance is not automatically created. To activate OSPF on a VRF instance, first create an OSPF instance, and then enable OSPF.
- You can configure a VRF so it can have IP interfaces with OSPF, RIP, static routes, and policies simultaneously.
- Every IPv4 interface is a member of VRF 0 unless explicitly defined to belong to another VRF.

4220 Series VRF Support

4220 Series switches support only a single active VRF with IP configuration. The VRF can be the Global Routing Table (GRT) or a non-default VRF:

- The GRT becomes the active VRF if you attach an IP interface to a VLAN. Otherwise, the first non-default VRF you create becomes the active VRF.
- If the GRT is the active VRF, you cannot create a second VRF.
- You cannot create more than one non-default VRF.
- You cannot configure IP interfaces in the GRT if the active VRF is a non-default VRF.
- To transition the active VRF from the GRT to a non-default VRF, remove all IP interfaces and then create the non-default VRF.
- To transition the active VRF from a non-default VRF to the GRT, first remove all router, ARP, and IP interfaces. Delete the VRF, and then add IP interfaces to the GRT.

Support for a single active VRF affects other features that rely on VRFs with IP configuration:

- ExtremeCloud SD-WAN—You must specify the VRF name that Auto-sense uses for the SD-WAN configuration on models that support a single active VRF. On these models, Auto-sense cannot create the dynamic SD-WAN VRF if an IP configuration already exists.
- Fabric Extend—on platforms that support multiple VRFs with IP configuration, you cannot configure the tunnel source address (**ip-tunnel-source-address** command) if the address belongs to a VRF with an attached I-SID, which presents an issue for single VRF platforms. On platforms with only one active VRF, you can use an *overlay* parameter to bypass this restriction.
- Fabric Extend—you must configure a route-map policy to suppress IS-IS redistribution of the FE tunnel subnet:
 - Configure route-maps to not permit redistribution of the local route used as the tunnel source address (**ip-tunnel-source-address** command).

- Configure an accept policy to deny IS-IS routes that overlap with the destination tunnel IP address.
- IP Multicast config-lite for Fabric Connect—A user-created VRF cannot be active if you configure **mvpn-isid <0-15999999>[0-511]** on a switch that supports only a single active VRF.
- IP Shortcuts and Layer 3 VSN—You cannot configure the IP source address (**ip-source-address** command) as an IP address in the GRT if the active VRF is a non-default VRF.

5320 Series VRF Support

For the 5320 Series, only the following models support more than one VRF with IP configuration:

- 5320-16P-2MXT-2X
- 5320-24T-4X-XT
- 5320-24T-24S-4XE-XT
- 5320-48P-8XE
- 5320-48T-8XE

Note

The supported VRF ID range on the 5320-16P-2MXT-2X differs from other Fabric Engine platforms. 5320-16P-2MXT-2X supports a range of 1-14. To verify the supported range on a specific model, use the CLI contextual help (?).

For VRF scaling information, see *Fabric Engine Release Notes*.

The other models support a single active VRF with IP configuration. The VRF can be the Global Routing Table (GRT) or a non-default VRF:

- The GRT becomes the active VRF if you attach an IP interface to a VLAN. Otherwise, the first non-default VRF you create becomes the active VRF.
- If the GRT is the active VRF, you cannot create a second VRF.
- You cannot create more than one non-default VRF.
- You cannot configure IP interfaces in the GRT if the active VRF is a non-default VRF.
- To transition the active VRF from the GRT to a non-default VRF, remove all IP interfaces and then create the non-default VRF.
- To transition the active VRF from a non-default VRF to the GRT, first remove all router, ARP, and IP interfaces. Delete the VRF, and then add IP interfaces to the GRT.

Support for a single active VRF affects other features that rely on VRFs with IP configuration:

- ExtremeCloud SD-WAN—You must specify the VRF name that Auto-sense uses for the SD-WAN configuration on models that support a single active VRF. On these models, Auto-sense cannot create the dynamic SD-WAN VRF if an IP configuration already exists.
- Fabric Extend—on platforms that support multiple VRFs with IP configuration, you cannot configure the tunnel source address (**ip-tunnel-source-address**

command) if the address belongs to a VRF with an attached I-SID, which presents an issue for single VRF platforms. On platforms with only one active VRF, you can use an *overlay* parameter to bypass this restriction.

- Fabric Extend—you must configure a route-map policy to suppress IS-IS redistribution of the FE tunnel subnet:
 - Configure route-maps to not permit redistribution of the local route used as the tunnel source address (**ip-tunnel-source-address** command).
 - Configure an accept policy to deny IS-IS routes that overlap with the destination tunnel IP address.
- IP Multicast config-lite for Fabric Connect—A user-created VRF cannot be active if you configure **mvpn-isid <0-15999999>[0-511]** on a switch that supports only a single active VRF.
- IP Shortcuts and Layer 3 VSN—You cannot configure the IP source address (**ip-source-address** command) as an IP address in the GRT if the active VRF is a non-default VRF.

VRF Lite Configuration using CLI

Use Virtual Router and Forwarding (VRF) Lite to provide many virtual routers using one switch.

The tasks in this section show you how to configure a VRF instance and how to associate ports and VLANs with VRF instances.

Create a VRF Instance

About This Task

Create a VRF instance to provide a virtual routing interface.

Note

You cannot configure BGP, OSPF, or RIP on a VRF instance unless you first configure the routing protocol trigger.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a VRF instance by specifying a VRF name:

```
ip vrf WORD<1-16> [vrfid <1-511>]
```

**Note**

The single VRF models of the 5320 Series display the following warning and prompt after you enter this command: Warning: creating a new VRF will activate Unicast Routing on it and this will de-activate Unicast routing on existing VRF GlobalRouter. Are you sure about creating new VRF? (y/n) ?

3. Configure the maximum number of routes:

- For IPv4: `ip vrf WORD<1-16> max-routes <max-routes>`
- For IPv6: `ip vrf WORD<1-16> ipv6-max-routes <max-routes>`

4. Enable max-routes traps:

- For IPv4: `ip vrf WORD<1-16> max-routes-trap enable`
- For IPv6: `ip vrf WORD<1-16> ipv6-max-routes-trap enable`

**Note**

The maximum number of IPv6 routes for the Global Router are fixed and cannot be changed.

5. Enter VRF Router Configuration mode:

```
router vrf WORD<1-16>
```

6. Configure the IP routing protocol triggers for the VRF:

Use one of the following commands on your switch:

- `ip bgp` creates both IPv4 and IPv6 instances.
- `ip ospf` creates an OSPFv3 instance.
- `ip rip` creates an IPv4 instance. RIPng is not virtualized

7. Ensure that the instance is configured correctly:

```
show ip vrf [detail] [WORD<1-16>]
```

Examples

Create a VRF instance:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip vrf vrfRED
```

Configure the maximum number of IPv4 routes and enable max-routes traps.

```
Switch:1(config)#ip vrf vrfRED max-routes 12000
Switch:1(config)#ip vrf vrfRED max-routes-trap enable
```

Enter Router Configuration mode and configure the routing protocol triggers for the VRF:

```
Switch:1(config)#router vrf vrfRED
Switch:1(router-vrf)#ip bgp
```

```
Switch:1(router-vrf)#ip ospf
Switch:1(router-vrf)#ip rip
```

To Configure OSPFv3 instance for the VRF:

```
Switch:1(config)#router vrf vrfRED
Switch:1(router-vrf)#ipv6 ospf
```

Exit to Global configuration mode:

```
Switch:1(router-vrf)#exit
```

Configure the maximum number of IPv6 routes and enable IPv6 max-routes traps.

```
Switch:1(config)#ip vrf vrfRED ipv6-max-routes 7700
Switch:1(config)#ip vrf vrfRED ipv6-max-routes-trap enable
```

Ensure that the instance is configured correctly:

```
Switch:1#show ip vrf vrfRED
```

```

Variable Definitions

The following table defines parameters for the **ip vrf** command.

Variable	Value
<code>max-routes <max-routes></code> Note: Exception: not supported on 5320-16P-4XE, 5320-24P-8XE, or 5320-24T-8XE.	Specifies the maximum number of IPv4 routes for the VRF. Depending on the hardware platform, the parameter range and default value can vary. Use the CLI Help to see the available range for the switch. For route scaling information, see <i>Fabric Engine Release Notes</i> .
<code>ipv6-max-routes <max-routes></code> Note: Exception: not supported on 5320-16P-4XE, 5320-24P-8XE, or 5320-24T-8XE.	Specifies the maximum number of IPv6 routes for the VRF. Depending on the hardware platform, the parameter range and default value can vary. Use the CLI Help to see the available range for the switch. For route scaling information, see <i>Fabric Engine Release Notes</i> .
<code>max-routes-trap enable</code>	Enables SNMP traps after the maximum number of IPv4 routes are reached.
<code>ipv6-max-routes-trap enable</code>	Enables SNMP trap generation based on the configured number of maximum IPv6 routes. The default is enabled.
<code>name WORD<0-16></code>	Renames the VRF instance.
<code>vrf-trap</code>	Enables the device to send VRF-related traps.
<code>vrfid <1-511></code>	Specifies a VRF ID. Note: The supported VRF ID range on the 5320-16P-2MXT-2X differs from other Fabric Engine platforms. 5320-16P-2MXT-2X supports a range of 1-14. To verify the supported range on a specific model, use the CLI contextual help (?).
<code>WORD<1-16></code>	Names the VRF instance.

The following table defines parameters for the **show ip vrf** command.

Variable	Value
<code>detail</code>	Displays detailed VRF information, including Segmented VRF information.
<code>max-routes [vrfids WORD<0-512>] [WORD <1-16>]</code>	Displays the maximum number of routes for the specified VRFs. <ul style="list-style-type: none"> • <code>vrfids WORD<0-512></code> specifies a list of VRFs by VRF IDs. • <code>WORD<1-16></code> specifies a VRF by name.

Variable	Value
<code>vrfids WORD<0-512></code>	Specifies a list of VRFs by VRF IDs.
<code>WORD<1-16></code>	Specifies a VRF by name.

Associate a VLAN or Port with a VRF Instance

You can assign a VRF instance to a port or VLAN. You cannot associate a VLAN or port and a VRF instance if the VLAN or port has an IP address. You can configure the IP address after you associate the port and VRF instance.

Before You Begin

- Ensure the VRF is already configured.

About This Task

You can assign a VRF instance to a port after you configure the VRF. The system assigns ports to the Global Router, VRF 0, by default.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port]}[-slot/port[/sub-port]]  
[,...][slot/all][all]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Associate the port or VLAN with a VRF instance:

```
vrf WORD<1-16>
```

Example

```
Switch:1> enable  
Switch:1# configure terminal
```

Create a VRF named Two:

```
Switch:1(config-if)# ip vrf Two
```

Create a VLAN of type byport:

```
Switch:1(config-if)# vlan create 33 name vlan-30 type port-mstprstp 0
```

Enter VLAN Interface Configuration mode:

```
Switch:1(config-if)# interface vlan 33
```

Assign the VLAN to VRF Two:

```
Switch:1(config-if)# vrf Two
```

Assign an IP address to the VLAN:

```
Switch:1(config-if)# ip address 192.0.2.2/24
```

Assign a secondary IP address to the VLAN:

```
Switch:1(config-if)# ip address 192.0.4.2/24
```

Enter VRF configuration mode:

```
Switch:1(config-if)# router vrf Two
```

Variable Definitions

Use the data in the following table to use the **vrf** command.

Variable	Value
<code>vrf WORD<1-16></code>	Specifies the VRF instance by name.

Create an IP VPN Instance on a VRF

Create an IP VPN instance to advertise IP routes from one VRF to another across a Shortest Path Bridging MAC (SPBM) network.

Before You Begin

- The VRF must exist.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

Note

You cannot use the derived name for the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF to enter this mode.

2. Create an IP VPN instance on the VRF:

```
ipvpn
```

3. Assign a service instance identifier (I-SID) to the IP VPN:

```
i-sid <0-16777215>
```

4. Enable IP VPN on the VRF:

```
ipvpn enable
```

By default, a new IP VPN instance is disabled.

5. Display all IP VPNs:

```
show ip ipvpn [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

Example

From Global Configuration mode, log on to Router VRF Configuration mode:

```
Switch:1(config)# router vrf red
```

Create the IP VPN instance:

```
Switch:1(router-vrf)# ipvpn
```

Enable IP VPN:

```
Switch:1(router-vrf)# i-sid 100
```

Enable IP VPN:

```
Switch:1(router-vrf)#ipvpn enable
```

```
=====
                        IPv4  IPVPN
=====
VRF Name          VRF ID   IPv4  IPVPN   IPv6  IPVPN   I-SID   I-SID Name
-----
red                1         enabled  disabled  100     ISID-1
-----
1 out of 1 Total active IPv4 L3 VSN displayed, including 0 active IPv6 L3 VSN.
```

Variable definitions

Use the data in the following table to use the **show ip ipvpn** command.

Variable	Value
<i>vrf WORD<1-16></i>	Specifies the VRF name.
<i>vrfids WORD<0-512></i>	Specifies the VRF ID.

Use the data in the following table to use the **i-sid** command.

Variable	Value
<i>i-sid <0-16777215></i>	Assigns an I-SID to the VRF to configure. Use the no or default option to remove the I-SID to VRF allocation for this VRF.

Create an IPv6 VPN Instance

Before You Begin

The VRF must exist.

About This Task

Create an IPv6 VPN instance to advertise IPv6 routes from a VRF to Shortest Path Bridging MAC (SPBM) network. For more information about Layer 3 Virtual Services Networks (VSNs) and SPBM, see [Layer 3 VSN Configuration](#) on page 1654.

Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

Note

You cannot use the derived name for the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF to enter this mode.

2. Create an IPv6 VPN instance:

```
ipv6 ipvpn
```

3. Assign a service instance identifier (I-SID) to the IPv6 VPN:

```
i-sid <0-16777215>
```

4. Enable IPv6 VPN:

```
ipv6 ipvpn enable
```

5. Display all IPv6 VPNs:

```
show ipv6 ipvpn [vrf WORD<1-16> | vrfids WORD<0-512>]
```

Example

Create and enable IPv6 VPN instance:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf vrfred
Switch:1(router-vrf)#ipv6 ipvpn
Switch:1(router-vrf)#i-sid 100
Switch:1(router-vrf)#ipv6 ipvpn enable
Switch:1(router-vrf)#show ipv6 ipvpn
```

```
=====
                        IPv6  IPVPN
=====
VRF Name          VRF ID   IPv6  IPVPN   IPv4  IPVPN   I-SID   I-SID Name
-----
vrfred             2       enabled disabled  5555   ISID-5555
-----
1 out of 1 Total IPv6 L3 VSN, 1 active IPv6 and 0 active IPv4 displayed.
```

Variable definitions

Use the data in the following table to configure the **ipv6 ipvpn** command.

Variable	Value
<i>enable</i>	Enables IPv6 IPVPN. The default is disabled.

Use the data in the following table to configure the **i-sid** command.

Variable	Value
<code><0-16777215></code>	Assigns an I-SID to the VRF being configured.

Use the data in the following table to configure the **show ipv6 ipvpn** command.

Variable	Value
<code>vrf WORD<1-16></code>	Specifies the VRF name.
<code>vrfids WORD<0-512></code>	Specifies the VRF ID.

Configure the Maximum Number of VRFs

Perform this procedure to change the maximum number of VRFs and Layer 3 VSNs that the switch supports. Increasing the number of VRFs or Layer 3 VSNs can be useful in a WAN scenario or other large network.

The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see *Fabric Engine Release Notes*.

Note

This procedure does not apply to all products. For feature support information, see *Fabric Engine and VOSS Feature Matrix*.

Before You Begin

- If the switch operates in SPBM mode, before you enable the boot config flag, perform the following actions:
 - Check in-VLAN filters. If a filter references a VLAN in the 3500 to 3998 range, you must delete the filter or the filter configuration fails when you restart the switch.
 - Delete VLANs in the 3500 to 3998 range.

About This Task

Important

If you enable this boot config flag, and the switch operates in SPBM mode (default configuration), the switch reduces the number of configurable VLANs. In such a configuration, the switch reserves VLANs 3500 to 3998 for internal use. You cannot use these VLANs as either platform VLANs or B-VLANs. You can still use the reserved VLAN range for customer VLANs (C-VLAN) on Flex UNI and B-VLANs on FE-VID.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Increase the maximum number of VRFs and Layer 3 VSNs:
`boot config flag vrf-scaling`
3. Verify the configuration:
`show boot config flags`
4. Save the configuration:
`save config`
5. Restart the switch for the change to take effect:
`reset`

Examples

Enable the boot config flag to increase the maximum number of VRFs and Layer 3 VSNs. In the following example, the switch operates in SPBM mode and reserves the VLAN ID range of 3500 to 3999. If the switch does not operate in SPBM mode, the system does not display the VLAN warning message when you enable VRF scaling.

```
Switch:1>en
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flag vrf-scaling
Warning: Vlan 3500 to 3999 will be reserved for internal use.

Warning: Please save the configuration and reboot the switch
         for this configuration to take effect.
```

Note

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
flags block-snmp false
flags debug-config false
flags debugmode false
flags dvr-leaf-mode false
flags enhancedsecure-mode false
flags factorydefaults false
flags flow-control-mode true
flags ftpd true
flags hsecure false
flags ipv6-egress-filter true
flags ipv6-mode false
flags logging true
flags macsec false
flags nni-mstp false
flags reboot true
flags spanning-tree-mode mstp
flags spbm-config-mode true
flags spbm-node-scaling true
flags sshd true
flags syslog-rfc5424-format true
flags telnetd true
```

```

flags tftpd true
flags trace-logging false
flags urpf-mode true
flags verify-config true
flags vrf-scaling true
flags vxlan-gw-full-interworking-mode false

```

The following example shows the message that the system displays if you try to enable the boot config flag and configured VLANs use IDs between 3500 and 3999.

```

Switch:1>en
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flag vrf-scaling

Error: Delete all configured platform vlans between 3500 and 3999 to enable vrf-scaling.

```

Enable IPv6 Trap Notifications

About This Task

Perform this procedure to enable SNMP traps when maximum number of IPv6 routes are reached.

Note

Different hardware platforms support different parameter ranges. Use the CLI Help to see the available range.

Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable max-routes trap:

```
ip vrf WORD<1-16> ipv6-max-routes-trap enable
```

Example

```

Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip vrf vrfRED ipv6-max-routes-trap enable

```

Variable definitions

Use the data in the following table to use the **ipv6-max-routes-trap** command.

Variable	Value
<i>enable</i>	Enables SNMP trap generation based on the configured number of maximum IPv6 routes. The default is enabled.

Display IPv6 max-routes Information

About This Task

Perform this procedure to display the maximum IPv6 routes configured.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display max-routes information:
show ip vrf ipv6-max-routes [vrfids *WORD*<0-512> | *WORD*<1-16>]

Example

