The existing ACL match criteria `icmp-type type` is exposed in dynamic ACLs and static ACL policies on the target platforms. This same match criteria is already supported for rules that specify IPv4 criteria on the target platforms.

### *Example Policy*

Here is a policy to detect and log a “simple” RA attack, only allow TCP/UDP/ICMP/xyz protocol traffic that can be parsed (i.e., has up to 2 extension headers and, if fragmented, the L4 NH is contained in the first fragment), and deny everything else including “complex” RA attacks:

```
entry disallow_and_log_RA_attacks
{
 if
 {protocol icmpv6; icmp-type 134;}
 then
 { deny; mirror-cpu; log; count RA_attack;}}
entry allow_tcp
{
 if {protocol tcp; first-fragments;}
 then {permit;}}
entry allow_udp
{
 if {protocol udp; first-fragments;}
 then {permit;}}
entry allow_icmp
{
 if {protocol icmpv6; first-fragments;}
 then {permit;}}
entry allow_xyz...entry denyall
{
 if{first-fragments; }
 then
 {
 deny;}}
```

The above policy works for newer chipsets, but leaves (at least) the following exposure for older chipsets: a malicious user could send an RA with a single extension header and it would be allowed to pass due to rule “allow\_icmp” (newer chipsets would block this packet through the first rule). To mitigate this exposure on older chipsets, you

could call out each “icmp-type” that is supported (ND, MLD, etc.), and then drop any ICMPv6 with an extension header.

For more information, please refer to <http://tools.ietf.org/html/draft-ietf-v6ops-ra-guard-implementation-04>.

## Managing Duplicate Address Detection

---

The Duplicate Address Detection (DAD) feature checks networks attached to a switch to see if IP addresses configured on the switch are already in use on an attached network. The following sections provide additional information on the DAD feature:

- [DAD Overview](#) on page 943
- [Configure DAD](#)
- [Display DAD Configuration and Statistics](#) on page 944
- [Clear the DAD Counters](#)

When you configure an active interface with an IPv6 address, the interface must send out an advertisement containing its address.

All other interfaces on the subnet have the opportunity to respond to the newly configured interface, and inform it that the address is a duplicate. Only after this process occurs, can the interface use the newly configured address. If the interface receives a message that the newly configured address is a duplicate, it cannot use the address.

Until the Duplicate Address Detection (DAD) process completes, the new address is considered tentative, and will be shown as such in any display output. If the address is a duplicate, it will also be labeled as such, and must be reconfigured. On an active interface, the DAD process should occur so quickly that you would not see the address labeled as tentative. However, if you are configuring an interface before enabling it, and you display the configuration, you will see that the address is currently tentative. As soon as you enable the interface, the address should be ready to use, or labeled as duplicate and must be reconfigured.

See RFC 2462, IPv6 Stateless Address Autoconfiguration, for more details.

### DAD Overview

When administratively enabled on a VR, Duplicate Address Detection (DAD) runs when an IPv6 address is added to a VLAN, the VLAN transitions to an operational state, or when the first valid link-local address is added to the VLAN.

DAD works by sending a neighbor solicitation for each IPv6 address configured on a VLAN. If another device replies to the neighbor solicitations by sending neighbor advertisements for any of these IPv6 addresses, the referenced IPv6 addresses are marked duplicate and are not used. If no responses are received, the IPv6 addresses become active and available for subsequent use. Once an IPv6 address becomes active, DAD does not run again for that address unless that address is deleted and re-added,

the VLAN goes down and comes back up, or the first valid link-local address is added to the VLAN.

IPv6 functionality requires at least one valid link-local address. If the last valid link-local address is marked duplicate, all non-duplicate IPv6 addresses become tentative.

## Configure DAD

- Enable or disable the DAD feature and configure feature operation.

```
configure ipv6 dad [off | on | {on} attempts max_solicitations] [{vr}
vr_name | vr all]
```

### Note

For IPv6 interfaces, the DAD feature is automatically enabled on all platforms that support the Edge (or higher) or Base (or higher) licenses.

### Display DAD Configuration and Statistics

- Display DAD configuration and statistics information.

```
show ipv6 dad [{vr} vr_name {ip_address} | vr all | [{ vlan }
vlan_name | vlan vlan_list] {tentative | valid | duplicate} | [{vr}
vr_name} ipaddress] | {tunnel} tunnel_name]
```

### Clear the DAD Counters

- Clear the DAD feature statistics counters.

```
clear ipv6 dad [{vr} vr_name {ipaddress} | vr all | {vlan} vlan_name]
{counters}
```

## Populating the Routing Table

The switch maintains an IP routing table for both network routes and host routes. The table is populated from the following sources:

- Dynamically, by way of routing protocol packets or by ICMP redirects exchanged with other routers
- Statically, by way of routes entered by the administrator:
  - Default routes, configured by the administrator
  - Locally, by way of interface addresses assigned to the system
  - By other static routes, as configured by the administrator

Once routes are populated using the above method, IPv6 forwarding needs to be enabled on the VLAN using the following command:

```
enable ipforwarding ipv6 {vlan vlan_name | tunnel tunnel_name | vr
vr_name}
```

**Note**

If you define a default route and subsequently delete the VLAN on the subnet associated with the default route, the invalid default route entry remains. You must manually delete the configured default route.

### Dynamic Routes

Dynamic routes are typically learned by enabling the *RIP (Routing Information Protocol)*, *OSPF (Open Shortest Path First)*, IS-IS or *BGP* protocols, and are also learned from *ICMP* redirects exchanged with other routers. These routes are called dynamic routes because they are not a permanent part of the configuration. The routes are learned when the router starts up and are dynamically updated as the network changes. Older dynamic routes are aged out of the tables when an update for the network is not received for a period of time, as determined by the routing protocol.

Once a routing protocol is configured, dynamic routes require no configuration and are automatically updated as the network changes.

### Static Routes

Static routes are routes that are manually entered into the routing tables and are not advertised through the routing protocols. Static routes can be used to reach networks that are not advertised by routing protocols and do not have dynamic route entries in the routing tables. Static routes can also be used for security reasons, to create routes that are not advertised by the router.

Static routes are configured in the ExtremeXOS software, remain part of the configuration when the switch is rebooted, and are immediately available when the switch completes startup. Static routes are never aged out of the routing table, however, the Bidirectional Forwarding Detection (BFD) feature, can be used to bring down static routes when the host link fails.

Without BFD, static routes always remain operationally active because there is no dynamic routing protocol to report network changes. This can lead to a black hole situation, where data is lost for an indefinite duration. Because upper layer protocols are unaware that a static link is not working, they cannot switch to alternate routes and continue to use system resources until the appropriate timers expire.

With BFD, a static route is marked operationally inactive if the BFD session goes down. Upper layer protocols can detect that the static route is down and take the appropriate action.

A default route is a type of static route that identifies the default router interface to which all packets are routed when the routing table does not contain a route to the packet destination. A default route is also called a default gateway.

### ExtremeXOS Resiliency Enhancement for IPv6 Static Routes

The ExtremeXOS Resiliency Enhancement feature provides a resilient way to use *ECMP (Equal Cost Multi Paths)* to load balance IPv6 traffic among multiple servers

or other specialized devices. ExtremeXOS automatically manages the set of active devices using ECMP static routes configured with ping protection to monitor the health of these routes. Such servers or specialized devices do not require special software to support Bidirectional Forwarding Detection (BFD), or IP routing protocols such as *OSPF*, or proprietary protocols to provide keepalive messages. ExtremeXOS uses industry-standard and required protocols ICMPv6/Neighbor Discovery for IPv6 to accomplish the following automatically:

- Initially verify devices and activate their static routes, without waiting for inbound user traffic, and without requiring configuration of device MAC addresses.
- Detect silent device outages and inactivate corresponding static routes.
- Reactivate static routes after device recovery, or hardware replacement with a new MAC address.

ExtremeXOS currently supports similar protection and resiliency using Bidirectional Forwarding Detection (BFD) on IPv4 and IPv6 static routes. However, BFD can only be used when the local and remote device both support BFD.

### *Multiple Routes*

When there are multiple, conflicting choices of a route to a particular destination, the router picks the route with the longest matching network mask. If these are still equal, the router picks the route using the following default criteria (in the order specified):

- Directly attached network interfaces
- Static routes
- *ICMP* redirects
- Dynamic routes
- Directly attached network interfaces that are not active.

#### **Note**

If you define multiple default routes, the route that has the lowest metric is used. If multiple default routes have the same lowest metric, the system picks one of the routes.

The criteria for choosing from multiple routes with the longest matching network mask is set by choosing the relative route priorities.

### Relative Route Priorities

Table 62 lists the relative priorities assigned to routes depending on the learned source of the route.

#### Note

Although these priorities can be changed, do not attempt any manipulation unless you are expertly familiar with the possible consequences.

**Table 62: Relative Route Priorities**

| Route Origin   | Priority |
|----------------|----------|
| Direct         | 10       |
| BlackHole      | 50       |
| Static         | 1100     |
| HostMobility   | 1150     |
| ICMP           | 1200     |
| Auto-peering   | 1699     |
| OSPFv3Intra    | 2200     |
| OSPFv3Inter    | 2300     |
| IS-IS          | 2350     |
| IS-IS L1       | 2360     |
| IS-IS L2       | 2370     |
| RIPng          | 2400     |
| OSPFv3 AExt    | 3100     |
| OSPFv3 Extern1 | 3200     |
| OSPFv3 Extern2 | 3300     |
| IS-IS L1Ext    | 3400     |
| IS-IS L2Ext    | 3500     |
| EBGP           | 1700     |
| IBGP           | 1900     |

To change the relative route priority, use the following command:

```
configure iproute ipv6 priority [auto-peering | ripng | blackhole |
icmp | host-mobility | static | ospfv3-intra | ospfv3-inter | ospfv3-as-
external | ospfv3-extern1 | ospfv3-extern2 | isis | isis-level-1 | isis-
level-2 | isis-level-1-external | isis-level-2-external | ebgp | ibgp]
priority {vr vr_name}
```

Route priority configurable value is between 11-65,534.

## Unique Local Address (ULA) for IPv6

RFC 4193 defines a globally unique address that is used for local communications. For instance, they are routable within a specified site or between sites. These ULAs are similar to private addresses in IPv4 (RFC 1918).

Of the 128 bits available in IPv6 address, the last 64-bits are used as the interface ID.

The remaining 64 bits are used as follows:

First 8 bits are used to define the known prefix FC00::/7 or FD00::/7

40 bits - global ID - Generated using a random algorithm specified in the RFC 4193. ExtremeXOS expects the operator to specify the 40-bit Global ID as ULA address management becomes easier, especially a multi-vendor environment.

16 bits - Used to create subnets within the site.

ULA prefixes should not be accepted by the border routers.

Additionally, ULA prefixes should not be advertised by the border routers. In ExtremeXOS, for *BGP* and *OSPFv3*, you must specify the policies to filter ULA prefixes.

There are no new CLI commands introduced to configure ULAs in ExtremeXOS. You can use the following existing command to configure a ULA:

```
configure {vlan} vlan_name ipaddress [ipaddress {ipNetmask} |
ipv6-link-local | {eui64} ipv6_address_mask]
```

Here is an example of the command:

```
configure vlan v1 ipaddress fd21:0941:2c55::/48
```

The scope of ULA is global by default in RFC 4193.

All applications treat these addresses in a similar manner as any other type of global IPv6 unicast addresses.

## Managing IPv6 Unicast Routing

You should be familiar with IP Route Sharing for both IPv4 and IPv6. For information about IP route sharing, see [Configuring IP Route Sharing](#) on page 891.

For SummitStack and ExtremeSwitching series switches that support Layer 3 routing, the ExtremeXOS software supports route sharing across up to 2, 4, 8, 16, or 32 next-hop gateways.

## Enabling Route Sharing for IPv6

To enable route sharing for IPv6, use the following command:

```
enable iproute ipv6 sharing
```

## Configuring Basic IP Unicast Routing

To configure basic IP unicast routing, do the following:

1. Create and configure two or more [VLANs](#).
2. Assign each VLAN that will be using routing an IP address using the following command:

```
configure {vlan} vlan_name ipaddress [ipaddress {ipNetmask} | ipv6-
link-local | {eui64} ipv6_address_mask]
```

Ensure that each VLAN has a unique IP address.

3. Configure a static route using the following command:

```
configure iproute add ipv6Netmask [ipv6Gateway | ipv6ScopedGateway]
{metric} {vr vr_name} {multicast | multicast-only | unicast | unicast-
only}
```

or

Configure a default route using the following command:

```
configure iproute add default [{gateway {metric} {vr vr_name}
{unicast-only | multicast-only}} | {lsp lsp_name {metric}}]
```

Default routes are used when the router has no other dynamic or static route to the requested destination.

4. Turn on IP routing for one or all VLANs using the following command:

```
enable ipforwarding ipv6 {vlan vlan_name | tunnel tunnel_name | vr
vr_name}
```

5. Configure the routing protocol, if required. For a simple network using [RIPng](#), default configuration might be acceptable.
6. Turn on RIPng or [OSPFv3](#) using one of the following commands:

```
enable ripng
```

```
enable ospfv3
```

### Note

[BGP](#) does not use ECMP by default, so if you require that functionality you must explicitly issue the `configure bgp maximum-paths max-paths` command with a value greater than 1.

## Managing Router Discovery

### Enable and Disable Router Discovery

- Enable or disable router discovery on a [VLAN](#).  

```
enable router-discovery {ipv6} vlan vlan_name
```

```
disable router-discovery {ipv6} vlan vlan_name
```

*Add and Delete Prefixes for Router Discovery*

- Add or delete prefixes for advertisement by router discovery.

```
configure vlan vlan_name router-discovery {ipv6} add prefix prefix
```

```
configure vlan vlan_name router-discovery {ipv6} delete prefix [prefix
| all]
```

*Configure Router Discovery Settings*

- Configure the router discovery settings using the following commands:
  - `configure vlan vlan_name router-discovery {ipv6} default-lifetime defaultlifetime`
  - `configure vlan vlan_name router-discovery {ipv6} link-mtu linkmtu`
  - `configure vlan vlan_name router-discovery {ipv6} managed-config-flag on_off`
  - `configure vlan vlan_name router-discovery {ipv6} max-interval maxinterval`
  - `configure vlan vlan_name router-discovery {ipv6} min-interval mininterval`
  - `configure vlan vlan_name router-discovery {ipv6} other-config-flag on_off`
  - `configure vlan vlan_name router-discovery {ipv6} reachable-time reachablename`
  - `configure vlan vlan_name router-discovery {ipv6} retransmit-time retransmittime`
  - `configure vlan vlan_name router-discovery {ipv6} set prefix prefix [autonomous-flag auto_on_off | onlink-flag onlink_on_off | preferred-lifetime preflife | valid-lifetime validlife]`
- Reset all router discovery settings to their default values using the command:
 

```
unconfigure vlan vlan_name router-discovery {ipv6}
```
- To reset an individual router discovery setting to its default value, enter one of the following commands:
  - `unconfigure vlan vlan_name router-discovery {ipv6} default-lifetime`
  - `unconfigure vlan vlan_name router-discovery {ipv6} hop-limit`
  - `unconfigure vlan vlan_name router-discovery {ipv6} link-mtu`
  - `unconfigure vlan vlan_name router-discovery {ipv6} managed-config-flag`
  - `unconfigure vlan vlan_name router-discovery {ipv6} max-interval`
  - `unconfigure vlan vlan_name router-discovery {ipv6} min-interval`
  - `unconfigure vlan vlan_name router-discovery {ipv6} other-config-flag`
  - `unconfigure vlan vlan_name router-discovery {ipv6} reachable-time`
  - `unconfigure vlan vlan_name router-discovery {ipv6} retransmit-time`

### Display Router Discovery Configuration Settings

To display router discovery settings, use the command: `show router-discovery {ipv6} {vlan vlan_name}`

## Managing Tunnels

IPv6-in-IPv4 and IPv6-to-IPv4 tunnels are introduced in [Tunnels](#) on page 935.

### Create an IPv6-in-IPv4 Tunnel

- Create an IPv6-in-IPv4 tunnel.

```
create tunnel tunnel_name ipv6-in-ipv4 destination destination-address
source source-address
```

The *source-address* refers to an existing address in the switch, and the *destination-address* is a remote destination accessible from the switch. A maximum of 255 IPv6-in-IPv4 tunnels can be configured.

### Create an IPv6-in-IPv4 Tunnel

- Create an IPv6-in-IPv4 tunnel.

```
create tunnel tunnel_name ipv6-in-ipv4 destination destination-address
source source-address
```

The *source-address* refers to an existing address in the switch, and the *destination-address* is a remote destination accessible from the switch. A maximum of 255 IPv6-in-IPv4 tunnels can be configured.

### Delete a Tunnel

To delete a tunnel, use the command: `delete tunnel tunnel_name`

### Configure an IPv6 Address for a Tunnel

To configure or unconfigure IPv6 addresses for the tunnels, use the commands:

```
configure tunnel tunnel_name ipaddress [ipv6-link-local | {eui64}
ipv6_address_mask]
```

```
unconfigure tunnel tunnel_name ipaddress ipv6_address_mask
```

### Display Tunnel Information

- Display tunnel information.

```
show [{tunnel} {tunnel_name}]
```

## Verifying the IP Unicast Routing Configuration

- To display the currently configured routes, which includes how each route was learned, use the command: `show iproute ipv6`

Additional verification commands include:

- `show neighbor-discovery cache ipv6`—Displays the neighbor discovery cache of the system.
- `show ipconfig ipv6`—Displays configuration information for one or more VLANs.
- `show ipstats ipv6`—Displays the IPv6 statistics for the switch for the specified VLANs.

## Managing IPv6 Routes and Hosts in External Tables

When external LPM tables are supported and configured on a switch, the configuration setting applies only to the external LPM tables. You can configure the external LPM to contain both IPv4 and, or, IPv6 routes. Internal LPM tables only store IPv4 routes.

The configure forwarding external-tables command using the ipv6 and ipv4-and-ipv6 variables supports larger IPv6 route and host scaling in external LPM tables.

When an external LPM table is configured for I3-only ipv6, no IPv6 routes or IPv6 hosts are configured in any of the internal hardware tables. This provides the highest IPv6 scale, and avoids contention with IP Multicast in the L3 Hash hardware table.

IPv6 hardware and slowpath forwarding are supported on user-created Virtual Routers, and IPv6 tunnels are only supported on *VR-Default*.

The size of the internal LPM tables, and the size of the L3 Hash and Next Hop tables are fixed. For specific information on hardware capacity, refer to the following table, the following table, and the following table in [IPv4 Unicast Routing](#).

## IPv6 ECMP and 32-Way ECMP

This feature adds IPv6 Equal-Cost Multi-Path (ECMP) support on several new platforms. Additionally, it adds support for 16-way and 32-way ECMP (for both IPv4 and IPv6), using static routes, and up to 8-way ECMP for IPv4 and IPv6 using routing protocols .

Sharing ECMP gateway sets now applies to IPv6 as well as IPv4. Sharing ECMP gateway sets for IPv6 means the entire IPv6 Longest-Prefix Match (LPM) hardware capacity can use ECMP, across up to 32 gateways.

## Feature Description

This feature adds IPv6 ECMP support on all platforms.

Additionally, ExtremeXOS supports 16-way and 32-way ECMP for both IPv4 and IPv6 using static routes, and up to 8-way ECMP for IPv4 and IPv6 using routing protocols. Now, the maximum number of gateways in each IPv4 or IPv6 gateway set in the ECMP hardware table can be configured as 16 or 32.

## DHCPv6 Relay Remote-ID Option

Available in ExtremeXOS 15.5, the remote-id option is added to the relay forward IPv6 message, if the specific VLAN has only the link local IPv6 address. This remote-id is added to all the request packets received from the client on that VLAN, if it is configured or not on the VLAN. The remoteID option added to the packet after the relay message header has the following format, as defined in RFC 4649:

**Figure 104: DHCPv6 Relay Remote-ID Option**

If the remote-id is configured through the CLI on a specified VLAN, it can have either a user defined value, or the system-name. If the user does not configure the value or marks “none” as the remote-id, the switch MAC address will be used as the remote-id. The value of the remote-id present in the packet will have the following format: `vlan_port_<remoteId>`, where *remoteId* will be either the configured string, or the system name or the switch MAC address. The Enterprise number field will be populated with the Extreme Networks enterprise number, “1916”.

The remote-id is added to the packets on a specified VLAN, only if:

- IPv6 bootprelay is enabled on the VLAN.
- the vlan has only the link local address.

Once a relay agent receives one of the following messages from the client or relay agent, the relay agent will verify if the specific interface has only the link local address:

- DHCPV6\_SOLICIT
- DHCPV6\_REQUEST
- DHCPV6\_CONFIRM
- DHCPV6\_RENEW
- DHCPV6\_REBIND
- DHCPV6\_RELEASE
- DHCPV6\_DECLINE
- DHCPV6\_INFORMATION\_REQUEST

- DHCPV6\_RELAY\_FORW
- DHCPV6\_LEASEQUERY

If so, it verifies if the specific VLAN has a remote-id configured. If a remote-id is present, it is added to the packet along with the VLAN and port, in the format mentioned above. If it is not configured, the default (switch MAC address) will be added as the remote id, along with the VLAN and port.