```
Switch:1#show ip vrf ipv6-max-routes
```

=====

VRF Lite Configuration Using EDM

Use VRF Lite to provide many virtual routers using a single switch.

Configure a VRF Instance

About This Task

Configure a VRF instance to provide a virtual routing interface for a user.

Note

The maximum routes of IPv4 and IPv6 for Global Router (GRT) are non-configurable and fixed at the system limits.

Maximum route traps are not generated on GRT. For non-default VRFs, the permitted maximum routes can be lower than system limits and traps generate when the limit is exceeded.

Procedure

1. In the navigation pane, expand **Configuration > VRF**.
2. Select **VRF**.
3. Select the **VRF** tab.
4. Select **Insert**.
5. Specify the VRF ID.

6. Type a name for the VRF instance.
7. Configure VRF Lite-related traps.
8. Configure the optional parameters as required.
9. Select **Insert**.

VRF Field Descriptions

Use the data in the following table to help you use the **VRF** tab.

Name	Description
Id	Specifies the ID number of the VRF instance. VRF ID 0 is reserved for the GlobalRouter.
Name	Names the VRF instance.
ContextName	Identifies the VRF. The SNMPv2 Community String or SNMPv3 contextName denotes the VRF context and is used to logically separate the MIB port management.
TrapEnable	Enables the VRF to send VRF Lite-related traps (VrfUp and VrfDown). The default is enabled.
MaxRoutes Note: Exception: not supported on 5320-16P-4XE, 5320-16P-4XE-DC, 5320-24P-8XE, or 5320-24T-8XE.	Configures the maximum number of routes allowed for the VRF, which varies depending on the hardware. For scaling information, see <i>Fabric Engine Release Notes</i> . The default value varies for the GlobalRouter and non-default VRFs, depending on your hardware platform.
RpTrigger	Specifies the Routing Protocol (RP) triggers for the VRF. The triggers are used to initiate or shutdown routing protocols on a VRF. You can act upon multiple RPs simultaneously. You can also use this option to bring individual RPs up in steps.
Segmented Note: Exception: not supported on 7830 Series or switch models that support a single active VRF.	Specifies if the VRF is a Segmented VRF. The default is false, which indicates the VRF is not segmented.
MaxRoutesTrapEnable	Enables the generation of the VRF Max Routes Exceeded traps. The default is enabled.
Ipv6MaxRoutes Note: Exception: not supported on 5320-16P-4XE, 5320-16P-4XE-DC, 5320-24P-8XE, or 5320-24T-8XE.	Configures the maximum number of IPv6 routes allowed for the VRF, which varies depending on the hardware. For scaling information, see <i>Fabric Engine Release Notes</i> . The default value varies for the GlobalRouter and non-default VRFs, depending on your hardware platform.

Name	Description
Ipv6MaxRoutesTrapEnable	Enables SNMP trap generation after the maximum number of IPv6 routes are reached. The default is enabled.
Active	Displays if the VRF is active (true). Some switch models support only a single active VRF with IP configuration; the VRF can be the GlobalRouter (GRT) or a non-default VRF. For information about VRF support, see <i>Fabric Engine Release Notes</i> or <i>Fabric Engine and VOSS Feature Matrix</i> .
Origin	Displays the VRF origin: <ul style="list-style-type: none"> • config • dynamic • segmented The Default VRF and the MGMT VRF are considered DYNAMIC. Note: Only manually configured VRFs are visible in running-config.
Sd-Wan Local Breakout Note: Not supported on switch models that support only a single active VRF with IP configuration.	Enables Local Breakout on the VRF. The default is false (disabled).
BgpOrigin	Specifies the origin of the BGP configuration in the VRF. config indicates the BGP instance was created manually. autoSense indicates the BGP instance was generated from Auto-sense. default is for Global Routing Table (GRT) only and indicates no BGP configuration.

Associate a Port to a VRF Instance

About This Task

Associate a port to a Virtual Router Forwarding (VRF) instance so that the port becomes a member of the VRF instance.

You can assign a VRF instance to a port after you configure the VRF. The system assigns ports to the GlobalRouter, VRF 0, by default.

Procedure

1. In the **Device Physical** View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.

4. Select the **VRF** tab.
5. Next to **BrouterVrfId**, select the ellipsis (...).
6. Select the required VRF.
7. Select **OK**.
8. Select **Apply**.

VRF Field Descriptions

Use the data in the following table to use the **VRF** tab.

Name	Description
VrfIds	Shows the VRF ID.
VrfNames	Shows the VRF name.
VrfCount	Shows the number of VRFs to which the port is associated.
BrouterVrfId	Specifies the VRF ID for a brouter port.
BrouterVrfName	Shows the VRF name for a brouter port.

Associate a VLAN with a VRF

You can assign a VRF instance to a VLAN. You cannot associate a VLAN and a VRF instance if the VLAN has an IP address. You can configure the IP address after you associate the VLAN and VRF.

Before You Begin

- Ensure the VRF is already configured.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**
2. Select **VLANs**.
3. Select the **Basic** tab.
4. In **VrfId** in the row for the VLAN, select a VRF ID.
5. Select **Apply**.

Associate an Extreme Integrated Application Hosting Port to a VRF Instance

Note

This procedure only applies to 5720-24MXW, 5720-48MXW, 7520 Series, and 7720 Series.

About This Task

Perform this procedure to associate an Extreme Integrated Application Hosting (IAH) port to a Virtual Router Forwarding (VRF) instance.

Note

You can associate a VRF instance to an IAH port after you configure the VRF. By default, the IAH ports are associated to the GlobalRouter.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **VRF** tab.
4. (Optional) In the **VrfNames** field, select the **ShowAll** button to view the VRF instances the IAH Port is associated with.
5. In the **BrouterVrflid** field, select the ellipsis (...) button, and select the required VRF instance(s).
6. Select **Ok**.
7. Select **Apply**.

VRF Field Descriptions

Use data in the following table to use the **VRF** tab.

Name	Description
Vrflids	Shows the VRF ID.
VrfNames	Shows the VRF name.
VrfCount	Shows the number of VRFs to which the Extreme Integrated Application Hosting (IAH) port is associated with.
BrouterVrflid	Specifies the VRF ID for a brouter port.
BrouterVrfName	Shows the VRF name for a brouter port.

Configure interVRF route redistribution policies

Configure interVRF route redistribution so that a VRF interface can announce routes that other protocols learn, for example, OSPF, RIP, or BGP. Use a route policy to control the redistribution of routes.

Before You Begin

- Ensure VRF instances exist.
- Configure route policies, if required.
- Change the VRF instance as required.

Procedure

1. In the navigation pane, expand **Configuration > IP**.

2. Select **Policy**.
3. Select the **Route Redistribution** tab.
4. Select **Insert**.
5. Select the ellipsis (...) near the **DstVrflid** box to select the source and destination VRF IDs.
6. Select the ellipsis (...) near the **SrcVrflid** box to select the source and destination VRF IDs.
7. In the **Protocol** option box, select the protocol.
8. In the **RouteSource** option box, select the route source.
9. Select **Enable**.
10. Choose the route policy to apply to the redistributed routes.
11. Configure other parameters as required.
12. Select **Insert**.
13. Select the **Applying Policy** tab.
14. Select **RedistributeApply**.
15. Select **Apply**.

Route Redistribution Field Descriptions

Use the data in the following table to use the **Route Redistribution** tab.

Name	Description
DstVrflid	Specifies the destination VRF ID to use in the redistribution.
Protocol	Specifies the protocols for which you want to receive external routing information.
SrcVrflid	Specifies the source VRF ID to use in the redistribution.
RouteSource	Indicates if the protocol receives notification about the routes this source learns. The route source is equivalent to the owner in the routing table.
Enable	Enables or disables route redistribution. The default is disabled.
RoutePolicy	Specifies the route policies to apply to the redistributed routes from the source VRF. Use the route policy to determine whether the system advertises a specific route to the specified protocol.
Metric	Specifies the metric announced in advertisements. The default is 0.
MetricType	Specifies the metric type (applies to OSPF and BGP only). Specifies a type 1 or a type 2 metric. For metric type 1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type 2, the cost of the external routes is equal to the external cost alone. The default is type2.
Subnets	Indicates that all the subnets must be advertised individually. The values are allow(1), and suppress(2). The default value is allow. This variable applies to OSPF only.

View Brouter Port and VRF Associations

About This Task

You can view each port and associated VRFs. You can also change the VRFs associated with the port if the port has no IP address.

Procedure

1. In the navigation pane, expand **Configuration > VRF**.
2. Select **VRF**.
3. Select the **VRF-Ports** tab.
4. To display the VRF names associated with a port, select a cell in one of the table rows, and then select **ShowVRFNames**.
5. To change the VRF, double-click the **BrouterVrfId** field for the port.

Tip

You can associate a port with more than one VRF.

6. Select the required VRFs, and then select **Ok**.
7. Select **Apply**.

VRF-Ports Field Descriptions

Use the data in the following table to use the **VRF-Ports** tab.

Name	Description
Index	Specifies the slot and port.
Type	Specifies the port type.
VrfIds	Identifies the set of VRF IDs to which this port belongs.
VrfCount	Shows the number of VRF instances associated with this port.
BrouterVrfId	Shows the VRF ID for this brouter port.
BrouterVrfName	Shows the VRF name for this brouter port.
Show VrfNames	You can use this toolbar button to identify the set of VRF names to which a port belongs.

Use the data in the following table to use the **Show VrfNames** button.

Name	Description
Index	Specifies the slot and port.
VrfNames	Shows the VRF name for this brouter port.

View Global VRF Status Information

About This Task

View global VRF status information to determine the number of VRFs that are configured and active.

Procedure

1. In the navigation pane, expand **Configuration > VRF**.
2. Select **VRF**.
3. Select the **Global Status** tab.

Global Status Field Descriptions

Use the data in the following table to use the **Global Status** tab.

Name	Description
ConfigNextAvailableVrflid	Specifies the number of the next available Virtual Router ID (index).
ConfiguredVRFs	Specifies the number of VRFs configured on this network element.
ActiveVRFs	Specifies the number of VRFs that are active on the network element. These are VRFs for which the OperStatus is up.

View VRF Instance Statistics and Status Information

About This Task

View VRF instance status information to determine the operational status of each VRF, as well as other operational parameters.

Procedure

1. In the navigation pane, expand **Configuration > VRF**.
2. Select **VRF**.
3. Select the **VRF Stats** tab.

VRF Stats Field Descriptions

Use the data in the following table to use the **VRF Stats** tab.

Name	Description
Id	Specifies the ID number of the VRF instance.
StatRouteEntries	Specifies the total number of routes for this VRF.
StatFIBEntries	Specifies the total number of Forwarding Information Base (FIB) entries for this VRF.
StatUpTime	Specifies the time in (in hundredths of a second) since this VRF entry has been operational.

Name	Description
OperStatus	Shows the operational status of the Virtual Router.
RouterAddressType	Specifies the router address type of this VRF.
RouterAddress	Specifies the router address of this VRF, derived from one of the interfaces. If a loopback interface is present, you can use the loopback interface address.
DhcpRelayNumRequests	Specifies the total number of DHCP requests on this VRF.
DhcpRelayNumReplies	Specifies the total number of DHCP replies on this VRF.

View Statistics for a VRF

About This Task

View VRF statistics to ensure the instance is performing as expected.

Procedure

1. In the navigation pane, expand **Configuration > VRF**.
2. Select **VRF**.
3. Select the **VRF** tab.
4. Select a VRF.
5. Select the **Stats** button.

Stats Field Descriptions

Use the data in the following table to use the **Stats** tab.

Name	Description
StatRouteEntries	Specifies the number of routes for this VRF.
StatFIBEntries	Specifies the number of Forwarding Information Base (FIB) entries for this VRF.

Select and Launch a VRF Context View

Use this procedure to open a VRF context view when you use EDM. GlobalRouter is the default view at log in. If you launch a VRF context view, EDM displays the VRF navigation in a new tab.

Note

You cannot launch a VRF Context View for the untrusted or unrestricted segments of a Segmented VRF.

The Set VRF Context view function is not available to users in a service provider deployment where only a tenant VRF view is assigned.

About This Task

Important

If you log out from the GRT view, the system generates a warning: all tabs close and your session terminates. If you close a VRF view tab, you close only that view.

You can configure both Global Router (GRT) and Virtual Routing and Forwarding (VRF) instances when you launch a VRF context view. You can open five tabs for each EDM session.

Procedure

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Select **Set VRF Context View**.
3. Select the **VRF** tab.
4. Select a context to view.
5. Select **Launch VRF Context view**.

A new browser tab opens containing the selected VRF view

VRF Field Descriptions

Use the descriptions in the following table to use the **VRF** tab.

Name	Description
Id	Shows the unique VRF ID.
Name	Shows the name of the virtual router.
ContextName	Shows the SNMPv3 context name that denotes the VRF context and logically separates the MIB port management.

Create an IP VPN Instance on a VRF

Create an IP VPN instance to advertise IP routes from one VRF to another across a Shortest Path Bridging MAC (SPBM) network.

Before You Begin

- You must configure the required SPBM IS-IS infrastructure.
- The VRF must exist.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IP-VPN**.
3. Select the **VPN** tab.
4. Select **Insert**.
5. Select the ellipsis ([...]), and then select a VRF from the list.
6. Select **OK**.

7. Select **Insert**.

By default, the new IP VPN instance is disabled.

8. In **Enable**, select **enable**.9. In **Trusted Isid**, specify an I-SID to associate with the VPN.10. Select **Apply**.**VPN Field Descriptions**

Use the data in the following table to use the **VPN** tab.

Name	Description
Vrflid	Specifies the ID of the VRF to configure.
Enable	Enables or disables the IP VPN instance on the VRF. The default is disabled.
Trusted Isid Note: Exception: not supported on 7830 Series or switch models that support a single active VRF.	Specifies the I-SID to associate with the VPN. By default, no I-SID is assigned. For a Segmented VRF, assigns an I-SID to advertise trusted routes to trusted and unrestricted segments.
Unrestricted Isid Note: Exception: not supported on 7830 Series or switch models that support a single active VRF.	Assigns an I-SID to advertise unrestricted routes to all segments. This parameter applies only to Segmented VRF. If you do not assign an I-SID to the unrestricted segment, the switch automatically derives a value based on the trusted I-SID, (trusted I-SID + 1).
Untrusted Isid Note: Exception: not supported on 7830 Series or switch models that support a single active VRF.	Assigns an I-SID to advertise untrusted routes to restricted segments. This parameter applies only to Segmented VRF. If you do not assign an I-SID to the untrusted segment, the switch automatically derives a value based on the trusted I-SID, (trusted I-SID + 2).
Isid Name	Specifies the name of the trusted I-SID associated with the VPN.

Create an IPv6 VPN Instance on a VRF

Create an IPv6 VPN instance to advertise IPv6 routes from a VRF to Shortest Path Bridging MAC (SPBM) network.

Before You Begin

- You must configure the required SPBM IS-IS infrastructure.
- The VRF must exist.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **IPv6-VPN**.
3. Select the **VPN** tab.
4. Select **Insert**.
5. Select the ellipses [...] button, and then select a VRF from the list.
6. Select **OK**.
7. Select **Insert**.
8. In the **IsidNumber** column, double-click the **0** value, and then enter the service instance identifier (I-SID) to assign to the IPv6-VPN.
9. In the **Enable** column, double-click the value and select **true** or **false** from the drop-down list.
10. Select **Apply**.

VPN Field Descriptions

Use the data in the following table to use the **VPN** tab.

Name	Description
VrfId	Specifies the ID of the VRF to configure.
Enable	Enables or disables the IPv6 VPN instance on the VRF. The default is disabled.
Isid Number	Specifies the I-SID to associate with the IPv6 VPN. By default, no I-SID is assigned.
Isid Name	Specifies the name of the I-SID.

Configure the Maximum Number of VRFs

Perform this procedure to change the maximum number of VRFs and Layer 3 VSNs that the switch supports. By default, the switch supports 24 VRFs and Layer 3 VSNs. Increasing the number of VRFs or Layer 3 VSNs can be useful in a WAN scenario or other large network.

The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see *Fabric Engine Release Notes*.

Before You Begin

- If the switch operates in SPBM mode, before you enable this boot config flag, perform the following actions:
 - Check in-VLAN filters. If a filter references a VLAN in the 3500 to 3998 range, you must delete the filter or the filter configuration fails when you restart the switch.
 - Delete VLANs in the 3500 to 3998 range.
- Before you disable this boot config flag, delete additional VRFs if more than 24 exist.

About This Task

Important

If you enable this boot config flag, and the switch operates in SPBM mode (default configuration), the switch reduces the number of configurable VLANs. In such a configuration, the switch reserves VLANs 3500 to 3998 for internal use. You cannot use these VLANs as either platform VLANs or B-VLANs. You can still use the reserved VLAN range for customer VLANs (C-VLAN) on Flex UNI and B-VLANs on FE-VID.

Enabling the boot config flag to use more than 24 VRFs requires a Premier or Premier + MACsec license.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **Boot Config** tab.
4. Perform one of the following actions:
 - a. To enable VRF scaling, select the **EnablevrfScaling** check box.
 - b. To disable VRF scaling, clear the **EnablevrfScaling** check box.
5. Select **Apply**.
6. Restart the switch for the change to take effect.

VRRP Fundamentals

Virtual Router Redundancy Protocol (VRRP) (RFC 2338) provides another layer of resiliency to your network design by providing default gateway redundancy for end users. VRRP eliminates the single point of failure that can occur when the single static default gateway router for an end station is lost. A loss of the default gateway router causes a loss of connectivity to the remote networks. If a VRRP-enabled router that connects to the default gateway fails, failover to the VRRP backup router ensures no interruption for end users who attempt to route from their local subnet.

VRRP shares a virtual IP address (transparent to users) between two or more routers that connect the common subnet to the enterprise network. With the virtual IP address as the default gateway on end hosts, VRRP provides dynamic default gateway redundancy in the event of failover.

The VRRP router that controls the IP addresses associated with a virtual router is the primary router and it forwards packets to these IP addresses. The election process provides a dynamic transition of forwarding responsibility if the primary router becomes unavailable. (The primary router is sometimes referred to as the *master*.)

Note

The first virtual IP configured on a VRRP interface is the primary virtual IP. This primary address is the equivalent of IPv6 VRRP link-local address and must be in the same subnet as the primary IP of the interface. The address owner of a VRRP interface is determined by the primary virtual IP.

In the following figure, the first three hosts install a default route to the R1 (virtual router 1) IP address and the other three hosts install a default route to the R2 (virtual router 2) IP address. This configuration not only shares the load of the outgoing traffic, but it also provides full redundancy. If either router fails, the other router assumes responsibility for both addresses.

Figure 253: Virtual Router Redundancy Protocol configuration

For information about the number of supported VRRP interfaces, see the scaling information in *Fabric Engine Release Notes*.

The following terms are specific to VRRP:

VRRP router

a router running the VRRP protocol

Virtual router

an abstract object acting as the default router for one or more hosts, consisting of a virtual router ID and a set of addresses

Primary IP address of the interface

the real IP address of the interface. This IP address is used as the source of the VRRP advertisement. In the case of multinetting, this is the primary IP address of the interface.

Primary IP VRRP address

a virtual IP address that is in the same subnet as the primary IP address of the interface. This address is mandatory for the creation of the VRRP instance. The primary VRRP router performs the following actions:

- adds this IP address to the VRRP advertisement
- responds to ARP requests for this IP address
- routes traffic destined to this IP address

Secondary IP VRRP address / Associated IP VRRP address

an IP address that is in the same subnet as the secondary IP address of the interface. If the primary VRRP address is the same subnet as the primary IP address of the interface, the secondary IP VRRP address also needs to be the same subnet as

the secondary IP address of the interface. This IP address is not mandatory for VRRP instance creation.

Virtual primary router

the router that assumes responsibility to forward packets sent to the IP address associated with the virtual router and answer ARP requests for these IP addresses. Only the VRRP Master router forwards traffic for a given subnet. (The primary router is sometimes referred to as the *master*.)

Virtual router backup

the virtual router that becomes the primary router if the current primary router fails. The backup VRRP router does not route traffic destined for the default gateway.

When a VRRP router is initialized it sends a VRRP advertisement. The VRRP router also broadcasts a gratuitous ARP request that contains the virtual router MAC address for each IP address associated with the virtual router. The VRRP router then transitions to the controlling state.

In the controlling state, the VRRP router functions as the forwarding router for the IP addresses associated with the virtual router. The VRRP router responds to ARP requests for these IP addresses, forwards packets with a destination MAC address equal to the virtual router MAC address, and accepts packets addressed to IP addresses associated with the virtual router.

In the backup state, a VRRP router monitors the availability and state of the primary router. The backup router does not respond to ARP requests and must discard packets with a MAC address equal to the virtual router MAC address. The backup router does not accept packets addressed to IP addresses associated with the virtual router. If a shutdown occurs, the backup router transitions back to the initialize state. If the primary router goes down, the backup router sends the VRRP advertisement and ARP request described in the preceding paragraph and transitions to the controlling state.

The router transitions to the backup state in the following situations:

- If the priority is greater than the local priority
- If the priority is the same as the local priority and the primary IP address of the sender is greater than the local primary IP address

Otherwise, the router discards the advertisement. If a shutdown occurs, the primary router sends a VRRP advertisement with a priority of 0 and transitions to the initialize state.

Critical IP Address

Within a VRRP VLAN, one link can go down while the remaining links in the VLAN remain operational. Because the VRRP VLAN continues to function, a virtual router associated with that VLAN does not register a master router failure.

As a result, if the local router IP interface connecting the virtual router to the external network fails, this does not automatically trigger a master router failover.

**Note**

In this context, local implies an address from the same VRF as the IP interface where VRRP is being configured.

The critical IP address resolves this issue. If the critical IP address fails, it triggers a failover of the master router.

You can specify the local router IP interface uplink from the VRRP router to the network as the critical IP address. This ensures that, if the local uplink interface fails, VRRP initiates a master router failover to one of the backup routers.

In VRRP, the local network uplink interface on router 1 is shown as the critical IP address for router 1. As well, the same network uplink is shown as the critical IP address for router 2. Router 2 also requires a critical IP address for cases in which it assumes the role of the master router.

With the support of VRRP and the critical IP interface linked to VRRP, you can build reliable small core networks that provide support for converged applications, such as voice and multimedia.

**Note**

A Brouter port with a VLACP critical IP address in a VRRP is supported.

VRRP Backup Master

To enable both VRRP switches to route traffic, the switch software has an extension to VRRP, the BackupMaster, that creates an active-active environment for routing. If you enable BackupMaster on the backup router, the backup router no longer switches traffic to the VRRP Master. Instead the BackupMaster routes all traffic received on the BackupMaster IP interface according to the switch routing table.

Stagger VRRP instances on a network or subnet basis.

The following figure shows the VRRP Masters and BackupMasters for two subnets.

Figure 254: VRRP network configuration

The VRRP BackupMaster uses the VRRP standardized backup switch state machine. Thus, VRRP BackupMaster is compatible with standard VRRP.

Handling of IPv4 Layer 2 Unicast Packets

Only the VRRP Master handles IPv4 Layer 2 unicast packets, for example, ARP Request and Reply, with the destination MAC as the VRRP MAC.

The BackupMaster forwards all IPv4 Layer 2 unicast packets to the Master and the Master VRRP sends an ARP reply only.

Processing of IP unicast packets (for example, ICMP packets to VRRP IP) or IPv4 routed packets (with destination MAC as VRRP MAC) on VRRP BackupMaster stays the same. For example, the VRRP BackupMaster replies to ICMP requests and routes Layer 3 routed packets to the destination and does not forward these packets to the Master when they arrive at the BackupMaster.

To reflect these changes, the VRRP MAC entry on the BackupMaster points to the Master instead of itself, and the ARP entry for VRRP IP on the BackupMaster points to local.

VRRP Fast Hello Timers

You can configure the advertisement time interval (in seconds) between sending advertisement messages. This interval permits fast network convergence with standardized VRRP failover. However, losing connections to servers for more than a second can result in missing critical failures. Customer network uptime in many cases requires faster network convergence, which means network problems must

be detected within hundreds of milliseconds. Fast Advertisement Enable and Fast Advertisement Interval meet these requirements.

Fast Advertisement Enable acts like a toggle device for the Advertisement Interval and the Fast Advertisement Interval. When Fast Advertisement Enable is enabled, the Fast Advertisement Interval is used instead of the Advertisement Interval.

When you enable the Fast Advertisement Interval, VRRP can communicate with other switch ports and networking products that have the same configuration.

Configure all routers to the identical number of seconds for the holddown timer. You can manually force the preemption of the primary over the backup before the delay timer expires.

When you use the Fast Advertisement Interval to configure a master and backup device, you must enable the Fast Advertisement Interval on both systems for VRRP to work correctly. If you configure one device with the Advertisement Interval, and the other device with the Fast Advertisement Interval, it causes an unstable state and drops advertisements.

VRRP Holddown Timer

To modify the behavior of the VRRP failover mechanism, use the holddown timer to enable the router enough time to detect and update routes. The timer delays preempting VRRP primary over the backup, when the primary becomes available.

The transition of virtual router to Master state is delayed in the following conditions:

- The VRRP holddown timer runs only when the VRRP virtual router transitions from initialization to backup to master. This occurs only on a system startup.
- The VRRP holddown timer does not run if the amount of time passed since VRRP virtual router initialization is greater than preset holddown time. In such a case, VRRP virtual router transitions to Master happens irrespective of the holddown timer.

The VRRP holddown timer also applies to the VRRP BackupMaster feature.

VRRP and SMLT

The standard implementation of VRRP supports only one active master device for each IP subnet. All other VRRP interfaces in a network are in backup mode.

A deficiency occurs when VRRP-enabled switches use Split MultiLink Trunking (SMLT). If VRRP switches are aggregated into two Split MultiLink Trunk switches, the end host traffic is load-shared on all uplinks to the aggregation switches (based on the Multilink Trunk traffic distribution algorithm).

However, VRRP usually has only one active routing interface enabled. All other VRRP routers are in backup mode. Therefore, all traffic that reaches the backup VRRP router is forwarded over the vIST towards the master VRRP router. In this case, the vIST does not have enough bandwidth to carry all the aggregated traffic.

To resolve this issue, assign the backup router as the backup master router. The backup master router can actively load-share the routing traffic with a master router.

When the backup master router is enabled, the incoming host traffic is forwarded over the SMLT links as usual. When the backup master router is configured along with the critical IP interface and the critical IP interface goes down, the VRRP router transitions to be the backup router with the backup master state down. In this state, the VRRP router does not forward traffic.

VRRP and Spanning Tree

The switch can use one of two spanning tree protocols: Rapid Spanning Tree Protocol (RSTP) and Multiple Spanning Tree Protocol (MSTP).

VRRP protects clients and servers from link or aggregation switch failures. Configure the network to limit the amount of time a link is out of service during VRRP convergence.

The following figure shows two possible configurations of VRRP and spanning tree; configuration A is optimal and configuration B is not.

Figure 255: VRRP and STG configurations

In this figure, configuration A is optimal because VRRP convergence occurs within 2 to 3 seconds. In configuration A, three spanning tree instances exist and VRRP runs on the link between the two routers. Spanning tree instance 2 exists on the link between the two routers, which separates the link between the two routers from the spanning tree instances found on the other devices. All uplinks are active.

In configuration B, VRRP convergence takes between 30 and 45 seconds because it depends on spanning tree convergence. After initial convergence, spanning tree blocks one link (an uplink), so only one uplink is used. If an error occurs on the uplink, spanning tree reconverges, which can take up to 45 seconds. After spanning tree reconvergence, VRRP can take a few more seconds to fail over.

VRRP Guidelines

The following list provides guidelines to use VRRP:

- If you configure VRRP and IP routing protocols on the same IP physical interface, you cannot select the interface address as the VRRP virtual IP address (logical IP address). You must use a separate dedicated IP address for VRRP.
- After you create a VRRP interface, you can add Secondary IP Interfaces, which are the equivalent of IPv6 VRRP global addresses. Secondary virtual IP addresses must be in the same subnet as a Secondary IP Interface on the VLAN.
- You can replace a primary virtual IP only if no secondary virtual IPs exist on the VRRP interface.
- Do not configure the virtual address as a physical interface that is used on the routing switches. Instead, use a third address, for example:
 - Interface IP address of VLAN A on Switch 1 = x.x.x.2
 - Interface IP address of VLAN A on Switch 2 = x.x.x.3
 - Virtual IP address of VLAN A = x.x.x.1

Note

The VRRP virtual IP address can be the same as the local IP address or Primary IP address of the interface on which VRRP is enabled. In this case, the router is the VRRP address owner on that interface and the priority is configured to the maximum value of 255.

- Configure the VRRP holddown timer with enough time that the Interior Gateway Protocol (IGP) routing protocol has time to update the routing table. In some cases, configuring the VRRP holddown timer to a minimum of 1.5 times the IGP convergence time is sufficient. For OSPF, as a best practice, use a value of 90 seconds if you use the default OSPF timers.
- Implement VRRP BackupMaster for an active-active configuration (BackupMaster works across multiple switches that participate in the same VRRP domain).
- Configure VRRP priority as 200 to configure VRRP Master.
- Stagger VRRP Masters between switches in the core to balance the load between switches.
- If you implement VRRP Fast, you create additional control traffic on the network and also create a greater load on the CPU. To reduce the convergence time of VRRP, the VRRP Fast feature allows the modification of VRRP timers to achieve subsecond failover of VRRP. Without VRRP Fast, normal convergence time is approximately 3 seconds.
- When you use the fast advertisement interval option to configure a master and backup device, you must enable the fast advertisement interval option on both systems for VRRP to work correctly. If you configure one device with the regular

advertisement interval, and the other device with the fast advertisement interval, it causes an unstable state and drops advertisements.

- Do not use VRRP BackupMaster and critical IP at the same time. Use one or the other.

VRRP for IPv6

For IPv6 hosts on a LAN to learn about one or more default routers, IPv6-enabled routers send router advertisements using the IPv6 ND protocol. The routers multicast these router advertisements every few minutes.

The ND protocol uses a mechanism called neighbor unreachability detection to detect the failure of a neighbor node (router or host) or the failure of the forwarding path to a neighbor. Nodes can monitor the status of a forwarding path by sending unicast ND neighbor solicitation messages to the neighbor node. To reduce traffic, nodes only send neighbor solicitations to neighbors to which they actively send traffic and only after the node receives no positive indication that the neighbors are up for a period of time. A host takes a minimum of 5 seconds to learn that a router is unreachable before it switches to another default router, but this minimum value increases ND traffic. This delay can cause service disruption.

VRRP for IPv6 provides a faster switchover to an alternate default router than is possible using the ND protocol. With VRRP for IPv6, a backup router can take over for a failed default router in approximately three seconds (using default parameters). The switchover is accomplished without interaction with the hosts and with a minimum amount of VRRP traffic.

The IPv6 VRRP implementation is similar to the existing IPv4 VRRP operation, including support for holddown timer, critical IP, fast advertisements, and backup master. With backup master enabled, the backup switch routes all traffic according to its routing table. The backup master switch does not perform Layer 2 switching for the traffic to the VRRP master.

You must specify a link-local address to associate with the virtual router. Optionally, you can also assign global unicast IPv6 addresses to associate with the virtual router. Network prefixes for the virtual router are derived from the global IPv6 addresses assigned to the virtual router.

One active master switch exists for each IPv6 network prefix. All other VRRP interfaces in a network are in backup mode.

VRRP for IPv6 Operation

VRRP uses a virtual IP address shared between two or more routers connecting the common network prefix to the enterprise network. With the virtual IP address as the default gateway on end hosts, VRRP provides dynamic default gateway redundancy in the event of failover.

The VRRP router with higher priority is called the master router. In case of equal priority the router with higher link-local address becomes the master router. The master router forwards packets sent to the virtual router IP addresses.

The following figure shows the minimum VRRP topology.

Figure 256: VRRP network topology

Traffic flows between users A and users B.

Router A uses VRRP global addresses as next hops for users B, and Router B for users A.

The VRRP master forwards the traffic and sends VRRP advertisements in the VLAN to announce to the backups that it is the master. If the master is no longer available, the backup takes over and becomes master. The only change occurs to the state of VRRP.

The VRRP router then transitions to the controlling state.

Note

The VRRP virtual IP address can be the same as the local IP address or Primary IP address of the interface on which VRRP is enabled. In this case, the router is the VRRP address owner on that interface and the priority is set to the maximum value of 255.

In the controlling state, the VRRP router functions as the forwarding router for the IP addresses associated with the virtual router. The router responds to ND neighbor solicitation and ND router solicitation messages for these IP addresses, forwards packets with a destination MAC address equal to the virtual router MAC address, and accepts packets addressed to IP addresses associated with the virtual router.

If you initialize the VRRP router and the priority is not 255, the router transitions to the backup state to ensure that all Layer 2 switches in the downstream path relearn the new origin of the VRRP MAC addresses.

In the backup state, a VRRP router monitors the availability and state of the master router. The backup does not respond to ND neighbor solicitation and ND router

solicitation messages for virtual router IP addresses and discards packets with a MAC address equal to the virtual router MAC address. The backup does not accept packets addressed to IP addresses associated with the virtual router. If a shutdown occurs, it transitions back to the initialize state. If the master router goes down, the backup router sends the VRRP advertisement and unsolicited ND neighbor advertisements and ND router advertisements described in the preceding paragraphs and transitions to the controlling state.

VRRP Advertisements and Master Router Failover

When you initialize a VRRP router, the master router continues to send advertisement messages at the advertisement interval period.

The other VRRP routers transition to the backup state in the following situations:

- if the priority in the received advertisement is greater than the local priority
- if the priority in the received advertisement is the same as the local priority and the primary IP address of the sender is greater than the local primary IP address

The backup routers use the advertisements from the master router as a keepalive to monitor the status of the master router. If the backup router does not receive an advertisement during the master downtime interval, calculated as $3 * \text{advertisement interval}$, then the master router is declared down.

If a shutdown occurs, the master router sends a VRRP advertisement with a priority of 0 and transitions to the initialize state.

The priority value 0 indicates that the master router has stopped participating in VRRP. This value triggers the backup router to transition to the master state without waiting for the current master to time out.

Edge devices learn the VRRP MAC address towards the master. After the backup becomes master and sends the advertisements, this causes the VRRP MAC address to move on the edge devices and point towards the new master.

Critical IPv6 Address and Holddown Timer

The critical IPv6 address is an interface that has primary impact on VRRP. If you enable critical IPv6 and the status of the critical IP changes, the master and backup relationship also changes.

If you configure and enable critical IPv6 address, the master transitions to backup if the critical IPv6 is down, and the backup becomes the master. After the critical IPv6 address of the original master resumes, if the hold-down timer is configured to 0, it becomes the master immediately. Otherwise, the original master transitions to the master state after the hold-down timer time out.

You can specify the local router IP interface uplink from the VRRP router to the network as the critical IP address. This ensures that, if the local uplink interface fails, VRRP initiates a master router failover to one of the backup routers.

The critical address can be one of the global unicast IPv6 addresses assigned to any local IPv6 interfaces.

The holddown timer is a proprietary enhancement to VRRP.

After a master transitions to backup by critical IP changing, one of the backup routers will be elected as the master router. After the critical IPv6 of the original master is restored, the original master remains in the backup state for a period of time that you configure by using the **holddown-timer** parameter. The router becomes the master immediately if you use the command **ipv6 vrrp <1-255> action preempt**.

The holddown timer allows the master router enough time to detect and update the dynamic routes. The timer delays the preemption of the master over the backup, when the master becomes available. If the hold-timer is configured to 0, it becomes the master router immediately. Otherwise, it transitions to the master state only after the holddown timer times out.

The holddown timer does not apply during failovers caused by VRRP router priority change. The holddown timer applies only to failovers caused by a critical IP failure.

Configure all of your routers to use identical values for the holddown timer.

Important

Do not use VRRP backup master and critical IP at the same time. Use one or the other. The critical IP address must be a local address.

VRRP Backup Master with Triangular SMLT

The standard implementation of VRRP supports one active master switch for each IPv6 subnet. All other VRRP interfaces in a network are in backup mode.

A deficiency occurs when VRRP-enabled switches use SMLT. If VRRP switches are aggregated into two SMLT switches, the end host traffic is load-shared on all uplinks to the aggregation switches (based on the Multilink Trunk [MLT] traffic distribution algorithm).

However, VRRP usually has only one active routing interface enabled. All other VRRP routers are in backup mode. Therefore, all traffic that reaches the backup VRRP router is forwarded over Virtual Inter-Switch Trunk (vIST) toward the master VRRP router. In this case, vIST potentially does not have enough bandwidth to carry all the aggregated traffic.

To resolve this issue, assign the backup router as the backup master router. The backup master router can actively load-share the routing traffic with a master router.

Because the two VRRP peer nodes exchange MAC address tables, the VRRP backup master can forward traffic directly, on behalf of the master router. The switch in the backup master state routes all traffic received on the backup master IP interface according to its routing table. The backup master switch does not perform Layer 2 switching for the traffic to the VRRP master.

If you enable SMLT on the backup master router, the incoming host traffic is forwarded over the SMLT links as usual.

**Important**

Do not use VRRP backup master and critical IP at the same time. Use one or the other.

Fast Advertisement

You can configure the advertisement time interval (in seconds) between sending advertisement messages. This interval permits fast network convergence with standardized VRRP failover. However, losing connections to servers for more than a second can result in missing critical failures. Customer network uptime in many cases requires faster network convergence, which means network problems must be detected within hundreds of milliseconds.

To meet these requirements, the fast advertisement interval are provided.

The fast advertisement interval is similar to the advertisement interval parameter except for the unit of measure and the range. The fast advertisement interval is expressed in milliseconds and the range is from 200 to 1,000 milliseconds. This unit of measure must be in multiples of 200 milliseconds.

To configure fast advertisement, you must specify a fast advertisement interval and explicitly enable the fast advertisement option. After you enable fast advertisement, the fast advertisement interval is used instead of the advertisement interval.

If you enable fast advertisement, VRRP can only communicate with other products that have the same configuration.

Accept-mode

When you configure VRRP for IPv6 on an interface you can configure the `accept-mode` parameter, which controls whether the VRRP master or backup master accepts packets destined for the IPv6 address associated with the virtual router.

By default, `accept-mode` is disabled. The `accept-mode` parameter does not affect the Neighbor Discovery packets. The master router forwards packets with a destination link-layer MAC address that matches the virtual MAC address, and accepts packets forwarded over the virtual interswitch trunk (vIST) toward the master router, if `accept-mode` is enabled. If you disable `accept-mode`, you cannot ping the virtual IPv6 address. If you enable `accept-mode`, the master router accepts packets addressed to the IPv6 address that is associated with the virtual router.

When you configure VRRP for IPv6 on an interface, you can configure the `accept-mode` parameter. By default, `accept-mode` is disabled. If you disable `accept-mode`, the master router does not drop neighbor solicitations or neighbor advertisements. The master router forwards packets with a destination link-layer MAC address that matches the virtual MAC address. If you disable `accept-mode`, you cannot ping the virtual IPv6 address.

VRRPv3

VRRPv3 is a combined protocol for both IPv4 and IPv6. It specifies an election protocol that dynamically assigns responsibility for a virtual router to one of the VRRP routers on a LAN. The VRRP router that controls the IPv4 or IPv6 addresses associated with a virtual router is called the Master, and it forwards packets sent to these IPv4 or IPv6 addresses. VRRP Backups wait for a Master and take ownership when the Master is no longer detected.

The election protocol provides dynamic failover in the forwarding responsibility when the Master is unavailable. VRRP for IPv4 gains a higher-availability default path without configuring dynamic routing or router discovery protocols on every end-host. VRRP for IPv6 gains a quick switch-over to Backup routers compared to the standard IPv6 Neighbor Discovery mechanisms.

Note

The VRRP IPv6 link-local address must be the same for all VRRP routers sharing the same link and the same virtual router ID, that is, the same VRRP instance. It is the address the VRRP advertisements are sent from. Also, the Router Advertisement packets from the VRRP interface are transmitted using this address, so, when IPv6 Stateless Address Autoconfiguration is used, this address is added to host Default Router List and is used as a gateway.

The software supports VRRPv3 for IPv4 and VRRPv3 for IPv6. VRRPv3 for IPv6 is compliant to RFC 5798. The software also supports VRRPv2 for IPv4.

VRRPv3 guidelines

The switch also supports VRRPv2 for IPv4. If you configure VRRP IPv6 on an interface, it runs independently of the IPv4 version. Configure the version of the VRRP IPv4 on the interface before you configure any other IPv4 VRRP attributes. By default, the version is not configured to a particular value. However, when sourcing older configuration files that do not have the version saved, the router configures the version to VRRPv2 by default. If you change the version, all IPv4 configuration under that interface is automatically removed, and you are prompted for a confirmation before this operation.

Perform the CLI configuration through **ip vrrp** or **ipv6 vrrp** nodes; CLI commands for IPv4 are common for version 2 and version 3.

The following list identifies the features that make both IPv4 and IPv6 VRRPv3 features compliant to RFC 5798:

- Advertisement vs Fast-advertisement — Prior to RFC 5798, the minimum advertisement interval was 1 second, with Fast-advertisement a sub-second interval could be configured. When this feature is enabled, the VRRP ADVERTISEMENT packets are sent with type 7 instead of 1. With RFC 5798 the sub-second interval is standardised, and the switch sends all packets for VRRPv3 with type 1. The use

of Fast-advertisement remains the same. VRRPv2 packets send with type 7, if Fast-advertisement is enabled.

- Add Master-advertisement-interval — Prior to RFC 5798 compliance, all virtual routers on the same VLAN had the same Advertisement-Interval configured. RFC 5798 states that you can use different Advertisement Intervals on the Master and Backup. On the Master, the Master-advertisement-interval and the Advertisement-Interval have the same value. On the Backup, the Master-advertisement-interval is used to calculate the timers, and the locally configured Advertisement-Interval is ignored until the Backup transitions to Master. The Master-advertisement-interval value is put in the advertisement packet type sent by the Master
- Transition to master as specified in RFC 5798 — Prior to RFC 5798, if a Backup receives an advertisement with a lower priority (or same priority but lower IP), it immediately sends its own advertisement and transitions to Master. However, RFC 5798 states that such packets must be discarded, which means it will transition to Master after the Master_Down_Timer expires
- Add skew-time — RFC 5798 states that skew-time is calculated depending on the priority, and Master-advertisement-interval assures that the Backup with highest priority sends the first advertisement when the Master goes down

Skew time is calculated using the formula: $((256 - \text{priority}) * \text{Master_Adver_Interval}) / 256$.

- Add preempt-mode — Preempt-mode is different from the **ipv6 vrrp <vrid> action preempt** command, which is an operational command issued when you want to stop the hold-down timer. RFC 5798 states that preempt-mode should be set to false when you do not want a higher priority Backup to transition to Master. By default, it is set to true

Note

Accept-mode is not fully implemented for IPv4 VRRPv3. You can only ping the virtual IP address, the same way as it is for IPv4 VRRPv2.

Configure VRRP Using CLI

This section provides procedures to configure VRRP using Command Line Interface (CLI).

Before You Begin

- Assign an IP address to the interface.
- Enable VRRP globally.

Configure the VRRP Version on an Interface

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port]}[-slot/port[/sub-port]]  
[,...][slot/all][all]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the VRRP version:

```
ip vrrp version <2-3>
```

Example

Configure VRRP version 3 for the specified interface:

```
Switch:1> enable  
Switch:1# configure terminal  
Switch:1(config)# interface gigabitethernet 1/2  
Switch:1(config-if)# ip vrrp version 3
```

Variable definitions

Use the data in the following table to use the **ip vrrp version** command.

Variable	Value
<i>version</i> <2-3>	Configures the VRRP version (2 or 3) on the specified interface

Configure VRRP on a Port or a VLAN

Configure VRRP on a port or a VLAN to forward packets to the virtual IP addresses associated with the virtual router and customize the VRRP configuration.

Before You Begin

- Create primary and, optionally, Secondary IP Interfaces on the VLAN.
- Configure the VRRP version on the interface.

About This Task

You can create secondary virtual IP addresses for VRRP instances on VLAN interfaces using the same **ip vrrp address** command included in this procedure. The first address you configure is the primary virtual IP address. Secondary virtual IP addresses must be in the same subnet as a Secondary IP Interface on the VLAN.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port]}[-slot/port[/sub-port]]  
[,...][slot/all][all]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure a primary virtual address and create the VRRP instance:

```
ip vrrp address <1-255> {A.B.C.D}
```

3. (Optional) Create a secondary virtual IP address:

Note

This step does not apply to brouter ports.

```
ip vrrp address <1-255> {A.B.C.D}
```

4. Enable the VRRP instance:

```
ip vrrp <1-255> enable
```

5. Show the global VRRP configuration:

```
show ip vrrp
```

Example

```
Switch:1>enable  
Switch:1#configure terminal  
Enter configuration commands, one per line. End with CNTL/Z.  
Switch:1(config)#interface gigabitethernet 1/2
```

Configure a primary VRRP address:

```
Switch:1(config-if)#ip vrrp address 28 192.0.2.1
```

Enable VRRP:

```
Switch:1(config-if)#ip vrrp 28 enable
```

Variable Definitions

Use the data in the following table to use the **ip vrrp** command.

Variable	Value
<i>1-255</i>	Specifies the number of the VRRP to create or modify.
<i>action {none preempt}</i>	Specifies the action of the VRRP interface: <ul style="list-style-type: none"> • none—do not override the holddown timer • preempt—override the holddown timer <p>Note: You can use this parameter only if the holddown timer is active.</p>
<i>address <1-255> {A.B.C.D}</i>	Configures the IP address of the VRRP physical interface that forwards packets to the virtual IP addresses associated with the virtual router. <i>A.B.C.D</i> is the IP address of the master VRRP.
<i>adver-int <1-255></i>	Configures the the time interval (in seconds) between sending VRRP advertisement messages. The default is 1. This value must be the same on all participating routers.
<i>backup-master enable</i>	Enables the VRRP backup master. When backup master functionality is enabled, the VRRP router forwards IP packets destined to the VRRP MAC even when the router is not the VRRP Master. Important: Do not enable backup master if you enable critical IP.
<i>critical-ip-addr <A.B.C.D></i>	Configures the critical IP address for VRRP. <i>A.B.C.D</i> is the IP address on the local router, which is configured so that a change in its state causes a role switch in the virtual router (for example, from master to backup) in case the interface stops responding. Note: In this context, <i>/local/</i> implies an address from the same VRF as the IP interface where VRRP is being configured.
<i>critical-ip enable</i>	Enables the critical IP address option. Important: Do not enable Critical IP if backup master is enabled.
<i>enable</i>	Enables VRRP on the port.
<i>fast-adv enable</i>	Enables the Fast Advertisement Interval. The default is disabled.

Variable	Value
<i>fast-adv-int</i> <200-1000>	Configures the Fast Advertisement Interval, the time interval between sending VRRP advertisement messages. <i>200-1000</i> is the range in milliseconds, and must be the same on all participating routers. The default is 200. You must enter values in multiples of 200 milliseconds.
<i>holddown-timer</i> <0-21600>	Specifies the time interval (in seconds) to wait before preempting the current VRRP primary router. The default is 0.
<i>preempt-mode</i>	Enables preempt mode for VRRP (v3).
<i>priority</i> <1-255>	Configures the port VRRP priority. <i>1-255</i> is the value used by the VRRP router. The default is 100. Assign the value 255 to the router that owns the IP address associated with the virtual router.

Display Information for all Configured VRRP Addresses

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about all addresses or filter the output based on a specified address, VRF name or ID, or VRRP ID:

```
show ip vrrp address [addr <A.B.C.D>] [vrf WORD<1-16>] [vrfids WORD<0-512>] [vrid <1-255>]
```

3. Display information for a specific VRRP version:

```
show ip vrrp address version <2-3>
```

4. Display version-based VRRP configuration for the specified VRF name:

```
show ip vrrp address vrf WORD<1-16> version <2-3>
```

5. Display version-based VRRP configuration for the specified VRF ID:

```
show ip vrrp address vrfids WORD<0-512> version <2-3>
```

Example

```
Switch:1>show ip vrrp address
```

```

Variable Definitions

Use the data in the following table to use the **show ip vrrp address** command.

Variable	Value
<i>addr</i> <A.B.C.D>	Specifies the physical local address of the master VRRP.
<i>vrf</i> WORD<1-16>	Specifies the name of the VRF.
<i>vrid</i> <1-255>	Specifies a unique integer value that represents the virtual router ID. The virtual router acts as the default router for one or more assigned addresses.
<i>vrfids</i> WORD<0-512>	Specifies the ID of the VRF.
<i>version</i> <2-3>	Specifies the VRRP version to include in the command output.

Display Extended VLAN VRRP

Perform this procedure to display the extended VRRP configuration for all VLANs or a specified VLAN on the device.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the extended VRRP configuration for all VLANs on the device or for the specified VLAN:

```

show ip vrrp interface vlan [<1-4059>] [portList] verbose [vrf
WORD<1-16>] [vrfids WORD<0-512>]

```

Example

```

Switch:1>show ip vrrp interface vlan
=====

```

Vlan Vrrp						
VLAN ID	VRF NAME	VRRP ID	IP ADDRESS	VIRTUAL MAC ADDRESS	VERSION	ORIGIN
2	GlobalRouter	10	203.0.113.2	00:00:5e:00:01:0a	2	config
222	GlobalRouter	1	192.0.2.1	00:00:5e:00:01:01	2	config
223	GlobalRouter	1	198.51.100.1	00:00:5e:00:01:01	3	config

Variable Definitions

The following table defines parameters for the **show ip vrrp interface vlan** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<i>portList</i>	Specifies the slot or port number of a range of ports.
<i>vrf WORD</i> <1-16>	Specifies the name of the VRF.
<i>vrfids WORD</i> <0-512>	Specifies the ID of the VRF.

Display VRRP Interface Information

About This Task

If you enter a virtual router ID or an IP address when showing VRRP interface information, the system displays the information only for that virtual router ID or for that interface.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display VRRPv2 information about the specified interface:
show ip vrrp interface version <2-3>
3. Display additional VRRPv2 information about the specified interface:
show ip vrrp interface verbose version <2-3>
4. Display VRRPv2 information for the specified VRF:
show ip vrrp interface vrf WORD<1-16> version <2-3>
5. Display VRRPv2 information for the specified virtual router:
show ip vrrp interface vrfids WORD<0-512> [version <2-3>]

Examples

```
Switch:1#show ip vrrp interface
```

```

Variable definitions

Use the data in the following table to use the **show ip vrrp interface** command.

Variable	Value
<i>gigabitethernet</i> { <i>slot/port</i> [- <i>slot/port</i>][,...]}	Specifies to show the VRRP information of which interface.
<i>verbose</i>	Specifies to show all available information about the VRRP interfaces.
<i>vlan</i>	Specifies the VLAN that contains the VRRP.
<i>vrf</i> <i>WORD</i> <1-16>	Specifies the name of the VRF.
<i>vrid</i> <1-255>	Specifies a unique integer value that represents the virtual router ID in the range 1–255. The virtual router acts as the default router for one or more assigned addresses.
<i>vrfids</i> <i>WORD</i> <0-512>	Specifies the ID of the VRF and is an integer in the range of 0–512.
<i>version</i> <2-3>	Specifies the VRRP version (2 or 3) configured.

View IP VRRPv3 Statistics

Use the following procedure to view IP VRRPv3 statistics to monitor network performance.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Enter the following command to view VRRP statistics:
show ip vrrp statistics version <2-3>
3. Enter the following command to view VRRP statistics for the specified VRF:
show ip vrrp statistics vrf *WORD*<1-16> version <2-3>
4. Enter the following command to view VRRP statistics for the specified virtual router:
show ip vrrp statistics vrfids *WORD*<0-512> version <2-3>

Example

View IP VRRPv3 statistics:

```
Switch:1#show ip vrrp statistics
```

```

VRRP ID	P/V	AUTHTYPE_ERR	PACKLEN_ERR	VERSION
3	3	0	0	2
2	1/1	0	0	3

Variable Definitions

Use the data in the following table to use the **ip vrrp version** command.

Variable	Value
<i>version</i> <2-3>	Specifies the version of VRRP (2 or 3) to be configured on the specified interface.
<i>vrf</i> WORD<1-16>	Specifies the name of the VRF.
<i>vrfids</i> WORD<0-512>	Specifies the ID of the VRF.

Enable Ping to a Virtual IP Address

Use the following procedure to enable ping to a virtual IP address. The default is enabled.

Procedure

- Enter VRRP Router Configuration mode:

```
enable
```

```
configure terminal
```

```
router vrrp
```
- Enable ping to a virtual IP address:

```
ping-virtual-address enable [vrf WORD<1-16>]
```

```
default ping-virtual-address enable [vrf WORD<1-16>]
```
- Display the configuration:

```
show ip vrrp [vrf WORD<1-16>]
```

Variable definitions

Use the data in the following table to use the `ping-virtual-address enable` and `show ip vrrp` commands.

Variable	Value
<code>enable</code>	Enables ping to a virtual IP address.
<code>vrf WORD<1-16></code>	Specifies the VRF.

Configure VRRP Notification Control

Use the following procedure to enable VRRP notification control. The generation of SNMP traps for VRRP events is enabled, by default.

About This Task

You can configure traps by creating SNMPv3 trap notifications, creating a target address to send the notifications, and specify target parameters. For more information about how to configure trap notifications, see [Logs and Traps](#) on page 2535.

Procedure

1. Enter VRRP Router Configuration mode:
`enable`
`configure terminal`
`router vrrp`
2. Enable a trap for VRRP events:
`send-trap enable [vrf WORD<1-16>]`
3. Disable a trap for VRRP events:
`no send-trap enable [vrf WORD<1-16>]`
4. Configure a trap for VRRP events to the default:
`default send-trap enable [vrf WORD<1-16>]`
5. Display the configuration:
`show ip vrrp [vrf WORD<1-16>]`

Variable definitions

Use the data in the following table to use the **`send-trap`** and **`show ip vrrp`** commands.

Variable	Value
<code>enable</code>	Enables generation of SNMP traps.
<code>vrf WORD<1-16></code>	Configures the send-trap for a particular VRF.

Enable IPv4 VRRP Preempt Mode

You can configure VRRP to preempt the existing router. If a new VRRP router is added to the network with a higher priority than the existing routers, then the new router becomes the master. If preempt-mode is disabled, then the new router does not become a master, it transitions to master only when the current master is down, that is when it does not receive any advertisement packets from the current master. By default, preempt-mode is enabled.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]]  
[,...][slot/all][all]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enter the following command:

```
ip vrrp <vrid> preempt-mode enable
```

Example

```
Switch:1> enable  
Switch:1# configure terminal  
Switch:1(config)# interface gigabitethernet 1/2
```

Enabling preempt-mode on interface 1/2:

```
Switch:1(config-if)# ip vrrp 1 preempt-mode enable
```

Variable definitions

Use the data in the following table to use the **ip vrrp <vrid>** command.

Variable	Value
<i>preempt-mode enable</i>	Enables preempt-mode for VRRPv3 for IPv4.

IPv6 VRRP Configuration using CLI

This section provides procedures to configure IPv6 VRRP using the command line interface (CLI).

Configure the VRRP Interface

Configure VRRP to provide fast failover of a default router for IPv6 LAN hosts, in order to create a VRRP instance.

Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Do not configure RSMLT on the VLAN.
- You must specify a link-local address to associate with the virtual router.

About This Task

VRRP supports a virtual IPv6 address shared between two or more routers that connect the common subnet to the enterprise network.

VRRP for IPv6 provides a faster switchover to an alternate default router than is possible using the ND protocol.

Perform this procedure to also configure the additional addresses for which the virtual router acts as a backup.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...][slot/all][all]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Associate an address with the virtual router for either link-local or global:

- `ipv6 vrrp address <1-255> link-local WORD <0-127>`
- `ipv6 vrrp address <1-255> global WORD <0-255>`

Note

You must configure the link-local address before you configure the global address.

3. Enable VRRP for the interface:

```
ipv6 vrrp <1-255> enable
```

Example

Associate a link-local address with the virtual router ID 12:

```
Switch:1(config-if)#ipv6 vrrp address 12 link-local fe80::1234
```

Associate a global address with the virtual router ID 12

```
Switch:1(config-if)#ipv6 vrrp address 12 global 3333::1234/64
```

Enable VRRP for the interface:

```
Switch:1(config-if)#ipv6 vrrp 12 enable
```

Variable Definitions

Use the data in the following table to use the **ipv6 vrrp address** command.

Variable	Value
<1-255>	Specifies the virtual router ID. The virtual router acts as the default router for one or more associated addresses.
<i>enable</i>	Enables IPv6 VRRP. The default is disabled.
<i>global WORD</i> <0-255>	Specifies a global IPv6 address and mask to associate with the virtual router.
<i>link-local WORD</i> <0-127>	Specifies a link-local IPv6 address to associate with the virtual router.

Use the data in the following table to use the **interface** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
{ <i>slot/port</i> [/ <i>sub-port</i>][<i>-slot/port</i> [/ <i>sub-port</i>]] [<i>,...</i>][<i>slot/all</i>][<i>all</i>]}	Identifies the slot and port in one of the following formats: <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>

View VRRP Information

Display VRRP port or VLAN information to verify your configuration. Show VRRP information by IPv6 address or virtual router ID. If you enter a virtual router ID or an IPv6 address when you view VRRP information, the information applies only to that virtual router ID or for that interface.

Procedure

1. Enter Privileged EXEC mode:
enable
2. View the configuration information for all interfaces:
show ipv6 vrrp interface [verbose] [vrf *WORD*<1-16> | vrfids *WORD*<0-512>]

3. View the configuration information for one or more ports:

```
show ipv6 vrrp interface gigabitethernet {slot/port[/sub-port]}[-slot/
port[/sub-port]][[,...][slot/all][all]] [verbose] [vrf WORD<1-16> |
vrfids WORD<0-512>]
```

4. View the configuration information for one or more VLANs:

```
show ipv6 vrrp interface vlan [<1-4059>] [verbose] [vrf WORD<1-16> |
vrfids WORD<0-512>]
```

5. View the configuration information for one or more virtual router IDs:

```
show ipv6 vrrp interface vrid <1-255> [verbose] [vrf WORD<1-16> |
vrfids WORD<0-512>]
```

6. View VRRP address information:

```
show ipv6 vrrp address [vrf WORD<1-16> | vrfids WORD<0-512>]
```

7. View VRRP address information for a link-local address:

```
show ipv6 vrrp address link-local WORD<0-127> [verbose] [vrf WORD<1-
16> | vrfids WORD<0-512>]
```

8. View VRRP address information for a virtual router ID:

```
show ipv6 vrrp address vrid <1-255> [vrf WORD<1-16> | vrfids WORD<0-
512>]
```

Example

```
Switch:1>show ipv6 vrrp address
```

```

Variable Definitions

Use the data in the following table to use the **show ipv6 vrrp** commands.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...][slot/all] [all]}</code>	<p>Identifies the slot and port in one of the following formats:</p> <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>
<code>link-local WORD<0-127></code>	Displays information by link-local IPv6 address.
<code>verbose</code>	Displays extended information.
<code>vlan [<1-4059>]</code>	<p>Identifies the slot and port in one of the following formats:</p> <ul style="list-style-type: none"> • a single slot and port (slot/port) • a range of slots and ports (slot/port-slot/port) • a series of slots and ports (slot/port,slot/port,slot/port) • all ports on the same slot (slot/all) • all ports on the switch (all) <p>If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>
<code>vrid <1-255></code>	Displays information by virtual router ID.
<code>vrf WORD<1-16></code>	Specifies the VRF name.
<code>vrfids WORD<0-512></code>	Specifies the VRF ID.

Configure VRRP Notification Control

Perform this procedure to configure VRRP notification control.

Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.

About This Task

By default, generation of SNMP traps for VRRP events is enabled.

Procedure

1. Enter VRRP Router Configuration mode:
`enable`

`configure terminal`

`router vrrp`
2. Enable the VRRP-router to generate SNMP traps for events:
`ipv6 send-trap enable`

Example

Disable generation of SNMP traps for VRRP events:

```
Switch:1(config-vrrp)#no ipv6 send-trap enable
```

Configure Additional VRRP Parameters for an Interface

Configure VRRP to provide fast failover of a default router for IPv6 LAN hosts. VRRP supports a virtual IPv6 address shared between two or more routers that connect the common subnet to the enterprise network. VRRP for IPv6 provides a faster switchover to an alternate default router than is possible using the ND protocol.

Configure the parameters in this procedure if the default values do not meet your requirements.

Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Do not configure RSMLT on the VLAN.

About This Task

A switch that acts as a VRRP master does not reply to SNMP get requests to the VRRP virtual interface address. The switch will, however, respond to SNMP get requests to the physical IP address.

Procedure

1. Enter Interface Configuration mode:
`enable`

`configure terminal`

`interface GigabitEthernet {slot/port[/sub-port]}[-slot/port[/sub-port]]`
`[,...][slot/all][all]} or interface vlan <1-4059>`

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the accept mode of the master router:

```
ipv6 vrrp <1-255> accept-mode enable
```

3. Determine if the router overrides the holddown timer:

```
ipv6 vrrp <1-255> action <none|preempt>
```

4. Configure the interval between advertisement messages:

```
ipv6 vrrp <1-255> adver-int <1-40>
```

5. Enable the backup VRRP switch for traffic forwarding:

```
ipv6 vrrp <1-255> backup-master enable
```

6. Configure the IP interface on the local router:

```
ipv6 vrrp <1-255> critical-ipv6-addr WORD<0-46> [critical-ipv6 enable]
```

7. Configure the fast advertisement interval:

```
ipv6 vrrp <1-255> fast-adv enable [fast-adv-int <200-1000>]
```

8. Configure the holddown timer:

```
ipv6 vrrp <1-255> holddown-timer <0-21600>
```

9. Configure the priority for the VRRP router:

```
ipv6 vrrp <1-255> priority <1-255>
```

Example

Configure the fast advertisement interval:

```
Switch:1(config-if)#ipv6 vrrp 12 fast-adv enable fast-adv-int 400
```

Configure the holddown timer:

```
Switch:1(config-if)#ipv6 vrrp 12 holddown-timer 30
```

Variable Definitions

Use the data in the following table to use the **ipv6 vrrp** command.

Variable	Value
<1-255>	Specifies a number that uniquely identifies a virtual router on a VRRP router. The virtual router acts as the default router for one or more assigned addresses.
<i>accept-mode enable</i>	Controls whether the VRRP master or backup master accepts packets (other than neighbor discovery packets) destined to the IPv6 address associated with the virtual router. The default value is disable.
<i>action <none preempt></i>	Lists options to override the holddown timer manually and force preemption: <ul style="list-style-type: none"> • <i>none</i> does not override the timer. • <i>preempt</i> preempts the timer. This parameter applies only if the holddown timer is active.
<i>adver-int <1-40></i>	Specifies the time interval, in seconds, between sending advertisement messages. The default is 1 second. Only the master router sends advertisements.

Variable	Value
<i>backup-master enable</i>	Uses the backup VRRP switch for traffic forwarding. This option reduces the traffic on the vIST. The default is disabled.
<i>critical-ipv6 enable</i>	Enables or disables the use of critical IP. When disabled, the VRRP ignores the availability of the address configured as critical IP. This address must be a local address. The default is disabled.
<i>critical-ipv6-addr WORD<0-46></i>	Specifies an IP interface on the local router configured so that a change in its state causes a role switch in the virtual router (for example, from master to backup) in case the interface stops responding.
<i>fast-adv enable</i>	Enables or disables the fast advertisement interval. When disabled, the regular advertisement interval is used. The default is disable.
<i>fast-adv-int <200-1000></i>	Configures the interval between VRRP advertisement messages. You must configure the same value on all participating routers. This unit of measure must be in multiples of 200 milliseconds. The default is 200.
<i>holddown-timer <0-21600></i>	Configures the amount of time, in seconds, to wait before preempting the current VRRP master. The default is 0.
<i>priority <1-255></i>	Specifies the priority value used by this VRRP router. The value 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.

View IPv6 VRRP Statistics

View IPv6 VRRP statistics to monitor network performance.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. View statistics for the device and for all interfaces:

```
show ipv6 vrrp statistics [link-local WORD<0-127>]] [vrid <1-255>]
```

Example

View IPv6 VRRP statistics for VRID 1.