On the reverse path, if it receives any of the following messages from the server or any other relay agent, and if the interface has only a link local address, it will verify for the presence of remote-id in the packet:

- DHCPV6\_ADVERTISE
- DHCPV6\_REPLY
- DHCPV6\_RECONFIGURE
- DHCPV6\_RELAY\_FORW
- DHCPV6\_LEASEQUERY\_REPLY

If it is not present, the agent will check for the interface-id. If one of these is present, it will verify if the value matches the local configuration. If it matches, after removing the remote-id and/or interface-id, the packet will be forwarded to the respective client. If the remote-id is present in the packet, and it does not match the configured value, the packet will be dropped. If none of them are present, the packet will be forwarded to the client, based on the IPv6 address of the VLAN.

## DHCPv6 Relay Agent Prefix Delegation

---

DHCPv6 Prefix Delegation options provide a mechanism for automated delegation of IPv6 prefixes using *DHCP (Dynamic Host Configuration Protocol)*. This mechanism is intended for delegating a long-lived prefix from a delegating router to a requesting router, across an administrative boundary, where the delegating router does not have/require knowledge about the topology of the networks to which the requesting router is attached, and the delegating router does not require other information aside from the identity of the requesting router to choose a prefix for delegation.

For example, these options would be used by a service provider to assign a prefix to a Customer Premise Equipment (CPE) device acting as a router between the subscriber's internal network and the service provider's core network.

This prefix delegation mechanism is appropriate for use by an ISP to delegate a prefix to a subscriber, where the delegated prefix would possibly be sub-netted and assigned to the links within the subscriber's network.

**Figure 105: Prefix Delgation Example**

The prefix delegation process begins when the requesting router requests configuration information through DHCP. When the delegating router receives the request, it selects and returns an available prefix or prefixes for delegation to the requesting router.

The requesting router now acts as a DHCP server for the subscriber network. It subnets the delegated prefix and assigns the longer prefixes to links in the subscriber's network. In a typical scenario based on the network shown in Figure 1, the requesting router subnets a single delegated /48 prefix into /64 prefixes and assigns one /64 prefix to each of the links in the subscriber network.

Prefix delegation with DHCP is independent of address assignment with DHCP. A requesting router can use DHCP for just prefix delegation or for prefix delegation along with address assignment and other configuration information.

## Relay Agent Behavior in Prefix Delegation

A relay agent forwards DHCP messages containing Prefix Delegation options in the same way as other DHCP messages.

RFC 3633 says "If a delegating router communicates with a requesting router through a relay agent (sitting in between the Aggregation device (PE) and the CPE), the delegating router may need a protocol or other out-of-band communication to add routing information for delegated prefixes into the provider edge router."

The requesting router acts as a DHCPv6 server behind the CPE and assigns IPv6 subnets to the customer devices. Since there is no mechanism to notify the delegating router about the IPv6 subnets assigned by the requesting router, the core routers have no clue about these IPv6 subnets and therefore have no dynamic route added into the routing tables in the core. RFC 3633 leaves it to the implementations to devise a mechanism to solve this problem.

When the ExtremeXOS DHCPv6 relay agent relays the DHCP messages with IA\_PD options and detects that a successful prefix delegation operation has been completed and a prefix or a set of prefixes have been delegated, it installs one route for each of prefixes that has been delegated. This ensures reachability between the customer devices and the service provider network.

When ExtremeXOS DHCPv6 relay agent detects a successful DHCP prefix delegation transaction (Solicit-Advertise-Request-Reply), it looks into the details of the prefix(es) that are being delegated. Each DHCP message with IA\_PD option can have multiple IAPREFIX options in it. Each IAPREFIX option represents a prefix that is being delegated.

ExtremeXOS DHCPv6 relay agent installs one route for each of the delegated prefixes. The route is installed on the VLAN on which the requesting router (CPE) is reachable and with the requesting router (CPE) as the gateway for the route, if the requesting router is directly connected to our ExtremeXOS DHCPv6 Relay agent. If the DHCPv6 messages from the requesting router have been received via another DHCPv6 Relay agent, the route is installed with the next hop DHCPv6 Relay agent as the gateway. If the DHCPv6 packets from the next hop DHCPv6 Relay agent have been IPv6 forwarded via other routers in between (which did not do DHCPv6 Relay, but just IPv6 forwarding), the next hop router to reach the next hop DHCPv6 Relay agent is used as the gateway for the route. ExtremeXOS DHCPv6 Relay uses Route Manager (rtMgr) client library APIs for adding and deleting these routes.

To ensure that the routes are retained across reboots (or restart process netTools), ExtremeXOS DHCPv6 relay agent stores these routes along with their validity times in an internal file. After a reboot, ExtremeXOS DHCPv6 relay agent reads this file and installs the routes once again. This file will be a flat file with the following format:

```
vlanName ipv6Prefix ipv6GatewayAddr startTime validTime.
```

Only those IPv6 prefixes which are still valid after the reboot are added again. The expired IPv6 prefixes are discarded. As the file format denotes, this file contains the details about the VLAN, the actual delegated IPv6 prefix, the IPv6 Gateway Address, the start time when it got delegated and the time for which the delegated prefix is deemed to be valid (in seconds). This file is internal to ExtremeXOS DHCPv6 relay agent and cannot/should not be edited by anyone else.

ExtremeXOS DHCPv6 relay agent checkpoints the prefix delegations that have been detected.

#### *Basic Snooping Configuration*

```
create vlan v1

enable bootprelay ipv6
```

```

conf bootprelay ipv6 prefix-del snooping on vlan v1

con bootprelay ipv6 prefix-delegation snooping add 5001:db8:3553:bf00::/56
fe80::a440:cf5:c05b:d324 vlan v1 valid-time 300

* (Engineering) Slot-1 Sharmila_DUT1_Stack-->.13 # sh bootprelay ipv6 prefix-delegation
snooping

```

## DHCPv6 Client

### Note

With ExtremeXOS 30.3, ISC DHCPv6 client version is upgraded to dhcp-4.4.1.

ExtremeXOS supports Dynamic Host Configuration Protocol version 6 (DHCPv6) clients, receiving its IPv6 address and corresponding parameters for any VLAN interface from an external DHCPv6 server. For the ExtremeXOS device to operate as a DHCPv6 client, we need to enable DHCPv6 client on a VLAN interface to obtain an IPv6 address from the DHCPv6 server in the network.

ExtremeXOS DHCPv6 client supports only the stateful DHCPv6 mode of operation in this release. This means an external DHCPv6 server is required to configure the IPv6 address and its related configurations.

**Note**

Stateless Auto configuration and stateless DHCPv6 modes are not supported in this release.

The mode of operation of the DHCPv6 client is based on the autonomous (A), managed (M) and other configuration (O) flags in the received router advertisement (RA) messages. If the managed bit is 1 and the other configuration bit is 0, the DHCPv6 client will act as a stateful client. In stateful mode, the client receives IPv6 addresses from the DHCPv6 server, based on the identity association for nontemporary addresses (IA\_NA) assignment.

In other words ExtremeXOS DHCPv6 client sends IA\_NA option as part of the DHCPv6 message.

**Note**

Identity association for temporary address (IA\_TA) and Identity association for prefix delegation (IA\_PD) is not supported in this release.

If the incoming RA points to act the interface in stateless DHCPv6 mode (managed bit is 0 and the other configuration bit is 1) or DHCPv6 auto configuration mode (autonomous bit is 1 and managed, other configuration bit is 0) ExtremeXOS will release the assigned (if already assigned using stateful DHCPv6 client mode) DHCPv6 IP and other parameters for this VLAN interface on which this RA is received.

This is because the mode of operation needs to be changed because ExtremeXOS did not support stateless DHCPv6 and auto configuration DHCPv6 client modes and there will not be any subsequent operation. In the stateful DHCPv6 client mode, the DHCPv6 client requests global addresses from the DHCPv6 server. Based on the DHCPv6 server's response, the DHCPv6 client assigns the global addresses to interfaces and sets a lease time for all valid responses. When the lease time expires, the DHCPv6 client renews the lease from the DHCPv6 server. To configure stateful DHCPv6 client based on identity association of non-temporary (IA\_NA) address assignment for a VLAN interface use the following command.

```
enable dhcp ipv6 vlan vlan_name
```

To unconfigure the stateful DHCPv6 client for an interface use:

```
disable dhcp ipv6 vlan vlan_name
```

To display the current status of the DHCPv6 client VLAN state use:

```
show dhcp-client ipv6 state {vlan}
```

DHCPv6 client is not supported on VR-MGMT.

## DHCP Unique Identifier

Each *DHCP* client and server has a DHCP unique identifier (DUID). A DHCP server uses DUIDs to identify clients for the selection of configuration parameters. DHCP clients use DUIDs to identify a server in messages where a server needs to be identified. Clients and servers treat DUIDs as opaque values and use it compare for equality.

The DUID is not required in all the DHCP messages. It has to be unique across all DHCP clients and servers. It has to be stable for any specific client or server - for example, a device's DUID should not change as a result of a change in the *VLAN*'s port.

## DHCP Unique Identifier Content

A *DHCP* unique identifier (DUID) consists of a two-octet type code followed by a variable number of octets that make up the actual identifier. A DUID can be no more than 128 octets long (not including the type code). The following types are currently defined:

- Link-layer address plus time
- Vendor-assigned unique ID based on Enterprise Number
- Link-layer address

ExtremeXOS uses Link-layer address plus time as its default client DUID. To configure DHCPv6 client identifier type for the client use:

```
configure dhcp ipv6 client identifier-type [link-layer | link-layer-
plus-time | vendor-specific]
```

## Client Requested DHCPv6 Options

The following default options are encapsulated by the DHCPv6 client when requesting DHCPv6 server.

1. **OPTION\_CLIENTID** (code 1). The Client Identifier option is used to carry a DUID identifying a client between a client and a server.
2. **OPTION\_SERVERID** (code 2). The Server Identifier option is used to carry a DUID identifying a server between a client and a server.

**Note**

**OPTION\_SERVERID** option is included if DHCPv6 client is responding to a particular server.

3. **OPTION\_IA\_NA** (code 3). The client uses IA\_NA options to request the assignment of non-temporary address assignment.
4. **OPTION\_IAADDR** (code 5). The IA\_ADDR is used to specify the IPv6 addresses associated with IA\_NA or IA\_TA option.

**Note**

**OPTION\_IAADDR** is included only if the client lease is present.

**Note**

IAID is the last 4 bytes of the hardware address

5. OPTION\_ORO (code 6). The Option Request option is used to identify a list of options in a message between client and server. A client includes an Option Request option in a Solicit, Request, Renew, Rebind, Confirm or Information-request message to inform the server about options the client is interested in.

The following are the Default requested options included by the ExtremeXOS DHCPv6 client as part of Option Request Option (OPTION\_ORO) option:

1. OPTION\_DNS\_SERVERS (code 23).
2. OPTION\_DOMAIN\_LIST (code 24). Reference for above ORO options: <http://tools.ietf.org/html/rfc3646>.
3. OPTION\_ELAPSED\_TIME (code 8). A client MUST include an Elapsed Time option in messages to indicate how long the client has been trying to complete a *DHCP* message exchange.

## Configuring DHCPv6 BOOTP Relay

To configure the relay function:

1. Configure *VLANs* and IP unicast routing.

**Note**

As in DHCPv4, when you create an IPV6 VLAN interface, the corresponding disabledV6VlanList has an entry. The VLAN interface entry is removed whenever the bootpRelayv6 for the respective VLAN is enabled, and vice versa.

2. Enable the *DHCP* or BOOTP relay function using the following commands:

```
enable bootprelay {ipv4|ipv6} {vlan[vlan_name] |{vr} vr_name}|all
[vr] vr_name}
enable bootprelay {vlan[vlan_name] |{vr} vr_name}|all [vr] vr_name}
```

3. Configure the addresses to which DHCP or BOOTP requests should be directed using the following command:

```
configure bootreplay {ipv4} | {{vlan}vlan_name} [[add ip_address] |
delete [ip_address | all]]] | ipv6 [[add ipv6_address] | [delete
ipv6_address | all]]]] {vr vrid}
configure bootprelay {ipv4 | ipv6} add ip_address {vr vrid}
```

**Note**

Use the configure bootprelay ipv6 **option interface-id** *InterfaceIDName* **vlan** {vlan\_name} command to set up a unique interface-id. It can be MAC-ID, or port-vlan combination. You can also use this command to set up dhcpv6 server/next hop for each VLAN interface, or across VR. A configuration applied to the VR level is populated to all VLAN V6 interfaces.

4. To delete an entry, use the following command:

```
configure bootprelay {ipv4 | ipv6} delete [ip_address | all] {vr vrid}
```

5. To disable BOOTP relay on one or more VLANs, use the following command

```
disable bootprelay {ipv4 | ipv6} {vlan [vlan_name] | {{vr} vr_name} | all [{vr} vr_name]}
```

```
disable bootprelay {{vlan} [vlan_name] | {{vr} vr_name} | all [{vr} vr_name]}
```

#### Note

When *VRRP (Virtual Router Redundancy Protocol)* and BOOTP/DHCP relay are both enabled on the switch, the relayed BOOTP agent IP address is the actual switch IP address, not the virtual IP address.

## Configure Route Compression

This helps with route optimization and scaling. This feature allows you to install only less specific routes in the table when overlapping routes with the same nexthop exist. For detailed information about route compression, see [Hardware Routing Table Management](#).

#### Note

This feature is enabled by default starting from ExtremeXOS 15.6.

- Enable this feature.

```
enable iproute ipv6 compression {vr vrname}
```

- Disable this feature.

```
disable iproute ipv6 compression {vr vrname}
```

## Hardware Forwarding Behavior

[Table 63](#) shows the Extreme switch platforms and the ExtremeXOS software versions that provide hardware forwarding support for IPv6 unicast features.

**Table 63: IPv6 Unicast Features**

| Switch Model | ExtremeXOS Release        | Features                                  |
|--------------|---------------------------|-------------------------------------------|
| 4120         | 32.7 and later            | IPv6 Unicast forwarding                   |

| 7720         | Switch Engine 32.4 and later | IPv6 Unicast forwarding<br>IPv6 tunneling |

## Hardware Forwarding Limitations

All switches can use hardware forwarding when the route mask is 64 bits or less. If the route mask is greater than 64 bits, limitations apply based on the hardware platform.

This support was added in ExtremeXOS Release 12.4 by using some of the slices previously used for [ACL](#) support to create a Greater Than 64 Bit (GT64B) table. The GT64B table stores only those routes with a mask greater than 64 bits. When IPv6 forwarding is enabled, the switch behavior is as follows:

- Fewer slices are available for ACLs.

Use `show access-list usage acl-slice` to check if any slice is unused. If no slice is available, consider disabling a feature that is consuming ACL slices if that feature is not required. Features that are enabled by default such as [IGMP \(Internet Group Management Protocol\)](#) Snooping or MLD Snooping can be disabled to free up ACL resources if not required.

- Table-full messages appear when there is no more space in the GT64B table.
- If an eligible route cannot be added to the GT64B table (because the table is full), there is no guarantee that traffic for that route will be properly routed.
- If enabled, route compression for IPv6 can make room for additional routes by reducing the number of entries in the GT64B table.
- When an IPv6 address with a mask greater than 64 bits is configured on a [VLAN](#) or tunnel, that address is automatically added to the GT64B table.

All switches support hardware forwarding routes with masks greater than 64 bits. For number of routes supported, see the limits for the particular switch in the [ExtremeXOS Release Notes](#).

Starting with ExtremeXOS 22.5, the `ipv6-mask-length` option provides greater hardware route scale and IP route sharing ([ECMP](#)) support for IPv6 “long-mask routes”, meaning IPv6 subnets with mask lengths 65–128 bits. This provides additional scale and resilience for IPv6 host routes whose mask length is 128 bits. Increasing scale and providing ECMP for IPv6 mask 65–128 routes decreases IPv4 route scale. The default IPv6 mask length is 64.

The `configure forwarding internal-tables [ 12-and-13 | more [12 | 13-and-ipmc | routes {ipv6-mask-length [64 | 128]}]]` command provides the ability to support additional L2 and L3 hosts, routes, or multicast table entries.

This support was added in ExtremeXOS Release 12.4 by using a hardware table designed for this purpose. When IPv6 forwarding is enabled, the switch behavior is as follows:

- If no space is available in the hardware table, there is no guarantee that traffic for that route will be properly routed.
- If enabled, route compression for IPv6 can make room for additional routes by reducing the number of entries in the hardware table.
- When an IPv6 address with a mask greater than 64 bits is configured on a VLAN or tunnel, that address is automatically added to the hardware table.

## Hardware Tunnel Support

The platforms and software versions that provide hardware forwarding support for IPv6 traffic for both IPv6-in-IPv4 and 6to4 tunnels for various platforms are shown in the following table. In all the other platforms, tunnel traffic is forwarded in software and the statistics can be viewed from the `show ipstats ipv6` command.

### Note

The MTU for IPv6 Tunnels is set to 1480 bytes, and is not user-configurable. Configuring jumbo frames has no effect on the MTU size for IPv6 tunnels.

## Routing Configuration Example

Figure 106 on page 964 illustrates a switch with three VLANs defined as follows:

- Finance
  - All ports on slots 1 and 3 have been assigned.
  - IP address 192.207.35.1.
- Personnel
  - Protocol-sensitive VLAN using the IP protocol.
  - All ports on slots 2 and 4 have been assigned.
  - IP address 192.207.36.1.
- MyCompany
  - Port-based VLAN.
  - All ports on slots 1 through 4 have been assigned.

**Figure 106: Unicast Routing Configuration Example**

The stations connected to the system generate a combination of IP traffic and NetBIOS traffic. The IP traffic is filtered by the protocol-sensitive VLANs. All other traffic is directed to the VLAN MyCompany.

In this configuration, all IP traffic from stations connected to slots 1 and 3 have access to the router by way of the VLAN Finance. Ports on slots 2 and 4 reach the router by way of the VLAN Personnel. All other traffic (NetBIOS) is part of the VLAN MyCompany.

The example in the above figure is configured as follows:

```
create vlan Finance tag 10
create vlan Personnel tag 11
create vlan MyCompany

configure Finance protocol ip
configure Personnel protocol ip

configure Finance add port 1:*,3:* tag
configure Personnel add port 2:*,4:* tag
configure MyCompany add port all

configure Finance ipaddress 192.207.35.1
configure Personnel ipaddress 192.207.36.1
configure rip add vlan Finance
configure rip add vlan Personnel

enable ipforwarding
enable rip
```

## Tunnel Configuration Examples

### 6in4 Tunnel Configuration Example

Figure 107 illustrates a 6in4 tunnel configured between two IPv6 regions across an IPv4 region.

**Figure 107: 6in4 Tunnel Example**

Router A has an interface to an IPv4 region with the address 192.168.1.1 (for this example we are using private IPv4 addresses, but to tunnel across the Internet, you would use a public address). Router B has an IPv4 interface of 10.2.0.1. The IPv4 interface must be created before the tunnel is configured and cannot be deleted until the tunnel is deleted.

This example has one subnet in each IPv6 region, 2001:db8:1::/64 for Router A and 2001:db8:2::/64 for Router B. Hosts A and B are configured to use IPv6 addresses 2001:db8:1::101 and 2001:db8:2::101 respectively.

For traffic to move from one region to the other, there must be a route. In this example, a static route is created, but you could enable [RIPng](#) or [OSPFv3](#) on the tunnel interface.

In this example, we assume that the IPv4 network can route from Router A to Router B (in other words, some IPv4 routing protocol is running on the public-ipv4 interfaces). For platforms on which hardware based tunneling is supported (See the following table), IPv4 forwarding needs to be enabled on the tunnel source [VLAN](#). However, in platforms on which IPv6-in-IPv4 tunnels are supported in software only, you do not need to enable IPv4 forwarding on the public interfaces in this example unless you are also routing IPv4 traffic on them (in this example, it is assumed you are running no IPv4 traffic inside your respective IPv6 networks, although you could).

When Host A needs to send a packet to 2001:db8:2::101 (Host B), it forwards it to Router A. Router A receives an IPv6 packet from the IPv6 source address 2001:db8:1::101 to the destination 2001:db8:2::101. Router A has the static route, for the route 2001:db8:2::/64 with next hop 2001:db8:a::2 (Router B) through the tunnel interface. So Router A encapsulates the IPv6 packet inside an IPv4 header with the source address 192.168.1.1 and destination address 10.2.0.1. The encapsulated IPv6 packet passes through the IPv4 network and reaches the other end of the tunnel—Router B. Router B decapsulates the packet and removes the IPv4 header. Router B then forwards the IPv6 packet to the destination host—Host B.

#### Note

Each IPv6 packet is encapsulated inside an IPv4 header (20 bytes) before it is forwarded via a IPv6-in-IPv4 tunnel. For example, a 66-byte packet from Host A will be encapsulated and forwarded as a 86-byte packet by Router A.