```
Switch:1(config)#show ipv6 vrrp statistics vrid 1

Variable Definitions

Use the data in the following table to use the **show ipv6 vrrp statistics** command.

Variable	Value
<i>link-local WORD<0-127></i>	Shows statistics for a specific link-local address.
<i>vrid <1-255></i>	Shows statistics for a specific VRID.

Enable IPv6 VRRP Preempt Mode

You can configure IPv6 VRRP to preempt the existing router. If a new VRRP router is added to the network with a higher priority than the existing routers, then the new router becomes the master. If preempt-mode is disabled, then the new router does not become a master, it transitions to master only when the current master is down. By default, preempt-mode is enabled.

Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port]}[-slot/port[/sub-port]]
[,...][slot/all][all]} or interface vlan <1-4059>
```

Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enter the following command:

```
ipv6 vrrp <vrid> preempt-mode enable
```

3. Use the following command to set the IPv6 VRRP preempt-mode to its default value:

```
default ipv6 vrrp <vrid> preempt-mode
```

4. Use the following command to disable the IPv6 VRRP preempt-mode:

```
no ipv6 <vrid> preempt-mode enable
```

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/2
```

Enabling IPv6 VRRP preempt-mode for interface 1/2

```
Switch:1(config-if)# ipv6 vrrp 1 preempt-mode enable
```

Variable definitions

Use the data in the following table to use the **ipv6 vrrp <vrid>** command.

Variable	Value
<i>enable</i>	Enables preempt-mode for VRRPv3 for IPv6.
<i>vrid <1-255></i>	Specifies the virtual router ID.

Configure VRRP using EDM

This section provides procedures to configure VRRP using Enterprise Device Manager (EDM).

Before You Begin

- Assign an IP address to the interface.
- Enable VRRP globally.

Enable VRRP Global Variables

Enable VRRP global variables to enable the VRRP function.

Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. You cannot launch a VRF Context View for the derived name of the untrusted (*-unt) or unrestricted (*-unr) segments of a Segmented VRF. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4100. All parameters might not be available in non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **VRRP**.
3. Select the **Globals** tab.
4. Configure the required features.
5. Select **Apply**.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
NotificationCntl	Indicates whether the VRRP-enabled router generates SNMP traps for events. <ul style="list-style-type: none">• enabled—SNMP traps are generated• disabled—no SNMP traps are sent The default is enabled.
PingVirtualAddrEnable	Configures whether this device responds to pings directed to a virtual router IP address. The default is enabled.

Modify VRRP Parameters for an Interface

Before You Begin

- You must enable VRRP on a brouter port or VLAN.

About This Task

You can manage and configure VRRP parameters for the routing interface.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **VRRP**.
3. Select the **Interface** tab.
4. Double-click **HoldDownTimer**, and type the number of seconds for the timer.

The **HoldDownState** field displays active when the hold-down timer is counting down and preemption occurs. The field displays dormant when preemption is not pending. When the hold-down timer is active, the **HoldDownTimeRemaining** field displays the seconds remaining before preemption.
5. In **Action**, select an option.
6. Select **Apply**.

Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
IfIndex	Specifies the index value that uniquely identifies the interface to which this entry applies.
VrId	Specifies a number that uniquely identifies a virtual router on a Virtual Router Redundancy Protocol (VRRP) router. The virtual router acts as the default router for one or more assigned addresses.

Name	Description
IpAddr	Specifies the assigned IP addresses for which a virtual router is responsible to provide backup.
VirtualMacAddr	Specifies the MAC address of the virtual router interface.
State	Specifies the state of the virtual router interface: <ul style="list-style-type: none"> • Initialize—waiting for a startup event • Backup—monitoring availability and state of the master router • Master—functioning as the forwarding router, the primary VRRP router, for the virtual router IP addresses.
Control	Specifies whether VRRP is enabled or disabled for the port (or VLAN). The default is enabled.
Priority	Specifies the priority value used by this VRRP router. The value 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.
AdvertisementInterval	Specifies the time interval, in seconds, between sending advertisement messages. The default is 1 second. Only the primary VRRP router sends advertisements. The default is 1.
MasterIpAddr	Specifies the IP address of the physical interface of the primary virtual router that forwards packets sent to the virtual IP addresses associated with the virtual router.
VirtualRouterUpTime	Specifies the time interval, in hundredths of a second, since the virtual router was initialized.
Action	Lists options to override the delay timer manually and force preemption: <ul style="list-style-type: none"> • none does not override the timer • preemptHoldDownTimer preempts the timer
HoldDownTimer	Configures the amount of time, in seconds, to wait before preempting the current VRRP primary router.
HoldDownState	Indicates the hold-down state of this VRRP interface. If the hold-down timer is operational, this variable is set to active; otherwise, this variable is set to dormant.

Name	Description
HoldDownTimeRemaining	Indicates the amount of time, in seconds, left before the HoldDownTimer expires.
CriticalIpAddr	<p>Configures the critical IP address for VRRP. This command specifies an IP interface on the local router, which is configured so that a change in its state causes a role switch in the virtual router (for example, from primary to backup) in case the interface stops responding.</p> <p>Note: In this context, <i>local</i> implies an address from the same VRF as the IP interface where VRRP is configured.</p>
CriticalIpAddrEnable	Configures the IP interface on the local router to enable or disable the backup. The default is disabled.
BackUpMaster	Enables the backup VRRP system traffic forwarding. The default is disabled.
BackUpMasterState	Indicates whether the backup VRRP system traffic forwarding is enabled or disabled. The default is disabled.
FasterAdvInterval	<p>Configures the Fast Advertisement Interval between sending VRRP advertisement messages. You must configure the same value on all participating routers. Enter the value in multiples of 200 milliseconds. The default is 200.</p>
FasterAdvIntervalEnable	Enables or disables the Fast Advertisement Interval. When disabled, the regular advertisement interval is used. The default is disable.
MasterHostname Note: Exception: not supported on 4220 Series, 5320 Series, or 5420 Series.	Displays the SPBM host name of the VRRP primary router for a Distributed Virtual Routing (DvR) interface.
Origin Note: Exception: not supported on 4220 Series, 5320 Series, or 5420 Series.	Displays how the VRRP interface was configured, either manually or through DvR.

Add a Secondary Virtual IP for VRRPv2

The first virtual IP configured on a VRRP interface is the primary virtual IP. After you create a VRRP interface, you can create secondary virtual IPs.

Before You Begin

- Create primary and secondary IP addresses on the VLAN.
- Create a VRRP instance on the VLAN.
- Configure a primary virtual IP.

About This Task

Secondary virtual IP addresses must be in the same subnet as a Secondary IP Interface on the VLAN.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **VRRP**.
3. Select the **Interface** tab.
4. Select an interface, and then select **AssociatedIPAddr**.
5. On the **Address List** tab, select **Insert**.
6. Type the IP address.
7. Select **Insert**.

Address List *Field Descriptions*

Use the data in the following table to use the **Address List** tab.

Name	Description
IpAddr	Specifies a secondary virtual IP address.

Configure VRRP on a V3 Interface

Before You Begin

- Assign an IPv4 address to the interface
- Enable routing globally
- Do not configure RSMLT on the VLAN

About This Task

Perform this procedure to configure VRRP on a V3 interface on either a brouter port or a VLAN.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **VRRP**.
3. Select the **V3 Interface** tab.

4. Select **Insert**.
5. Beside **IfIndex**, select **Port** or **VLAN**.
6. Select a port or VLAN.
7. Select **OK**.
8. Type the virtual router ID.
9. Type the primary IP address.
10. Type the advertisement interval.
11. Select **Insert**.

Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
IfIndex	Shows the index value that uniquely identifies the interface to which this entry applies.
InetAddrType	Specifies the source network INET Address Type.
VrId	Specifies a number that uniquely identifies a virtual router on a VRRP router.
PrimaryIpAddr	Specifies the virtual address assigned to the VRRP.
VirtualMacAddr	Specifies the MAC address of the virtual router interface.
State	Shows the state of the virtual router interface. The possible states are <ul style="list-style-type: none"> • initialize—waiting for a startup event • backup—monitoring availability and state of the master router • master—functioning as the forwarding router for the virtual router IP addresses
Control	Displays whether VRRP is enabled or disabled for the port or VLAN.
Priority	Specifies the priority value used by this VRRP router. The value 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.
AdvInterval	Specifies the time interval, in seconds, between sending advertisement messages. The default is 1 second.
MasterIpAddr	Specifies the IP address of the physical interface of the Master's virtual router.
UpTime	Indicates the time interval since this virtual router exited the INIT state.

Name	Description
CriticalIpAddr	Indicates the IP address of the interface that is critical to VRRP. If that IP interface is down, the VRRP state will transition to Backup, even if it has higher priority.
CriticalIpAddrEnabled	Enables or disables the use of critical IP. When disabled, the VRRP ignores the availability of the address configured as critical IP. This address must be a local address. The default is disabled.
BackUpMaster	Uses the backup VRRP switch for traffic forwarding. This option reduces the traffic on the v1ST. The default is disabled.
BackUpMasterState	Indicates if the Backup-Master is operational up. If the switch is in Master state but the Backup-Master is enabled, then the BACKUP MASTER STATE will be down.
FasterAdvIntervalEnabled	Enables or disables the fast advertisement interval. When disabled, the regular advertisement interval is used. The default is disabled.
FasterAdvInterval	Configures the interval between VRRP advertisement messages. The default is 200. Enter the values in multiples of 200 milliseconds.
PreemptMode	Issued to preempt the existing router. If a new router is added to the network with its priority higher than the existing routers, then the new router becomes the master. The default is enabled.
Action	Lists options to override the hold-down timer manually and force preemption: <ul style="list-style-type: none"> • none does not override the timer. • preemptHoldDownTimer preempts the timer. This parameter applies only if the holddown timer is active.
HoldDownTimer	Configures the amount of time, in seconds, to wait before preempting the current VRRP master. The default is 0.

Name	Description
HoldDownTimeRemaining	Indicates the amount of time, in seconds, left before the HoldDownTimer expires.
MasterAdvInterval	On the VRRPv3 master, the master advertisement interval is same as the advertisement interval. On the VRRPv3 Backup, the master advertisement interval is set to the Advertisement configured on the Master (received in the packet).

Configure VRRPv3 Checksum

About This Task

Perform this procedure to configure VRRPv3 checksum on either a brouter port or a VLAN.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **VRRP**.
3. Select the **V3 Checksum** tab.
4. Select **Insert**.
5. In **Interface**, select **Port** or **Vlan**.
6. Select the ports or VLANs from the list, and then select **OK**.
7. Select a type of checksum computation.
8. Select a VRRP version.
9. Select **Insert**.

V3 Checksum Field Descriptions

Use the data in the following table to use the **V3 Checksum** tab.

Name	Description
Interface	Shows VRRPv3 information about a specified interface.
rcIpConflIndex	Shows the index value that uniquely identifies the interface to which this entry applies.
ChkSumComputation	Specifies the type of checksum computation, with Pseudo Header or without Pseudo Header.
VrrpVersion	Specifies the VRRP version as unspecified, v2, or v3.

Configure Fast Advertisement Interval on a Port

About This Task

Configure the Fast Advertisement Interval to send VRRP advertisement messages. The interval can be between 200 and 1000 milliseconds, and it must be the same on all participating routers. The default is 200. Enter the values in multiples of 200 milliseconds.

Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **IP**.
4. Select the **VRRP** tab.
5. Select **Insert**.
6. Select **FasterAdvIntervalEnable**.
7. In **FasterAdvInterval**, type a value using multiples of 200 milliseconds.
8. Select **Insert**.

Configure Fast Advertisement Interval on a VLAN

About This Task

Configure the Fast Advertisement Interval to send VRRP advertisement messages. The interval can be between 200 and 1000 milliseconds, and it must be the same on all participating routers. The default is 200. Enter the values in multiples of 200 milliseconds.

Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Basic** tab.
4. Select a VLAN.
5. Select **IP**.
6. Select the **VRRP** tab.
7. Select **Insert**.
8. Select **FasterAdvIntervalEnable**.
9. In **FasterAdvInterval**, type a value using multiples of 200 milliseconds.
10. Select **Insert**.

View VRRP Statistics

About This Task

View VRRP statistics to monitor network performance.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **VRRP**.
3. Select the **Stats** tab.

Stats Field Descriptions

The following table describes parameters on the **Stats** tab.

Name	Description
ChecksumErrors	Specifies the number of VRRP packets received with an invalid VRRP checksum value.
VersionErrors	Specifies the number of VRRP packets received with an unknown or unsupported version number.
VrIDErrors	Specifies the number of VRRP packets received with an invalid VrID for this virtual router.

View VRRP Interface Statistics

About This Task

View VRRP statistics to manage network performance.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **VRRP**.
3. Select the **Interface** tab.
4. Select an interface.
5. Select **Graph**.

Interface Field Descriptions

The following table describes parameters on the **Interface** tab.

Name	Description
AdvertiseRcvd	Specifies the number of VRRP advertisements received by this virtual router.
AdvertiseIntervalErrors	Specifies the number of received VRRP advertisement packets with a different interval is than configured for the local virtual router.
IPtTlErrors	Specifies the number of VRRP packets received by the virtual router with IP TTL (Time-To-Live) not equal to 255.
PriorityZeroPktsRcvd	Specifies the number of VRRP packets received by the virtual router with a priority of 0.

Name	Description
PriorityZeroPktsSent	Specifies the number of VRRP packets sent by the virtual router with a priority of 0'.
InvalidTypePktsRcvd	Specifies the number of VRRP packets received by the virtual router with an invalid value in the 'type' field.
AddressListErrors	Specifies the packets received address list the address list does not match the locally configured list for the virtual router.
AuthTypeMismatch	Specifies the count of authentication type mismatch messages.
PacketLengthErrors	Specifies the count of packet length errors.
AuthFailures	Specifies the count of authentication failure messages.

View IP VRRPv3 Statistics

About This Task

Use the following procedure to view IPv6 VRRPv3 statistics for monitoring the network performance.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **VRRP**.
3. Select the **V3 Stats** tab.

V3 Stats Field Descriptions

Use the data in the following table to interpret the **V3 Stats** tab.

Name	Description
InetAddrType	Shows that the address type of the statistical entry is IPv4.
ChecksumErrors	Specifies the total number of VRRP packets received with an invalid VRRP checksum value.
VersionErrors	Specifies the total number of VRRP packets received with an unknown or unsupported version number.
VrIdErrors	Specifies the total number of VRRP packets received with an invalid VRID for the virtual router.

Graph IP VRRPv3 Statistics

About This Task

Use the following procedure to view and graph IP VRRPv3 statistics for monitoring the network performance.

Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **VRRP**.
3. Select the **V3 Interface** tab.
4. Select an interface, and then select **Graph**.
5. Select one or more values.
6. Select a graph type:
 - Line Chart
 - Area Chart
 - Bar Chart
 - Pie Chart

V3 Interface Field Descriptions

Use the data in the following table to use the **V3 Interface** tab.

Name	Description
IfIndex	Shows the index value that uniquely identifies the interface to which this entry applies.
VrId	Specifies a number that uniquely identifies a virtual router on a VRRP router.
PrimaryIpAddr	Specifies the virtual address assigned to the VRRP.
VirtualMacAddr	Specifies the MAC address of the virtual router interface.
State	Specifies the state of the virtual router interface: <ul style="list-style-type: none">• Initialize—waiting for a startup event• Backup—monitoring availability and state of the master router• Master—functioning as the forwarding router for the virtual router IP addresses.
Control	Specifies whether VRRP is enabled or disabled for the port (or VLAN). The default is enabled.

Name	Description
Priority	Specifies the priority value used by this VRRP router. Set a value from 1 to 255, where 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.
AdvInterval	Specifies the time interval (in seconds) between sending advertisement messages. The range is 1 to 255 seconds with a default of 1 second. Only the master router sends advertisements. The default is 1.
UpTime	Specifies the time interval (in hundredths of a second) since the virtual router was initialized.
CriticalIpAddr	<p>This command specifies an IP interface on the local router, which is configured so that a change in its state causes a role switch in the virtual router (for example, from master to backup) in case the interface stops responding.</p> <p>Note: In this context, local implies an address from the same VRF as the IP interface where VRRP is being configured.</p>
CriticalIpAddrEnabled	Configures the IP interface on the local router to enable or disable the backup. The default is disabled.
BackUpMaster	Enables the backup VRRP system traffic forwarding. The default is disabled.
BackUpMasterState	Indicates whether the backup VRRP system traffic forwarding is enabled or disabled. The default is disabled.
FasterAdvIntervalEnabled	Enables or disables the Fast Advertisement Interval. When disabled, the regular advertisement interval is used. The default is disable.
FasterAdvInterval	Configures the Fast Advertisement Interval between sending VRRP advertisement messages. The interval is between 200 and 1000 milliseconds, and you must enter the same value on all participating routers. The default is 200. You must enter the values in multiples of 200 milliseconds.
PreemptMode	Issued to preempt the existing router. If a new router is added to the network with its priority higher than the existing routers, then the new router becomes the master.

Name	Description
Action	Lists options to override the delay timer manually and force preemption: <ul style="list-style-type: none"> • none does not override the timer • preemptHoldDownTimer preempts the timer
HoldDownTimer	Indicates the hold-down state of this VRRP interface. If the hold-down timer is operational, this variable is set to active; otherwise, this variable is set to dormant.
HoldDownTimeRemaining	Indicates the amount of time (in seconds) left before the HoldDownTimer expires.
MasterAdvInterval	On the VRRPv3 master, the master advertisement interval is same as the advertisement interval. On the VRRPv3 Backup, the master advertisement interval is set to the Advertisement configured on the Master (received in the packet).

IPv6 VRRP Configuration using EDM

This section provides procedures to configure IPv6 VRRP using Enterprise Device Manager (EDM).

Configure VRRP for an Interface

Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Do not configure RSMLT on the VLAN.
- Change the VRF instance as required to configure a VRRP for an interface on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

Configure VRRP to provide fast failover of a default router for IPv6 LAN hosts. VRRP supports a virtual IPv6 address shared between two or more routers that connect the common subnet to the enterprise network. VRRP for IPv6 provides a faster switchover to an alternate default router than is possible using the ND protocol.

Perform this procedure to configure VRRP on either a brouter port or a VLAN.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **VRRP**.
3. Select **V3 Interface**

4. Select **Insert**.
5. Beside **IfIndex**, select **Port** or **VLAN**.
6. In the dialog box that opens, select a port or VLAN.
7. Select **OK**.
8. Type the virtual router ID.
9. To control the packets sent to the IPv6 address associated to the virtual router, select **AcceptMode**.
10. Type the primary IP address.
11. Select **Insert**.

V3 Interface *Field Descriptions*

Use the data in the following table to use the **V3 Interface** tab.

Name	Description
IfIndex	Shows the index value that uniquely identifies the interface to which this entry applies.
InetAddrType	Specifies the address type for the VRRP interface.
VrId	Specifies a number that uniquely identifies a virtual router on a VRRP router.
PrimaryIpAddr	Specifies the link-local address assigned to the VRRP.
VirtualMacAddr	Specifies the MAC address of the virtual router interface.
State	Shows the state of the virtual router interface. The possible states are <ul style="list-style-type: none"> • initialize—waiting for a startup event • backup—monitoring availability and state of the master router • master—functioning as the forwarding router for the virtual router IP addresses
Control	Displays whether VRRP is enabled or disabled for the port or VLAN.
Priority	Specifies the priority value used by this VRRP router. The value 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.
AdvInterval	Specifies the time interval, in seconds, between sending advertisement messages. The default is 1 second.
MasterIpAddr	Specifies the IP address of the physical interface of the Master's virtual router.

Name	Description
UpTime	Indicates the time interval since this virtual router exited the INIT state.
CriticalIpAddr	Indicates the IP address of the interface that is critical to VRRP. If that IP interface is down, the VRRP state will transition to Backup, even if it has higher priority.
CriticalIpAddrEnabled	Enables or disables the use of critical IP. When disabled, the VRRP ignores the availability of the address configured as critical IP. This address must be a local address. The default is disabled.
BackUpMaster	Uses the backup VRRP switch for traffic forwarding. This option reduces the traffic on the v1ST. The default is disabled.
BackUpMasterState	Indicates if the Backup-Master is up. If the switch is in Master state, but Backup-Master is enabled, then the BACKUP MASTER STATE will be down.
FasterAdvIntervalEnabled	Enables or disables the fast advertisement interval. When disabled, the regular advertisement interval is used. The default is disable.
FasterAdvInterval	Configures the interval between VRRP advertisement messages. The default is 200. Enter the values in multiples of 200 milliseconds.
AcceptMode	Controls whether the VRRP master or backup master accepts packets (other than neighbor discovery packets) destined to the IPv6 address associated with the virtual router. The default value is disable.
PreemptMode	Issued to preempt the existing router. If a new router is added to the network with its priority higher than the existing routers, then the new router becomes the master. The default is enabled.
Action	Lists options to override the hold-down timer manually and force preemption: <ul style="list-style-type: none"> • none does not override the timer. • preemptHoldDownTimer preempts the timer. This parameter applies only if the holddown timer is active.
HoldDownTimer	Configures the amount of time, in seconds, to wait before preempting the current VRRP master. The default is 0.

Name	Description
HoldDownTimeRemaining	Indicates the amount of time, in seconds, left before the HoldDownTimer expires.
MasterAdvInterval	On the VRRP master, the master advertisement interval is same as the advertisement interval. On the VRRPv3 Backup, the master advertisement interval is set to the Advertisement configured on the Master (received in the packet).

Configure VRRP Notification Control

Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Change the VRF instance as required to configure VRRP notification control on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

Perform this procedure to configure VRRP notification control.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **VRRP**.
3. Select the **Globals** tab.
4. Select **enabled**.
5. Select **Apply**.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
NotificationCntrl	Indicates whether the VRRP-enabled router generates SNMP traps for events. <ul style="list-style-type: none">• enabled: Generate SNMP traps.• disabled: Do not generate SNMP traps. The default is enabled.

View IPv6 VRRP Statistics

View IPv6 VRRP statistics to monitor network performance.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.

2. Select **VRRP**.
3. Select the **Stats** tab.

Stats Field Descriptions

Use the data in the following table to use the **Stats** tab.

Name	Description
InetAddrType	Shows the type of IP address (IPv4 or IPv6).
ChecksumErrors	Shows the number of VRRP packets received with an invalid VRRP checksum value.
VersionErrors	Shows the number of VRRP packets received with an unknown or unsupported version number.
VrIdErrors	Shows the number of VRRP packets received with an invalid VrID for this virtual router.

View IPv6 VRRP Statistics for an Interface

View IPv6 VRRP statistics for a VLAN or port.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **VRRP**.
3. Select the **V3 Interface** tab.
4. Select an interface.
5. Select **Statistics**.

Statistics Field Descriptions

Use the data in the following table to use the **Statistics** tab.

Name	Description
MasterTransitions	Shows the total number of times that the state of this virtual router has transitioned to master. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
RcdAdvertisements	Shows the total number of VRRP advertisements received by this virtual router. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
AdvIntervalErrors	Shows the total number of VRRP advertisement packets received for which the advertisement interval is different than the one configured for the local virtual router. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
IpTtlErrors	Shows the total number of VRRP packets received by the virtual router with IPv4 TTL (for VRRP over IPv4) or IPv6 Hop Limit (for VRRP over IPv6) not equal to 255. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
RcvdPriZeroPackets	Shows the total number of VRRP packets received by the virtual router with a priority of 0. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
SentPriZeroPackets	Shows the total number of VRRP packets sent by the virtual router with a priority of 0. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.

Name	Description
RcvdInvalidTypePkts	Shows the number of VRRP packets received by the virtual router with an invalid value in the 'type' field. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
AddressListErrors	Shows the total number of packets received for which the address list does not match the locally configured list for the virtual router. Discontinuities in the value of this counter can occur at reinitialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
PacketLengthErrors	Shows the total number of packets received with a packet length less than the length of the VRRP header. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
RcvdInvalidAuthentications	Shows the total number of packets received with an unknown authentication type.

View IPv6 VRRP Statistics

View IPv6 VRRP statistics for a VLAN or port.

Before You Begin

Change the VRF instance as required to view IPv6 VRRP statistics on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Port**.
2. Select **IPv6**.
3. Select the **VRRP** tab.
4. Select an interface.
5. Select **Statistics**.

Statistics Field Descriptions

Use the data in the following table to use the **Statistics** tab.

Name	Description
MasterTransitions	Shows the total number of times that the state of this virtual router has transitioned to master. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
RcdAdvertisements	Shows the total number of VRRP advertisements received by this virtual router. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
AdvIntervalErrors	Shows the total number of VRRP advertisement packets received for which the advertisement interval is different than the one configured for the local virtual router. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
IpTtlErrors	Shows the total number of VRRP packets received by the virtual router with IPv4 TTL (for VRRP over IPv4) or IPv6 Hop Limit (for VRRP over IPv6) not equal to 255. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
RcvdPriZeroPackets	Shows the total number of VRRP packets received by the virtual router with a priority of 0. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
SentPriZeroPackets	Shows the total number of VRRP packets sent by the virtual router with a priority of 0. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.

Name	Description
RcvdInvalidTypePkts	Shows the number of VRRP packets received by the virtual router with an invalid value in the 'type' field. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
AddressListErrors	Shows the total number of packets received for which the address list does not match the locally configured list for the virtual router. Discontinuities in the value of this counter can occur at reinitialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
PacketLengthErrors	Shows the total number of packets received with a packet length less than the length of the VRRP header. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.
RcvdInvalidAuthentications	Shows the total number of packets received with an unknown authentication type.

Graph IPv6 VRRP Statistics

About This Task

Use the following procedure to graph IPv6 VRRPv3 statistics for monitoring the network performance.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **VRRP**.
3. Select the **Stats** tab.
4. Select an interface, and then select **Graph**.
5. Select one or more values.
6. Select a graph type:
 - Line Chart
 - Area Chart
 - Bar Chart
 - Pie Chart

Stats *Field Descriptions*

Use the data in the following table to use the **Stats** tab.

Name	Description
InetAddrType	Shows the type of IP address (IPv4 or IPv6).
ChecksumErrors	Shows the number of VRRP packets received with an invalid VRRP checksum value.
VersionErrors	Shows the number of VRRP packets received with an unknown or unsupported version number.
VrIdErrors	Shows the number of VRRP packets received with an invalid VrID for this virtual router.

Configure Additional Addresses on the VRRP Brouter Port

Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.

About This Task

Perform this procedure to configure the additional addresses for which the virtual router acts as a back up.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Port**.
2. Select **IPv6**.
3. Select the **VRRP** tab.
4. Select **AssociatedIPAddr**.
5. Select **Insert**.
6. Type the address.
7. Type the prefix length.
8. Select **Insert**.

Address List *Field Descriptions*

Use the data in the following table to use the **Address List** tab.

Name	Description
IpAddr	Specifies an IP address that is associated with a virtual router. The number of rows on this tab equals the number of IP addresses associated (backed up) by the virtual router
IpAddrPrefixLength	Specifies the length of the prefix in bits.

Configure Additional Addresses on a VRRP Interface

Perform this procedure to configure the additional addresses for which the virtual router acts as a back up.

Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Do not configure RSMLT on the VLAN.
- To create a secondary virtual IP address on a VLAN:
 - Create primary and secondary IP addresses on the VLAN.
 - Create a VRRP instance on the VLAN.
 - Configure a primary virtual IP.
- Change the VRF instance as required to configure additional addresses on the VRRP interface on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

About This Task

The first virtual IP configured on a VRRP interface is the primary virtual IP. After you create a VRRP interface, you can create secondary virtual IPs. Secondary virtual IP addresses must be in the same subnet as a Secondary IP Interface on the VLAN.

Note

You can also complete this configuration through the **Configuration > IP > VRRP > V3 Interface** navigation path.

Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **VRRP**.
3. Select the **V3 Interface** tab.
4. Select an interface.
5. Select **AssociatedIPAddr**.
6. Select **Insert**.
7. Type the address.
8. Type the prefix length.
9. Select **Insert**.

Address List *Field Descriptions*

Use the data in the following table to use the **Address List** tab.

Name	Description
IpAddr	Specifies an IP address that is associated with a virtual router. The number of rows on this tab equals the number of IP addresses associated (backed up) by the virtual router
IpAddrPrefixLength	Specifies the length of the prefix in bits.

Troubleshooting IPv6 VRRP

The following sections describe troubleshooting information for IPv6 Virtual Router Redundancy Protocol (VRRP).

VRRP Transitions

When a VRRP transition takes place with the backup taking over as the master, look for the following message in the syslog on the new master, as well as the old master. This message provides information to allow you to determine the cause of the transition.

```
IPv6 Vrrp State Transition Trap(Port/Vlan=200, Type=masterToInitialize,
Cause=shutdownReceived, VrId=20,VrIpAddr=fe80:0:0:0:0:0:0:200,
Addr=fe80:0:0:0:224:7fff:fe9d:1a03)
```

In this message, see the Type and Cause fields.

**Note**

Although the possible causes and types are listed in the following table, the system does not display all of the listed causes and types in the trap/log message.

The following table describes the VRRP transition types.

Table 354: Transition type

Type value	Type definition
1	None
2	Master to backup
3	Backup to master
4	Initialize to master
5	Master to initialize
6	Initialize to backup
7	Backup to initialize

Table 354: Transition type (continued)

Type value	Type definition
8	Backup to backup master
9	Backup master to backup

The following table describes the VRRP transition causes.

Table 355: Transition cause

Cause value	Cause definition
1	None
2	Higher priority advertisement received
3	Shutdown received
4	VRRP address and physical address match
5	Master down interval
6	Preemption
7	Critical IP goes down
8	User disabling VRRP
9	VRRP status synced from primary
10	IPv6 interface on which VRRP is configured goes down
11	Lower priority advertisement received
12	Advertisement received from higher interface IP address with equal priority
13	Advertisement received from lower interface IP address with equal priority
14	User enabled VRRP
15	Transition because of any other cause

Enable Trace Messages for IPv6 VRRP Troubleshooting

Use this procedure to enable trace messages for IPv6 VRRP.

When VRRP is enabled on two routing switches, the master-backup relationship forms with one router taking the responsibility of routing. If the master-backup relationship is not formed between the VRRP virtual routers, look for the following trace messages to ensure that the master is sending the advertisements correctly and the backup is processing them.

Procedure

1. Enter Privileged EXEC mode:
`enable`

2. To troubleshoot IPv6 VRRP, you can enable RCIP6 trace messages with the following command:

```
trace level 66 3
```

3. Obtain additional trace information:

```
trace ipv6 nd enable
```

```
trace ipv6 base enable all
```

```
trace ipv6 forwarding enable all
```

```
trace ipv6 rtm enable all
```

```
trace ipv6 transport enable all
```

4. When VRRP is enabled on two routing switches, the master-backup relationship forms with one router taking the responsibility of routing. If the master-backup relationship is not formed between the VRRP virtual routers, look for the following trace messages to ensure that the master is sending the advertisements correctly and the backup is processing them. On the master router, look for the following RCIP6 trace messages.

- tMainTask RCIP6: rcip6_vrrp.c: 5118: VRF name: GlobalRouter (VRF id 0): ipv6VrrpTic: Am Master for Vrid 200 on IfIndex 2053 Timer 1

If VRRP is enabled on the interface, this timer kicks off every second and shows the state for the VRID.

- [11/18/09 15:08:20:383] tMainTask RCIP6: rcip6_vrrp.c: 5924: ipv6VrrpSendAdvertisement: for Vrid 200 on IfIndex 2053

```
[11/18/09 15:08:20:583] tMainTask RCIP6: rcip6_vrrp.c:
5175: VRF name: GlobalRouter (VRF id 0): ipv6VrrpTic:
ipv6VrrpSendAdvertisement
```

The preceding trace messages show that the VRRP master is sending the advertisements correctly at the end of advertisement interval for a VRID.

5. On the backup router, look for the following RCIP6 trace messages.

- tMainTask RCIP6: rcip6_vrrp.c: 5236: VRF name: GlobalRouter (VRF id 0): ipv6VrrpTic: Am Backup for VrId 200 on IfIndex 2052 Timer 1
- tMainTask RCIP6: rcip6_vrrp.c: 4854: ipv6VrrpIn: Vrid 200 on IfIndex 2052
- tMainTask RCIP6: rcip6_vrrp.c: 5545: VRF name: GlobalRouter (VRF id 0): rcIpVrrpProcessAdvt: Am backup for Vrid 200 on IfIndex 2052

The preceding trace messages show that the backup router is receiving the advertisements sent by the master and correctly processing them.

Risks Associated with Enabling Trace Messages

When traces are enabled on VRRP master, VrrpTic messages are logged for every second and any other configured traces keep displaying, so there is no guarantee that the backup will receive the advertisement from the master within 3 seconds, so it can

transit to master also. There is also the risk of toggling of VRRP states (from backup to master and back again).

Enable the limited traces based on whichever is required.

VRRP with Higher Priority Running as Backup

The VRRP router with the higher priority can display as the backup for the following reasons

- Hold-down timer is running.
- The configured Critical IP is not reachable or does not exist.

If the critical-IP is configured for VRRP master, and the critical interface goes down or is deleted, the master transitions to the backup state. In this case, the log shows the transition cause as 1 like many other cases.

If the holddown timer is configured for VRRP master, the holddown timer delays the preemption, giving the device, which is becoming the master enough time to construct routing tables.

Procedure

1. To determine that the issue is with the critical interface, look for the following trace message.

```
tMainTask RCIP6: rcip6_vrrp.c: 5152: VRF name: GlobalRouter (VRF id 0): ipv6VrrpTic: Becoming backup for Vrid 200 on IfIndex 2052 because of invalid critical IP
```

2. If the holddown Timer is configured for VRRP master, the holddown timer delays the preemption, giving the device, which is becoming the master enough time to construct routing tables.

```
tMainTask RCIP6: rcip6_vrrp.c: Enter in HoldDown processing,Vrid 200 LastRecvd 0 MasterDown 3, Holddown time remaining 970, Holddownstate 2
```

VXLAN Gateway

VXLAN Gateway Fundamentals

VXLAN Gateway terminates virtual extensible LAN (VXLAN) tunnels that stretch emulated Layer 2 segments over an IP network.

VXLAN is an encapsulation protocol for running an overlay network over an existing Layer 3 infrastructure. This tunneling scheme uses a VLAN-like encapsulation mechanism to encapsulate MAC-based traffic. The VXLAN overlays separate workloads from physical networks, which facilitates the movement of VMs in a multi-tenant environment.

For more information about VXLAN, see the Internet Engineering Task Force (IETF) standard RFC 7348.

VXLAN Gateway as a VTEP

The VXLAN Gateway feature terminates VXLAN tunnels and operates as a VXLAN tunnel endpoint (VTEP). The VXLAN Gateway is a hardware-based VTEP that allows a VXLAN to communicate with VLANs, other VXLANs, as well as Fabric Connect I-SIDs.

The following figure shows a VXLAN Gateway (labeled as VTEP Source) connecting VXLAN segments to an SPB network. This type of deployment provides a solution for VXLAN in data centers to interoperate with Fabric Connect networks (labeled as SPB).

VXLAN Segments

VXLAN tunnels are also called VXLAN segments. VXLAN segments provide the ability to separate, abstract, and decouple the physical topology from a logical or virtual topology by using encapsulated tunneling. VXLAN segments allows only VMs within the same VXLAN tunnel to communicate with each other.

VNID

Each VXLAN segment has a 24-bit segment ID called a VXLAN Network Identifier (VNID). VNID allows up to 16 million VXLAN segments to coexist within the same administrative domain, which enables VMs to migrate between servers in the same data center or between distributed data centers. Each VTEP can support multiple VNIDs. For information about maximum scaling numbers, see *Fabric Engine Release Notes*.

The VNID uses the inner MAC frame originated by the individual VM. Overlapping MAC addresses can cross VXLAN segments, but never have traffic crossover because the traffic is isolated using the VNID qualifier. Due to this encapsulation, only the VTEP knows the VNID and its associated VXLAN tunnel. VMs are unaware of the VXLAN.

VM Traffic

Only VMs within the same VXLAN segment can communicate with each other. The following steps show how a VM communicates with a VM on a different host within the same VXLAN segment:

1. The VM sends a MAC frame destined to the target.
2. The VTEP looks up the VNID that the VM is associated with to verify that the destination MAC is on the same segment. If the destination MAC is on the same segment, the process continues.
3. The VTEP inserts an outer header comprising an outer MAC, outer IP address, and VXLAN header in front of the original MAC frame.
4. The VTEP transmits the final packet out to the destination IP address of the remote VTEP, connecting the destination VM addressed by the inner MAC destination address.
5. The remote VTEP verifies that the VNID is valid for the destination VM.
6. If the VNID is valid, the remote VTEP strips the packet outer header and passes the packet to the destination VM. The destination VM never knows about the VNID, or that the frame transmitted with VXLAN encapsulation.

VXLAN Gateway Management Methods

Two methods are available to manage VXLAN Gateway:

- Static management using CLI and local configuration files.
- Dynamic management using OVSDb protocol support for VXLAN Gateway.

For static management, you use CLI or local configuration files to configure and manage the VXLAN Gateway hardware-based VTEP functions. You must manually configure the Source-VTEP, VNID, VNID to I-SID bindings, Remote-VTEP, and VNI to Remote-VTEP associations, and MAC learning on the VNID only occurs at the data-plane level.

For dynamic management, you use OVSDb protocol support for VXLAN Gateway to configure and manage the VXLAN Gateway hardware-based VTEP functions with Open vSwitch Database Management Protocol (OVSDb). You must configure at least one physical Network Virtualization Controller (NVC) running VMware NSX with OVSDb features. You can add a Hardware VTEP, add a logical switch, configure VNID to VTEP bindings, and configure a replication cluster in NSX. The VXLAN Gateway must have OVSDb enabled and the Network Virtualization Controller (NVC) must communicate on the OVSDb managed interface. You must manually configure the Source-VTEP and NVC IP addresses, and the VNID to I-SID binding in NSX. The NVC can manage the VNID, Remote-VTEP, and VNI to Remote-VTEP associations. The NVC distributes the hosts MAC and IP addresses learned by the VTEP over the VXLAN.

The following table shows the functional differences between the two VXLAN Gateway management methods.

Table 357: VXLAN Gateway Management Methods

Function	Static management	Dynamic management
VNID provisioning	Manually from CLI or EDM	Automatically from NVC
VNID to I-SID binding	Manually from CLI or EDM	Automatically from NVC
Remote-VTEP	Manually from CLI or EDM	MAC learning from NVC
VNID to VTEP association for replicating BUM traffic	Manually from CLI or EDM	MAC learning from NVC
MAC learning at data-plane	Not distributed to other VXLAN Gateways	Distributed from NVC to other VXLAN Gateways
ARP suppression	Not supported	Not supported

VXLAN Modes

The VXLAN Gateway implementation is available in two modes: Base Interworking Mode and Full Interworking Mode. By default, the Base Interworking Mode is enabled and Full Interworking Mode is disabled. You change modes through the **vxlan-gw-full-interworking-mode** boot flag.

Important

Changing the mode requires a reboot for the change to take effect, which can cause a loss of traffic.

Base Interworking Mode

Base Interworking Mode is the default mode. In this mode, VXLAN Gateway supports Layer 2 gateway communication at line rate between VXLAN and traditional VLAN environments.

Base Interworking Mode has the following limitations:

- No support for VXLAN-to-VXLAN communication.
- No support for VXLAN-to-SPB communication.
- No support for SMLT, vIST, or Simplified vIST.
- No support for OVSDB protocol support for VXLAN Gateway.

Each VNID represents a service instance for the VXLAN Gateway. To enable a VNID to extend into the SPB network, you must use Full Interworking Mode.

Note

If your configuration does not have a VXLAN Gateway but has SMLT or vIST, you can enable VXLAN Gateway in the Full Interworking Mode only. SMLT and vIST are incompatible and mutually exclusive with the Base Interworking Mode.

Full Interworking Mode

Full Interworking Mode is not the default mode. To configure Full Interworking Mode, you must enable the **vxlan-gw-full-interworking-mode** boot flag, save the configuration, and then reboot the switch.

Full Interworking Mode supports the Base Interworking Mode communication between VXLAN and traditional VLAN environments as well as VXLAN-to-VXLAN communication and all SPB functionality including vIST and SMLT. Layer 2 and Layer 3 services extend across VXLAN, VLAN, and SPB domains using an internal loopback. In Full Interworking Mode, VXLAN traffic flows at less than full line rate and the total amount of available internal loopback bandwidth depends on the platform used.

Full Interworking Mode has the following limitations:

- No support for Simplified vIST.
- A VNID cannot have the same value as an I-SID. A consistency check ensures that this does not happen if you change the boot configuration flag to turn off Full Interworking Mode and go into Base Interworking Mode.

Types of VXLAN Gateway Deployments

VXLAN Gateway provides the following deployment solutions:

- [VXLAN-to-VLAN Layer 2 gateway deployment](#)
- [VXLAN-to-VXLAN Layer 3 gateway deployment](#)
- [VXLAN-to-SPB gateway deployment](#)

These gateways provide VXLAN tunnel termination functions for switches that could be Top of Rack (ToR) switches, access switches, or switches higher up in the data center network topology such as a core switch or even WAN edge devices. The last case (WAN edge) could involve a Provider Edge (PE) router that terminates VXLAN tunnels in a hybrid cloud environment.

VXLAN-to-VLAN Layer 2 Gateway Deployment

The VXLAN-to-VLAN deployment is where the VXLAN Gateway communicates between VXLAN segments and VLAN segments. Use this scenario when nodes on a VXLAN overlay network need to communicate with nodes on legacy networks that are VLAN based as shown in the following figure.

Figure 257: VXLAN-to-VLAN deployment

In this type of deployment, the VXLAN Gateway maps the VXLAN VNID to a VLAN in the following way:

- When packets traverse a VXLAN segment into the VLAN segment, the VXLAN VTEP removes the VXLAN header and forwards regular VLAN packets to a physical port based on the destination MAC address of the inner Ethernet frame.

The VTEP discards decapsulated frames with the inner VLAN ID unless you explicitly configure them to be passed on to the non-VXLAN interface. The VXLAN VNID to VLAN mapping is statically configured.

- In the reverse direction when packets traverse a VLAN segment into a VXLAN segment, the VXLAN VTEP maps the incoming frames from the non-VXLAN interfaces to a specific VXLAN overlay network based on the VLAN ID in the frame. This complies with the standard VXLAN RFC.

The VTEP also accepts both untagged and tagged inner frames and adds or replaces the tag of the inner frame with the local VLAN mapped to the VNID before sending out the frame.

The VTEP removes the VLAN ID of the original frame before it encapsulates the frame for VXLAN.

VXLAN-to-VXLAN Layer 3 Gateway Deployment

The VXLAN-to-VXLAN deployment is where the VXLAN Gateway communicates between VXLAN segments. Use this scenario when one VXLAN segment needs to communicate with another VXLAN segment.

When a packet traverses a VXLAN segment and enters the VXLAN Gateway, the VXLAN VTEP maps one VXLAN segment to another in the following way:

- Decapsulates the VXLAN header.
- Performs a route lookup of the customer packet.
- Identifies that the next hop VLAN is in another VXLAN segment.

- Encapsulates the packet with a new VXLAN header with a new VNID.
- Forwards the packet out.

The following figure shows two virtualized servers attached to a Layer 3 infrastructure. The servers could be on the same rack, on different racks, or across data centers within the same administrative domain.

There are four VXLAN overlay networks identified by the VNIDs: 22, 34, 74, and 98. Notice how the VMs are associated with a VNID. For example, VM1-1 in Server 1 and VM2-4 on Server 2 are on the same VXLAN overlay network identified by VNID 22.

The VMs do not know about the overlay networks and transport method because the encapsulation and decapsulation happen transparently at the VTEPs on Servers 1 and 2. The other overlay networks and the corresponding VMs are: VM1-2 on Server 1 and VM2-1 on Server 2 both on VNID 34, VM1-3 on Server 1 and VM2-2 on Server 2 on VNID 74, and finally VM1-4 on Server 1 and VM2-3 on Server 2 on VNID 98.

Figure 258: VXLAN-to-VXLAN deployment

VXLAN-to-SPB Gateway Deployment

The VXLAN-to-SPB deployment is where the VXLAN Gateway communicates between a VXLAN segment and an SPB domain. This type of deployment provides a solution for customers using VXLAN in their data-centers to interoperate with Fabric Connect as shown in the following figure.

Figure 259: VXLAN-to-SPB deployment

The VXLAN Gateway maps the VXLAN VNID to I-SID in the following way:

- When packets traverse a VXLAN segment into an SPB domain, the VXLAN VTEP decapsulates the VXLAN packet, encapsulates it with MAC-in-MAC encapsulation, and then forwards it into the SPB domain.
- In the reverse direction, the VXLAN VTEP decapsulates the MAC-in-MAC packet from an SPB domain, encapsulates it with a VXLAN header, and then forwards it into a VXLAN segment.

VXLAN Gateway Considerations and Limitations

Review the following considerations, limitations, and behavioral characteristics associated with VXLAN Gateway.

Unsupported Features

VXLAN Gateway does not support the following features:

- IP Multicast over Layer 3 VSN Fabric Connect traffic cannot be carried over into a VXLAN domain through a VXLAN Gateway. Layer 3 VSN Fabric Connect requires MAC-in-MAC encapsulation over VXLAN encapsulation, and the VXLAN Gateway data plane does not support double-encapsulation. However, IP Multicast over IP Shortcuts Fabric Connect can be carried over into a VXLAN domain through a VXLAN Gateway.
- SPB-PIM Gateway and VXLAN Gateway interoperability is not supported.
- VXLAN Gateway does not support Simplified vIST in any mode.

QoS and VXLAN Gateway

- If present in the packet, VXLAN Gateway honors user-configured ingress dot1p and DSCP mappings to derive the internal CoS.
- Customer packets are not remarked.
- Control packets are handled by high priority CoS queues.
- DSCP bits in the outer IP header of VXLAN-encapsulated packets are always derived from the internal QoS, irrespective of the ingress port DiffServ configuration.

Customer packet IP DSCP bits are not modified as part of VXLAN encapsulation. For more information about QoS, see [Quality of Service](#) on page 2983.

- DSCP bits in the inner IP header of VXLAN-encapsulated packets change when traffic comes in on a Layer 2 Trusted or a Layer 3 Untrusted port with DiffServ enabled.

ECMP Support for VXLAN Gateway and Fabric Extend

VXLAN Gateway requires ECMP support to communicate with remote VTEPs. The software extended this ECMP support to Fabric Extend Layer 3 core tunnels. Therefore, if your switch supports VXLAN Gateway, it also supports ECMP for both VXLAN Gateway and Fabric Extend.

Base Interworking Mode Considerations and Limitations

- After associating a VNID with an I-SID (**vnid <vnid value> i-sid <isid value>**), you cannot create an I-SID with the same value as the **<vnid value>** and vice versa.
- There is no support for SMLT, vIST, or Simplified vIST in Base Interworking Mode.
- Neither Base Interworking Mode nor Full Interworking Mode support Fabric Attach endpoints.
- Base Interworking Mode does not permit SMLT and vIST configurations. If you change from Full Interworking Mode to Base Interworking Mode, make sure there are none of these configurations.
- In Base Interworking Mode, the **untagged-traffic <port> << mlt>** support is limited to untagged traffic forwarding only. No control packet forwarding is supported on this port or MLT.

LACP MLT is not supported as part of **untagged-traffic <mlt>**.

Full Interworking Mode Considerations and Limitations

- Whenever you change from Base Interworking Mode to Full Interworking Mode, you have to reboot the switch. The software automatically changes the configuration to be in line with Full Interworking Mode.
- Full Interworking Mode does not have VXLAN endpoints. Configure ELAN endpoints under the ELAN I-SID only.
- Neither Base Interworking Mode nor Full Interworking Mode support Fabric Attach endpoints.

General Configuration Guidelines

- In VXLAN environments that have an underlying IP network with SMLT deployment, you must enable RSMLT in the underlying network on vIST VTEP devices.
- If you use more than one VXLAN Gateway node for the same I-SID, you must ensure that loops are prevented.
- The VTEP remote destination IP table in the datapath hardware is shared with the Fabric Extend IP core remote tunnel destination IP table.
 - The maximum number of FE tunnel destination IP addresses is 256.
 - The maximum number of VTEP IP addresses is 500.

For every FE tunnel destination IP you configure, you must reduce the number of VTEP IPs by one. For example, if you configure the maximum number of FE tunnel destination IPs then the maximum of VTEP remote destination that you can configure is $500-256=244$.

- The total number of MACs that the VTEP learns in the switch is constant and includes the MACs learned on VNID, I-SID, and on VLANs (normal and CVLANs).
 - MAC addresses that the VTEP learns from the VNID table are also learned when an I-SID is associated with the VNID. Therefore, the maximum number of MAC addresses that the VTEP can support is reduced accordingly.
 - If a VLAN is associated with an I-SID, and that I-SID is associated with a VNID, then the VTEP learns each customer MAC address from three different tables (VLAN, I-SID, and VNID). This consumes three MAC entry records. In a vIST scenario where all I-SIDs have associated VNIDs, then the max number of CMACs that the VTEP learns is reduced by $224K$ divided by $3 = 74K$ MAC addresses.
 - If a Switched-UNI endpoint is associated with an I-SID, then the VTEP learns the CMAC only once in the I-SID table. If this I-SID is associated with a VNID, then the VTEP learns the CMAC twice: once in the I-SID table and once in the VXLAN VNID table.
- IP filter rules that you create do not work for VXLAN tunnel terminated packets. This restriction also applies to the Fabric Extend Layer 3 core.
- All ports in an MLT configured as a Switched-UNI endpoint or a VXLAN endpoint have the same properties as configured under the MLT interface.
- A VXLAN tunnel VTEP source IP cannot be a broadcast or multicast IP address. Configure it as a loopback IP address and not a router IP address.
- The VXLAN source address (**vtep-source-ip**) should be different from the SPBM IP Shortcut (**ip-source-address**) and Fabric Extend (**ip-tunnel-source-address**) source addresses.
- If you configure the loopback IP address under a VRF, the **vtep-source-ip** address must be set up under the same VRF.
- The remote VTEP IP address (**vtep <id> ip <ip address>**) cannot be local to the system.
- You can configure a maximum of 500 remote VTEPs per VNID.
- You can change the VTEP source IP and remote VTEP IP dynamically.
- VTEPs have to be reachable for the tunnel to be up.
- The tunnel ID for a VTEP has to be the same on both vIST peers.
- If the VTEP source IP is configured under a VRF, then the VRF cannot have an I-SID associated with it or vice versa.
- Two VNIDs cannot be mapped to the same I-SID.
- An I-SID associated with a VNID cannot be a T-UNI or E-Tree I-SID.
- To prevent routing loops, the platform VLANs used for VXLAN interworking should NOT be in the same VRF or GRT as the IP interfaces in the underlay network.
- You cannot delete a VTEP source IP address (**vtep-source-ip**) when VTEPs are configured.