#### Router A

```
configure vlan default delete port all
create vlan public-ipv4
configure vlan public-ipv4 add port 1 untagged
configure vlan public-ipv4 ipaddress 192.168.1.1/24
create tunnel public6in4 ipv6-in-ipv4 destination 10.2.0.1 source 192.168.1.1
configure tunnel public6in4 ipaddress 2001:db8:a::1/64
enable ipforwarding ipv6 public6in4
create vlan private-ipv6
configure vlan private-ipv6 add port 2 untagged
configure vlan private-ipv6 ipaddress 2001:db8:1::1/64
enable ipforwarding ipv6 private-ipv6
configure iproute add 2001:db8:2::/64 2001:db8:a::2
enable ipforwarding public-ipv4
```

#### Router B

```
configure vlan default delete port all
create vlan public-ipv4
configure vlan public-ipv4 add port 1 untagged
configure vlan public-ipv4 ipaddress 10.2.0.1/24
create tunnel public6in4 ipv6-in-ipv4 destination 192.168.1.1 source 10.2.0.1
configure tunnel public6in4 ipaddress 2001:db8:a::2/64
enable ipforwarding ipv6 public6in4
create vlan private-ipv6
configure vlan private-ipv6 add port 2 untagged
configure vlan private-ipv6 ipaddress 2001:db8:2::1/64
enable ipforwarding ipv6 private-ipv6
configure iproute add 2001:db8:1::/64 2001:db8:a::1
enable ipforwarding public-ipv4
```

## 6to4 Tunnel Configuration Example

**Figure 108** illustrates a 6to4 tunnel configured between two IPv6 regions across an IPv4 region.

**Figure 108: 6to4 Tunnel Configuration Example**

Router 1 has an interface to an IPv4 region with the address 192.168.1.1 (for this example we are using private IPv4 addresses, but to tunnel across the Internet, you would use a public address). Router 2 has an IPv4 interface of 10.0.0.1. The IPv4 interface must be created before the tunnel is configured and cannot be deleted until the tunnel is deleted.

The IPv6 endpoints of 6to4 tunnels must follow the standard 6to4 address requirement. The address must be of the form 2002:<IPv4\_source\_endpoint>::/16, where <IPv4\_source\_endpoint> is replaced by the IPv4 source address of the endpoint, in hexadecimal, colon separated form. For example, for a tunnel endpoint located at IPv4 address 10.20.30.40, the tunnel address would be 2002:0a14:1e28::/16. In hex, 10 is 0a, 20 is 14, 30 is 1e and 40 is 28.

This example shows a simple setup on the Router 1 side (one big /48 IPv6 routing domain with no subnets), and a slightly more complex setup on the Router 2 side (two subnets :0001: and :0002: that are /64 in length). Hosts 1, 2, and 3 will communicate using their global 2002: addresses.

The hosts in this example configure themselves using the EUI64 interface identifier derived from their MAC addresses. Refer to your host OS vendor's documentation for configuring IPv6 addresses and routes.

In this example, we assume that the IPv4 network can route from Router 1 to Router 2 (in other words, some IPv4 routing protocol is running on the public-ipv4 interfaces). However, you do not need to enable IPv4 forwarding on the public interfaces in this example unless you are also routing IPv4 traffic on them (in this example, it is assumed you are running no IPv4 traffic inside your respective IPv6 networks, although you could).

#### Router 1

```
configure vlan default delete port all
create vlan public-ipv4
configure vlan public-ipv4 add port 1 untagged
configure vlan public-ipv4 ipaddress 192.168.1.1/24
create tunnel public6to4 6to4 source 192.168.1.1
configure tunnel public6to4 ipaddress 2002:c0a8:0101::1/16
enable ipforwarding ipv6 public6to4
create vlan private-ipv6
configure vlan private-ipv6 add port 2 untagged
configure vlan private-ipv6 ipaddress 2002:c0a8:0101::2/48
enable ipforwarding ipv6 private-ipv6
```

#### Router 2

```
configure vlan default delete port all
create vlan public-ipv4
configure vlan public-ipv4 add port 1 untagged
configure vlan public-ipv4 ipaddress 10.0.0.1/24
create tunnel public6to4 6to4 source 10.0.0.1
configure tunnel public6to4 ipaddress 2002:0a00:0001::1/16
enable ipforwarding ipv6 public6to4
create vlan private-ipv6-sub1
configure vlan private-ipv6-sub1 add port 2 untagged
configure vlan private-ipv6-sub1 ipaddress 2002:0a00:0001:0001::1/64
enable ipforwarding ipv6 private-ipv6-sub1
create vlan private-ipv6-sub2
configure vlan private-ipv6-sub2 add port 3 untagged
configure vlan private-ipv6-sub2 ipaddress 2002:0a00:0001:0002::1/64
enable ipforwarding ipv6 private-ipv6-sub2
```

#### Host Configurations

The IPv6 addresses of these hosts are based on their MAC address-derived EUI64 interface identifiers and the address prefixes for their subnets. Each host must also have a static route configured on it for 6to4 addresses.

##### Host 1:

- MAC address—00:04:96:1F:A5:2A
- IPv6 address—2002:c0a8:0101::0204:96ff:fe1f:a52a/48
- Static route—destination 2002::/16, gateway 2002:c0a8:0101::2

##### Host 2:

- MAC address—00:04:96:1F:A4:32
- IP address—2002:0a00:0001:0001:0204:96ff:fe1f:a432/64
- Static route—destination 2002::/16, gateway 2002:0a00:0001:0001::1

**Host 3:**

- MAC address—00:01:30:00:C2:00
- IP address—2002:0a00:0001:0002:0201:30ff:fe00:c200/64
- Static route—destination 2002::/16, gateway 2002:0a00:0001:0002::1

## GRE Tunnel Configuration Example

### *Router 1 Configuration*

```
unconfigure switch all
configure default del port all
create vlan inet
configure vlan inet add port 24
configure vlan inet ipa 1.1.1.1/24
create vlan users
configure vlan users add port 1
configure vlan users ipa 100.0.0.1/24
create tunnel mytunnel gre destination 1.1.1.2 source 1.1.1.1
configure tunnel "mytunnel" ipaddress 2.0.0.1/24
configure iproute add 200.0.0.0/24 2.0.0.2
enable ipforwarding
```

### *Router 2 Configuration*

```
create vlan inet
configure vlan inet add port 10:1
configure vlan inet ipa 1.1.1.2/24
create vlan users
configure vlan users add port 10:2
configure vlan users ipa 200.0.0.1/24
create tunnel mytunnel gre destination 1.1.1.1 source 1.1.1.2
configure tunnel "mytunnel" ipaddress 2.0.0.2/24
configure iproute add 100.0.0.0/24 2.0.0.1
enable ipforwarding
```

```
Host IP connected to router 1-100.0.0.1
Host IP connected to router 2-200.0.0.1
```

**Note**

If a transit node is present between the tunneling sites, you should configure static or enable IBCP between the sites for network connectivity.

## IS-IS Overview

---

IS-IS is a link state protocol that distributes routing information between routers belonging to a single IP domain; the IP domain is also known as an autonomous system (AS). In a link-state routing protocol, each router maintains a database describing the topology of the AS. Each participating router has an identical database maintained from the perspective of that router.

From the link state database (LSDB), each router constructs a tree of shortest paths, using itself as the root. The shortest path tree provides the route to each destination in the AS. When several equal-cost routes to a destination exist, traffic can be distributed among them. The cost of a route is described by a single metric.

IS-IS is an interior gateway protocol (IGP), as are [\*RIP \(Routing Information Protocol\)\*](#) and [\*OSPF \(Open Shortest Path First\)\*](#). Unlike RIP and OSPF, IS-IS was not initially designed for IP. RFC 1195 specifies how IS-IS can run in an IP environment. The Extreme Networks implementation supports IS-IS only in IP environments. RIP, OSPF, and IS-IS are compared in [RIP](#). The IPv6 versions of these protocols are compared in [RIPng](#).

## Establishing Adjacencies

An adjacency is an acknowledged relationship between two IS-IS routers. An adjacency must be established before two IS-IS routers can exchange routing information.

IS-IS routers establish adjacencies by exchanging hello PDUs, which are also called Intermediate System to Intermediate System Hellos (IIHs). Hello PDUs contain some interface configuration and capability information. Once a pair of neighbors exchanges hello PDUs with acceptably matching configuration and capabilities, an adjacency is formed. Hello PDUs are sent periodically by each party to maintain the adjacency.

After an adjacency is formed, information about the adjacency is stored in a link state PDU (LSP), which is stored in the router link state database (LSDB). Routers periodically flood all of their LSPs to all other network nodes. When a router receives LSPs, it adds the LSPs to its LSDB, and uses the LSDB to calculate routes to other routers. These database maintenance operations are performed a little differently for the two adjacency types, point-to-point, and broadcast.

### *Point-to-Point Adjacency*

Point-to-point adjacencies can include no more than two routers in the same [\*VLAN \(Virtual LAN\)\*](#). [Figure 109](#) shows a point-to-point adjacency.

**Figure 109: Point-to-Point Adjacency**

Once a point-to-point adjacency is established, each router sends a CSNP (Complete Sequence Number PDU) listing a summary of all its LSPs. When a router receives its neighbor's CSNP, it sends any LSP it has that is either not present in the CSNP or is newer than the version in the CSNP. In a point-to-point adjacency, partial sequence number PDUs (PSNPs) are used to acknowledge each LSP a router receives from its neighbor. If a PSNP is not received within a configurable period of time, unacknowledged LSPs are re-sent.

A disadvantage to point-to-point adjacencies is that they do not scale well. [Figure 110](#) shows a four-router network with point-to-point adjacencies.

**Figure 110: Point-to-Point Adjacencies in a Four-Router Network**

In this network, each of the ellipses represents a point-to-point adjacency. Each of the four routers periodically sends all of its LSPs to the other three routers. Each, in turn, will flood the received LSPs to the other two since they have no way of knowing which routers have already received them, generating N2 LSPs. This network routing traffic reduces the bandwidth available for data traffic. For networks that only have two routers and are not likely to grow, a point-to-point adjacency is appropriate.

### Broadcast Adjacency

Broadcast adjacencies can include two or more routers in a single adjacency. [Figure 111](#) depicts a broadcast adjacency.

**Figure 111: Broadcast Adjacencies in a Four-Router Network**

When broadcast adjacencies are formed, one of the routers participating in the adjacency is elected designated intermediate system (DIS). The election is determined by a DIS priority configured for each router. In the event of a tie, the router with the numerically highest MAC address wins.

A broadcast network can be considered a virtual node, or pseudonode, to which all routers have a zero-cost adjacency.

The DIS acts on behalf of the pseudonode by advertising an LSP listing all routers in the adjacency with zero-cost metric. The DIS also periodically sends a complete sequence number PDU (CSNP), which lists all LSPs in the link-state database. If a router sees that it is missing one or more of the entries, it multicasts a request for them using a PSNP. Only the DIS responds to this request by sending the requested LSPs. All routers multicast their originated LSPs as they are refreshed, and multicast periodic hellos to the network.

The default configuration creates broadcast adjacencies.

## IS-IS Hierarchy

IS-IS has a two-level hierarchy. IS-IS routers may participate in either level or both. [Figure 112](#) shows a basic IS-IS AS.

**Figure 112: Basic Autonomous System**

In the network in the above figure, each of the ellipses represents an adjacency. Level 1 (L1) routers within an area need only know the topology within that area as well as the location of the nearest L1/L2 attached router. An attached router is one that participates in both levels and can reach at least one other L1/L2 or L2 router with a different area address.

In an AS, there is only one L2 area, and it serves as a backbone area between L1 areas. This L2 area is also called a domain (not to be confused with the entire AS routing domain). L2 routers communicate with one another irrespective of L1 area membership or L2 area address.

### Note

On any switch, the maximum number of L1/L2 adjacencies is one half the maximum number of L1 or L2 adjacencies because an L1/L2 adjacency defines both an L1 adjacency and an L2 adjacency. The supported adjacency limits are defined in the [ExtremeXOS Release Notes](#).

For information on creating and managing IS-IS areas, see [Managing an IS-IS Area Address](#) on page 988.

## IS-IS and IP Routing

IS-IS is not inherently an IP Routing protocol. Its control packets do not use IP. RFC 1195 specifies the use of IS-IS for IP Routing.

The ExtremeXOS software implementation of IS-IS requires that at least one IPv4 or IPv6 address be assigned to an interface.

IP addresses and subnets can be assigned independent of area structure provided that neighboring interfaces are on the same subnet. L1 routers exchange directly reachable IP address/mask/metric tuples. When routing in an L1 area, packets are routed via L1 if the destination address is reachable within the area. Otherwise packets are forwarded to the nearest L2 router. L2 routers advertise all IP addresses reachable in their L1 area (if they are a member of one), as well as directly reachable addresses.

### *Summary Addresses*

Routers can be manually configured to advertise abbreviated versions of reachable addresses, which are called summary addresses. By aggregating many routes into one summary address, route computation and lookup can be made more efficient. If packets arrive at the router as a result of the summary address but have no actual route (as a result of the summary address covering more address space than is actually used), the packets are discarded.

For instructions on managing summary addresses, see [Managing IP Summary Addresses](#) on page 987.

### *External Connectivity*

Externally reachable IP addresses are those learned or exported from other routing protocols like *RIP*, *BGP (Border Gateway Protocol)*, and *OSPF*. When using narrow metrics, external routes may use internal or external metrics. When calculating SPF, routes with internal metrics are preferred over routes with external metrics. When external metrics are used to compare routes, the internal cost is not considered unless the external metrics are equal.

## Authentication

Entire packets (as opposed to individual TLVs in a packet) can be authenticated. If authentication fails on a packet, the entire packet is discarded. Multi-part packets are authenticated separately. Routers are not required to support authentication. The ExtremeXOS software provides optional support for plain-text authentication.

## Dynamic Hostname

The dynamic hostname exchange extension helps address the usability issues of maintaining IS-IS routers. IS-IS system IDs (which default to the switch MAC address) are not very readable. When the dynamic hostname feature is enabled, learned IS-IS hostnames are used in place of system IDs in log entries where possible. In addition, hostname TLVs appear in the `show isis lsdb detail` command display.

For instructions on managing the dynamic hostname feature, see [Configuring the Dynamic Hostname Feature](#) on page 983.

## Route Leaking

Route leaking allows L2 LSPs to be sent into L1 areas. Route leaking is configured with the command:

```
configure isis area area_name interlevel-filter level 2-to-1 [policy |
block-all | allow-all] {ipv4 | ipv6}
```

The supplied policy defines what route or routes should be leaked.

### Caution

Route leaking can reduce scalability and performance.

### Note

Tracert does not work if the VRF leaked route is one of the hop(s) to destination.

## Metric Types

Interface metrics are available in two sizes: a 6-bit narrow metric and a 24-bit wide metric. By default only narrow metrics are used. Wide metrics allow for greater flexibility, however, and are required in order to use some extensions of IS-IS, such as IPv6. All routers in an IS-IS area must use the same metric style.

For instructions on configuring interface metric style and values, see [Configuring VLAN Interface Metrics](#) on page 989. Refer to RFC 3787, Section 5.1, for migration details. Note that the ExtremeXOS software does not support section 5.2.

## IS-IS Restart

When an IS-IS router restarts, neighbors time out adjacencies and the network converges around it. IS-IS restart support, with the help of restart helper neighbors, can prevent this. A restarting router can send a restart request to indicate to its neighbors that it is restarting. Neighbors—provided they are helpers—send the restarting router a CSNP so that it can reconstruct its LSDB by tracking which LSPs it has and has not received. Neighbors can still time out the adjacency, so this might not work in environments with low hold timers.

IS-IS restart can be configured for planned and unplanned events. Planned events are user-initiated process restarts and user-initiated failovers. Unplanned events are process restarts or failovers that are not administratively initiated.

For information on configuring IS-IS restart, see [Configuring the Graceful Restart Feature](#).

## IPv4 and IPv6 Topology Modes

Interfaces can be IS-IS-enabled for IPv4, IPv6, or both. Within an IS-IS area, IPv4 and IPv6 can be supported in a single topology or in a multiple topology. A transition configuration is provide for migrating between the single and multiple topologies.

In a single topology, all interfaces in an area must be configured for IPv4, IPv6, or both IPv4 and IPv6. Adjacencies are denied if the topology configuration between two routers does not match. A single SPF calculation is performed for each route in a single topology area.

In a multiple topology area, each interface can be configured for IPv4, IPv6, or both IPv4 and IPv6. The router creates separate topologies for IPv4 and IPv6. Adjacencies are permitted between interfaces with different configurations, provided that the neighbors support at least one common protocol. Separate SPF calculations are computed for IPv4 and IPv6 routes.

**Note**

Although the IPv4 and IPv6 topologies can be different when multiple topologies are enabled, the topologies must be convex. That is, no IPv4 interface can be reachable only through traversal of IPv6 interfaces, and vice versa. All routers in an area must use the same topology mode.

When the transition topology mode is configured, the router allows adjacencies between any two interfaces, and distributes both single topology and multiple topology TLVs. Transition mode permits both single and multiple topologies to coexist, but it generates more traffic. Transition mode should be used only for transitioning between modes and should be disabled after the transition is complete.

By default, a single topology is used for both IPv4 and IPv6. As a result, all interfaces must be homogeneously ISIS-enabled for IPv4, IPv6, or both.

To change the configured topology mode, see [Configure the Multi-Topology Feature](#) on page 984.

## Route Redistribution

---

More than one routing protocol can be enabled simultaneously on the switch.

Route redistribution allows the switch to exchange routes, including static routes, between the routing protocols. [Figure 113](#) is an example of route redistribution between an OSPF AS and a RIP AS.

**Figure 113: OSPF Route Redistribution**

## Configuring Route Redistribution

Exporting routes from one protocol to another and in the reverse direction are discrete configuration functions. For example, to run IS-IS and *RIP* simultaneously, you must first configure both protocols and then verify the independent operation of each. Then you can configure the routes to export from IS-IS to RIP and the routes to export from RIP to IS-IS. Likewise, for any other combinations of protocols, you must separately configure each to export routes to the other.

This section describes how to inject routing information learned from other IP routing protocols into an IS-IS domain, thereby advertising their reachability in the IS-IS domain. These routes are included in the locally originated LSPs. For information on exporting routes learned in IS-IS to another routing protocol, see the chapter that describes the destination routing protocol.

When you export routes from another protocol to IS-IS, the metric and the type of metric are configured. You can also configure a policy to filter out unwanted external routes.

- To enable or disable the exporting of *BGP*, *OSPF*, *RIP*, static, and direct (interface) IPv4 routes to IS-IS, use the following commands:
 

```
enable isis area area_name export {ipv4} route-type [policy | metric
mvalue {metric-type [internal | external]}} {level[1 | 2 | both-1-
and-2]}
disable isis area area_name export {ipv4} route-type
```
- To enable or disable the exporting of *OSPFv3 (Open Shortest Path First version 3)*, *RIPng (Routing Information Protocol Next Generation)*, static, and direct (interface) IPv6 routes to IS-IS, use the following commands:
 

```
enable isis area area_name export ipv6 route-type [policy | metric
mvalue] {level[1 | 2 | both-1-and-2]}
```

```
disable isis area area_name export ipv6 route-type
```

The cost metric is inserted for all *OSPF*, RIP, static, and direct routes injected into IS-IS.

The same cost and type values can be inserted for all the export routes, or policies can be used for selective insertion. When a policy is associated with the export command, the policy is applied on every exported route. The exported routes can also be filtered using policies.

- Verify the configuration using the command:

```
show isis area [area_name | all]
```

## Configuring IS-IS

### Configuring L1 Routers

To configure a switch to operate as a level 1 IS-IS router, do the following:

1. Prepare the IP interfaces that will support level 1 IS-IS routing as follows:
  - a. Add an IPv4 or IPv6 address.
  - b. Enable IP or IPv6 forwarding.
2. Create the IS-IS routing process, which is also called an area, using the following command:

```
create isis area area_name
```

3. Configure the routing process to serve as a L1-only router using the following command:

```
configure isis area area_name is-type level [1 | 2 | both-1-and-2]
```

Specify 1 for the level option using the following command:

4. Add an IS-IS area level-1 address to the router using the following command:

```
configure isis area area_name add area-address area_address
```

5. Add IS-IS-eligible interfaces to the area using the following command:

```
configure isis add [vlan all | {vlan} vlan_name] area area_name {ipv4
| ipv6}
```

An IS-IS-eligible interface is one that already has the appropriate IP address type (IPv4 or IPv6) address assigned to it.

6. The default IS-IS system ID is the switch MAC address. If you want to change the default IS-IS system ID, using the following command:

```
configure isis area area_name system-id [automatic | system_id]
```

7. Enable the IS-IS router using the following command:

```
enable isis {area area_name}
```

## Configuring L1/L2 Routers

To configure a switch to operate as a L1/L2 IS-IS router, do the following:

1. Prepare the IP interfaces that will support level 1 IS-IS routing as follows:
  - a. Add an IPv4 or IPv6 address.
  - b. Enable IP or IPv6 forwarding.
2. Create the IS-IS routing process, which is also called an area, using the following command:

```
create isis area area_name
```

3. Configure the routing process to serve as an L1/L2 router using the following command:

```
configure isis area area_name is-type level [1 | 2 | both-1-and-2]
```

Specify both-1-and-2 for the level option using the following command:

### Note

When no other L2 processes are defined on the router, the default IS type level is L1/L2, and this command can be omitted.