- If an ELAN I-SID attached to a VNID has a platform VLAN associated with it, then you cannot delete the platform VLAN or change the I-SID associated with that VLAN.
- You cannot delete the loopback IP associated with a VTEP source IP.
- If the VTEP source IP is configured under a VRF, then you cannot delete the VRF.
- You cannot delete or modify the VLAN with I-SID that is associated with a VNID.
- If an ELAN I-SID attached to a VNID also has a platform VLAN associated with it, then you cannot delete the platform VLAN or change the I-SID associated with that VLAN.
- VXLAN Gateway cannot coexist with virtual NNI links on boundary nodes. You cannot enable VXLAN Gateway on a loopback interface for a virtual NNI link and you cannot create a loopback interface for a virtual NNI link when VXLAN Gateway is enabled.

OVSDB protocol support for VXLAN Gateway Considerations and Limitations

Review the following considerations, limitations, and behavioral characteristics associated with OVSDB protocol support for VXLAN Gateway.

Network Virtualization Controllers Dependencies and Restrictions

OVSDB protocol support for VXLAN Gateway requires at least one Network Virtualization Controller (NVC) that runs OVSDB:

- OVS is an open source implementation of a virtual switch and OVSDB is a standard defined in RFC 7047.
- You require at least one NVC. The NVC is an ESXi host server that runs the VMware NSX Network Virtualization and Security Platform (minimum version 6.2.4).

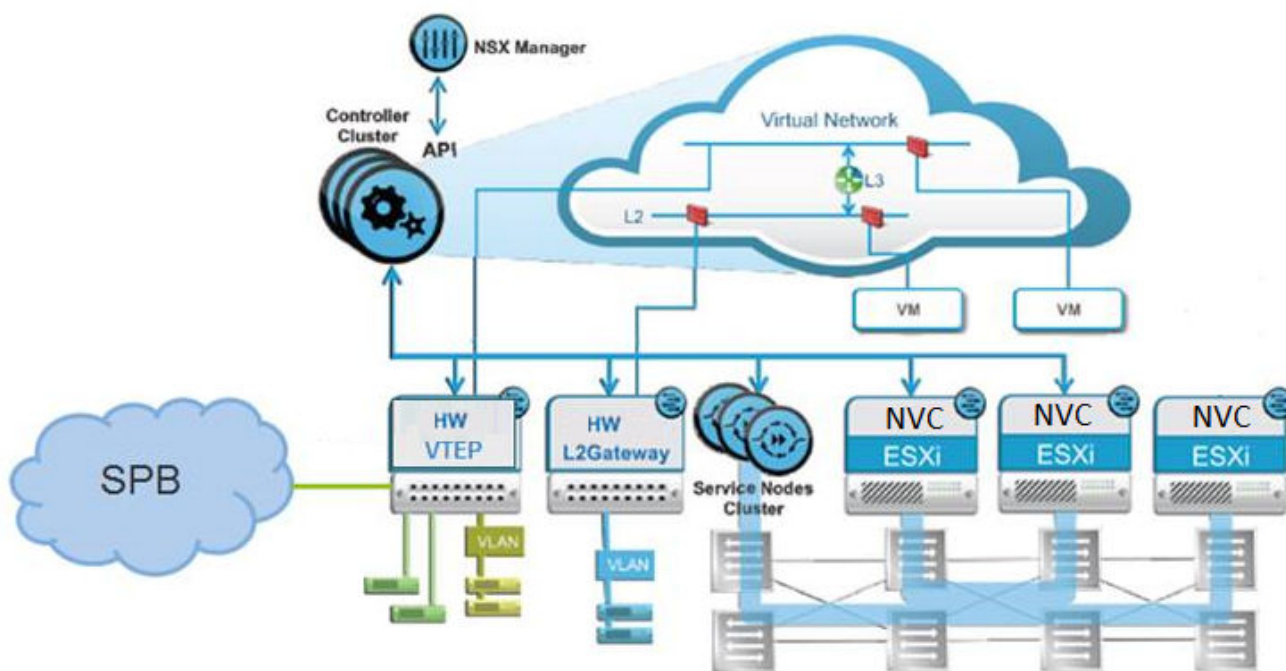

Note

VMware NSX 6.2.4 has known issues that can cause VXLAN discovery delays and NVC connectivity issues in certain scenarios, for more information see *Fabric Engine Release Notes*.

- You must configure VMware NSX. You can add a Hardware VTEP, add a logical switch, configure VNID to VTEP bindings, and configure a replication cluster in NSX.
- The NSX logical switch on the NVC is assigned a VNID. The VXLAN Gateway is assigned an OVSDB managed interface I-SID. You must configure the VNID to I-SID binding in NSX.
- SSL is the default protocol for NVC to VXLAN Gateway communications.
- You can configure more than one NVC in a controller cluster for high availability and load-balancing.
- The NVC performs MAC learning on the VXLAN tunnel.
- ARP suppression is not supported.
- One NVC manages all encapsulated Broadcast, Unknown Unicast, and Multicast (BUM) traffic. This NVC replicates the BUM traffic to all other VTEPs in the network. If connectivity to the NVC managing BUM traffic fails, a loss of BUM traffic can occur. NVC cluster NSX service node replication is not applicable for BUM traffic.

The following diagram shows an example of NVCs managing a distributed virtual network.

OVSDB protocol support for VXLAN Gateway Dependencies and Restrictions

- The VXLAN Gateway must operate in Full Interworking mode.
- You must configure at least one NVC connection to the VXLAN Gateway.
- You can configure up to three NVCs connections to one VXLAN Gateway in this release.
- The VXLAN Gateway must use the Segmented Management Instance IP address to connect with the NVCs. For more information about how to configure Segmented Management Instance, see [Segmented Management](#) on page 106.
- You cannot change or delete the VTEP source IP address when OVSDB is enabled.
- The OVSDB managed interface I-SIDs are communicated to the NVC as physical ports of the switch.
- EDM support for OVSDB is limited in this release. You can use CLI where EDM configuration is unavailable.
- The VXLAN Gateway general considerations and limitations also apply to OVSDB protocol support for VXLAN Gateway.

Note

NVC connectivity issues for SSL communication failures are not logged on the switch. You can use the logs on the NVC to troubleshoot SSL communications with the VXLAN Gateway.

OVS Modules on VXLAN Gateway

OVSDB protocol support for VXLAN Gateway uses OVS modules on the VXLAN Gateway. The switch runs the following OVS modules:

- OVSDB server — Manages the database.
- Database — Manages the OVS schema and HW VTEP schema and JSON content.

OVSDB Replication Considerations and Limitations

Note

OVSDB replication is different than NSX service node replication. Service node replication is configured and supported in NSX. OVSDB replication uses vIST and is configured and supported on the VXLAN Gateway.

- You require at least two NVCs to enable OVSDB replication.
- OVSDB replication operates in an ACTIVE-STANDBY server configuration.
- You must disable OVSDB on the standby vIST device before disabling OVSDB on the active vIST device.
- One active NVC and one standby NVC are supported by the VXLAN Gateway.
- VNID to I-SID binding, Remote VTEPs, VNI to Remote VTEPs for BUM, Remote MACs, and Local MACs are replicated across NVCs.

VXLAN Gateway configuration using the CLI

This section provides procedures to configure VXLAN Gateway using the CLI.

Enable VXLAN Gateway in Full Interworking Mode

Enables VXLAN Gateway in Full Interworking Mode, which supports SPB, SMLT, and vIST.

About This Task

Important

After you change this boot flag, you must save the change to the configuration file and reboot the switch.

By default, the Base Interworking Mode is enabled and Full Interworking Mode is disabled. You change modes by enabling this boot configuration flag.

The **no** operator results in the default Base Interworking Mode. In this mode, VXLAN Gateway supports Layer 2 gateway communication between VXLAN and traditional VLAN environments.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`

2. Enable Full Interworking Mode:
`boot config flags vxlan-gw-full-interworking-mode`
3. Save the changed configuration.
`save config`
4. Restart the switch.
`reset`
5. Verify that VXLAN Gateway is in Full Interworking Mode:
`show boot config flags`

The **true** parameter in the output indicates that Full Interworking Mode is enabled.

Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags vxlan-gw-full-interworking-mode
```

Configure VXLAN Gateway

Use the following procedure to configure VXLAN Gateway parameters to enable SPBM to operate on the switch.

Before You Begin

Use the **show boot config flags** to verify that you are in the mode you want. The **vxlan-gw-full-interworking-mode** should be set to **false** for the Base Interworking Mode (default) and **true** for the Full Interworking Mode.

Procedure

1. Enter Global Configuration mode:
`enable`
`configure terminal`
2. Configure the VTEP source IP address:
`vtep source-ip <A.B.C.D> [vrf WORD<1-16>]`
3. Configure the remote VTEP IP address:
`vtep <1-500> ip <A.B.C.D> [name WORD<1-64>]`
4. Create a VNID instance:
`vnid <1-16777215> i-sid <1-16777215>`

Note

The command prompt changes to **#vxlan** to indicate that you are now in VXLAN Configuration mode for the VNID specified in `vnid <1-16777215>`.

5. Associate VLANs in a port or MLT list to this VNID instance:

```
c-vid <1-4094> port <{slot/port[/sub-port]}[-slot/port[/sub-port]]
[,...][slot/all][all]]>
```

or

```
c-vid <1-4094> mlt <1-4094>
```

6. Specify the ports or MLT in this VNID instance that will support untagged traffic:

```
untagged-traffic port <{slot/port[/sub-port]]>
```

or

```
untagged-traffic mlt <1-4094>
```

7. Associate VTEPs to this VNID instance:

```
vtep <1-255>
```

Example

For an example of this procedure, see [VXLAN Gateway configuration example in Base Interworking mode](#) or [VXLAN Gateway configuration example in Full Interworking mode](#).

Variable Definitions

Use the data in the following table to use the **vtep** command.

Variable	Value
<i>source-ip</i> <A.B.C.D> [<i>vrf</i> <i>WORD</i> <1-16>]	Specifies the VXLAN tunnel end point (VTEP) source IP address, which can be on the GRT or a VRF. Note: The VTEP source IP address must be on a loopback interface.
<1-500> <i>ip</i> <A.B.C.D> [<i>name</i> <i>WORD</i> <1-64>]	Specifies an index value and an IP address that uniquely identifies this remote VTEP. Optionally, you can assign a specific name to this tunnel. By default, the switch assigns a name in this format: VTEP-<#ID>-<IP address> Note: The remote VTEP IP address cannot be a local, broadcast, or multicast IP address.

Use the data in the following table to use the **vnid** command.

Variable	Value
<code><1-16777215> i-sid <1-16777215></code>	Uses this VNID and I-SID information to create a VNID instance and enter VXLAN Configuration Mode in the CLI. Note: A VNID must not have the same value as an I-SID.

Use the data in the following table to configure commands in the VXLAN Configuration Mode (`#vxlan`). These commands apply to the VNID instance that you specified in the `vnid <1-16777215> i-sid <1-16777215>` command.

Variable	Value
<code>c-vid <1-4094> port <{slot/port[/sub- port] [-slot/port[/ sub-port]] [,...] [slot/all] [all]}></code>	Specifies a value that uniquely identifies the customer VLAN ID and ports of this ELAN end point. The switch reserves the following VLAN IDs: <ul style="list-style-type: none"> • VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. • VLAN IDs 4060 to 4094 are reserved for internal use. • VLAN IDs 3500 to 3999 are reserved if you enable VRF scaling and SPBM mode. • VLAN ID 4095 is not used. • VLAN ID 4096 is reserved for untagged traffic.
<code>c-vid <1-4094> mlt <1-4094></code>	Specifies a value that uniquely identifies the customer VLAN ID and MLTs of this ELAN end point. The switch reserves the following VLAN IDs: <ul style="list-style-type: none"> • VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. • VLAN IDs 4060 to 4094 are reserved for internal use. • VLAN IDs 3500 to 3999 are reserved if you enable VRF scaling and SPBM mode. • VLAN ID 4095 is not used. • VLAN ID 4096 is reserved for untagged traffic.
<code>untagged-traffic port <{slot/port[/sub- port] [-slot/port[/ sub-port]] [,...] [slot/all] [all]}></code>	Specifies the ports that support untagged traffic.
<code>untagged-traffic mlt <1-4094></code>	Specifies the MLTs that support untagged traffic.
<code>vtep <1-255></code>	Lists the remote VTEP destinations to associate with the specified VNID.

Flush the MAC Forwarding Table

Use this procedure to flush all the learned MAC addresses from the forwarding database of the selected VNID.

Procedure

1. Enter Global Configuration mode:
`enable`

`configure terminal`
2. Flush the MAC FDB:
`vnid mac-address-entry <1-16777215> flush`

Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# vnid mac-address-entry 100 flush
```

VXLAN Gateway show commands

Use the procedures in this section to display specific information about VXLAN Gateway on the switch.

Display VTEP Source Information

Use the following procedure to display information about the VTEP source.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Display the VTEP's source IP address and the name of the VRF:
`show vtep local`

Example

```
Switch:1# show vtep local
=====
                        VTEP General Info
=====
vtep source-ip-address: 198.51.100.1
vtep vrf : GlobalRouter
```

Display Remote VTEP Information

Use the following procedure to display information about the remote VTEP.

Procedure

1. Enter Privileged EXEC mode:
`enable`
2. Display information about all of the remote VTEPs or use the option to specify a particular VTEP:
`show vtep remote [<1-500>]`

Example

```
Switch:1# show vtep remote
=====
Remote VTEP Info
=====
ID      NAME      VTEP      L3_VTEP_NEXT_HOP_INFO
  DEST-IP  PORT/MLT  VLAN      VRF
-----
1       vtep-1      198.51.100.6  Mlt78      3851      GlobalRouter
56      vtep-56     198.51.100.22 Mlt130     3855      underlay-vxlan

-----
2 out of 2 Total Num of remote vteps
-----
```

Display the Name of the Remote VTEP

Use the following procedure to display the name of the remote VTEP.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display the names of all remote VTEPs or use the option to specify a particular VTEP:
show vtep remote name [<vtepId>]

Example

```
Switch:1# show vtep remote name
=====
Remote VTEP Name
=====
ID      NAME
-----
1       vxlan_tunnel_1
2       --
3       --

-----
3 out of 3 Total Num of remote vteps
-----
```

Display VNID Information

Use the following procedure to display information about the VNID.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display information about all the VNIDs or use the option to specify a particular VNID:
show vnid i-sid [<1-500>]

Example

```
Switch:1# show vnid i-sid
=====
vnid Info
=====
```

VNID ID	ISID ID	PORT INTERFACES	MLT INTERFACES	VTEP IDS
110	120	c3:1/10	-	2,56
11000060	1060	c60:1/10	-	56
11000065	1065	c65:1/10	-	56
11000066	1066	c66:1/48	-	2
.				
.				
.				

Display the MAC Addresses in the VNID FDB

Use the following procedure to display the MAC addresses in the VNID forwarding database.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display all the VNIDs in the FDB table or use one of the options to specify a particular VNID:
show vnid mac-address-entry [<1-16777215> | port <{slot/
port[/sub-port]}[-slot/port[/sub-port]][,...][slot/all][all]]> | mac
<0x00:0x00:0x00:0x00:0x00:0x00> | remote]

Example

```
Switch:1# show vnid mac-address-entry
```

VNID Fdb Table				
VNID	STATUS	MAC-ADDRESS	INTERFACE	TYPE
11000065	learned	00:00:5e:00:01:01	vtep_56	REMOTE
14000100	learned	a4:25:1b:51:a5:04	vtep_67	REMOTE
14000100	learned	a4:25:1b:52:a5:04	vtep_67	REMOTE
14000100	learned	a4:25:1b:52:bd:03	vtep_2	REMOTE

```
c: customer vid    u: untagged-traffic

All 4 out of 4 Total Num of vnid FDB Entries displayed
```

Display the VXLAN Running Configuration

Use the following procedure to display the currently running VXLAN configuration.

Procedure

1. Enter Privileged EXEC mode:
enable
2. Display the running configuration:
show running-config module vxlan

Example

This example shows the VXLAN information only; it does not show the hardware-specific information that the system also displays in the output for this command.

The example shows the VXLAN Gateway in Base Interworking Mode. It also shows an external loopback (see **c-vid** commands), which enables communication between the VNID and an I-SID in an SPB network.

```
Switch:1# show running-config module vxlan

#
# VTEP CONFIGURATION
#
vtep source-ip 1.1.1.1 vrf underlay-vxlan

#
# REMOTE VTEP CONFIGURATIONS
#
vtep 2 ip 1.1.1.1 name "vtep-2"
vtep 67 ip 1.1.1.67 name "vtep-67"

#
# VNID CONFIGURATION
#
vnid 12002105 i-sid 102105
c-vid 105 port 1/11
c-vid 2105 port 1/10
vtep 67
exit
```

OVSDB protocol support for VXLAN Gateway Configuration Using CLI

This section provides procedures to configure OVSDB protocol support for VXLAN Gateway using the Command Line Interface (CLI).

Configure OVSDB Managed Interfaces

Use the following procedure to configure OVSDB managed interfaces on the switch.

Before You Begin

- You must enable VXLAN Gateway Full Interworking Mode. For more information, see [Enable VXLAN Gateway in Full Interworking Mode](#) on page 4183.
- You must create the required Flex UNI or CVLAN I-SIDs before you configure the OVSDB managed interface.

Procedure

1. Enter OVSDB Configuration mode:
enable

configure terminal

ovsdb
2. Configure the OVSDB managed interface:
managed-interface i-sids WORD<1-1024>

Example

The following is an example configuring two I-SIDs as OVSDB management interfaces.

```
SWITCH:1>enable
SWITCH:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
SWITCH:1(config)#ovsdb
SWITCH:1(config-ovsdb)#managed-interface i-sids 300
SWITCH:1(config-ovsdb)#managed-interface i-sids 500
```

What to Do Next

Configure the OVSDB protocol support for VXLAN Gateway, see [Configure OVSDB protocol support for VXLAN Gateway](#) on page 4191.

Variable Definitions

Use the data in the following table to use the **managed-interface** command.

Variable	Value
<i>i-sids</i> WORD<1-1024>	Specifies the I-SID information to create an interface to manage OVSDB protocol support for VXLAN Gateway. Note: You must create the required Flex UNI or CVLAN I-SIDs before you configure the managed interface I-SID.

Configure OVSDB protocol support for VXLAN Gateway

Use the following procedure to configure OVSDB protocol support for VXLAN Gateway on the switch.

Before You Begin

- You must enable VXLAN Gateway Full Interworking Mode. You can use **show boot config flags** to verify the current VXLAN Gateway mode. For more information, see [Enable VXLAN Gateway in Full Interworking Mode](#) on page 4183.
- You must configure and use the Segmented Management Instance IP address on the VXLAN Gateway to establish connectivity with the NVC. For more information about Segmented Management Instance, see [Segmented Management Instance Configuration using the CLI](#) on page 123.
- You must configure an OVSDB management interface. For more information, see [Configure OVSDB Managed Interfaces](#) on page 4190.
- You must transfer an OVSDB certificate file and private-key file to the flash storage of the switch. You can use an ovs-pki utility with SSL libraries to generate the private keys and certificates. You can use **boot config flags FTPD** and then an SCP utility to transfer the private key and certificate file to the flash storage of the switch.
- If the switch is an aggregation switch, the IST peer must support OVSDB, have the same source VTEP-IP and OVSDB managed-interface, and must communicate with the NVC management IP.

Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```
2. Configure the source VTEP IP address:

```
vtep source-ip <A.B.C.D> [vrf WORD<1-16>]
```
3. Enter OVSDDB Configuration mode:

```
ovsdb
```
4. Install the OVSDDB certificate file:

```
install-cert-file WORD<1-128>
```
5. Install the OVSDDB private key:

```
private-key WORD<1-128>
```
6. Enable OVSDDB protocol support for VXLAN Gateway:

```
enable
```
7. Configure the NVC:

```
controller <1-100> ip address <A.B.C.D> protocol <ssl|tcp> [port <1-65535>]
```

Example

The following is an example of configuring a VTEP source IP, installing an OVSDDB certificate file, installing an OVSDDB private key, enabling OVSDDB protocol support for VXLAN Gateway, and configuring the IP address, protocol, and port for one NVC.

```
SWITCH:1>enable
SWITCH:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
SWITCH:1(config)#vtep source-ip 192.0.2.1 vrf vxlan-underlay
SWITCH:1(config)#ovsdb
SWITCH:1(config-ovsdb)#install-cert-file /intflash/tom/sc-cert.pem
SWITCH:1(config-ovsdb)#private-key /intflash/tom/sc-privkey.pem
SWITCH:1(config-ovsdb)#enable
SWITCH:1(config-ovsdb)#controller 1 ip address 192.0.2.2 protocol ssl port 6640
```

Note

You can configure multiple controllers for high availability. One VXLAN Gateway can support a maximum of three controllers.

Important

If you add or delete a controller, or modify the OVSDDB managed interface when a controller is configured, the existing controller connections reset. Log messages generate to indicate the status changes as the controllers disconnect and reconnect.

If you change a previously configured VTEP source-ip and re-enable OVSDDB, the controller sees a new VXLAN tunnel instead of updating the existing VXLAN. You must configure the VNID to I-SID binding on the controller for the new VXLAN tunnel associated with the new VTEP IP address.

Variable Definitions

Use the data in the following table to use the **vtep source-ip** command.

Variable	Value
<code><A.B.C.D> [vrf WORD<1-16>]</code>	Specifies the VXLAN tunnel end point (VTEP) source IP address in IPv4 format. Optionally you can specify a VRF. Note: The VTEP source IP address must be on a loopback interface.

Use the data in the following table to use the **install-cert-file** command.

Variable	Value
<code>WORD<1-128></code>	Specifies the path and file name of the OVSDB certificate file.

Use the data in the following table to use the **private-key** command.

Variable	Value
<code>WORD<1-128></code>	Specifies the path and file name of the OVSDB private key.

Use the data in the following table to use the **controller** command.

Variable	Value
<code><1-100></code>	Specifies the ID of the controller.
<code>ip address <A.B.C.D></code>	Specifies the IP address of the controller in IPv4 format.
<code>protocol <ssl tcp></code>	Specifies the networking protocol as SSL or TCP for controller communications.
<code>port <1-65535></code>	Specifies the networking port of the controller.

Configure OVSDB Replication

Use the following procedure to configure OVSDB replication to support vIST.

Before You Begin

- You must enable VXLAN Gateway Full Interworking Mode on the switch.
- You must configure an OVSDB managed interface on the switch.
- You must configure and enable OVSDB protocol support for VXLAN Gateway on the switch.
- You must have at least two NVCs configured to communicate on the managed interface network.

Procedure

1. Enter OVSDb Configuration mode:

```
enable
```

```
configure terminal
```

```
ovsdb
```
2. Configure the OVSDb replication:

```
replication peer-ip <A.B.C.D> local-ip <A.B.C.D>
```

Example

The following is an example of configuring OVSDb replication to support vIST.

```
SWITCH:1>enable
SWITCH:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
SWITCH:1 (config)#ovsdb
SWITCH:1 (config-ovsdb)#replication peer-ip 192.0.2.3 local-ip 192.0.2.2
```

Variable definitions

Use the data in the following table to use the **replication** command.

Variable	Value
<i>peer-ip</i> <A.B.C.D>	Specifies the IP address of the secondary controller for OVSDb replication support.
<i>local-ip</i> <A.B.C.D>	Specifies the IP address of the primary controller for OVSDb replication support.

Display the OVSDb Configuration

Use the following procedure to display the OVSDb protocol support for VXLAN Gateway configuration.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the OVSDb configuration:

```
show ovsdb config
```

Example

The following is an example of displaying the OVSDb configuration.

```
SWITCH:1>show ovsdb config
=====
                        Ovldb Config Info
=====
                        Status - Enabled
                        Certificate - Installed
                        Private Key - Installed
                        Replication Peer NLS-IP - 192.0.2.3
                        Replication Local NLS-IP - 192.0.2.2
```

Ovsdb Controller Config Info			
ID	Protocol	IP	Port
1	ssl	192.0.2.10	6640

Display the OVSDb Controller Status

Use the following procedure to display the OVSDb controller status.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the OVSDb controller status:

```
show ovsdb controller status
```

Example

The following is an example of displaying the OVSDb controller status.

```
SWITCH:1>show ovsdb controller status
```

OVSDb Controller Status				
Protocol	IP	Port	status	source
ssl	192.0.2.2	6640	Up	Learnt
ssl	192.0.2.3	6640	Down	Learnt
2 out of 2 Total Num of Controllers displayed				

Display the OVSDb Replication State

Use the following procedure to display the OVSDb replication state.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the OVSDb controller status:

```
show ovsdb replication state
```

Example

The following is an example of displaying the OVSDb replication state.

```
SWITCH:1>show ovsdb replication state
```

Ovsdb Replication Status		
Local NLS IP	Peer NLS IP	State
192.0.2.2	192.0.2.3	ENABLED

Display the OVSDb Managed Interfaces

Use the following procedure to display the OVSDb managed interfaces.

Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the OVSDb managed interfaces:

```
show ovssdb managed-interface
```

Example

The following is an example of displaying the OVSDb managed interfaces.

```
SWITCH:1>show ovssdb managed-interface
=====
OVSDb Managed Interfaces - ISID
=====
50001
1 out of 1 Total Num of Managed Interfaces displayed
```

VXLAN Gateway configuration using EDM

This section provides procedures to configure VXLAN Gateway using the Enterprise Device Manager (EDM).

Configure the VXLAN Gateway Boot Flag

There are two configuration modes: Base Interworking Mode and Full Interworking Mode. The Base Interworking Mode is the default mode. To switch to the Full Interworking Mode, use this procedure.

**Important**

After you change this boot flag, you must save the change to the configuration file and reboot the switch.

Procedure

1. In the navigation pane, expand **Configuration > Edit > Chassis**.
2. Select the **Boot Config** tab.
3. Select **EnableVxlanGwFullInterworkingMode** to enable Full Interworking Mode.
4. Select **Apply**.

Configure a VTEP Source IP Address

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **VTEP**.
3. Select the **Globals** tab.
4. In **SourceIp**, type the VTEP source IP address.
5. In **Vrf**, select `GlobalRouter` or a VRF ID.
6. Select **Apply**.

Globals *Field Descriptions*

Use the data in the following table to use the **Globals** tab.