4. Add an IS-IS area level-1 address to the router using the following command:

```
configure isis area area_name add area-address area_address
```

5. Add an IS-IS area level-2 address to the router using the following command:

```
configure isis area area_name add area-address area_address
```

6. Add IS-IS-eligible interfaces to the area using the following command:

```
configure isis add [vlan all | {vlan} vlan_name] area area_name {ipv4
| ipv6}
```

An IS-IS-eligible interface is one that already has the appropriate IP address type (IPv4 or IPv6) address assigned to it.

7. If your topology requires interfaces to operate at a specific topology level, configure the appropriate interfaces with the following command:

```
configure isis [vlan all | {vlan} vlan_name] circuit-type level [1 | 2
| both-1-and-2]
```

8. The default IS-IS system ID is the switch MAC address. If you want to change the default IS-IS system ID, use the following command:

```
configure isis area area_name system-id [automatic | system_id]
```

### Note

Although the IS-IS protocols manage IP routing, they use the Connectionless Network Protocol (CLNP) for IS-IS communications between routers. The IS-IS system ID is required to identify the router in the AS.

9. Enable the IS-IS router using the following command:

```
enable isis {area area_name}
```

## Configuring L2 Routers

To configure a switch to operate as a level 2 IS-IS router, do the following:

1. Prepare the IP interfaces that will support level 2 IS-IS routing as follows:
  - a. Add an IPv4 or IPv6 address.
  - b. Enable IP or IPv6 forwarding.
2. Create the IS-IS routing process, which is also called an area, using the following command:

```
create isis area area_name
```

3. Configure the routing process to serve as a L2-only router using the following command:

```
configure isis area area_name is-type level [1 | 2 | both-1-and-2]
```

Specify 2 for the level option.

4. Add an IS-IS area level-2 address to the router using the following command:

```
configure isis area area_name add area-address area_address
```

5. Add IS-IS-eligible interfaces to level 2 using the following command:

```
configure isis add [vlan all | {vlan} vlan_name] area area_name {ipv4
| ipv6}
```

An IS-IS-eligible interface is one that already has the appropriate IP address type (IPv4 or IPv6) address assigned to it.

6. Add an IS-IS system ID to the router using the following command:

```
configure isis area area_name system-id [automatic | system_id]
```

Use the automatic option to assign the switch MAC address to the IS-IS system ID. The default option is **automatic**, so you can also enter the command without options to select the switch MAC address.

7. Enable the ISIS router using the following command:

```
enable isis {area area_name}
```

## Configuring IS-IS Timers

IS-IS timers allow you to fine tune IS-IS operation. [Table 64](#) lists the IS-IS timers and the command you can use to adjust them.

**Table 64: IS-IS Configuration Timers and Commands**

| Timer                     | Command                                                                                                                                                  |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| T1 hello restart interval | <code>configure isis [<b>vlan all</b>   {<b>vlan</b>} <i>vlan_name</i>] <b>timer restart-hello-interval</b> <i>seconds</i> {<b>level</b> [1   2]}</code> |
| T2 restart timer          | <code>configure isis area <i>area_name</i> <b>timer restart</b> <i>seconds</i> {<b>level</b> [1   2]}</code>                                             |
| T3 restart grace period   | <code>configure isis restart grace-period <i>seconds</i></code>                                                                                          |
| LSP generation interval   | <code>configure isis area <i>area_name</i> <b>timer lsp-gen-interval</b> <i>seconds</i> {<b>level</b> [1   2]}</code>                                    |

**Table 64: IS-IS Configuration Timers and Commands (continued)**

| Timer                   | Command                                                                                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LSP maximum lifetime    | <code>configure isis area <i>area_name</i> timer max-lsp-lifetime <i>seconds</i></code>                                                                      |
| LSP refresh interval    | <code>configure isis area <i>area_name</i> timer lsp-refresh-interval <i>seconds</i></code>                                                                  |
| SPF interval            | <code>configure isis area <i>area_name</i> timer spf-interval <i>seconds</i> {<b>level</b> [1   2]}</code>                                                   |
| CSNP interval           | <code>configure isis [<b>vlan all</b>   {<b>vlan</b>} <i>vlan_name</i>] timer csnp-interval <i>seconds</i> {<b>level</b> [1   2]}</code>                     |
| Hello interval          | <code>configure isis [<b>vlan all</b>   {<b>vlan</b>} <i>vlan_name</i>] timer hello-interval [<i>seconds</i>   <b>minimal</b>] {<b>level</b> [1   2]}</code> |
| Hello multiplier        | <code>configure isis [<b>vlan all</b>   {<b>vlan</b>} <i>vlan_name</i>] hello-multiplier <i>multiplier</i> {<b>level</b> [1   2]}</code>                     |
| LSP retransmit interval | <code>configure isis [<b>vlan all</b>   {<b>vlan</b>} <i>vlan_name</i>] timer retransmit-interval <i>seconds</i></code>                                      |
| LSP transmit interval   | <code>configure isis [<b>vlan all</b>   {<b>vlan</b>} <i>vlan_name</i>] timer lsp-interval <i>milliseconds</i></code>                                        |

## Configuring the Graceful Restart Feature

The graceful restart feature enables a router process to restart with minimal impact on the network. Without graceful restart, every other IS-IS router in the network must update its LSDB when the router goes down, and this generates a lot of traffic, and it introduces delays while new routes are established. With graceful restart, the router process requests restart support from its neighbors, and the neighbors wait for a predefined time before declaring routes dead. If the restart completes before the predefined time ends, the restart causes minimal impact on the network operation. For more information on graceful restart, see [IS-IS Restart](#).

- To enable or disable the graceful restart feature, use the following commands:  

```
enable isis restart-helper
disable isis restart-helper
```
- To configure which events trigger a graceful restart, use the following commands:  

```
configure isis restart [none | planned | unplanned | both]
```
- To configure the timers used to control graceful restart operation, use the commands in [Table 65](#).

**Table 65: Timers that Control Graceful Restart**

| Timer                     | Configuration Command                                                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| T1 restart hello interval | <code>configure isis [<b>vlan all</b>   {<b>vlan</b>} <i>vlan_name</i>] timer restart-hello-interval <i>seconds</i> {<b>level</b> [1   2]}</code> |
| T2 restart timer          | <code>configure isis area <i>area_name</i> timer restart <i>seconds</i> {<b>level</b> [1   2]}</code>                                             |

**Table 65: Timers that Control Graceful Restart (continued)**

| Timer                   | Configuration Command                                                                                                                                                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T3 restart grace period | <code>configure isis restart grace-period <i>seconds</i></code>                                                                                                                   |
| Hello interval          | <code>configure isis [<b>vlan all</b>   {<b>vlan</b>} <i>vlan_name</i>] <b>timer hello-interval</b> [<i>seconds</i>   <b>minimal</b>] {<b>level</b> [<b>1</b>   <b>2</b>]}</code> |
| Hello multiplier        | <code>configure isis [<b>vlan all</b>   {<b>vlan</b>} <i>vlan_name</i>] <b>hello-multiplier</b> <i>multiplier</i> {<b>level</b> [<b>1</b>   <b>2</b>]}</code>                     |

## Configuring Hello Padding

Hello PDUs are padded to the MTU by default, and this is called hello padding. This is to help identify and correct cases where switches have mismatched MTUs. Because IS-IS packets cannot be fragmented in transit, maintaining consistent MTUs is important to ensure the reliability of packets traversing the network. However, this extra padding could be a waste of bandwidth in scenarios where the MTU is fixed throughout the network.

- To disable hello padding, use the following command:  
`disable isis [vlan all | {vlan} vlan_name] hello-padding`
- To enable hello padding, use the following command:  
`enable isis [vlan all | {vlan} vlan_name] hello-padding`

## Configuring Interlevel Filters

Interlevel filters allow you to control how routes are redistributed between IS-IS levels 1 and 2. The redistribution of routes from level 2 to level 1 is called route leaking. For more information, see [Route Leaking](#) on page 976.

- To set an interlevel filter for redistribution from level 1 to level 2, use the following command:  
`configure isis area area_name interlevel-filter level 1-to-2 [policy | none] {ipv4 | ipv6}`
- To set an interlevel filter for redistribution from level 2 to level 1, use the following command:  
`configure isis area area_name interlevel-filter level 2-to-1 [policy | block-all | allow-all] {ipv4 | ipv6}`

## Configuring the Dynamic Hostname Feature

[Dynamic Hostname](#) on page 975 introduces the dynamic hostname feature, which causes text names to replace numbers in some logs.

- To enable the dynamic hostname feature, use the following command:  
`enable isis area area_name dynamic-hostname [area-name | snmp-name]`
- To disable the dynamic hostname feature, use the following command:  
`disable isis area area_name dynamic-hostname`

## Configuring the Adjacency Check Feature

When enabled, the adjacency check feature permits an adjacency between two IS-IS interfaces only when both are configured for the same IP address type (IPv4 or IPv6) and are configured for the same subnet.

- To enable the adjacency check feature, use the following command:

```
enable isis area area_name adjacency-check {ipv4 | ipv6}
```

- To disable the adjacency check feature, use the following command:

```
disable isis area area_name adjacency-check {ipv4 | ipv6}
```

## Configuring an Import Policy

When applied to a router process, an import policy controls how routes are imported to the FIB from all IS-IS processes on this .

- To apply a policy to a router process, use the following command:

```
configure isis import-policy [policy-map | none]
```

### Note

The import policy cannot be used to select which routes are added to the routing table. The import policy can only modify the route attributes as routes are added to the routing table.

## Configure the Multi-Topology Feature

The multi-topology feature is introduced in [IPv4 and IPv6 Topology Modes](#) on page 976.

- To configure the multi topology feature, use the following command:

```
configure isis area area_name topology-mode [single | multi | transition] {level [1 | 2]}
```

## Displaying IS-IS Information

### Displaying General Information for Global IS-IS

- To display general information for global IS-IS, use the following command:

```
show isis
```

### Displaying Router-Specific Information

- To display router-specific information, use the following command:

```
show isis area [area_name | all]
```

### Displaying Router Summary Addresses

- To display router summary addresses, use the following command:

```
show isis area area_name summary-addresses
```

## Displaying IS-IS Interface Information

- To display IS-IS interface information, use the following command:

```
show isis vlan {enabled | { vlan_name | all } }
```

## Displaying Link State Database Information

- To display link state database information, use the following command:

```
show isis lsdb {area area_name {lsp-id lsp_id} } {level [1|2] } {detail
| stats}
```

## Displaying IPv4 and IPv6 Topology Information

- To display IPv4 and IPv6 topology information, use the following command:

```
show isis topology {area area_name {level [1 | 2]}} {ipv4 | ipv6}
```

## Displaying IS-IS Neighbors

- To display IS-IS neighbor information, use the following command:

```
show isis neighbors {area area_name} {vlan vlan_name} {ipv4 | ipv6}
{detail}
```

## Displaying IS-IS Counter Data

- To display IS-IS counter data, use the following command:

```
show isis counters {area [area_name | all] | vlan [vlan_name | all]}
```

## Managing IS-IS

---

### Configuring Password Security

The ExtremeXOS software supports passwords for the following IS-IS AS components:

- Level 2 domains
- Level 1 areas
- VLAN interfaces

Domain and area authentication prevents intruders from injecting invalid routing information into the router. Because passwords must be configured to match at both ends of a connection, password security also helps detect unconfigured and

misconfigured interfaces. After configuration, the password is inserted into LSP, CSNP, and PSNP PDUs and are validated on the receiving end.

#### Note

The password configuration commands in this section provide an encrypted option, which controls how the passwords are saved and displayed on the switch. The encrypted option does not encrypt messages that are transmitted on the network. All passwords are transmitted in clear text.

- To configure password security for a level 2 domain, use the following command:  

```
configure isis area area_name domain-password [none | {encrypted}]

simple password {authenticate-snp {tx-only}}}
```
- To configure password security for a level 1 area, use the following command:  

```
configure isis area area_name area-password [none | {encrypted}] simple

password {authenticate-snp {tx-only}}}
```

Interface authentication prevents unauthorized routers from forming an adjacency. This is achieved by inserting a password in hello PDUs and validating the password on the receiving end. You can configure password protection separately for level 1 and level 2.

- To configure password security for a VLAN interface, use the following command:  

```
configure isis [vlan all | {vlan} vlan_name] password [none |

{encrypted}] simple password level [1 | 2]
```

## Managing Transit Traffic with the Overload Bit

If a router lacks the resources to maintain a complete link state database, routing packets to it could result in a blackhole or routing loop. The overload bit prevents this undesirable behavior by indicating to the other routers that the afflicted router should not be used as a transit router. Packets destined for directly attached routes can still be routed to a router with the overload bit set, but all other routing paths reconverge around it.

- To manually enable the overload bit feature, use the following command:  

```
enable isis area area_name overload-bit {suppress [external |

interlevel | all]}
```
- To configure the router to automatically set the overload bit on startup, use the following command:  

```
configure isis area area_name overload-bit on-startup [off |

{suppress [external | interlevel | all]}] seconds
```

- To disable the overload bit feature, use the following command:

```
disable isis area area_name overload-bit
```

#### Note

Enabling or disabling the overload bit feature does not modify the configuration of the command:

```
configure isis area area_name overload-bit on-startup [off |
{suppress [external | interlevel | all]} seconds]
```

## Clearing the IS-IS Counters

The `show isis counters` {**area** [*area\_name* | **all**] | **vlan** [*vlan\_name* | **all**]} command can display all counters or only those specific to the router process or the configured VLANs.

- To clear the IS-IS counters for the router and the VLANs, use the following command:

```
clear isis counters
```

- To clear the IS-IS counters only for the router process, use the following command:

```
clear isis counters area [area_name | all]
```

- To clear the IS-IS counters only for one or all VLANs, use the following command:

```
clear isis counters [vlan all | {vlan} vlan_name]
```

## Originating an L2 Default Route

This feature injects a zero-cost route to 0.0.0.0 in LSPs originated by an L2 router, thereby advertising the router as the default gateway.

- To enable default route origination, use the following command:

```
enable isis area area_name originate-default {ipv4 | ipv6}
```

- To disable default route origination, use the following command:

```
disable isis area area_name originate-default {ipv4 | ipv6}
```

## Managing IP Summary Addresses

Summary addresses are introduced in [Summary Addresses](#) on page 975. L2 routers include in their L2 LSPs a list of all destinations reachable in the L1 area attached to them by default. Summarization of the L1 destinations reduces the amount of information stored on each L2 router and helps in scaling to a large routing domain.

- To add summary addresses to an IS-IS router, use the following command:

```
configure isis area area_name add summary-address [ipv4_address_mask |
ipv6_address_mask] {level [1 | 2]}
```

- To delete summary addresses from an IS-IS router, use the following command:

```
configure isis area area_name delete summary-address
[ipv4_address_mask | ipv6_address_mask] {level [1 | 2]}
```

- To display the configured summary addresses for an IS-IS router, use the following command:

```
show isis area area_name summary-addresses
```

## Managing an IS-IS Area Address

IS-IS was not originally designed for IP routing. Some aspects of CLNP routing, such as system IDs and area addresses, exist in the IP extension of IS-IS. The IS-IS area address is required to identify the area in which the router participates.

- Before you can configure the area address, you must create the IS-IS routing process, which is also called an area, using the following command:

```
create isis area area_name
```

- To add an IS-IS area address to the router, use the following command:

```
configure isis area area_name add area-address area_address
```

- To delete an IS-IS area address from a router, use the following command:

```
configure isis area area_name delete area-address area_address
```

### Note

The ExtremeXOS software implementation of IS-IS supports no more than three area addresses.

## Managing VLAN Interfaces

### Adding a VLAN Interface

- To add a VLAN interface to a router, use the following command:

```
configure isis add [vlan all | {vlan} vlan_name] area area_name {ipv4
| ipv6}
```

### Note

The interface is not enabled separately from the area. If the area is enabled, the interface will begin transmitting hellos as soon as this command is executed, provided the interface is in forwarding mode and has active links.

### Setting the VLAN Interface Link Type

The default link type is broadcast. You can change the link type to point-to-point.

- To set the link type, use the following command:

```
configure isis [vlan all | {vlan} vlan_name] link-type [broadcast |
point-to-point]
```

### Setting the VLAN Interface Circuit Type

- The circuit type can be level 1, level 2, or both level 1 and level 2. To set the circuit type, use the following command:

```
configure isis [vlan all | {vlan} vlan_name] circuit-type level [1 | 2
| both-1-and-2]
```

### Configuring VLAN Interface Metrics

Normally, IS-IS metrics can have values up to 63. These metrics are narrow metrics. IS-IS generates two type, length, and value (TLV) codings, one for an IS-IS adjacency (code, length, and value (TLV) 2) and the second for an IP prefix (TLV 128 and TLV 130). During SPF, if the total cost of the path to a destination exceeds 1023, then according to ISO/IEC 10587, the path is ignored.

To overcome these restrictions, a second pair of TLVs is available, one for IP prefixes (TLV 135) and the second for IS-IS adjacency (TLV 22). With these TLVs, IS-IS metrics can have values up to 16,777,215 and the maximum path metric allowed is 4,261,412,864. This allows more flexibility while designing a domain. These metrics are wide metrics.

- To configure the metric style used on the router, use the following command:

```
configure isis area area_name metric-style [[narrow | wide]
{transition}] | transition] {level [1 | 2]}
```

- To configure the narrow metric used on one or all interfaces, use the following command:

```
configure isis [vlan all | {vlan} vlan_name] metric metric {level [1 |
2]}
```

- To configure the wide metric used on one or all interfaces, use the following command:

```
configure isis [vlan all | {vlan} vlan_name] wide-metric metric
{level [1 | 2]}
```

#### Note

Configured narrow and wide metrics for a particular interface must be identical in value while migrating from metric style narrow to metric style wide. Only if the metric style is “narrow” or “wide” (that is, no “transition”) is it okay to have different values (because one of the values is not used).

### Configuring the DIS Priority for Broadcast Interfaces

The designated intermediate system (DIS) is introduced in [Establishing Adjacencies](#) on page 971. When you configure the DIS priority, higher priority means higher election precedence (60 gets elected before 50).

- To configure the DIS priority, use the following command:

```
configure isis [vlan all | {vlan} vlan_name] priority priority
{level [1 | 2]}
```

#### Note

DIS priority 0 is the lowest priority value. Unlike an [OSPFDR](#) election, a DIS priority of 0 does not make a router ineligible for DIS election.

### Configuring Interface Participation in a Mesh Environment

Fully-meshed point-to-point topologies suffer from a potentially large amount of needless LSP flooding. At the trade-off of resiliency, interfaces can be restricted from flooding received LSPs.

- To configure an interface for a mesh environment, use the following command:  

```
configure isis [vlan all | {vlan} vlan_name] mesh [block-none | block-all | block-group group_id]
```

  - a. To block the flooding of received LSPs altogether, use the mesh block-all option.
  - b. To block the flooding of LSPs received on a specific group of interfaces (which are those with the same mesh group ID), use the mesh block-group *group\_id* option.
  - c. To remove blocking for an interface, use the mesh block-none option.

### Resetting a VLAN Interface to the Default Values

- To reset a VLAN interface to the default values, use the following command:  

```
unconfigure isis [vlan all | {vlan} vlan_name] {level [1|2]}
```

### Deleting a VLAN Interface

- To delete a VLAN interface from a router, use the following command:  

```
configure isis delete [vlan all | {vlan} vlan_name] {area area_name} {ipv4 | ipv6}
```

## Managing IS-IS Routers

### Adding an IS-IS Router

- To add an IS-IS router, use the following command:  

```
create isis area area_name
```

### Changing the IS-IS Level of a Router

- To change the IS-IS level of a router, use the following command:  

```
configure isis area area_name is-type level [1 | 2 | both-1-and-2]
```

### Resetting an IS-IS Router to the Default Values

- To reset an IS-IS router to the default values, use the following command:  

```
unconfigure isis area area_name {level [1|2]}
```

### Restarting All IS-IS Routers in a Virtual Router

- To restart all IS-IS routers in a virtual router, use the following command and specify the IS-IS process:

```
restart process [class cname | name {msm slot}]
```

For example:

```
restart process isis
```

### Disabling an IS-IS Router

- To disable an IS-IS router, use the following command:  
`disable isis {area area_name}`

### Deleting an IS-IS Router

- To delete an IS-IS router, use the following command:  
`delete isis area [all | area_name]`

## Configuration Example

Below is a sample configuration of CFM support in *EAPS (Extreme Automatic Protection Switching)*:

```
switch 1 # sh configuration cfm
#
Module dotlag configuration.
#
create cfm domain string "MD1" md-level 6
configure cfm domain "MD1" add association string "MD1v1" vlan "v1"
configure cfm domain "MD1" add association string "MD1v2" vlan "v2"
configure cfm domain "MD1" association "MD1v1" ports 17 add end-point down 6
configure cfm domain "MD1" association "MD1v1" ports 23 add end-point down 5
configure cfm domain "MD1" association "MD1v2" ports 31 add end-point down 13
configure cfm domain "MD1" association "MD1v1" ports 17 end-point down add group
"eapsCfmGrp1"
configure cfm domain "MD1" association "MD1v1" ports 23 end-point down add group
"eapsCfmGrp2"
configure cfm domain "MD1" association "MD1v2" ports 31 end-point down add group
"eapsCfmGrp3"
configure cfm group "eapsCfmGrp1" add rmep 2
configure cfm group "eapsCfmGrp2" add rmep 4
configure cfm group "eapsCfmGrp3" add rmep 12
switch 2 # sh configuration "eaps"s
#
Module eaps configuration.
#
enable eaps
create eaps d1
configure eaps d1 mode transit
configure eaps d1 primary port 17
configure eaps d1 secondary port 23
enable eaps d1
create eaps d2
configure eaps d2 mode transit
configure eaps d2 primary port 31
configure eaps d2 secondary port 23
enable eaps d2
configure eaps d1 add control vlan v1
configure eaps d1 add protected vlan pv1
configure eaps d2 add control vlan v2
configure eaps d2 add protected vlan pv2
create eaps shared-port 23
configure eaps shared-port 23 mode partner
configure eaps shared-port 23 link-id 100
configure eaps cfm add group eapsCfmGrp1
configure eaps cfm add group eapsCfmGrp2
configure eaps cfm add group eapsCfmGrp3
```

# Keychain Manager

---

[Keychain Manager Overview](#) on page 992

[Configuring and Using Keychain Manager](#) on page 994

This chapter introduces Keychain Manager (KCM), a convenient and centralized way for the user to store and manage keys in ExtremeXOS. KCM allows the user configure sets of keys in keychains with fixed periods of validity. It manages the selection, activation, and expiry of keys for the keychains, and it handles rollover to new keys when active keys expire.

## Keychain Manager Overview

---

Keychain Manager (KCM) creates and manages authentication keys in ExtremeXOS. In KCM, all keys are grouped into sets called keychains. KCM stores keychains and manages the activation, expiration, and rollover of keys.

When an ExtremeXOS application registers to use a keychain, KCM informs the application of key-related events and provides information about keys the application needs for authentication.

## Keys and Keychains

A keychain contains up to 8 keys. Each key has a *key identifier*, or key ID, that is unique within the keychain, and a secret *key string* that is used for authentication of protocol packets.

Each key has a cryptographic algorithm, which is used with the key string to calculate the key's hash value. You select an algorithm for each key: either HMAC-SHA-1, HMACSHA-256 (the default), HMAC-SHA-384, or HMAC-SHA-512. All of the algorithms are NIST FIPS 180-4 compliant. Keys in the same keychain can have different algorithms.

## Key Lifetimes

An *active key* is the key currently being used by the applications registered to a keychain. Within a keychain, only one key can be active at a time. When an active key expires, KCM attempts to roll over to a new active key. KCS selects the new active key based on *key lifetimes* you have defined.

You configure a key's lifetime -- the time period during which it is valid -- by specifying a start time (a date and time, either in UTC or local time) and an end time (the duration,

in seconds, from the start time). The maximum lifetime for a key is 180 days. You need to define only one lifetime for each key, because ExtremeXOS uses the same value for a key's send lifetime, used for outgoing communication, and its accept lifetime, used for incoming communication.

There is no default lifetime. As a result, a key cannot become active until you configure its lifetime.

## How KCM Manages Keys and Keychains

When an application is registered to use a keychain, and the active key expires, KCM selects a new active key from within the keychain. The new active key is the one with the earliest start time, unless its end time is in the past. If more than one key has the earliest start time, the key with the latest end time is selected. If there is still no clear choice, then the key with the lowest key ID is selected. (If all of the keys' end times are in the past, then no key is selected.)

### Note

Time changes, for example moving to daylight saving time, can affect KCM operations. When a time change occurs, active keys are cancelled and KCM attempts to assign new active keys. However, when a time zone is changed on a switch, KCM operation is not affected. Key lifetimes configured in local time are changed to reflect the new time zone.

When an active key expires and when a new key becomes active, KCM notifies the registered applications for that keychain. The notification includes the key string for the new active key.

We recommend that you configure keys in each keychain so that keys roll over at predetermined times. However, you can configure a grace period of up to 600 seconds so that a recently expired key can be accepted for incoming packets by applications that support the feature.

You can delete a key unless it is the active key for a keychain. However, you cannot change a key's key string.

## Supported Platforms

All ExtremeSwitching Universal switches.

### Note

OSPFv3 is the only application that currently uses Keychain Manager.

## Keychain Manager CLI Commands

```
configure keychain keychain_name accept-tolerance seconds
```

```

configure keychain keychain_name add key key_id key-string [text_string
active-lifetime local start start_time [end end_time | [duration
[seconds | maximum]]] | encrypted encrypted_string]

configure keychain keychain_name key key_id active-lifetime local start
start_time [end end_time | [duration [seconds | maximum]]]

configure keychain keychain_name key key_id hash-algorithm algorithm

create keychain keychain_name

delete keychain keychain_name

show keychain keychain_name detail

```

## Configuring and Using Keychain Manager

---

Extreme recommends to synchronize the clocks on all devices that will use Keychain Manager.

Complete the following steps in order to configure Keychain Manager:

1. Create a keychain using the following command:

```
create keychain keychain_name
```

2. Add keys to the keychain and configure options with the following commands:

```

configure keychain keychain_name add key key_id key-string
[text_string {active-lifetime {local} start start_time [end
end_time | [duration [seconds | maximum]]}] | encrypted
encrypted_string]configure keychain keychain_name key key_id active-
lifetime {local} start start_time [end end_time | [duration [seconds
| maximum]]]configure keychain keychain_name key key_id hash-algorithm
algorithm

configure keychain keychain_name key key_id active-lifetime
{local} start start_time [end end_time | [duration [seconds |
maximum]]]configure keychain keychain_name key key_id hash-algorithm
algorithm

configure keychain keychain_name key key_id hash-algorithm algorithm

```

3. Configure a supported client to use keychain. The authentication peer of the client must use the same key information.

# Layer 2 Tunneling and Filtering

---

[Layer 2 Protocol Tunneling](#) on page 995

[Protocol Tunneling](#) on page 997

[Protocol Filtering](#) on page 1000

[L2PT Limitations](#) on page 1002

This ExtremeXOS feature introduces the ability to tunnel and filter Layer 2 PDUs. Tunneling allows you to send Layer 2 PDUs across a service provider network, and be delivered to remote switches. It is useful when a network includes remote sites that are connected through a service provider network. Using tunneling, you can make the service provider network transparent to the customer network.

Filtering prevents Layer 2 PDUs from being received on a port.

## Layer 2 Protocol Tunneling

---

Layer 2 protocol tunneling (L2PT) is achieved by encapsulating the PDUs at the ingress PE device before transmitting them over the service provider network. The encapsulation prevents the PDUs from being processed by the switches in the SP network. At the egress PE device, the encapsulated packets are de-encapsulated, and transmitted to the CE device.

The encapsulation used for different types of networks is as follows:

- VLAN (Virtual LAN)/VMAN – The Destination Address (DA) MAC of the Layer 2 PDU is changed to the L2PT DA MAC. The switch shall also add any VLAN tags that may be required to the Layer 2 PDU before transmitting over the SP network.
- VPLS/VPWS – The DA MAC of the Layer 2 PDU is changed to L2PT DA MAC. The Layer 2 PDU is then treated like any other data packet by the MPLS (Multiprotocol Label Switching) stack. The MPLS stack shall add the labels and L2 headers as per its configuration to the Layer 2 PDU before transmitting over the SP network.
- VXLAN – The DA MAC of the Layer 2 PDU is changed to L2PT DA MAC at the ingress remote tunnel end-point (RTEP). The modified packet is then encapsulated into a VXLAN packet and sent over the network. At the egress RTEP, the packet is lifted to the CPU for L2PT processing. After VXLAN decapsulation, the DA MAC is changed from L2PT MAC to the protocol MAC and is sent on the access ports of the tenant VLAN.

Tunneling is configured on a service by specifying a tunneling action for each interface of the service. The possible actions are:

- **Tunnel** – Configuring an interface of a service to tunnel for a protocol enables the interface to tunnel PDUs of the configured protocol that are received by the underlying port of the interface. Any PDUs that are received in its native format are tunneled instead of processing locally by the switch. Any PDUs of the protocol that are received in its encapsulated format are dropped by the switch (receiving an encapsulated packet on an interface configured to tunnel is considered proof of network misconfiguration, or loops).
- **Encapsulate/Decapsulate** – Configuring an interface of a service to encapsulate or de-encapsulate for a protocol enables the interface to transmit and receive PDUs of that protocol in its encapsulated format. Native PDUs of the protocol may still be received by the underlying port of the interface, but they will not be tunneled and instead are processed locally by the switch.
- **None** – Configuring an interface of a service to none for protocol marks the interface as not participating in tunneling for that protocol. Native PDUs of the protocol that are received on the underlying port of the interface shall either be processed locally by the switch or be tunneled by another service which is configured to tunnel that protocol. Encapsulated PDUs that are received on the interface are treated like any other L2 packet.

An operator can specify a CoS (Class of Service) value for the tunneled PDUs. This can be useful since some L2 protocols may have a higher priority than others (for example, STP (Spanning Tree Protocol) may be considered higher priority than LLDP (Link Layer Discovery Protocol)). If a CoS value is specified for a protocol for which tunneling is enabled, the switch will transmit the encapsulated PDUs for that protocol with the operator specified CoS towards the network. The CoS value specified by the operator is transmitted on the SP network as follows:

- **VLAN/VMAN** – The CoS value is written to the PRI bits of the outermost VLAN tag if available.
- **VPLS/VPWS** – The CoS value is written to the EXP bits of the outermost MPLS label. The action taken by the switch for PDUs of a protocol is as described in the following table.
- **VXLAN** – The CoS value configured on the profile attached to the access port is written to the PRI bits of the outer VLAN header of the VXLAN encapsulated frames before transmitting them to other RTEPs.

As VXLAN tunneled packets cross L3 boundaries in the underlay network, the CoS can get lost when traversing L3 boundaries. An operator may choose to configure a Differentiated Services Code Point (DSCP) that needs to be set in the outer IP header of the encapsulated packets. If the packet encapsulated into the VXLAN tunnel is an IP packet, the DSCP from inner IP header is typically copied to DSCP of the outer IP header. A configuration option is provided to overwrite this outer DSCP value. In case of

L2 protocols (which do not have an inner DSCP), the configured DSCP value is set in the outer IP header.

**Table 66: L2 PDU Actions**

| Ingress Action      | Egress Action | Switch Action         |
|---------------------|---------------|-----------------------|
| None or Encap/Decap | NA            | Process locally       |
| Tunnel              | None          | Discard PDU at egress |
| Tunnel              | Tunnel        | Tx PDU natively       |
| Tunnel              | Encap/Decap   | Tx PDU encapsulated   |

The action taken by the switch for encapsulated PDUs for a protocol is as described in the following table.

**Table 67: L2 Encapsulated PDU Actions**

| Service has at least one I/F with tunnel action | Ingress Action      | Egress Action       | Switch Action             |
|-------------------------------------------------|---------------------|---------------------|---------------------------|
| No                                              | None or Encap/Decap | None or Encap/Decap | Forward                   |
| Yes                                             | None or Tunnel      | NA                  | Discard packet at ingress |
| Yes                                             | Encap/Decap         | None                | Discard packet at egress  |
| Yes                                             | Encap/Decap         | Tunnel              | Tx PDU natively           |
| Yes                                             | Encap/Decap         | Encap/Decap         | Tx PDU encapsulated       |

## Protocol Tunneling

To make L2PT configuration easier, in ExtremeXOS you can create L2PT profiles. An L2PT profile specifies the tunneling action and other parameters for protocols (specified using protocol filters) that should be tunneled. You can then apply the profile to the interfaces of the service that are participating in L2PT. And you can also change the profile when it is already bound to an interface.

The L2PT parameters that can be configured through a profile include the following:

- Tunneling Action
- Tunneling CoS
- Tunneling DSCP for VXLAN case

The following validity checks are performed when an entry for a protocol filter is created in an L2PT profile:

- Ensure that all protocols in the protocol filter define a destination MAC address.
- Ensure that all protocols in the protocol filter define a protocol identifier.
- Ensure that all protocols in the protocol filter are unique within the L2PT profile.
- If the action for the protocol filter is 'encapsulate':
  - Ensure that there are no entries with action as 'tunnel' in the L2PT profile.

- Ensure that the service interface is either a tagged VLAN port, a PW, or a VXLAN RTEP.
- If the action for the protocol filter is 'tunnel':
  - Ensure that there are no entries with action as 'encapsulate' in the L2PT profile.
  - For every service interface using the L2PT profile:
    - Ensure that none of the protocols in the protocol filter are filtered on the underlying port of the interface.
    - Ensure that none of the protocols in the protocol filter are tunneled on the underlying port of the interface.

The following validity checks are performed when a L2PT profile is bound to an interface of a service:

- If the profile specifies the action as 'tunnel' for protocol filter:
  - Ensure that the interface is not a PW or a VXLAN RTEP.
  - Ensure that none of the protocols in the L2PT profile are filtered on the underlying port of the interface.
  - Ensure that none of the protocols in the L2PT profile are tunneled on the underlying port of the interface.

Typically, you will want to configure the tunneling action for all customer facing interfaces of the service that participate in L2PT as tunnel, and the tunneling action for all network facing interfaces as encapsulate/decapsulate. Once any interface of the service is configured to tunnel a protocol, the switch will configure all tagged ports and PWs or VXLAN RTEPs of the service to encapsulate/decapsulate mode. You can override this implicit configuration by binding the RTEPs a profile to the service interface that specifies a different tunneling action.

For example, consider a VMAN service named c1 with customer facing ports 1, 2 and 3 and network facing ports 4, 5, 6. Ports 4, 5 and 6 are added as tagged to the VMAN and 1, 2 and 3 are added as untagged to the VMAN. The operator wants to tunnel LACP and EFM OAM on all customer facing ports at CoS 5. The configurations that he or she must make are as follows:

```
Create a protocol filter
create protocol filter "my_slow_protocols_filter"

Add LACP to the protocol filter
configure protocol filter "my_slow_protocols_filter"
add dest-mac 01:80:C2:00:00:02 etype 0x8809 field offset 14 value 01 mask FF

Add EFM OAM to the protocol filter
configure protocol filter "my_slow_protocols_filter"
add dest-mac 01:80:C2:00:00:02 etype 0x8809 field offset 14 value 03 mask FF

Create an L2PT profile for the customer facing ports named c1_l2pt_profile
create l2pt profile "c1_l2pt_profile"

Enable CDP tunneling with CoS 5
configure l2pt profile "c1_l2pt_profile" add protocol filter
"my_slow_protocols_filter" action tunnel cos 5

Enable CDP tunneling with CoS 3 and DSCP 38 in case of VXLAN tenant VLAN
configure l2pt profile "c1_l2pt_profile" add protocol filter
```

```

"my_slow_protocols_filter" action tunnel cos 5 dscp 38

Bind c1_l2pt_profile to all customer facing ports
configure vman c1 ports 1,2,3 l2pt profile "c1_l2pt_profile"

Please note that the network facing port 4, 5 and 6 don't have to be explicitly
configured to encapsulate/decapsulate mode since the switch implicitly sets all
tagged ports to encapsulate/decapsulate mode when an L2PT profile is bound to
any port of the service.

```

The operator also has the option to configure the L2PT destination MAC address (i.e., the DA used by L2PT encapsulated PDUs). This may be done using the following CLI command:

```
configure l2pt encapsulation dest-mac mac_address
```

The L2PT destination MAC address may only be changed when no L2PT profiles have been bound to any service interface. The default L2PT DA MAC is 01:00:0C:CD:CD:D0 (selected to be interoperable with Cisco and Juniper).

Use the following commands to view the status and statistics of L2PT:

```

show [vlan | vman] vlan_name {ports port_list} l2pt {detail}

show {l2vpn} [vpls vpls_name | vpws vpws_name] {peer ipaddress} l2pt
{detail}

show [{vlan} vlan_name] [{vxlan {vr vr_name} rtep rtep_ipv4}}] l2pt
{detail}

```

Use the following commands to clear L2PT stats:

```

clear l2pt counters [{vlan | vman] vlan_name {ports port_list}}

clear l2pt counters [{vpls vpls_name {peer ipaddress} | vpws vpws_name}]

clear l2pt counters [{vman} vlan_name [{vxlan {vr vr_name} rtep rtep_ipv4}}]

```

## Implementing L2PT in ExtremeXOS

In ExtremeXOS, the L2PT data-plane is implemented almost entirely in software. When you attach a L2PT profile to a service interface, the following *ACL (Access Control List)* rules are configured:

- An ACL rule is added to copy and drop all packets with a destination address equal to the L2PT destination MAC address, and an outer VLAN ID equal to the VLAN tag of the service. In case of VXLAN tenant VLAN, the condition for VLAN ID is modified so that the packet is copied to CPU on any VLAN received. The traffic for the destined tenant VLAN ID can be received on any underlay L3 VLAN.
- For each protocol that is tunneled on the service interface, an ACL rule is added to copy and drop all packets with the same the destination address as the protocol. If the protocol defines an EtherType, then the rule is also qualified with the EtherType.

- If any protocol is tunneled on the service interface, an ACL rule is added to drop all packets received on the service interface with a destination address equal to the L2PT destination MAC address.

## Protocol Filtering

---

You can enable filtering of PDUs of a protocol on any port. If you enable filtering for a protocol on a port, the switch discards PDUs of that protocol on that port.

Use the following command to view protocol filter status and statistics:

```
show ports [port_list | all] protocol filter {detail}
```

Use the following command to clear protocol filtering stats:

```
clear counters ports {port_list} protocol filter
```

## Implementing Protocol Filtering in ExtremeXOS

In ExtremeXOS, the protocol filtering data-plane is implemented partially in hardware and partially in software. Filtering is performed only on the ingress. When a protocol filter is attached to a port, the following [ACL](#) rules are configured:

- For each protocol in the protocol filter: If the protocol does not define a user-defined field, and the protocol identifier is EtherType, or does not have a protocol identifier:
  - An ACL rule is added to drop all packets on the port that match the destination address of the packet. The rule is also qualified with the EtherType of the protocol if it defines one.
- Else:
  - An ACL rule is added to copy and drop all packets on the port that match the destination address of the packet. The rule is also qualified with the EtherType of the protocol if it defines one.

The protocol filtering data-plane inspects all packets received from ports that have protocol filters attached, and drops any packet that matches any of the protocols configured in the protocol filter.

Protocol filtering is also supported for VXLAN tenant VLANs. However, filtering has to be configured on access ports only, and is not supported on RTEPs. This aligns with the existing behavior where filtering cannot be supported on pseudo wires.

## Protocol Filters

Both L2PT and protocol filtering allow you to tunnel or filter many protocols on an interface. For this purpose, ExtremeXOS supports creating protocol filters. A protocol filter contains a number of protocols to which you can apply some action (like tunneling and filtering). Each protocol in a protocol filter is defined using the following fields:

- The destination MAC address of PDUs of the protocol. This field is mandatory for all protocols that are to be tunneled or filtered.

- The protocol id (EtherType, LLC, SNAP). This field is mandatory for all protocols that are to be tunneled.
- User defined field. This is an arbitrary field in the PDU of the protocol that is specified using the offset of the field from the start of the PDU, the value of the field and a mask.

For example, use the following command to create a protocol filter that includes LACP and EFM OAM:

```
Create a protocol filter
create protocol filter my_slow_protocols_filter

Add LACP to the protocol filter
configure protocol filter my_slow_protocols_filter add dest-mac
01:80:C2:00:00:02 etype 0x8809 field offset 14 value 01 mask FF

Add EFM OAM to the protocol filter
configure protocol filter my_slow_protocols_filter add dest-mac
01:80:C2:00:00:02 etype 0x8809 field offset 14 value 03 mask FF
```

The following validity checks are performed when a protocol is added to a protocol filter:

- Ensure that the protocol does not already exist in the protocol filter.
- If the protocol filter is used by any L2PT profile:
  - Ensure that the protocol defines a destination MAC address.
  - Ensure that the protocol defines a protocol identifier.
- For every L2PT profile that is using the protocol filter:
  - Ensure that the protocol is unique within the L2PT profile. If the action for the protocol filter is 'tunnel' in the L2PT profile:
    - For every service interface using the L2PT profile: ensure that the protocol is not filtered on the underlying port of the service interface.
    - It ensures that the protocol is not tunneled on the underlying port of the service interface.
- If the protocol filter is used by any port for the purpose of protocol filtering (configure ports *port#* protocol filter *filter-name*):
  - Ensure that the protocol defines a destination MAC address.
- For every port that has the protocol filter attached for the purpose of protocol filtering:
  - Ensure that the protocol is not tunneled by a service on that port.

#### Note

Protocol filters may be used with features other than L2PT and protocol filtering (for example, Protocol Based VLANs). The validity tests listed above are only the ones relevant to L2PT and protocol filtering.