Name	Description
SourceIp	Specifies the VXLAN tunnel end point (VTEP) source IP address in an A.B.C.D format.
Vrf	<p>Specifies the VRF name used for the source IP address, which you select from the drop down menu. This IP address can be on the GRT or a VRF.</p> <p>Note: The VTEP source IP address must be on a loopback interface.</p>

Configure a Remote VTEP

Use the following procedure to configure the remote VTEP destination.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **VTEP**.
3. Select the **Vtep** tab.
4. In **Id**, assign a unique index value to this remote VTEP.
5. In **IpAddr**, enter the IP address of this remote VTEP.
6. In **Name**, assign a name to this remote VTEP.
7. Select **Apply**.

Vtep *Field Descriptions*

Use the data in the following table to use the **Vtep** tab.

Name	Description
Id	Specifies an index value in the range from 1 to 500 that uniquely identifies this remote VTEP.
IpAddr	<p>Specifies an IP address that uniquely identifies this remote VTEP.</p> <p>Note: The remote VTEP IP address cannot be a local, broadcast, or multicast IP address.</p>
Name	Assigns a name to this remote VTEP tunnel.

Name	Description
NextHopVrfName	Displays the VRF name of the next hop to reach the remote VTEP.
OvsdbConfigured	Specifies if the VTEP is configured with OVSDB protocol support for VXLAN Gateway.

Configure a VNID

Use the following procedure to configure a VNID, which identifies one of the potential 16 million VXLAN segments that can coexist within the same administrative domain.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **VTEP**.
3. Select the **Vnid** tab.
4. In **Identifier**, assign a unique value to this VNID.
5. In **Isid**, specify the I-SID associated with this VNID.
6. In **Action**, select one of the available actions: none or flush.
7. Select **Apply**.

Vnid Field Descriptions

Use the data in the following table to use the **Vnid** tab.

Name	Description
Identifier	Specifies a value that uniquely identifies the VNID of this VXLAN tunnel end point.
Isid	<p>Specifies a value that uniquely identifies the I-SID associated with this VXLAN tunnel end point.</p> <p>Note: A VNID must not have the same value as an I-SID.</p>
Action	<p>Choose one of the following actions to take with the MAC FDB:</p> <ul style="list-style-type: none"> • none: Don't take any action. This is the default. • flushMacFdb: Flush all the learned MAC addresses from the forwarding database of the selected VNID.
OvsdbConfigured	Specifies if the VNID is configured with OVSDB protocol support for VXLAN Gateway.

Configure VNID Endpoints

Use the following procedure to configure a VNID and the VXLAN tunnel end point.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **VTEP**.
3. Select the **Vnid End Points** tab.
4. In **Vnid**, type the VNID ID.
5. In **Vtepld**, type the ID of the remote VTEP.
6. Select **Apply**.

Vnid End Points Field Descriptions

Use the data in the following table to use the **Vnid End Points** tab.

Name	Description
Vnid	Specifies a value that uniquely identifies the VNID of this VXLAN tunnel end point.
Vtepld	Specifies an index value in the range from 1 to 500 that uniquely identifies this remote VTEP.
Isid	Displays a value that uniquely identifies the I-SID associated with this VXLAN tunnel end point.

Configure ELAN Endpoints

Use the following procedure to configure information associated with ELAN end points.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **VTEP**.
3. Select the **Elan End Points** tab.
4. In **Vnid**, specify the VNID associated with this ELAN.
5. In **Cvid**, specify the customer VLAN ID.
6. In **Ifindex**, specify the interface index for this ELAN endpoint.
7. Select **Apply**.

Elan End Points Field Descriptions

Use the data in the following table to use the **Elan End Points** tab.

Name	Description
Vnid	Specifies a value that uniquely identifies the VNID of this ELAN tunnel end point.
Cvid	<p>Specifies a value that uniquely identifies the customer VLAN ID of this ELAN endpoint.</p> <p>The switch reserves the following VLAN IDs:</p> <ul style="list-style-type: none"> • VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. • VLAN IDs 4060 to 4094 are reserved for internal use. • VLAN IDs 3500 to 3999 are reserved if you enable VRF scaling and SPBM mode. • VLAN ID 4095 is not used. • VLAN ID 4096 is reserved for untagged traffic.
IfIndex	Specifies the interface index for the MLT or port for this ELAN endpoint.
Isid	Specifies the I-SID associated with this VNID.

Display the VTEP Next Hop

Use the following procedure to display information about the remote VTEP.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **VTEP**.
3. Select the **Next Hop** tab.

Next Hop Field Descriptions

Use the data in the following table to use the **Next Hop** tab.

Name	Description
VtepId	Specifies an index value in the range from 1 to 500 that uniquely identifies this remote VTEP.
Ip	Specifies an IP address that uniquely identifies this remote VTEP tunnel.
IfIndex	Specifies the interface index of the next hop to reach the remote VTEP.
Vid	Specifies the VLAN ID of the next hop to reach remote VTEP.

Display the VNID Forwarding Database

Use the following procedure to display information about the VNID forwarding database (FDB).

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **VTEP**.
3. Select the **Vnid FDB** tab.

Vnid FDB Field Descriptions

Use the data in the following table to use the **Vnid FDB** tab.

Name	Description
Vnid	Displays the VNID IDs of the VXLAN tunnel endpoints.
Address	Displays all the learned MAC addresses in the forwarding database of the selected VNID.
Status	Displays whether or not the MAC address was learned.
InterfaceIndex	Displays the interface index name for the VNID.
Type	Displays whether the VNID is local or remote.

OVSDB protocol support for VXLAN Gateway configuration using EDM

This section provides procedures to configure OVSDB protocol support for VXLAN Gateway using the Enterprise Device Manager (EDM).

Configure OVSDB Globally

Use the following procedure to configure the OVSDB certificates, private key, and replication global settings.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **OVSD**.
3. Select the **Globals** tab.
4. Select **Enable**.
5. In **CertificateFilename**, type the file path/file name.
6. In **CertFileInstallAction**, select **install**.
7. Select **Apply**.
8. In **PrivateKeyFilename**, type the file path/file name.
9. In **PrivateKeyInstallAction**, select **install**.

10. Select **Apply**.
11. Select **ReplicationEnable**.
12. In **ReplicationPeerIpAddr**, type the IP address.
13. In **ReplicationLocalIpAddr**, type the IP address.
14. Select **Apply**.
15. Verify the **ReplicationState**.

Globals Field Descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
Enable	Enables or disables the feature. Default is disabled (cleared).
CertificateFilename	Specifies the file name of the certificate.
CertFileInstallAction	Specifies to install or uninstall the certificate. You must have a certificate file on the switch.
PrivateKeyFilename	Specifies the file name of the private key.
PrivateKeyInstallAction	Specifies to install or uninstall the private key. You must have a private key file on the switch.
ReplicationEnable	Enables or disables replication support. Default is disabled (cleared).
ReplicationPeerIpAddr	Specifies the replication server peer IP address in A.B.C.D format.
ReplicationLocalIpAddr	Specifies the replication local IP address in A.B.C.D format.
ReplicationState	Displays the current replication status.

Configure an OVSDB Controller

Use the following procedure to configure an OVSDB controller ID, IP address, protocol, and port.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **OVSDB**.
3. Select the **Controller** tab.
4. Select **Insert**.
5. In **Id**, assign a unique index value to this controller.
6. In **IpAddr**, enter the IP address of this controller.
7. In **Protocol**, select **tcp** or **ssl**.
8. In **Port**, enter a port number.
9. Select **Insert**.

Controller Field Descriptions

Use the data in the following table to use the **Controller** tab.

Name	Description
Id	Specifies an ID number for a controller. Value range of 1 to 100.
IpAddr	Specifies the IP address of a controller. Type an IP address in A.B.C.D format.
Protocol	Specifies the communications protocol for the controller. Select tcp or ssl .
Port	Specifies the communications port for the controller. Value range of 1 to 65535.

Display the OVSDb Controller Status

Use the following procedure to display status information about the OVSDb controller.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **OSVDB**.
3. Select the **Status** tab.

Status Field Descriptions

Use the data in the following table to use the **Status** tab.

Name	Description
IpAddress	Displays the IP address of a controller.
Protocol	Displays the communications protocol of a controller as TCP or SSL.
Port	Displays the communications port for the controller. Value range of 1 to 65535.
Source	Displays the source of the controller as learned or configured.
OperStatus	Displays the operational status of the controller.

Configure OVSDb Managed Interface

Use the following procedure to configure a I-SID interface for the OVSDb.

Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **OSVDB**.
3. Select the **Interface** tab.

4. Select **Insert**.
5. In **Isid**, type the I-SID identifier.
6. Select **Insert**.

Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
Isid	Specifies an I-SID to use as the managed interface.

Configuration Examples

This section provides network configuration examples for VXLAN Gateway and OVSDB protocol support for VXLAN Gateway.

VXLAN Gateway Configuration Example

This example shows how to configure the VXLAN Gateway. Remember that there are two modes:

- Base Interworking Mode is the default mode so there is no need to set the mode boot flag. However, you should use the **show boot config flags** command to verify that the **vxlan-gw-full-interworking-mode** is set to *false*.
- Full Interworking Mode supports all SPB functionality including vIST and SMLT using an internal loopback. Full Interworking Mode is not the default mode. To configure Full Interworking mode, you must enable the **vxlan-gw-full-interworking-mode** boot flag.

Important

Changing the mode requires a reboot for the change to take effect, which can cause a loss of traffic.

OVSDB protocol support for VXLAN Gateway Configuration Example

This example shows how to configure OVSDB protocol support for VXLAN Gateway.

Important

OVSDB protocol support for VXLAN Gateway also requires an ESXi host running VMware NSX configured with a HW-VTEP, and a Logical Switch configured with VNID to HW-VTEP bindings to function. See VMware NSX documentation for more information.

Important

OVSDB requires full interworking mode on the VXLAN Gateway. Changing the mode requires a reboot for the change to take effect, which can cause a loss of traffic.

Port Numbering and MAC Address Assignment Reference

[Port Numbering](#) on page 4211

[Interface Indexes](#) on page 4242

[MAC Address Assignment](#) on page 4244

This section provides information about the port numbering and Media Access Control (MAC) address assignment used on the switch.

Port Numbering

A port number includes the slot location of the port in the chassis, as well as the port position, using the format slot/port. For example, the second port in the first slot is structured as 1/2. The number of slots and ports varies depending on the hardware platform. For more information about hardware, see the hardware documentation for your platform.

4220 Series

The following diagrams illustrate the components on the front panels of the 4220 Series switches.

4220-12P-4X and 4220-12T-4X

The following diagram illustrates the components of the front panel of the 4220-12P-4X and 4220-12T-4X. The only difference between these two models is PoE support. All ports are in slot 1.

The back panel (not shown) includes:

- AC power inlet connector
- Redundant power inlet connector (behind cover)
- Grounding lug

5320-24T-24S-4XE-XT

The following diagram illustrates the components of the front panel of the 5320-24T-24S-4XE-XT switch. All ports are in slot 1.

Figure 272: 5320-24T-24S-4XE-XT Front Panel

Table 367: Figure call outs

Callout	5320-24T-24S-4XE-XT
1	Mode button for port LED control. Port LED mode indicators: system (SYS) and speed (SPD)
2	System LEDs
3	10/100/1000BASE-T out-of-band management port (RJ-45)
4	24 x 10/100/1000BASE-T (autosensing) full/half duplex MACsec capable ports Note: The 10/100 ports support half duplex; the 1000 port supports full duplex. Half-duplex is not supported on these ports when operating at 1Gbps.
5	4 x 1/10Gb SFP+ MACsec capable Universal ports (unpopulated)
6	24 x 100Mb/1G SFP MACsec capable ports
7	USB Micro-B console port
8	USB Type-A port for management or external USB flash
9	Serial console port (RJ-45)

The back panel (not shown) includes:

- AC power inlet connector
- Redundant power inlet connector (behind cover)
- Grounding lug

5320-48P-8XE and 5320-48T-8XE

The following diagram illustrates the components of the front panel of the 5320-48P-8XE and 5320-48T-8XE switches. All ports are in slot 1.

Figure 273: 5320-48P-8XE Front Panel

Figure 274: 5320-48T-8XE Front Panel

Table 368: Figure call outs

Callout	5320-48P-8XE	5320-48T-8XE
1	RJ-45 serial console port	RJ-45 serial console port
2	USB Type-A port	USB Type-A port
3	USB Micro-B console port	USB Micro-B console port
4	10/100/1000BASE-T ports — These ports support 802.3af Type 1 PoE and 802.3at Type 2 PoE+	10/100/1000BASE-T ports
5	1/10Gb SFP+ uplink ports	1/10Gb SFP+ uplink ports
6	1/10Gb SFP+ Universal Ports	1/10Gb SFP+ Universal Ports

The back panel (not shown) includes:

- Grounding lug
- 1 AC power inlet connector

5420 Series

In addition to the regular fixed ports, all 5420 Series switches have two SFP-DD Universal Ethernet ports that are reserved for advanced features (factory default). You can also use these ports as regular ports if you do not require the advanced features. For more information about using the advanced-feature-bandwidth-reservation boot flag to configure the functionality of these ports, see [Advanced Feature Bandwidth Reservation](#) on page 275.

When advanced features are disabled on these SFP-DD Universal Ethernet ports, they can function as regular Ethernet ports, supporting data rates of either 10Gb using SFP+ optics or 20Gb using SFP-DD optics. 5420M switch models support two 10Gb channels on each SFP-DD port. 5420F switch models support one 10Gb channel on each SFP-DD port when the ports are used as Ethernet ports.

Note

SFP28 direct attach cables (DAC) handling in SFP28 and SFP+ ports can be used for 25Gb and 10Gb by setting speed or Custom Auto-Negotiation Advertisement (CANA) at both ends.

Front panel ports 1/1-1/28, 1/29/1, 1/29/2, 1/30/1, and 1/30/2 can be used for traffic on the following switches:

- 5420F-8W-16P-4XE
- 5420F-24P-4XE
- 5420F-24S-4XE
- 5420F-24T-4XE
- 5420M-24W-4YE
- 5420M-24T-4YE

Front panel ports 1/1-1/52, 1/53/2, 1/53/1, 1/53/2, 1/54/1, and 1/54/2 can be used for traffic on the following switches:

- 5420F-16W-32P-4XE
- 5420F-48P-4XE
- 5420F-48P-4XL
- 5420F-48T-4XE
- 5420M-16MW-32P-4YE
- 5420M-48T-4YE
- 5420M-48W-4YE
- 5420M-24W-24S-4YE

On the following switches, you can create two 10Gb channels on each SFP-DD port:

- 5420M-24W-4YE
- 5420M-24T-4YE
- 5420M-16MW-32P-4YE
- 5420M-48T-4YE
- 5420M-48T-4YE
- 5420M-24W-24S-4YE

5420F-8W-16P-4XE

The following diagram illustrates the components of the front panel of the 5420F-8W-16P-4XE switch.

Figure 275: 5420F-8W-16P-4XE Front Panel

The front panel of the 5420F-8W-16P-4XE switch includes:

1. 8 10/100/1000BASE-T full-duplex (FDX), half-duplex (HDX) 802.3bt Type 4 PoEMACsec-capable ports, 16 1000BASE-T FDX/HDX Type 2 PoE+ MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK, and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

Note

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10 Gbps SFP+ ports

The back panel (not shown) includes two fixed fan modules, an AC power inlet connector, a power supply slot, and a grounding lug.

5420F-24P-4XE

The following diagram illustrates the components of the front panel of the 5420F-24P-4XE switch.

Figure 276: 5420F-24P-4XE Front Panel

The front panel of the 5420F-24P-4XE switch includes:

1. 24 10/100/1000BASE-T FDX/HDX 802.3bt Type 2 PoE+ MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

Note

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10 Gbps SFP+ ports

The back panel (not shown) includes 2 fixed fan modules, an AC power inlet connector, a power supply slot, and a grounding lug.

5420F-24S-4XE

The following diagram illustrates the components of the front panel of the 5420F-24S-4XE switch.

Figure 277: 5420F-24S-4XE Front Panel

The front panel of the 5420F-24S-4XE switch includes:

1. 24 1000BASE-X SFP MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

Note

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 10 Gbps SFP+ ports

The back panel (not shown) includes 2 fixed fan modules, an AC power inlet connector, a power supply slot, and a grounding lug.

5420F-24T-4XE

The following diagram illustrates the components of the front panel of the 5420F-24T-4XE switch.

Figure 278: 5420F-24T-4XE Front Panel

The front panel of the 5420F-24T-4XE switch includes:

1. 24 10/100/1000BASE-T FDX/HDX MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

Note

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10 Gbps SFP+ ports

The back panel (not shown) includes 2 fixed fan modules, an AC power inlet connector, a power supply slot, and a grounding lug.

5420F-16MW-32P-4XE

The following diagram illustrates the components of the front panel of the 5420F-16MW-32P-4XE switch.

Figure 279: 5420F-16MW-32P-4XE Front Panel

The front panel of the 5420F-16MW-32P-4XE switch includes:

1. 16 100Mb/1GB/2.5GB 802.3bt Type 4 PoE ports.
2. 32 10/100/1000BASE-T FDX/HDX Type 2 PoE+ MACsec-capable ports.

3. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

Note

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

4. 1 Micro-B USB console port
5. 1 RJ-45 out of band (OOB) management port
6. 1 RJ-45 serial console port
7. 2 Type-A USB ports
8. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
9. 4 1/10 Gbps SFP+ ports

The back panel (not shown) includes three fixed fan modules, a power supply slot, an AC power inlet connector, and a grounding lug.

5420F-16W-32P-4XE

The following diagram illustrates the components of the front panel of the 5420F-16W-32P-4XE switch.

Figure 280: 5420F-16W-32P-4XE Front Panel

The front panel of the 5420F-16W-32P-4XE switch includes:

1. 16 10/100/1000BASE-T FDX/HDX 802.3bt Type 4 PoE MACsec-capable ports.
2. 32 10/100/1000BASE-T FDX/HDX Type 2 PoE+ MACsec-capable ports.
3. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

Note

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

4. 1 Micro-B USB console port
5. 1 RJ-45 out of band (OOB) management port
6. 1 RJ-45 serial console port
7. 2 Type-A USB ports
8. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
9. 4 1/10 Gbps SFP+ ports

The back panel (not shown) includes three fixed fan modules, a power supply slot, an AC power inlet connector, and a grounding lug.

5420F-48P-4XE

The following diagram illustrates the components of the front panel of the 5420F-48P-4XE switch.

Figure 281: 5420F-48P-4XE Front Panel

The front panel of the 5420F-48P-4XE switch includes:

1. 48 10/100/1000BASE-T FDX/HDX Type 2 PoE+ MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

Note

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10 Gbps SFP+ ports

The back panel (not shown) includes three fixed fan modules, a power supply slot, an AC power inlet connector, and a grounding lug.

5420F-48P-4XL

The following diagram illustrates the components of the front panel of the 5420F-48P-4XL switch.

Figure 282: 5420F-48P-4XL Front Panel

The front panel of the 5420F-48P-4XL switch includes:

1. 48 10/100/1000BASE-T FDX/HDX Type 2 PoE+ MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

Note

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10 Gbps LRM/MACsec-capable SFP+ ports

The back panel (not shown) includes three fixed fan modules, a power supply slot, an AC power inlet connector, and a grounding lug.

5420F-48T-4XE

The following diagram illustrates the components of the front panel of the 5420F-48T-4XE switch.

Figure 283: 5420F-48T-4XE Front Panel

The front panel of the 5420F-48T-4XE switch includes:

1. 48 10/100/1000BASE-T FDX/HDX MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

Note

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10 Gbps SFP+ ports

The back panel (not shown) includes two fixed fan modules, a power supply slot, an AC power inlet connector, and a grounding lug.

5420M-24T-4YE

The following diagram illustrates the components of the front panel of the 5420M-24T-4YE switch.

Figure 284: 5420M-24T-4YE Front Panel

The front panel of the 5420M-24T-4YE switch includes:

1. 24 10/100/1000BASE-T FDX/HDX Type 2 MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

Note

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10/25 Gbps SFP28 ports

The back panel (not shown) includes a removable fan module, two power supply slots, and a grounding lug.

5420M-24W-4YE

The following diagram illustrates the components of the front panel of the 5420M-24W-4YE switch.

Figure 285: 5420M-24W-4YE Front Panel

The front panel of the 5420M-24W-4YE switch includes:

1. 24 10/100/1000BASE-T FDX/HDX 802.3bt Type 4 PoE MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

Note

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10/25 Gbps SFP28 ports

The back panel (not shown) includes a removable fan module, two power supply slots, and a grounding lug.

5420M-16MW-32P-4YE

The following diagram illustrates the components of the front panel of the 5420M-16MW-32P-4YE switch.

Figure 286: 5420M-16MW-32P-4YE Front Panel

The front panel of the 5420M-16MW-32P-4YE switch includes:

1. 16 100Mb/1Gb/2/5Gb 802.3bt Type 4 PoE ports.
2. 32 10/100/1000BASE-T FDX/HDX Type 2 PoE+ MACsec-capable ports.
3. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

Note

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

4. 1 Micro-B USB console port
5. 1 RJ-45 out of band (OOB) management port
6. 1 RJ-45 serial console port
7. 2 Type-A USB ports
8. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
9. 4 1/10/25 Gbps SFP28 ports

The back panel (not shown) includes a removable fan module, two power supply slots, and a grounding lug.

5420M-48T-4YE

The following diagram illustrates the components of the front panel of the 5420M-48T-4YE switch.

Figure 287: 5420M-48T-4YE Front Panel

The front panel of the 5420M-48T-4YE switch includes:

1. 48 10/100/1000BASE-T FDX/HDX MACsec-capable ports.
2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

Note

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

3. 1 Micro-B USB console port
4. 1 RJ-45 out of band (OOB) management port
5. 1 RJ-45 serial console port
6. 2 Type-A USB ports
7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
8. 4 1/10/25 Gbps SFP28 ports

The back panel (not shown) includes a removable fan module, two power supply slots, and a grounding lug.

5420M-48W-4YE

The following diagram illustrates the components of the front panel of the 5420M-48W-4YE switch.

Figure 288: 5420M-48W-4YE Front Panel

The front panel of the 5420M-48W-4YE switch includes:

- 1. 48 10/100/1000BASE-T FDX/HDX 802.3bt Type 4 PoE MACsec-capable ports.
- 2. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2), fan (FAN), and System Locator LED (LOC).

Note

The software only supports SYS and SPD LED mode indicators. STK and BT LED indicators remain off.

- 3. 1 Micro-B USB console port
- 4. 1 RJ-45 out of band (OOB) management port
- 5. 1 RJ-45 serial console port
- 6. 2 Type-A USB ports
- 7. 2 SFP-DD Universal Ethernet ports (labeled U1 and U2)
- 8. 4 1/10/25 Gbps SFP28 ports

The back panel (not shown) includes a removable fan module, two power supply slots, and a grounding lug.

5420M-24W-24S-4YE front panel

The following figure illustrates the components on the front panel of the 5420M-24W-24S-4YE.

Figure 289: 5420M-24W-24S-4YE Front Panel

The front panel of the switch includes:

Table 369: Figure call outs

Callout	5420M-24W-24S-4YE
1	10/100/1000BASE-T full/half duplex, MACsec capable ports
2	24x100M (FX/LX)/1G SFP ports
3	100MB/1Gb/2.5Gb ports with 802.3bt Type 4 PoE (90W)
4	Mode button
5	Type- C USB console port
6	System LEDs
7	RJ-45 Management and Console ports
8	Type A USB ports

Table 369: Figure call outs (continued)

Callout	5420M-24W-24S-4YE
9	SFP-DD Universal Ethernet ports
10	10G SFP+ or 10/25G SFP28 uplink ports

The back panel (not shown) includes a removable fan module, two power supply slots, and a grounding lug.

5520 Series

The following diagrams illustrate the components on the front panels of the 5520 Series switches.

For information about supported VIM modules, see *5520 Series Installation Guide*.

Additional Ports

In addition to the regular fixed ports, all 5520 Series switches have two QSFP28/QSFP+ Universal Ethernet ports and a Versatile Interface Module (VIM) slot. If you install a VIM, the switch reserves the Universal Ethernet ports for advanced features. If you do not install a VIM, the switch reserves two internal VIM ports for advanced features and you can use the Universal Ethernet ports as regular ports. If you do not require advanced features, you can use the Universal Ethernet ports as regular ports. For more information about using the advanced-feature-bandwidth-reservation boot flag to configure the functionality of these ports, see [Advanced Feature Bandwidth Reservation](#) on page 275.

When used as regular ports, the port speed is 40 Gbps as a single channel port. Although the maximum supported single channel port speed is 40 Gbps, the ports can be channelized to operate as four 10 or 25 Gbps channels. You can use 100 Gbps LR4 optics in Universal Ethernet ports to have a 100 Gbps connection with a 4x25 Gbps MLT. When the switch detects the optic, it automatically channelizes the port.

5520-24T

The following diagram illustrates the components of the front panel of the 5520-24T switch. Slot 1 is used for the 24 copper ports and the two QSFP28/QSFP+ ports, and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

**Figure 290: 5520-24T**

1. 24 10/100/1000BASE-T full-duplex (FDX), half-duplex (HDX), MACsec-capable ports
2. 1 USB A port
3. 1 USB micro B management port

4. 2 Universal Ethernet QSFP28 ports
5. VIM slot (shown with VIM covered). Port numbering depends on the type of VIM installed in the slot.

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, a USB A port, locator LED, two PSU slots, and hot-swappable fan units.

5520-24W

The following diagram illustrates the components of the front panel of the 5520-24W switch. Slot 1 is used for the 24 copper ports and the two QSFP28/QSFP+ ports, and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

Figure 291: 5520-24W

1. 24 10/100/1000BASE-T FDX/HDX 802.3bt Type 4 PoE MACsec-capable ports
2. 1 USB A port
3. 1 USB micro B management port
4. 2 Universal Ethernet QSFP28 ports
5. VIM slot (shown with VIM covered). Port numbering depends on the type of VIM installed in the slot.

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, a USB A port, locator LED, two PSU slots, and hot-swappable fan units.

5520-48T

The following diagram illustrates the components of the front panel of the 5520-48T switch. Slot 1 is used for the 48 copper ports and the two QSFP28/QSFP+ ports, and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

Figure 292: 5520-48T

1. 48 10/100/1000BASE-T FDX/HDX MACsec-capable ports
2. 1 USB A port
3. 1 USB micro B management port

4. 2 Universal Ethernet QSFP28 ports
5. VIM slot (shown with VIM covered). Port numbering depends on the type of VIM installed in the slot.

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, a USB A port, locator LED, two PSU slots, and hot-swappable fan units.

5520-48W

The following diagram illustrates the components of the front panel of the 5520-48W switch. Slot 1 is used for the 48 copper ports and the two QSFP28/QSFP+ ports, and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

Figure 293: 5520-48W

1. 48 10/100/1000BASE-T FDX/HDX 802.3bt Type 4 PoE MACsec-capable ports
2. 1 USB A port
3. 1 USB micro B management port
4. 2 Universal Ethernet QSFP28 ports
5. VIM slot (shown with VIM covered). Port numbering depends on the type of VIM installed in the slot.