Protocol filters for the following protocols are created automatically by the switch when the switch is set to default configuration:

- Cisco Discovery Protocol (CDP)
- Unidirectional Link Detection (UDLD)
- VLAN Trunking Protocol (VTP)
- Port Aggregation Protocol (PAgP)
- Dynamic Trunking Protocol (DTP)
- Link Aggregation Control Protocol (LACP)
- LLDP
- STP
- EDP (Extreme Discovery Protocol)

## L2PT Limitations

---

- L2PT and protocol filtering is implemented in software, so the number of frames that can be filtered or tunneled is limited.
- Both L2PT and protocol filtering can be configured only through CLI. Configuration through SNMP (Simple Network Management Protocol)/XML is not supported for this release.
- If L2PT configurations are made on PWs, these configurations are lost on a restart of the MPLS process unless the L2PT process is also restarted.
- If L2PT configurations are made on a VPLS or VPWS service, dot1p tag inclusion must be enabled on the VPLS/VPWS. Also, VPLS or VPWS service must have same VLAN IDs at each end of a PW.
- When tunneling protocols are point-to-point in nature, it is your responsibility to ensure that there are only two tunnel endpoints for the protocol.
- If a protocol that is configured to be tunneled on a service interface cannot be uniquely identified by its destination address and EtherType, then all packets with the same DA and EtherType of the protocol being tunneled (but that are not really PDUs of the protocol) will be slow path forwarded.
- Tagged protocol PDUs cannot be tunneled over VLANs. Tagged protocol PDUs can only be tunneled over VMANs (the VMAN can be the service VMAN for a VPLS/VPWS service, or a standalone VMAN). Untagged protocol PDUs can be tunneled over both VLANs and VMANs (the VLAN/VMAN can be standalone, or be the service VMAN for a VPLS/VPWS service).
- Untagged protocol PDUs cannot be bypassed if the ingress port is an untagged VMAN port with a default CVID. Untagged protocol PDUs can be bypassed if the ingress port is an untagged VMAN port without a default CVID.
- In VPLS, only full-mesh configuration is supported for L2PT.
- L2PT is not supported on VLAN ports that have a port specific tag.
- L2PT is not supported on provider edge ports when MACSEC was enabled on customer edge."

# Layer 3 Virtual Private Network

This chapter introduces Layer 3 VPN, a way to create a tunnel between customer sites through a Provider Backbone, and its features and options in a *BGP (Border Gateway Protocol)/MPLS (Multiprotocol Label Switching)* VPN environment. This chapter also provides an example showing L3VPN configuration on a BGP/MPLS setup.

## Overview of Layer 3 VPN

---

Layer 3 Virtual Private Networks (L3VPN) is a specific implementation of PPVPN (Provider Provisioned VPN). L3VPN is a way to create a tunnel between customer sites through a Provider Backbone, and that tunnel is established and maintained by the Service Provider.

Within a Layer 3 VPN, the customer advertises IP routing knowledge to the provider network. The ISP then advertises this routing information across its network to the other customer locations. This simple concept requires some coordination between the provider and the customer. Also, the provider must configure its network to support the advertisement of these routes and have a way to segregate the customer routes. This is accomplished with the help of a specially designed Network Layer Reachability Information (NLRI).

Within a L3VPN, several routers will play a different role. On the customer site, there is a CE router (Customer Edge). This router is the property of the customer and is managed by them. This router is outside of the Autonomous System (AS) of the Provider. On the Provider side there are some PE routers (Provider Edge) and P routers (Provider). The PE routers are facing the CE routers. They have all the customer's IP routing knowledge. The P routers do not have that knowledge; they are not facing any CE routers, and they serve only to transport the data from PE routers to other PE routers. Their knowledge is very limited, and they usually are intended only for swapping *MPLS* labels. In other

words the Provider's core is pure MPLS and has no knowledge of L3VPN, while the edge is L3VPN aware.

**Figure 114: Different Router Roles in L3 VPN**

A L3VPN requires an MPLS transport mechanism in the Provider Backbone for the data forwarding and Multiprotocol *BGP* (MBGP) between the PE routers to exchange VPN-IPv4 routing information.

## Overview of BGP/MPLS Network

This section introduces the basic concepts of *BGP/MPLS* VPNs as described in the Internet RFC 4364. [Figure 115](#) illustrates an example BGP/MPLS VPN network configuration that includes two VPNs: VPN-A comprises three sites, and VPN-B comprises two. Both VPNs use the same set of IP addresses as defined in RFC 1918.

**Figure 115: BGP/MPLS VPN Example**

The Customer Edge boxes represent switches or routers, while the Provider Edge and P(rovider) boxes are routers. If the CE box is a router, then it only needs to peer with the adjacent PE router(s). The PE and P routers form the core MPLS network. The P routers only maintain routing information for the core MPLS network, while the PE routers only maintain routing information for the VPNs they support. This ensures that no single router maintains routing information for all the VPNs.

Since a PE router can support multiple VPNs that may have overlapping address spaces, each PE router must maintain multiple Virtual Routing and Forwarding tables (VRFs). In the example, each site is a member of one VPN, and the PE router is configured to associate a particular VPN with each physical interface to a CE router. The PE router maintains one VRF for each VPN, and packets received from a particular physical interface are forwarded using the VRF for the VPN associated with that interface.

VRFs for a specific VPN are populated in two ways: (1) when the PE router learns routes from a directly-attached CE router that is a member of the VPN, and (2) when the PE router receives routes for the VPN through MBGP from another PE router. The PE router can learn the routes that are reachable at a particular CE router's site through configuration (static routes), or by routing protocol exchanges with the CE router.

VPN route distribution uses BGP-4 Multiprotocol Extensions that enable BGP to carry routes from multiple address families. The VPN-IPv4 address family supports BGP/MPLS VPNs. A VPN-IPv4 address is a 12-byte entity, beginning with an 8-byte (RD) and ending with a 4-byte IPv4 address. The RD makes it possible to create distinct routes to a common IPv4 address prefix, which is necessary when the same IPv4 address prefix is used in two different VPNs.

The purpose of the RD is solely to allow one to create distinct routes to a common IPv4 address prefix. The Route target attribute is used to identify a set of VRFs. Every VRF is

associated with one or more route targets. Export route targets identify the set of route targets that a PE router attaches to a route learned from a particular CE site. Import route targets identify the set of route targets that determine whether a route received from another PE router can be inserted in a particular VRF. A VPN-IPv4 route can only be installed in a particular VRF if there is a route target that is both one of the route's targets, and one of the VRF's import route targets. Route targets allow a PE router to only maintain routing information for the VPNs it is supporting. Using import and export route targets offers flexibility in constructing a variety of VPN topologies (such as a fully-meshed closed user group, or a hub-and-spoke architecture). Route Targets are encoded as BGP Extended Communities attributes.

When distributing a VPN route through BGP, a PE router includes its own IP address as the BGP next hop (next-hop-self). The PE router always assigns and distributes an MPLS label for each customer VPN VRF that it receives from directly connected sites (CEs). BGP-distributed MPLS labels require that there be a label switched path between the PE router that installs the BGP-distributed route and the PE router that is the BGP next hop of that route. This is necessary because a multi-label stack is used to forward VPN packets across the MPLS backbone.

The outer MPLS label gets the packet across the backbone. This label is obtained from the MPLS signaling protocols, and is associated with the best LSP to the BGP next hop address of the PE Router that advertised the VPN route. The inner MPLS label is obtained from BGP, and is associated with the best route to the VPN destination address. This label identifies the VRF that the egress PE Router uses to forward the packet to a CE device, and may indicate the outgoing interface that the packet should be forwarded over (along with the appropriate link layer header for that interface).

The use of a two-level MPLS label stack is an important scalability attribute of the model, because it is the two-level label stack that enables the P routers to operate without containing routes for any of the VPNs.

In summary, key aspects of the BGP/MPLS VPN model include:

- Direct peering of customer routers with service provider routers.
- Maintenance of multiple forwarding tables by PE routers.
- Introduction of the VPN-IPv4 address family.
- Constrained distribution of routing information via Route Targets.
- Use of MPLS label switching in the backbone network.

## VPNv4 NLRI

One of the core principles of operating a VPN is maintaining separation between the customer networks. L3VPN uses a special format to represent customer routes within the provider's network. This format allows each provider router to uniquely view routes from different customers as separate, even when they advertise the same IPv4 prefix. The format consists of these fields: Mask, MPLS label, route distinguisher, and IPv4 prefix.

## Limitations

The following list identifies the limitations of the L3VPN feature:

- RIP (Routing Information Protocol) is not supported for PE – CE peering routing protocol.
- IP Multicast BGP/MPLS VPN is not supported
- OSPFv2 and ISIS is not supported for PE-CE peering routing protocol.
- IPv6 VPN is not supported.
- Graceful restart mechanism for BGP with MPLS (RFC-4781) is not supported.
- Constraint Route distribution for BGP/MPLS VPN (RFC-4684) is not supported.
- Carrier of carriers BGP/MPLS VPN configuration is not supported.
- XML support to configure BGP/MPLS VPN parameters.
- Carrier's carrier (RFC 4364, Section 9).
- Inter-AS / inter-provider VPNs (RFC 4364, Section 10).
- No other BGP related MIB other than RFC 1657 is supported.

## Overlapping Customer Address Spaces

VPN customers often manage their own networks and use the RFC-1918 private address space. If globally unique IPv4 addresses are not used, the same 32-bit IPv4 address can be used to identify different systems in different VPNs. This causes routing problems because BGP assumes that each IPv4 address that it carries is globally unique. To solve this problem, BGP/MPLS VPN converts non-unique IPv4 addresses into unique VPN-IPv4 address families. Each IPv4 address is prepended with an 8-bytes long Route Distinguisher (RD).

A VPN-IPv4 address is a 12-byte quantity composed of an 8-byte RD and 4 byte IPv4 address. The 8-byte RD is composed of a 2-bytes type field and a 6-bytes value field. The value of the Type field determines the lengths of the Value field's two subfields (Administrator and Assigned Number), as well as the semantics of the Administrator field.

Most commonly, the Admin field holds a 2-byte non-private AS number and the Assigned number field holds a 4-byte number assigned by the VPN service provider. Another common format for the RD is the Admin field holds a global 4-byte IPv4 address, and the Assigned number field holds 2 byte number assigned by the VPN service provider.

## Multi-protocol BGP Extension

BGP is originally designed to carry routing information for IPv4 address families only. Since VPN-IPv4 addresses are 12 bytes wide, BGP requires some kind of extension to carry VPN-V4 address family routing information. This is achieved by using MBGP extension which allows BGP to carry multiprotocol address families routing information. Therefore, to deploy BGP/MPLS VPNs and to support the distribution of VPN-IPv4 routes, PE routers are required to support the MP-BGP extensions with VPN-IPv4 address family support.

---

## Multiple Forwarding Tables

---

Each PE router needs to maintain one forwarding table per VPN that it is directly connected. These forwarding tables are called Virtual Routing and Forwarding tables (VRF). When a PE router is configured, each of its VRF is associated with one or more VLAN (Virtual LAN)s, that is, there is a many to one mapping from VLAN to VPN/VRF. When receiving inbound data traffic from a directly attached CE router, PE router determines the VRF for the packet based on which VLAN the packet has been received. The ingress VLAN will uniquely map to a particular VRF in the system. Then, PE router performs a route lookup for the packet's destination IP address in the associated VRF. In the figure above, both PE1 and PE3 have two VRFs, one each for VPN-A and VPN-B, whereas, PE2 has only one VRF which is for VPN-A.

---

## Quality of Service in BGP/MPLS VPN

---

The L3VPN implementation uses the existing ACL and QoS (Quality of Service) framework available in ExtremeXOS to achieve QoS on a PE. Please refer to the [Quality of Service](#) on page 1414 section for more information.

---

## Virtual Routing and Forwarding Instances

---

The concept of Virtual Routing and Forwarding (VRF) is similar to the already present in Extreme Switches. Like a VR, each VRF also has a distinct set of VLANs and ports, as well as a unique name assigned to it across the system. VLANs are created, and ports are added to in the same manner as is done for VRs. Logically separate instances of the same routing protocol may run in the contexts of multiple VRFs of the same switch, simultaneously. In addition, a VRF may also contain a Route Distinguisher (RD), multiple import and export Router Targets (RTs), as well as a VPN ID. These three items allow a VRF to support L3VPNs.

The goal of VRF is to provide separation of overlapping address spaces belonging to separate routing domains. The objective of the VR is to split the switch into multiple routing domains so that traffic originating on one VR never enters another VR. The objective of VRFs is to control the flow of traffic across various VPN sites. As the PE-PE connection is always part of the default VR or a user VR, the forwarding table corresponding to a particular VRF has the incoming interface belonging to the VRF, and egress interfaces belonging to the default, or user VR. Similarly, the forwarding table (MPLS label table) corresponding to a user, or default VR, could have an interface belonging to a VRF as part of its egress interfaces. In this sense a VRF is "associated" with the user, or default VR (also referred to as parent VRs).

A VRF is not the same as a VR. A VRF always requires that you have a Parent VR, and this can either be the default VR or User VR. Protocols running in a VRF run as a separate logical instance within the context of the protocol process that is running in the Parent VR. ExtremeXOS VRFs come in two types:

- Non-VPN VRFs - Non-VPN VRFs are used for L3 Routing and Forwarding just like VRs. These provide the ability to scale protocol deployments. BGP and static routing are supported in the Non-VPN VRF.

- VPN VRFs - VPN VRFs enable configuration of RD and RT to realize L3VPN topologies.

**Note**

MPLS and BGP must be configured in the parent VR (PE-facing).

BGP and static routing are supported in the VPN VRF.

Again, a VRF always requires that you have a Parent VR, and this can either be the default VR or User VR. Protocols running in a VRF run as a separate logical instance within the context of the protocol process that is running in the Parent VR. For example, the BGP process for a VR running MPLS will handle all PE to CE instances of BGP by virtualizing the data structures. This approach of allowing VRFs in a VR is more scalable than having a process for every instance of PE-to-CE routing protocol.

## L3VPN BOOTP Relay

---

A DHCP Relay agent relays DHCP requests from the client to the DHCP server and relays the DHCP replies from the server to the client. It acts as a proxy, thereby reducing the number of DHCP servers required in the network. The DHCP relay agent inserts its own IP address in the giaddr field (gateway address) of the DHCP request. The DHCP server can look into this IP address, identify the DHCP client's subnet and assign an IP address accordingly.

You can enable BOOTP Relay over VRFs and VPN-VRFs in the same manner as with normal VRs. Normally, you must enable BOOTP Relay on both ingress and egress VLANs. However, with BOOTP Relay over L3VPN, you do not need to enable BOOTP Relay on egress VLANs, since ingress and egress VLANs are present in different VRs/VRFs.

## Limitations

The following are limitations of the BOOTP Relay L3VPN feature:

- VPN-ID is not supported on DHCP-Relay Option 82, which services clients across VPNs.
- IPv6 BOOTP Relay not supported, since there is no IPv6 support for L3VPN.

## L3VPN Configuration Example

---

Here is an example of a Layer 3 VPN. In this example CE1 and CE2 are in different AS. You can put them in the same AS by adding the `allowas-in` command.

In this example, you should be able to ping CE2 "fool's" IP address from CE1.

**Figure 116: Layer 3 Virtual Private Network**

# LLDP

---

- [Supported Advertisements \(TLVs\)](#) on page 1015
- [LLDP Redundancy Support on Stacking](#) on page 1019
- [LLDP Packets](#) on page 1020
- [Transmitting LLDP Messages](#) on page 1020
- [Receiving LLDP Messages](#) on page 1021
- [LLDP Management](#) on page 1022
- [Configuring and Managing LLDP](#) on page 1022
- [Displaying LLDP Information](#) on page 1032

The Link Layer Discovery Protocol (LLDP) is defined by IEEE standard 802.1ab and provides a standard method for discovering physical network devices and their capabilities within a given network management domain.

LLDP-enabled network devices include repeaters, bridges, access points, routers, and wireless stations, and LLDP enables these devices to do the following:

- Advertise device information and capabilities to other devices in the management domain.
- Receive and store device information received from other network devices in the management domain.

LLDP-discovered information can be used to do the following:

- Discover information from all LLDP compatible devices in a multivendor environment.
- Trigger universal port profiles that can configure a switch port for a remote device (see [Universal Port](#)).
- Supply identity information that can be used for authentication and identity management.
- Provide device information to SNMP (Simple Network Management Protocol) compatible Network Management Systems such as Extreme Management Center or Ridgeline, which can present the information in inventory reports and topology maps.

The following sections provide additional information on LLDP support in the software.

## Supported Advertisements (TLVs)

*LLDP (Link Layer Discovery Protocol)* defines a set of common advertisement messages. These are distributed in Type Length Value (TLV) format in an LLDP packet (see [LLDP Packets](#) on page 1020).

The individual advertisements within the packet are called TLVs, and each TLV advertises device information or a device capability. Certain TLVs are mandatory and are always advertised after LLDP is enabled; optional TLVs are advertised only when so enabled by default or during configuration.

The following sections provide more information on TLVs.

### Mandatory TLVs

Mandatory TLVs are those TLVs that must be advertised (as defined in IEEE standard 802.1ab) when *LLDP* is enabled.

If you enable LLDP on a port, the mandatory TLVs are advertised and there is no command to disable this advertising.

**Table 68: Mandatory TLVs**

| Name               | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Chassis ID         | The ExtremeXOS software advertises the system's MAC address in this TLV to uniquely identify the device.<br><br><b>Note:</b> <i>EDP (Extreme Discovery Protocol)</i> also uses the MAC address to identify the device.                                                                                                                                                                                                                                                                                                                       |
| Port ID            | The ExtremeXOS software advertises the port ID in this TLV to uniquely identify the port that sends the TLVs. This port ID is the ifName object in the MIB.                                                                                                                                                                                                                                                                                                                                                                                  |
| Time to live (TTL) | This TLV indicates how long the record should be maintained in the LLDP database. The default value is 120 seconds (or 2 minutes). When a port is shutting down or LLDP is disabled on a port, this TLV is set to value 0, which indicates that the record for this port should be deleted from the database on other devices.<br>Although you cannot directly configure the TTL TLV, you can configure the transmit hold value, which is used to calculate the TTL TLV. (See <a href="#">Configuring LLDP Timers</a> for more information.) |
| End-of-LLDP PDU    | The end-of-LLDPDU (LLDP protocol data unit) TLV marks the end of the data in each LLDP packet.                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### Optional TLVs

IEEE standard 802.1ab defines a set of optional TLVs, which are listed in the following table.

The system description TLV is advertised by default. All other optional TLVs must be configured to enable advertising. You can use the CLI to configure the optional TLVs, or you can use an [SNMP \(Simple Network Management Protocol\)](#)-compatible network management system (NMS). For more information on the optional TLVs, see [Configuring Optional TLV Advertisements](#).

**Table 69: Optional TLVs**

| Name                         | Comments                                                                                                                                                                                                                                                                                                              |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Port description             | Advertises the display-string that is configured for the port.                                                                                                                                                                                                                                                        |
| System name                  | Advertises the device's configured system name, which is configured with the <code>configure snmp sysname</code> command.                                                                                                                                                                                             |
| System description           | Advertises show version command information similar to the following:<br><pre>ExtremeXOS version 11.2.0.12 v1120b12 by release- manager on Fri Mar 18 16:01:08 PST 2005</pre> The default configuration advertises this optional TLV when <a href="#">LLDP</a> is enabled.                                            |
| System capabilities          | Advertises bridge capabilities. If IP forwarding is enabled on at least one <a href="#">VLAN (Virtual LAN)</a> in the switch, the software also advertises router capabilities.                                                                                                                                       |
| Management address           | Advertises the IP address of the management VLAN in the management address TLV. If the management VLAN does not have an assigned IP address, the management address TLV advertises the system's MAC address, unless another VLAN's IP address is specified (see <a href="#">Management Address TLV</a> on page 1026). |
| VLAN name                    | Advertises the name of a tagged VLAN for the port. You can configure this TLV multiple times to support multiple VLANs.                                                                                                                                                                                               |
| Port VLAN ID                 | Advertises the untagged VLAN on the port.                                                                                                                                                                                                                                                                             |
| Port and protocol VLAN ID    | Advertises a VLAN and whether the port supports protocol-based VLANs or not. You can configure this TLV multiple times to support multiple VLANs.                                                                                                                                                                     |
| MAC/PHY configuration/status | Advertises the autonegotiation and physical layer capabilities of the port.                                                                                                                                                                                                                                           |
| Power via MDI                | For Ethernet ( <a href="#">PoE (Power over Ethernet)</a> ) or PoE+ ports, this TLV advertises the device type, power status, power class, and pin pairs used to supply power.                                                                                                                                         |
| Link aggregation             | Advertises information on the port's load-sharing (link aggregation) capabilities and status.                                                                                                                                                                                                                         |
| Maximum frame size           | Advertises the maximum supported frame size for a port to its neighbors. When jumbo frames are not enabled on the specified port, the TLV advertises a value of 1518. If jumbo frames are enabled, the TLV advertises the configured value for the jumbo frames.                                                      |

## Avaya–Extreme Networks Optional TLVs

The software supports a set of TLVs that are proprietary to Avaya and Extreme Networks.

These TLVs advertise and receive information for Avaya voice over IP (VoIP) telephones, which include powered device (PD) information. Some TLVs are advertised by the switch, and some are advertised by the telephone. The switch starts advertising these proprietary TLVs when you enable LLDP and configure the specified TLVs to be advertised. The switch receives the proprietary TLVs when LLDP is enabled; you do not have to configure the switch to receive individual TLVs.

**Table 70: Avaya–Extreme Networks TLVs**

| Name                                  | Comments                                                                                                                                                                                                                   |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <u>PoE</u> conservation level request | When the switch software needs to reduce power on a PoE-enabled port, this TLV advertises that request to the connected Avaya device.                                                                                      |
| Call server                           | The switch uses this TLV to advertise the IP addresses of up to eight call servers to an Avaya phone.                                                                                                                      |
| File server                           | The switch uses this TLV to advertise the IP addresses of up to four file servers to an Avaya phone.                                                                                                                       |
| 802.1Q framing                        | The switch uses this TLV to advertise information about Layer 2 priority tagging to an Avaya phone.                                                                                                                        |
| PoE Conservation level support        | An Avaya phone uses this TLV to communicate the current power consumption level and current conservation level for the phone, including typical power value, maximum power value, and available conservation power levels. |
| IP phone address                      | An Avaya phone uses this TLV to communicate the IP address and mask configured in the phone, as well as a default gateway address.                                                                                         |
| CNA server                            | An Avaya phone uses this TLV to communicate the IP address of a Converged Network Analyzer (CNA).                                                                                                                          |
| Fabric Attach (FA) Element            | Used by FA elements to advertise their FA capabilities.                                                                                                                                                                    |
| Fabric Attach (FA) Assignment         | Used by FA clients to advertise service requests and by FA proxy and FA server elements to return the status of FA client service requests.                                                                                |

## LLDP MED Optional TLVs

LLDP Media Endpoint Discovery (MED) is an extension to LLDP that is published as standard ANSI/TIA-1057. LLDP MED TLVs advertise and receive information for endpoint

devices, which can include powered device (PD) information. Some TLVs are advertised by the switch, and some are advertised by the endpoint device.

**Table 71: LLDP MED TLVs**

| Name                   | Comments                                                                                                                                                                                                                                                                                                                    |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LLDP MED capabilities  | The switch uses this TLV to advertise the switch LLDP MED capabilities to endpoint devices. This TLV must be configured for advertisement before any other LLDP MED TLVs can be configured for advertisement, and advertisement for all other MED TLVs, must be disabled before advertisement for this TLV can be disabled. |
| Network policy         | The switch uses this TLV to advertise network policy information for specific applications to endpoint devices.<br><br><b>Note:</b> Network policies cannot be configured by <i>SNMP</i> -based management programs.                                                                                                        |
| Location ID            | The switch uses this TLV to advertise a location ID to an endpoint device.                                                                                                                                                                                                                                                  |
| Extended power via MDI | The switch uses this TLV to advertise a power information and settings to an endpoint device on a <i>PoE</i> -capable port.                                                                                                                                                                                                 |
| Hardware revision      | An endpoint device uses this TLV to advertise the configured hardware revision to the switch.                                                                                                                                                                                                                               |
| Firmware revision      | An endpoint device uses this TLV to advertise the configured firmware revision to the switch.                                                                                                                                                                                                                               |
| Software revision      | An endpoint device uses this TLV to advertise the configured software revision to the switch.                                                                                                                                                                                                                               |
| Serial number          | An endpoint device uses this TLV to advertise the configured serial number to the switch.                                                                                                                                                                                                                                   |
| Manufacturer name      | An endpoint device uses this TLV to advertise the configured manufacturer name to the switch.                                                                                                                                                                                                                               |
| Model name             | An endpoint device uses this TLV to advertise the configured model name to the switch.                                                                                                                                                                                                                                      |
| Asset ID               | An endpoint device uses this TLV to advertise the configured asset ID to the switch.                                                                                                                                                                                                                                        |

You must enable the LLDP-MED capabilities TLV for advertising before you configure any other LLDP MED TLVs for advertising. Likewise, when disabling LLDP MED TLV advertisement, you can disable the LLDP-MED capabilities TLV only after you have disabled advertisement for all other LLDP MED TLVs.

After the LLDP-MED capabilities TLV is configured for advertising, the switch can receive LLDP MED TLVs from endpoints; you do not have to configure the switch to receive individual TLVs.

The switch advertises LLDP MED TLVs only after the switch receives an LLDP MED TLV from an endpoint, and the switch only advertises on ports from which an LLDP MED TLV has been received. This approach prevents the switch from advertising LLDP

MED TLVs to another switch, and it prevents the wasted bandwidth and processing resources that would otherwise occur.

The LLDP MED protocol extension introduces a new feature called MED fast start, which is automatically enabled when the LLDP MED capabilities TLV is configured for advertisement.

When a new LLDP MED-capable endpoint is detected, the switch advertises the configured LLDP MED TLVs every one second for the configured number of times (called the repeat count). This speeds up the initial exchange of LLDP MED capabilities. After the repeat count is reached, the LLDP MED TLVs are advertised at the configured interval.

#### Note

The fast-start feature is automatically enabled, at the default level of 3, when you enable the LLDP MED capabilities TLV on the port.

## BGP Config Discovery Optional TLV

*LLDP BGP (Border Gateway Protocol)* Peer Discovery is an extension to LLDP from the IETF BGP LLDP Peer Discovery draft. The TLVs advertise BGP information that is used to discover BGP peers. The TLV is advertised when Auto-peering is created. LLDP BGP Config consists of a single TLV with multiple sub-TLVs within the TLV.

**Table 72: BGP Config Discovery Optional TLV**

| Name                     | Comments                                                                                                                                             |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| Peering address          | Advertises the local IP addresses used for BGP sessions. When Auto-peering is created, this advertises the IPv6 link-local IP address of the system. |
| BGP local AS             | Advertises the BGP local Autonomous System (AS) numbers. When Auto-peering is created, this advertises Auto-peering's AS-number.                     |
| BGP identifier           | Advertises the local BGP identifier. When Auto-peering is created, this advertises Auto-peering's router ID.                                         |
| Session group-ID         | Advertises a value to identify a BGP session class or category.                                                                                      |
| BGP session capabilities | Advertises the capabilities of the BGP session.                                                                                                      |
| Key chain                | Advertises the key chain name used for BGP session authentication.                                                                                   |

## LLDP Redundancy Support on Stacking

ExtremeXOS 31.6 introduces active redundancy support for LLDP on stacking.

LLDP information (for example, LLDP neighbors, Fabric Attach Elements and Assignments) is continuously synchronized from the Primary to the Backup nodes. In case of Failover, the Backup becomes the Primary node, with all existing LLDP information retained. Existing LLDP and Fabric Attach neighbors are not re-learned.

Because Fabric Attach Assignments are retained, there is no impact on the traffic during Failover.

#### Note

Statistics information is not synchronized to the Backup. LLDP and Fabric Attach statistics start from empty on Failover.

## LLDP Packets

LLDP packets transport TLVs to other network devices (see [Figure 117](#)).

The LLDP packet contains the destination multicast address, the source MAC address, the LLDP EtherType, the LLDPDU data (which contains the TLVs), and a frame check sequence (FCS). The LLDP multicast address is defined as 01:80:C2:00:00:0E, and the EtherType is defined as 0x88CC.

**Figure 117: LLDP Packet Format**

The following characteristics apply to LLDP packets:

- They are IEEE 802.3 Ethernet frames.
- The frames are sent as untagged frames.
- The frames are sent with a link-local-assigned multicast address as the destination address.
- The STP (Spanning Tree Protocol) state of the port does not affect the transmission of LLDP frames.

The length of the packet cannot exceed 1500 bytes. As you add TLVs, you increase the length of the LLDP frame. When you reach 1500 bytes, the remaining TLVs are dropped. We recommend that you advertise information regarding only one or two VLANs on the LLDP port, to avoid dropped TLVs.

If the system drops TLVs because of exceeded length, the system logs a message to the EMS and the `show lldp statistics` command shows this information under the Tx Length Exceeded field.

#### Note

The LLDPDU maximum size is 1500 bytes, even with jumbo frames enabled. TLVs that exceed this limit are dropped.

## Transmitting LLDP Messages

You can configure each port to transmit LLDP messages, receive LLDP messages, or both.

When configured to transmit LLDP messages, the LLDP agent running on the switch passes serially through the list of ports that are enabled for LLDP. For each LLDP-enabled port, the switch periodically sends out an untagged LLDP packet that contains the mandatory LLDP TLVs as well as the optional TLVs that are configured for advertisement. These TLVs are advertised to all neighbors attached to the same network. LLDP agents cannot solicit information from other agents by way of this protocol.

**Note**

When both IEEE 802.1X and LLDP are enabled on the same port, LLDP packets are not sent until one or more clients authenticate a port.

Also, LLDP MED TLVs are advertised only after an LLDP MED TLV is received on a port that is configured for LLDP MED. (See [LLDP MED Optional TLVs](#) on page 1017.)

The source information for TLVs is obtained from memory objects such as standard MIBs or from system management information. If the TLV source information changes at any time, the LLDP agent is notified. The agent then sends an update with the new values, which is referred to as a triggered update. If the information for multiple elements changes in a short period, the changes are bundled together and sent as a single update to reduce network load.

## Receiving LLDP Messages

You can configure each port to transmit [LLDP](#) messages, receive LLDP messages, or both.

After you configure a port to receive TLVs, all LLDP TLVs are received (even if the LLDP MED capabilities TLV is not enabled). Each port can store LLDP information for a maximum of four neighbors.

**Note**

When both IEEE 802.1X and LLDP are enabled on the same port, incoming LLDP packets are accepted only when one or more clients are authenticated.

When configured to receive LLDP messages, the TLVs received at a port are stored in a standard Management Information Base (MIB), which makes it possible for the information to be accessed by an [SNMP](#)-compatible NMS. Unrecognized TLVs are also stored on the switch, in order of TLV type. TLV information is purged after the configured timeout interval, unless it is refreshed by the remote LLDP agent. You can also manually clear the LLDP information for one or all ports with the [clear lldp neighbors](#) command.

- To display TLV information received from LLDP neighbors, use the following command:

```
show lldp neighbors detailed
```

You must use the detailed variable to display all TLV information.

## LLDP Management

---

You can manage [LLDP](#) using the CLI and/or an [SNMP](#)-compatible NMS. LLDP works concurrently with the [EDP](#). It also works independently; you do not have to run EDP to use LLDP.

You can use the `save configuration` command to save LLDP configurations across reboots.

The switch logs EMS messages regarding LLDP, including when optional TLVs exceed the 1500-byte limit and when more than four neighbors are detected on a port.

After you enable LLDP, you can enable LLDP-specific SNMP traps; the traps are disabled by default. After you enable LLDP-specific traps, the switch sends all LLDP traps to the configured trap receivers. You can configure the period between SNMP notifications; the default interval is five seconds.

You can configure an optional TLV to advertise or not advertise the switch management address information to the neighbors on a port. When enabled, this TLV sends out the IPv4 address configured on the management [VLAN](#). If you have not configured an IPv4 address on the management VLAN, the software advertises the system's MAC address. LLDP does not send IPv6 addresses in this field.

## Configuring and Managing LLDP

---

The following sections describe how to configure [LLDP](#) on the switch.

### Configuration Overview

You configure LLDP per port, and each port can store received information for a maximum of four neighbors.

**Note**

LLDP runs with link aggregation

You can configure LLDP per port.

1. Enable LLDP on the desired port(s) as described in [Enabling and Disabling LLDP](#).
2. If you want to change any default timer values, see [Configuring LLDP Timers](#).
3. Enable the SNMP traps and configure the notification interval as described in [Configuring SNMP for LLDP](#).
4. Configure any optional TLV advertisements as described in [Configuring Optional TLV Advertisements](#).

**Note**

By default, an LLDP-enabled port advertises the optional system description TLV. By default, all other optional TLVs are not advertised.

## Enabling and Disabling LLDP

LLDP is enabled on all ports by default. When you enable LLDP on one or more ports, you select whether the ports will only transmit LLDP messages, only receive the messages, or both transmit and receive LLDP messages.

After you enable LLDP, the following TLVs are automatically added to the LLDPDU:

- Chassis ID
- Port ID
- TTL
- System description
- End of LLDPDU

All of these, except the system description, are mandated by the 802.1ab standard and cannot be configured. For information on changing the system description TLV advertisement, see [System Description TLV](#) on page 1025.

- Enable LLDP.

```
enable lldp ports [all | port_list] {receive-only | transmit-only}
```

- Disable LLDP.

```
disable lldp ports [all | port_list] {receive-only | transmit-only}
```

## Configuring LLDP Timers

The LLDP timers apply to the entire switch and are not configurable by port. After you enable LLDP, LLDP timers control the time periods for the transmission and storage of LLDP TLVs as follows:

- Reinitialization period (default is two seconds).
- Delay between LLDP transmissions (default is two seconds)—applies to triggered updates, or updates that are initiated by a change in the topology.
- Transmit interval (default is 30 seconds)—applies to messages sent periodically as part of protocol.
- Time-to-live (TTL) value (default is two minutes)—time that the information remains in the recipient's LLDP database.

### Note

Once the LLDP MED TLVs begin transmitting (after detecting LLDP MED TLVs from a connected endpoint), those TLVs are also controlled by these timers.

When LLDP is disabled or if the link goes down, LLDP is reinitialized. The reinitialize delay is the number of seconds the port waits to restart the LLDP state machine; the default is two seconds.

The time between triggered update LLDP messages is referred to as the transmit delay, and the default value is two seconds. You can change the default transmit delay value to a specified number of seconds or to be automatically calculated by multiplying the transmit interval by 0.25.

Each LLDP message contains a TTL value. The receiving LLDP agent discards all LLDP messages that surpass the TTL value; the default value is 120 seconds. The TTL is calculated by multiplying the transmit interval value and the transmit hold value; the default transmit hold value is four.

- To change the default reinitialize delay period, use the following command:

```
configure lldp reinitialize-delay seconds
```

LLDP messages are transmitted at a set interval; this interval has a default value of every 30 seconds.

- To change this default value, use the following command:

```
configure lldp transmit-interval seconds
```

- To change the value for the transmit delay, use the following command:

```
configure lldp transmit-delay [auto | seconds]
```

- To change the default transmit hold value, use the following command:

```
configure lldp transmit-hold hold
```

## Configuring SNMP for LLDP

By default, *SNMP LLDP* traps are disabled on all ports. The default value for the interval between SNMP LLDP trap notifications is 5 seconds.

- To enable LLDP SNMP traps on one or more ports, use the following command:

```
enable snmp traps lldp {ports [all | port_list]}
```

The traps are only sent for those ports that are both enabled for LLDP and have LLDP traps enabled.

- To disable the LLDP SNMP traps on one or more ports, use the following command:

```
disable snmp traps lldp {ports [all | port_list]}
```

- To change the default value for the interval for the entire switch, use the following command:

```
configure lldp snmp-notification-interval seconds
```

### Note

If you want to send traps for LLDP MED, you must configure it separately. Use the `enable snmp traps lldp-med {ports [all | port_list]}` command to enable these traps.

## Configuring Optional TLV Advertisements

By default, the ExtremeXOS software advertises the mandatory *LLDP* TLVs (which are not configurable) and the optional system description TLV. For details, see [Supported Advertisements \(TLVs\)](#) on page 1015). All other optional TLVs are not advertised.

You can choose to advertise or not advertise any optional TLV, but be aware that the total LLDPDU length, which includes the mandatory TLVs, cannot exceed 1500 bytes. Optional TLVs that cause the LLDPDU length to exceed the 1500-byte limit are

dropped. You can see if the switch has dropped TLVs by referring to the EMS log or by issuing the `show lldp statistics` command.

The following sections describe configuration for the following types of optional TLVs.

### *Configuring Standards-Based TLVs*

This section describes the following optional standards-based TLVs.

#### **Port description TLV**

The port description TLV advertises the ifDescr MIB object, which is the ASCII string you configure.

The string can be configured using the `configure ports display-string` command.

If you have not configured this parameter, the TLV carries an empty string.

To control advertisement of the port description TLV, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise] port-
description
```

#### **System name TLV**

The system name TLV advertises the configured system name for the switch. This is the sysName as defined in RFC 3418, which you can define using the `configure snmp sysname` command.

To control advertisement of the system name TLV, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
system-name
```

#### **System Description TLV**

By default, the ExtremeXOS software advertises this TLV whenever you enable `LLDP` on a port, but you can disable advertisement. This TLV advertises show version command information similar to the following in the system description TLV:

```
ExtremeXOS version 11.2.0.12 v1120b12 by release-manager
on Fri Mar 18 16:01:08 PST 2005
```

To control advertisement of the system description TLV, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
system-description
```

#### **System Capabilities TLV**

The system capabilities TLV advertises the capabilities of the switch and which of these capabilities are enabled. When so configured, the ExtremeXOS software advertises bridge capabilities. If IP forwarding is enabled on at least one `VLAN` in the switch, the software also advertises router capabilities.

To control advertisement of the system capabilities TLV, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
system-capabilities
```

### Management Address TLV

The management address TLV advertises the IP address of the management VLAN. If the management VLAN does not have an assigned IP address, the management address TLV advertises the system's MAC address, unless another VLAN's IP address is specified. LLDP does not recognize IPv6 addresses in this field.

To specify a VLAN IP address, other than the Management VLAN, for advertisement as the management address, use the following command:

```
configure lldp management-address [[[vlan} vlan_name | vlan vlan_id]
{primary-ip | secondary-ip secondary_ip_address}] | mac-address]
```

To turn on or off advertisement of the management address TLV, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
management-address
```

#### Note

The ExtremeXOS software sends only one management address.

### VLAN Name TLV

The VLAN name TLV advertises a VLAN name for one or more VLANs on the port. You can advertise this TLV for tagged and untagged VLANs. When you enable this TLV for tagged VLANs, the TLV advertises the IEEE 802.1Q tag for that VLAN. For untagged VLANs, the internal tag is advertised.

If you do not specify a VLAN when you configure this TLV, the switch advertises all VLAN names on the specified ports. You can choose to advertise one or more VLANs for the specified ports by specifying the name of a VLAN in the configuration command. You can repeat the command to specify multiple VLANs.

To control advertisement of the port VLAN Name TLV, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific dot1 vlan-name {vlan [all | vlan_name]}
```

#### Note

Because each VLAN name requires 32 bits and the LLDPDU cannot exceed 1500 bytes, we recommend that you configure each port to advertise no more than one or two specific VLANs. Optional TLVs that cause the LLDPDU length to exceed the 1500-byte limit are dropped.

### Port VLAN ID TLV

The port VLAN ID advertises the untagged VLAN on that port. Thus, only one port VLAN ID TLV can exist in the LLDPDU. If you configure this TLV and there is no untagged VLAN on the specified port, this TLV is not included in the LLDPDU.

- To control advertisement of the port VLAN ID TLV, use the following command:  
`configure lldp ports [all | port_list] [advertise | no-advertise]  
vendor-specific dot1 port-vlan-ID`

### Port and Protocol VLAN ID TLV

When configured for advertisement, this TLV advertises whether the specified VLANs on the specified ports support protocol-based VLANs or not.

If you do not specify a VLAN when you configure this TLV, the switch advertises protocol-based VLAN support for all VLAN names on the specified ports. You can choose to advertise support for one or more VLANs for the specified ports by specifying the name of a VLAN in the configuration command. You can repeat the configuration command to specify multiple VLANs.

Because all VLANs on Extreme Networks switches support protocol-based VLANs, the switch always advertises support for protocol-based VLANs for all VLANs for which this TLV is advertised. If no protocol-based VLANs are configured on the port, the switch sets the VLAN ID value to 0.

- To control advertisement of the port and protocol VLAN ID TLV, use the following command:  
`configure lldp ports [all | port_list] [advertise | no-advertise]  
vendor-specific dot1 port-protocol-vlan-ID {vlan [all | vlan_name]}`

#### Note

Because a TLV is advertised for every VLAN that is advertised, and because the LLDPDU cannot exceed 1500 bytes, we recommend that you advertise this VLAN capability only for those VLANs that require it. Optional TLVs that cause the LLDPDU length to exceed the 1500-byte limit are dropped.

### MAC/PHY Configuration/Status TLV

When configured for advertisement, this TLV advertises the autonegotiation and physical layer capabilities of the port. The switch adds information about the port speed, duplex setting, bit rate, physical interface, and autonegotiation support and status.

- To control advertisement of the port and protocol MAC/PHY configuration/status TLV, use the following command:  
`configure lldp ports [all | port_list] [advertise | no-advertise]  
vendor-specific dot3 mac-phy`

### Power Via MDI TLV

When configured for advertisement on Ethernet (PoE) or PoE+ ports, this TLV advertises the device type, power status, power class, and pin pairs used to supply power.

The device type field contains a binary value that represents whether the *LLDP*-compatible device transmitting the LLDPDU is a power sourcing entity (PSE) or powered device (PD), as listed in [Table 73](#).

**Table 73: Power Management TLV Device Information**

| Value | Power source |
|-------|--------------|
| 0     | PSE device   |
| 1     | PD device    |
| 2-3   | Reserved     |

Control advertisement of the power via MIDI TLV.