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, a USB A port, locator LED, two PSU slots, and hot-swappable fan units.

5520-12MW-36W

The following diagram illustrates the components of the front panel of the 5520-12MW-36W switch. Slot 1 is used for the 48 copper ports and the two QSFP28/QSFP+ ports, and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

Figure 294: 5520-12MW-36W

1. 36 10/100/1000BASE-T FDX/HDX 802.3bt Type 4 PoE MACsec-capable ports
2. 1 USB A port
3. 1 USB micro B management port
4. 2 Universal Ethernet QSFP28 ports
5. VIM slot (shown with VIM covered). Port numbering depends on the type of VIM installed in the slot.
6. 12 100 Mbps/1 Gbps/2.5 Gbps/5 Gbps 802.3bt Type 4 PoE MACsec-capable ports

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, a USB A port, locator LED, two PSU slots, and hot-swappable fan units.

5520-24X

The following diagram illustrates the components of the front panel of the 5520-24X switch. Slot 1 is used for the 24 SFP+ ports and the two QSFP28/QSFP+ ports, and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

Figure 295: 5520-24X

1. 24 100/1000BASE-X/10GBASE-X SFP+ ports
2. 1 USB A port
3. 1 USB micro B management port
4. 2 Universal Ethernet QSFP28 ports
5. VIM slot (shown with VIM covered). Port numbering depends on the type of VIM installed in the slot.

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, a USB A port, locator LED, two PSU slots, and hot-swappable fan units.

5520-48SE

The following diagram illustrates the components of the front panel of the 5520-48SE switch. Slot 1 is used for the 48 SFP ports and the two QSFP28/QSFP+ ports, and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

Figure 296: 5520-48SE

1. 48 100/1000BASE-X MACsec-capable SFP ports
2. 1 USB A port
3. 1 USB micro B management port
4. 2 Universal Ethernet QSFP28 ports
5. VIM slot (shown with VIM covered). Port numbering depends on the type of VIM installed in the slot.

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, a USB A port, locator LED, two PSU slots, and hot-swappable fan units.

5720 Series

The following diagrams illustrate the components on the front panels of the 5720 Series switches.

Note

In addition to the regular fixed ports, all 5720 Series switches have two QSFP28/QSFP+ Universal Ethernet ports and a Versatile Interface Module (VIM) slot. If you install a VIM, the 48-port models reserve the Universal Ethernet ports for advanced features. If you do not install a VIM, the switch reserves two internal VIM ports for advanced features and you can use the Universal Ethernet ports as regular ports. If you do not require advanced features, you can use the Universal Ethernet ports as regular ports. For more information about using the advanced-feature-bandwidth-reservation boot flag to configure the functionality of these ports, see [Advanced Feature Bandwidth Reservation](#) on page 275.

When used as regular ports, the port speed is 100 Gbps as a single channel port. Although the maximum supported single channel port speed is 100 Gbps, the ports can be channelized to operate as four 10 or 25 Gbps channels.

5720-24MW

The following diagram illustrates the components of the front panel of the 5720-24MW switch.

Figure 297: View of the 5720-24MW front panel

1. USB Micro-B console port
2. USB Type-A port
3. System LEDs
4. Mode button
5. 2 Universal Ethernet/QSFP28 ports (unpopulated)
6. VIM Slot. Port numbering depends on the type of VIM installed in the slot.
7. 24 100M/1/2.5/5GbaseT 802.3bt PoE (90W) full-duplex (FDX), MACsec-capable ports

5720-48MW

The following diagram illustrates the components of the front panel of the 5720-48MW switch.

1. USB Micro-B console port
2. USB Type-A port
3. System LEDs
4. Mode button
5. 2 Universal Ethernet/QSFP28 ports (unpopulated)
6. VIM Slot. Port numbering depends on the type of VIM installed in the slot.
7. 48 100M/1/2.5/5GbaseT 802.3bt PoE (90W) full-duplex (FDX), MACsec-capable ports

5720-24MXW

The following diagram illustrates the components of the front panel of the 5720-24MXW switch.

1. USB Micro-B console port
2. USB Type-A port
3. System LEDs
4. Mode button
5. 24 100M/1/2.5/5/10GbaseT full-duplex (FDX), MACsec capable ports with 802.3bt Type 4 PoE (90W)
6. VIM Slot. Port numbering depends on the type of VIM installed in the slot.
7. 2 Universal Ethernet/QSFP28 ports (unpopulated)

5720-48MXW

The following diagram illustrates the components of the front panel of the 5720-48MXW switch.

Figure 298: 5720-48MXW Front Panel

1. USB Micro-B console port
2. USB Type-A port
3. System LEDs
4. Mode button
5. 2 Universal Ethernet/QSFP28 ports (unpopulated)
6. VIM Slot. Port numbering depends on the type of VIM installed in the slot.
7. 48 100M/1/2.5/5/10GbaseT full-duplex (FDX), MACsec capable ports with 802.3bt Type 4 PoE (90W)

VIMs

- 5720-VIM-6YE

Versatile Interface Module that provides six 25GbE SFP28 MACsec-capable ports

- 5720-VIM-2CE

Versatile Interface Module that provides two 100GbE QSFP28 MACsec-capable ports

For more information about VIM modules, see *5720 Series Installation Guide*.

5720 Series Back Panel View

The following diagram illustrates the components of the back panel of the 5720 Series

1. SSD slot
2. Fan modules
3. 10/100/1000 BASE-T out-of-band management port
4. Power supply slots
5. Grounding lug
6. Serial console port (RJ-45)
7. Type-A USB port for management or external USB flash

7520 Series

7520-48Y-8C

The following figure illustrates the components on the front panel of the 7520-48Y-8C.

Figure 299: 7520-48Y-8C front panel view

1. 48 1/10/25 Gbps SFP28 ports
2. 8 40/100 Gbps QSFP28 ports
3. 1 RJ-45 management port for CPU and BMC network access
4. 1 USB Type-A port
5. 1 RJ-45 serial console port
6. System LEDs

7520-48YE-8CE

The following figure illustrates the components on the front panel of the 7520-48YE-8CE.

Figure 300: 7520-48YE-8CE front panel view

1. 48 10/25 Gbps SFP28 MACsec-capable ports
2. 8 40/100 Gbps QSFP28 MACsec-capable ports
3. 1 RJ-45 management port for CPU and BMC network access
4. 1 USB Type-A port
5. 1 RJ-45 serial console port
6. System LEDs

7520-48XT-6C

The following figure illustrates the components on the front panel of the 7520-48XT-6C.

Figure 301: 7520-48XT-6C front panel view

1. 48 1G/10GBase-T ports
2. 6 40/100 Gbps QSFP28 ports
3. 1 RJ-45 management port for CPU and BMC network access
4. 1 USB Type-A port
5. 1 RJ-45 serial console port
6. System LEDs

The back panel (not shown) includes dual redundant hot-swappable power supplies and six hot-swappable fan units.

The 7520 Series supports one internal IAH port, 1/s1, used by IAH virtual machines. For conceptual information see [Extreme Integrated Application Hosting](#) on page 1097. For configuration instructions to use internal IAH ports, see [Virtual Services Configuration using CLI](#) on page 1112 and [Virtual Services Configuration using EDM](#) on page 1126.

7720 Series

7720-32C

The following figure illustrates the components on the front panel of the 7720-32C.

Table 370: Figure call outs

Callout	7720-32C
1	32 40/100 Gbps QSFP28 ports
2	1 RJ-45 serial console port
3	1 USB Type-A port
4	Two RJ-45 management ports: <ul style="list-style-type: none">• MGMT2 - CPU and BMC (secondary)• MGMT1 - Direct to CPU (primary)

The back panel (not shown) includes dual redundant hot-swappable power supplies and six hot-swappable fan units.

The 7720-32C supports two internal Extreme Integrated Application Hosting (IAH) ports labeled as Insight ports, 1/s1 and 1/s2, used by IAH virtual machines. For conceptual information see [Extreme Integrated Application Hosting](#) on page 1097. For configuration instructions to use internal IAH ports, see [Virtual Services Configuration using CLI](#) on page 1112 and [Virtual Services Configuration using EDM](#) on page 1126.

7830 Series

The following diagrams illustrate the components on the front panels of the 7830 Series switches.

7830-32CE-8DE

The following diagram illustrates the components of the front panel of the 7830-32CE-8DE switch.

**Table 371: Figure call outs**

Callout	7830-32CE-8DE
1	100M/1G/10G RJ-45 out-of-band management port
2	System LEDs
3	RJ-45 Serial console ports
4	Global Navigation Satellite System for GPS signal (not supported)
5	Mode button and channel selection LEDs
6	Advanced services port for the processor to offload to external appliance (not supported)
7	Time of Day (TOD), 1PPS signal inputs
8	HD-BNC connector for Time synchronization, 1PPS and 10MHz
9	USB Type A port
10	VIM slots (unpopulated)
11	QSPF56-DD 10G/25G/100G/400G MACsec capable ports
12	QSFP28 10G/25G/40G/100G MACsec capable ports
13	1G/10G SFP+ out-of-band management port

The back panel (not shown) includes a grounding lug, 4 fan modules, and 2 modular power supplies.

Interface Indexes

The Simple Network Management Protocol (SNMP) uses interface indexes to identify ports, Virtual Local Area Networks (VLAN), and Multilink Trunking (MLT).

Port Interface Index

To determine the interface index (IfIndex), you can calculate it, or use the CLI command provided in this section.

As a result of channelization support, the IfIndex of each channelization-capable port increases by 4. The number is reserved for the 3 sub-ports when channelization is enabled.

For switches that include channelization-capable ports, use the following equations to determine the IfIndex of a port:

- If the port does not support channelization, use $(64 \times \text{slot number}) + 128 + (\text{port number} - 1)$.
- If the port supports channelization, use the following equations:
 - for the port in question: $(64 \times \text{slot number}) + 128$
 - for subsequent ports: $(64 \times \text{slot number}) + 128 + ((\text{port number} - 1) * 4)$

This equation reserves space for the creation of the 3 sub-ports on the previous port, if or when you enable channelization.

Table 372: Number of slots per platform

Platform	Number of slots
4220 Series	1
5320 Series	1
5420 Series	1
5520 Series	2
5720 Series	2
7520 Series	1
7720 Series	1
7830 Series	3

CLI command

To determine the port interface index through the CLI, use the following command:

```
show interfaces gigabitEthernet
```

The following example shows output for this command:

```
Switch:1(config)#show interfaces gigabitEthernet
```

Port Interface								
PORT NUM	INDEX	DESCRIPTION	LINK TRAP	PORT LOCK	MTU	PHYSICAL ADDRESS	STATUS	
							ADMIN	OPERATE
1/1	192	1000BaseTX	true	false	1950	f0:64:26:70:f8:00	up	up
1/2	193	1000BaseTX	true	false	1950	f0:64:26:70:f8:01	up	down
1/3	194	1000BaseTX	true	false	1950	f0:64:26:70:f8:02	up	down
1/4	195	1000BaseTX	true	false	1950	f0:64:26:70:f8:03	up	down
1/5	196	1000BaseTX	true	false	1950	f0:64:26:70:f8:04	up	down
1/6	197	1000BaseTX	true	false	1950	f0:64:26:70:f8:05	up	down
1/7	198	1000BaseTX	true	false	1950	f0:64:26:70:f8:06	up	down
1/8	199	1000BaseTX	true	false	1950	f0:64:26:70:f8:07	up	down
1/9	200	1000BaseTX	true	false	1950	f0:64:26:70:f8:08	up	down

```

1/10    201    1000BaseTX      true  false    1950  f0:64:26:70:f8:09 up    down
1/11    202    1000BaseTX      true  false    1950  f0:64:26:70:f8:0a up    down
1/12    203    1000BaseTX      true  false    1950  f0:64:26:70:f8:0b up    down
1/13    204    1000BaseTX      true  false    1950  f0:64:26:70:f8:0c up    down
--More-- (q = quit)

```

VLAN interface index

The interface index of a VLAN is computed using the following formula:

Because the default VLAN always uses an MGID value of 1, its interface index is always 2049.

$\text{ifIndex} = 2048 + \text{VLAN multicast group ID (MGID)}$

MLT interface index

The interface index of a multilink trunk (MLT) is computed using the following formula:

$\text{ifIndex} = 6143 + \text{MLT ID number}$

MAC Address Assignment

You must understand MAC addresses assignment if you perform one of the following actions:

- Define static Address Resolution Protocol (ARP) entries for IP addresses in the switch
- Use a network analyzer to decode network traffic

Each chassis is assigned a base number of MAC addresses with a number reserved for ports and other internal purposes, and the remainder assigned to routable VLANs. The following table identifies the numbers provided by the switch.

Base assignment	Reserved	Assigned to routable VLANs
1,024	First 256	remaining 768

Virtual MAC Addresses

Virtual MAC addresses are the addresses assigned to VLANs. The system assigns a virtual MAC address to a VLAN when it creates the VLAN. The MAC address for a VLAN IP address is the virtual MAC address assigned to the VLAN.

Supported Standards, RFCs, and MIBs

[Supported IEEE Standards](#) on page 4245

[Supported RFCs](#) on page 4246

[Standard MIBs](#) on page 4253

[Proprietary MIBs](#) on page 4256

This section provides information about supported IEEE standards, RFCs, and MIBs.

Supported IEEE Standards

Table 373: Supported IEEE Standards

IEEE standard	Description
802.1AB	LLDP
802.1ag	Connectivity Fault Management
802.1ah	Provider Backbone Bridging
802.1aq	Shortest Path Bridging (SPB)
802.1AX	Link Aggregation
802.1D	MAC Bridges
P802.1p	Traffic Class Expediting and Dynamic Multicast Filtering
802.1Q	Virtual LANs
802.1s	Multiple Spanning Trees
802.1t	802.1D Technical & Editorial Corrections
802.1w	Rapid Spanning Tree Protocol (RSTP)
802.1X-2010	Port-based Network Access Control (NAC)
802.3 CSMA/CD Ethernet ISO/IEC 8802	International Organization for Standardization (ISO) /International Eletrotechnical Commission (IEC) 8802-3
802.3ab	1000 Mbps Operation, implemented as 1000BASE-T Copper
802.3ac	Carrier sense multiple access with collision detection (CSMA/CD) frame extensions for Virtual Bridged Local Area Networks (VLAN) tagging on 802.3 networks

Table 373: Supported IEEE Standards (continued)

IEEE standard	Description
802.1AE	MAC Security
802.3ae	10 Gbps Operation, implemented as 10GBASE-X SFP+
802.3af 802.3at 802.3bt (Type 3 and Type 4)	Power over Ethernet (PoE)
802.3az	Energy Efficient Ethernet (EEE)
802.3ba	40 Gbps and 100 Gbps Operation, implemented as 40GBASE-QSFP+ and 100GBASE-QSFP28
802.3x	Full Duplex & Flow Control
802.3z	1000 Mbps Operation, implemented as 1000BASE-X SFP
ANSI/TIA-1057	LLDP-MED

Supported RFCs

The following table and sections list the RFCs that the switch supports.

Table 374: Supported request for comments

Request for comment	Description
draft-grant-tacacs-02.txt	TACACS+ Protocol
RFC 768	UDP Protocol
RFC 783	Trivial File Transfer Protocol (TFTP)
RFC 791	Internet Protocol (IP)
RFC 792	Internet Control Message Protocol (ICMP)
RFC 793	Transmission Control Protocol (TCP)
RFC 815	IP Datagram Reassembly Algorithm
RFC 826	Address Resolution Protocol (ARP)
RFC 854	Telnet protocol
RFC 894	A standard for the Transmission of IP Datagrams over Ethernet Networks
RFC 896	Congestion control in IP/TCP internetworks
RFC 906	Bootstrap loading using TFTP
RFC 950	Internet Standard Subnetting Procedure
RFC 951	BootP
RFC 959, RFC 1350, and RFC 2428	FTP and TFTP client and server

Table 374: Supported request for comments (continued)

Request for comment	Description
RFC 1027	Using ARP to implement transparent subnet gateways/Nortel Subnet based VLAN
RFC 1042	Encapsulating the Internet Protocol (IP) datagrams and Address Resolution Protocol (ARP) Note: Applicable for 802.3 networks only
RFC 1058	RIPv1 Protocol
RFC 1112	Host Extensions for IP Multicasting (IGMPv1)
RFC 1122	Requirements for Internet Hosts
RFC 1155	SMI
RFC 1156	MIB for network management of TCP/IP
RFC 1157	SNMP
RFC 1195	Use of OSI IS-IS for Routing in TCP/IP and Dual Environments
RFC 1212	Concise MIB definitions
RFC 1213	TCP/IP Management Information Base
RFC 1215	Convention for defining traps for use with the SNMP
RFC 1253	OSPF MIB
RFC 1256	ICMP Router Discovery
RFC 1305	Network Time Protocol v3 Specification, Implementation and Analysis ³
RFC 1323	TCP Timestamp (The switch is only compliant if the TCP timestamp is enabled.)
RFC 1340	Assigned Numbers
RFC 1350	TFTP Protocol (Revision 2)
RFC 1389	Ethernet MIB
RFC 1442	Structure of Management Information for version 2 of the Simple Network Management Protocol (SNMPv2)
RFC 1450	Management Information Base for v2 of the Simple Network Management Protocol (SNMPv2)
RFC 1519	Classless Inter-Domain Routing (CIDR): an Address Assignment and Aggregation Strategy

Table 374: Supported request for comments (continued)

Request for comment	Description
RFC 1541	Dynamic Host Configuration Protocol
RFC 1542	Clarifications and Extensions for the Bootstrap Protocol
RFC 1573	Interface MIB
RFC 1587	The OSPF NSSA Option
RFC 1591	DNS Client
RFC 1650	Definitions of Managed Objects for the Ethernet-like Interface Types
RFC 1657	BGP-4 MIB using SMIv2
RFC 1723	RIP v2 — Carrying Additional Information
RFC 1812	Router requirements
RFC 1866	Hypertext Markup Language version 2 (HTMLv2) protocol
RFC 1981	Path MTU discovery
RFC 1907	Management Information Base for Version 2 of the Simple Network Management Protocol (SNMPv2)
RFC 1930	Guidelines for creation, selection, and registration of an Autonomous System (AS)
RFC 2021	Remote Network Monitoring (RMON) MIB using SMIv2
RFC 2068	Hypertext Transfer Protocol
RFC 2080	RIP
RFC 2131	Dynamic Host Control Protocol (DHCP)
RFC 2132	DHCP Options and BOOTP Vendor Extensions
RFC 2138	RADIUS Authentication
RFC 2139	RADIUS Accounting
RFC 2178	OSPF MD5 cryptographic authentication / OSPFv2
RFC 2233	The Interfaces Group MIB using SMIv2
RFC 2236	IGMPv2 Snooping
RFC 2358	Definitions of Managed Objects for the Ethernet-like Interface Types
RFC 2284	PPP Extensible Authentication Protocol

RFC 5321	Simple Mail Transfer Protocol
RFC 5340	OSPF for IPv6

Table 374: Supported request for comments (continued)

Request for comment	Description
RFC 5746	Secure SSL Renegotiation
RFC 5798	Virtual Router Redundancy Protocol (VRRP) Version 3 for IPv4 and IPv6
RFC 5905	Network Time Protocol Version 4: Protocol and Algorithms Specification
RFC 5997	Use of Status-Server Packets in the Remote Authentication Dial In User Service (RADIUS) Protocol
RFC 6105	IPv6 Router Advertisement Guard
RFC 6329	IS-IS Extensions supporting Shortest Path Bridging
RFC 7047	The Open vSwitch Database Management Protocol
RFC 7348	Virtual Extensible LAN (VXLAN)
RFC 7610	DHCPv6 Shield
RFC 7627	Transport Layer Security (TLS) Session Hash and Extended Master Secret Extension

Standard MIBs

The following table details the standard MIBs that the switch supports.

Table 375: Supported MIBs

Standard MIB name	Institute of Electrical and Electronics Engineers/ Request for Comments (IEEE/RFC)	File name
STD MIB2— Link Aggregation Control Protocol (LACP) (802.3ad)	802.3ad	ieee802-lag.mib
STD MIB3—Extensible Authentication Protocol Over Local Area Networks (EAPoL) (802.1x)	802.1x	ieee8021x.mib
STD MIB4—Internet Assigned Numbers Authority (IANA) Interface Type		iana_if_type.mib
STD MIB5—Structure of Management Information (SMI)	RFC1155	rfc1155.mib

Table 375: Supported MIBs (continued)

Standard MIB name	Institute of Electrical and Electronics Engineers/ Request for Comments (IEEE/RFC)	File name
STD MIB6—Simple Network Management Protocol (SNMP)	RFC1157	rfc1157.mib
STD MIB7—MIB for network management of Transfer Control Protocol/Internet Protocol (TCP/IP) based Internet MIB2	RFC1213	rfc1213.mib
STD MIB8—A convention for defining traps for use with SNMP	RFC1215	rfc1215.mib
STD MIB10—Definitions of Managed Objects for Bridges	RFC1493	rfc1493.mib
STD MIB11—Evolution of the Interface Groups for MIB2	RFC2863	rfc2863.mib
STD MIB12—Definitions of Managed Objects for the Ethernet-like Interface Types	RFC1643	rfc1643.mib
STD MIB15—Remote Network Monitoring (RMON)	RFC2819	rfc2819.mib
STD MIB17—Management Information Base of the Simple Network Management Protocol version 2 (SNMPv2)	RFC1907	rfc1907.mib
STD MIB21—Interfaces Group MIB using SMIv2	RFC2233	rfc2233.mib
STD MIB26b—Message Processing and Dispatching for the SNMP	RFC2572	rfc2572.mib
STD MIB26c—SNMP Applications	RFC2573	rfc2573.mib
STD MIB26d—User-based Security Model (USM) for version 3 of the SNMP	RFC2574	rfc2574.mib
STD MIB26e—View-based Access Control Model (VACM) for the SNMP	RFC2575	rfc2575.mib

Table 375: Supported MIBs (continued)

Standard MIB name	Institute of Electrical and Electronics Engineers/ Request for Comments (IEEE/RFC)	File name
STDMIB26f—Coexistence between Version 1, Version 2, and Version 3 of the Internet-standard Network Management Framework	RFC2576	rfc2576.mib
STDMIB29—Definitions of Managed Objects for the Virtual Router Redundancy Protocol	RFC2787	rfc2787.mib
STDMIB31—Textual Conventions for Internet Network Addresses	RFC2851	rfc2851.mib
STDMIB32—The Interface Group MIB	RFC2863	rfc2863.mib
STDMIB33—Definitions of Managed Objects for Remote Ping, Traceroute, and Lookup Operations	RFC2925	rfc2925.mib
STDMIB35—Internet Group Management Protocol MIB	RFC2933	rfc2933.mib
STDMIB36—Protocol Independent Multicast MIB for IPv4	RFC2934	rfc2934.mib
STDMIB38—SNMPv3 These Request For Comments (RFC) make some previously named RFCs obsolete	RFC3411, RFC3412, RFC3413, RFC3414, RFC3415	rfc2572.mib, rfc2573.mib, rfc2574.mib, rfc2575.mib
STDMIB39—Entity Sensor Management Information Base	RFC3433	
STDMIB40—The Advanced Encryption Standard (AES) Cipher Algorithm in the SNMP User-based Security Model	RFC3826	rfc3826.mib
STDMIB41—Management Information Base for the Transmission Control protocol (TCP)	RFC4022	rfc4022.mib
STDMIB43—Management Information Base for the User Datagram Protocol (UDP)	RFC4113	rfc4113.mib

Table 375: Supported MIBs (continued)

Standard MIB name	Institute of Electrical and Electronics Engineers/ Request for Comments (IEEE/RFC)	File name
Q-BRIDGE-MIB — Management Information Base for managing Virtual Bridged LANs	RFC4363	q-bridge.mib
LLDP-EXT-MED-MIB — LLDP-MED	ANSI/TIA-1057	lldpExtMed.mib

Proprietary MIBs

The following table details the proprietary MIBs that the switch supports.

Table 376: Proprietary MIBs

Proprietary MIB name	File name
Extreme Networks Energy Saver MIB	bayStackNes.mib
Extreme Networks Link-state tracking (LST) MIB	bayStackLinkStateTracking.mib
Extreme Networks IGMP MIB	rfc_igmp.mib
Extreme Networks IP Multicast MIB	ipmroute_rcc.mib
Extreme Networks MIB definitions	wf_com.mib
Extreme Networks PIM MIB	pim-rcc.mib
Extreme Networks RSTP/MSTP proprietary MIBs	nnrst000.mib, nnmst000.mib
Other SynOptics definitions	s5114roo.mib
Other SynOptics definitions	s5emt103.mib
Other SynOptics definitions	s5tcs112.mib
Other SynOptics definition for Combo Ports	s5ifx.mib
Other SynOptics definition for PoE	bayStackPethExt.mib
Rapid City MIB Note: The MACsec tables, namely, rcMACSecCATable and rcMACSecIfConfigTable are a part of the Rapid City MIB.	rapid_city.mib
SynOptics Root MIB	synro.mib

ICMPv6 Type and Code

The Internet Control Message Protocol (ICMPv6) uses many messages identified by a type and code field (see RFC 4443). Error messages use message types 0 to 127. Informational messages use message types 128 to 255. The following table provides the type and code reference.

Table 377: ICMPv6 type and code details

Type	Name	Code	Reference
1	Destination Unreachable	0—no route to destination 1—communication with destination administratively prohibited 2—(not assigned) 3—address unreachable 4—port unreachable	RFC 4443
2	Packet Too Big		RFC 4443
3	Time Exceeded	0—hop limit exceeded in transit 1—fragment reassembly time exceeded	RFC 4443
4	Parameter Problem	0—erroneous header field encountered 1—unrecognized Next Header type encountered 2—unrecognized IPv6 option encountered	RFC 4443
128	Echo Request		RFC 4443
129	Echo Reply		RFC 4443
130	Multicast Listener Query		
131	Multicast Listener Report		

Table 377: ICMPv6 type and code details (continued)

Type	Name	Code	Reference
132	Multicast Listener Done		
133	Router Solicitation		RFC 4861
134	Router Advertisement		RFC 4861
135	Neighbor Solicitation		RFC 4861
136	Neighbor Advertisement		RFC 4861
137	Redirect Message		RFC 4861
138	Router Renumbering	0—router renumbering command 1—router renumbering result 255—sequence number reset	
139	ICMP Node Information Query		
140	ICMP Node Information Response		
141	Inverse neighbor discovery Solicitation Message		RFC 3122
142	Inverse neighbor discovery Advertisement Message		RFC 3122
143	Version 2 Multicast Listener Report		RFC 3810
144	Home Agent Address Discovery Request Message		RFC 3775
145	Home Agent Address Discovery Reply Message		RFC 3775
146	Mobile Prefix Solicitation		RFC 3775
147	Mobile Prefix Advertisement		RFC 3775