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific dot3 power-via-mdi {with-classification}
```

Refer to for [Configuring Avaya-Extreme TLVs](#) on page 1028 and [Configuring LLDP MED TLVs](#) on page 1030 more information on power-related TLVs.

### Link Aggregation TLV

When configured for advertisement, this TLV advertises information on the port's load-sharing (link aggregation) capabilities and status.

To control advertisement of the link aggregation TLV, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific dot3 link-aggregation
```

### Maximum frame size TLV

When configured for advertisement, this TLV advertises the maximum supported frame size for a port to its neighbors. When jumbo frames are not enabled on the specified port, the TLV advertises a value of 1518. If jumbo frames are enabled, the TLV advertises the configured value for the jumbo frames.

To control advertisement of the maximum frame size TLV, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific dot3 max-frame-size
```

### Configuring Avaya-Extreme TLVs

This section describes the following optional proprietary Avaya-Extreme Networks TLVs that you can configure the switch to transmit.

#### Note

You can display the values for these TLVs using the `show lldp neighbors detailed` command.

### PoE Conservation Level Request TLV

When configured for advertisement, this TLV advertises a request to the connected PD to go into a certain power conservation level or go to the maximum conservation level. This *LLDP* TLV is sent out only on *PoE*-capable Ethernet ports.

By default, the requested conservation value on this proprietary LLDP TLV is 0, which is no power conservation. You can change this level temporarily using a network station or *SNMP* with the MIB; this change is not saved across a reboot.

- To control advertisement of the PoE conservation level request TLV, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific avaya-extreme poe-conservation-request
```

### Call Server TLV

When configured for advertisement, this TLV advertises the IP addresses of up to eight call servers. Avaya phones use this addressing information to access call servers.

- To control advertisement of the call server TLV and define call server addresses, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific avaya-extreme call-server ip_address_1 {ip_address_2
{ip_address_3 {ip_address_4 {ip_address_5 {ip_address_6 {ip_address_7
{ip_address_8}}}}}}}
```

### File Server TLV

When configured for advertisement, this TLV advertises the IP addresses of up to 4 file servers. Avaya phones use this address information to access file servers.

- To control advertisement of the file server TLV and define file server addresses, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific avaya-extreme file-server ip_address_1 {ip_address_2
{ip_address_3 {ip_address_4}}
```

### 802.1Q Framing TLV

When configured for advertisement, this TLV advertises information about Layer 2 priority tagging for Avaya phones.

- To control advertisement of the 802.1Q framing TLV, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific avaya-extreme dot1q-framing [tagged | untagged | auto]
```

#### Note

For this command to work, you must have previously enabled both the `configure lldp ports vendor-specific med capabilities` and the `configure lldp ports vendor-specific med policy application` commands. (See [Configuring LLDP MED TLVs](#) on page 1030 for complete information.)

## Configuring LLDP MED TLVs

### Note

After you enable an LLDP MED TLV, the switch waits until it detects a MED-capable device before it begins transmitting the configured LLDP MED TLVs. You must configure the LLDP MED capabilities TLV to advertise before any of the other LLDP MED TLVs can be configured. Also, this TLV must be set to no-advertise after all other MED TLVs are set to no-advertise.

This approach assures that network connectivity devices advertise LLDP MED TLVs only to end-devices and not to other network connectivity devices.

The following sections describe LLDP MED TLVs and features.

### Note

You can display the values for these TLVs using the `show lldp neighbors detailed` command.

## LLDP MED capabilities TLV

This TLV advertises the LLDP MED capabilities of the switch and must be enabled before any of the other LLDP MED TLVs can be enabled.

To enable configuration and transmission of any other LLDP MED TLV and to determine the LLDP MED capabilities of endpoint devices, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific med capabilities
```

## LLDP MED Fast-Start Feature

The LLDP MED fast-start feature allows you to increase the learning speed of the switch for LLDP MED TLVs. The fast-start feature is automatically enabled once you enable the LLDP MED capabilities TLV.

By default, the switch sends out the LLDPDU every second for up to the default repeat count, which is 3. Once the repeat count is reached, the configured transmit interval value is used between LLDPDUs. You can configure the repeat count to any number in the range of 1 to 10.

To configure the LLDP fast-start feature, use the following command:

```
configure lldp med fast-start repeat-count count
```

## Network policy TLV

This TLV advertises which VLAN an endpoint should use for the specified application. You can configure only one instance of an application on each port, and you can configure a maximum of eight applications, each with its own DSCP value and/or priority tag.

To control advertisement and configure one or more network policy TLVs for a port, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific med policy application [voice | voice-signaling | guest-voice | guest-voice-signaling | softphone-voice | video-conferencing | streaming-video | video-signaling] vlan vlan_name dscp dscp_value {priority-tagged}
```

### Location identification TLV

This TLV advertises one of three different location identifiers for a port, each with a different format.

- Coordinate-based, using a 16-byte hexadecimal string.
- Civic-based, using a hexadecimal string with a minimum of six bytes.
- ECS ELIN, using a numerical string with a range of 10-25 characters.

To control advertisement and configure location information, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific med location-identification [coordinate-based hex_value | civic-based hex_value | ecs-elin elin]
```

### Extended power-via-MDI TLV

This TLV advertises fine-grained power requirement details, including the [PoE](#) settings and support. You can enable this TLV only on PoE-capable ports; the switch returns an error message if you attempt to transmit this [LLDP](#) TLV over a non-PoE-capable port.

To control advertisement for this TLV, use the following command:

```
configure lldp ports [all | port_list] [advertise | no-advertise]
vendor-specific med power-via-mdi
```

### SNMP Traps for LLDP MED

To receive [SNMP](#) traps on the [LLDP](#) MED, you must enable these separately from the other LLDP traps. (See [Configuring SNMP for LLDP](#).)

- Enable the LLDP MED SNMP traps.  
`enable snmp traps lldp-med {ports [all | port_list]}`
- Disable the LLDP MED SNMP traps.  
`disable snmp traps lldp-med {ports [all | port_list]}`

## Clearing LLDP Neighbor Entries

- To remove the [LLDP](#) entries received on one or more ports from the switch database, use the following command:

```
clear lldp neighbors [all | port port_list]
```

## Unconfiguring LLDP

- To unconfigure the *LLDP* timers, use the following command:

```
unconfigure lldp
```

This command returns the LLDP timers to default values; LLDP remains enabled, and all the configured TLVs are still advertised.

- To leave LLDP enabled, but reset the advertised TLVs to the five default TLVs, use the following command, and specify the affected ports:

```
unconfigure lldp port [all | port_list]
```

## Instant Port Enhancements

Version 33.2.1 adds the Cisco Discovery Protocol (CDP) and Link Layer Discovery Protocol (LLDP) Voice VLAN options to the VLAN part of Instant Port Profile. This adds the following feature functionality:

- LLDP Voice VLAN options:
  - Enable or disable LLDP advertisement of 802.1 VLAN ID and port protocol of VLAN.
  - Enable or disable med Voice VLAN DSCP:
    - Med VLAN DSCP Value
  - Enable or disable LLDP advertisement of med Voice Signaling VLAN DSCP:
    - VLAN DSCP Value
- CDP Voice VLAN Options:
  - Enable or disable CDP advertisement of VLAN.
  - Enable or disable CDP advertisement of power available.

*Supported Platforms*

All platforms.

## Displaying LLDP Information

The following sections describe how to display *LLDP* information for the switch. The system displays information on the LLDP status and statistical counters of the ports, as well as about the LLDP advertisements received and stored by the system.

You can display information on the LLDP port configuration and on the LLDP neighbors detected on the port.

## Displaying LLDP Port Configuration Information and Statistics

- To display *LLDP* port configuration information, use the following command:

```
show lldp {port [all | port_list]} {detailed}
```

- To display the statistical counters related to the LLDP port, use the following command:

```
show lldp {port [all | port_list]} statistics
```

## Display LLDP Information Collected from Neighbors

- Display information collected from LLDP neighbors.

`show lldp neighbors`

### Note

You must use the detailed option to display information on the proprietary Avaya-Extreme Networks TLVs and the LLDP MED TLVs.

# MPLS

[Troubleshooting MPLS](#) on page 1123

Multiprotocol Label Switching (MPLS) is a connection-oriented technology that allows routers to make protocol-independent forwarding decisions based on fixed-length labels. This chapter provides an overview and discusses how to configure, monitor and troubleshoot the MPLS feature. The chapter provides specific configuration examples.

## MPLS Overview

---

*MPLS (Multiprotocol Label Switching)* provides advanced IP services for switches that contain advanced ASICs that support MPLS.

To configure MPLS, L2 VPNs, and/or L3 VPNs on your switch, you need the MPLS enabled feature pack license .

### Note

MPLS and MPLS subfeatures are supported on the platforms listed for specific features in the [Switch Engine v33.3.1 Licensing Guide](#) document.

### Note

ExtremeXOS MPLS does not support Graceful Restart. Any restart of the MPLS process or failover to a backup node requires re-signaling of all MPLS-related connections and entities.

## How MPLS Works

*MPLS* is a connection-oriented technology that allows routers to make protocol-independent forwarding decisions based on fixed-length labels.

The use of MPLS labels enables routers to avoid the processing overhead of delving deeply into each packet and performing complex route lookup operations based upon destination IP addresses.

MPLS protocols are designed primarily for routed IP networks and work together to establish multiple, unidirectional Label Switched Path (LSP) connections through an MPLS network. Once established, an LSP can be used to carry IP traffic or to tunnel other types of traffic, such as bridged MAC frames. The tunnel aspects of LSPs, which are important in supporting virtual private networks (VPNs), result from the fact that forwarding is based solely on labels and not on any other information carried within the packet.

The MPLS protocols operate on Label Switch Routers (LSRs). The router where an LSP originates is called the ingress LSR, while the router where an LSP terminates is called the egress LSR. Ingress and egress LSRs are also referred to as Label Edge Routers (LERs). For any particular LSP, a router is either an ingress LER, an intermediate LSR, or an egress LER. However, a router may function as an LER for one LSP, while simultaneously functioning as an intermediate LSR for another LSP.

Figure 118 illustrates an MPLS network.

**Figure 118: MPLS Network**

In an MPLS environment, incoming packets are initially assigned labels by the ingress LER. The labels allow more efficient packet handling by MPLS-capable routers at each point along the forwarding path.

An MPLS label essentially consists of a short fixed-length value carried within each packet header that identifies a Forwarding Equivalence Class (FEC). The FEC tells the router how to handle the packet. An FEC is defined to be a group of packets that are forwarded in the same manner. Examples of FECs include an IP prefix, a host address, or a *VLAN (Virtual LAN) ID*.

**Note**

The label concept in MPLS is analogous to other connection identifiers, such as an ATM VPI/VCI or a Frame Relay DLCI.

By mapping to a specific FEC, the MPLS label efficiently provides the router with all of the local link information needed for immediate forwarding to the next hop. MPLS creates an LSP along which each LSR can make forwarding decisions based solely upon

the content of the labels. At each hop, the LSR simply strips off the Incoming label and applies a new Outgoing label that tells the next LSR how to forward the packet. This allows packets to be tunneled through an IP network.

## MPLS Protocol Preference

When LSPs from different protocols exist to the same destination/FEC, LSPs from only one protocol are used at a time for that destination/FEC. The preference, or precedence, for each LSP user is defined as follows.

For both IP/L3VPN and L2VPN the order of preference is:

- RSVP-TE
- LDP
- static

## MPLS Terms and Acronyms

Table 74 defines common *MPLS* terms and acronyms.

**Table 74: MPLS Terms and Acronyms**

| Term or Acronym | Description                                                                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| CSPF            | Constrained Shortest Path First. Route selection determined by an algorithm based on available link bandwidth and path cost.                        |
| DoD             | Downstream-on-Demand. Distribution of labels as a result of explicit upstream label requests.                                                       |
| DU              | Downstream Unsolicited. Distribution of labels downstream without an explicit label request.                                                        |
| EXP bits        | A three-bit experimental field in an MPLS shim header.                                                                                              |
| FEC             | Forward Equivalence Class. A group of packets that are forwarded in the same manner (for example, over the same Label Switched Path).               |
| Label           | A short, fixed-length identifier used to forward packets from a given link.                                                                         |
| Label stack     | A set of one or more MPLS labels used by MPLS to forward packets to the appropriate destination.                                                    |
| Label swapping  | Lookup and replacement of an incoming label with the appropriate outgoing label.                                                                    |
| LDP             | Label Distribution Protocol. A protocol defined by the IETF used to establish an MPLS Label Switched Path (LSP).                                    |
| LER             | Label Edge Router. A Label Switch Router that is at the beginning (ingress) or end (egress) of an LSP.                                              |
| LSP             | Label Switched Path. The unidirectional MPLS connection between two routers over which packets are sent. LSPs are established using LDP or RSVP-TE. |

**Table 74: MPLS Terms and Acronyms (continued)**

| Term or Acronym | Description                                                                                                                                                                                                             |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LSR             | Label Switch Router. A router that receives and transmits packets on an MPLS network.                                                                                                                                   |
| MPLS            | MultiProtocol Label Switching. A set of protocols defined by the IETF used to transmit information based on a label-switching forwarding algorithm.                                                                     |
| NHLFE           | Next Hop Label Forwarding Entry. The NHLFE represents the MPLS router next hop along the LSP.                                                                                                                           |
| PHP             | Penultimate Hop Popping. A label stack optimization used for conserving the number of allocated labels.                                                                                                                 |
| PW              | Pseudowire. A logical point-to-point connection.                                                                                                                                                                        |
| RSVP            | Resource ReSerVation Protocol (RSVP). A resource setup protocol designed for an integrated services network.                                                                                                            |
| RSVP-TE         | Resource ReSerVation Protocol-Traffic Engineering (RSVP-TE). The combination of RSVP and MPLS label signaling to provide traffic engineered LSPs as specified in RFC 3209, RSVP-TE: Extensions to RSVP for LSP Tunnels. |
| Shim header     | MPLS-specific header information that is inserted between layer-2 and layer-3 information in the data packet.                                                                                                           |
| SP              | Service Provider. An entity that provides network services for individuals or organizations.                                                                                                                            |
| TE              | Traffic Engineering. The provisioning of an autonomous flow along a specified network path.                                                                                                                             |
| Transport LSP   | Any active LSP used to forward traffic through an MPLS network.                                                                                                                                                         |
| VPLS            | Virtual Private LAN Service (VPLS). A multipoint Layer 2 VPN service that has the property that all PW tunnels within a VPN are signaled with the same vcid, where the vcid represents the VPN identifier.              |
| VPN             | Virtual Private Network (VPN). A logical private network domain that spans a public or service provider network infrastructure.                                                                                         |
| VPWS            | Virtual Private Wire Service (VPWS). A point-to-point Layer 2 VPN service that operates over MPLS.                                                                                                                      |

## LDP Support

The Label Distribution Protocol (LDP) is a protocol defined by the IETF for the purpose of establishing *MPLS* LSPs. Using LDP, peer LSRs exchange label binding information to create LSPs. The LDP features supported in this release include:

- Downstream unsolicited label advertisement.
- Liberal label retention.
- Ordered control mode.
- Advertisement of labels for direct interfaces, *RIP (Routing Information Protocol)* routes, and static routes.

- Ability to use multiple IGP routing protocols (for example IS-IS, *OSPF (Open Shortest Path First)*, and *BGP (Border Gateway Protocol)*).
- LDP loop detection.
- Configurable LDP timers.

**Note**

To use BGP as an IGP routing protocol, issue the `enable mpls ldp bgp-routes` command.

### *LDP Neighbor Discovery*

LDP includes a neighbor discovery protocol that runs over UDP.

Using the basic discovery mechanism, each LSR periodically multicasts a hello message to a well-known UDP port to which all LSRs listen. These hello messages are transmitted to the all routers on this subnet multicast group. When a neighbor is discovered, a hello-adjacency is formed and the LSR with the numerically greater IP address is denoted as the active LSR.

Hello messages must continue to be received periodically for the hello-adjacency to be maintained. The hold time that specifies the duration for which a hello message remains valid can be negotiated by the peer LSRs as part of the HELLO exchange. During the HELLO exchange, each LSR proposes a value and the lower of the two is used as the hold time.

Targeted LDP hello-adjacencies between potentially non-directly connected LSRs are supported using an extended discovery mechanism. In this case, targeted hello messages are periodically sent to a specific IP address.

After the hello-adjacency is formed, the active LSR initiates establishment of a TCP connection to the peer LSR. At this point, an LDP session is initiated over the TCP connection. The LDP session consists of an exchange of LDP messages that are used to set up, maintain, and release the session.

### *Advertising Labels*

You can control whether label mappings are advertised for:

- Direct routes
- *RIP* routes
- Static routes

In these cases, the switch is acting as the egress LER for these LSPs.

### *Propagating Labels*

LDP propagates label mappings for FECs that exactly match a routing table entry.

In the case of label mappings received from an LDP peer, LDP checks for an exactly matching entry with a next hop IP address that is associated with the LDP peer from which a label mapping was received.

### *Label Advertisement Modes*

LDP provides two modes for advertising labels:

- Downstream-on-demand (DoD)
- Downstream unsolicited (DU)

Using DoD mode, label bindings are only distributed in response to explicit requests. A typical LSP establishment flow begins when the ingress LER originates a label request message to request a label binding for a particular FEC (for a particular IP address prefix or IP host address). The label request message follows the normal routed path to the FEC. The egress LER responds with a label mapping message that includes a label binding for the FEC. The label mapping message then follows the routed path back to the ingress LSR, and a label binding is provided by each LSR along the path. LSP establishment is complete when the ingress LER receives the label mapping message.

Conversely, using DU mode, an LSR may distribute label bindings to LSRs that have not specifically requested them. These bindings are distributed using the label mapping message, as in downstream-on-demand mode. From an LDP message perspective, the primary difference using DU mode is the lack of a preceding label request message.

Architecturally, the difference is more significant, because the DU mode is often associated with a topology-driven strategy, where labels are routinely assigned to entries as they are inserted into the routing database. In either case, an LSR only uses a label binding to switch traffic if the binding was received from the current next hop for the associated FEC.

Both label advertisement modes can be concurrently deployed in the same network. However, for a given adjacency, the two LSRs must agree on the discipline. Negotiation procedures specify that DU mode be used when a conflict exists when using Ethernet links. Label request messages can still be used when *MPLS* is operating in unsolicited mode.

The Extreme LDP implementation supports DU mode only.

### *Label Retention Modes*

LDP provides two modes for label retention:

- Conservative
- Liberal

Using conservative label retention mode, an LSR retains only the label-to-FEC mappings that it currently needs (mappings received from the current next hop for the FEC).

Using liberal retention mode, LSRs keep all the mappings that have been advertised to them. The trade-off is memory resources saved by conservative mode versus the potential of quicker response to routing changes made possible by liberal retention (for example, when the label binding for a new next hop is already resident in memory).

The Extreme *MPLS* implementation supports liberal label retention only.

### LSP Control Modes

LDP provides two LSP control modes:

- Independent
- Ordered

Using independent LSP control, each LSR makes independent decisions to bind labels to FECs. By contrast, using ordered LSP control, the initial label for an LSP is always assigned by the egress LSR for the associated FEC (either in response to a label request message or by virtue of sending an unsolicited label mapping message).

More specifically, using ordered LSP control, an LSR only binds a label to a particular FEC if it is the egress LSR for the FEC, or if it has already received a label binding for the FEC from its next hop for the FEC. True to its name, the mode provides a more controlled environment that yields benefits such as preventing loops and ensuring use of consistent FECs throughout the network.

The Extreme MPLS implementation supports ordered LSP control only.

## MPLS Routing

This section describes how MPLS and IP routing work together to forward information on your network.

MPLS provides a great deal of flexibility for routing packets. Received IP unicast frames can be routed normally or tunneled through LSPs. If a matching FEC exists for a received packet, the packet may be transmitted using an LSP that is associated with the FEC. The packet is encapsulated using an MPLS shim header before being transmitted.

Received MPLS packets can be label switched or routed normally toward the destination. Packets that are in the middle of an LSP are label switched. The incoming label is swapped for a new outgoing label and the packet is transmitted to the next LSR. For packets that have arrived at the end of an LSP (the egress end of the LSP), the label is popped. If this label is the bottom of the stack, the shim header is stripped and the packets are routed to the destination as normal IP packets.

#### Note

Multicast routing and ECMP (Equal Cost Multi Paths) on MPLS are not supported.

An MPLS domain is generally defined to be an OSPF or IS-IS autonomous system (AS). You can use MPLS to reach destinations inside one of these AS types. You can also use MPLS to tunnel through all or part of an AS in order to reach destinations outside of the AS.

### MPLS Layer Details

MPLS can be thought of as a shim-layer between Layer 2 and Layer 3 of the protocol stack. MPLS provides connection services to Layer 3 functions while making use of link-layer services from Layer 2. To achieve this, MPLS defines a shim header that is

inserted between the link layer header and the network layer header of transmitted frames. The format of a 32-bit MPLS shim header is illustrated in the following figure.

|                    |                 |                            |                 |
|--------------------|-----------------|----------------------------|-----------------|
| Label<br>(20 bits) | EXP<br>(3 bits) | bottom-of-stack<br>(1 bit) | TTL<br>(8 bits) |
|--------------------|-----------------|----------------------------|-----------------|

**Figure 119: MPLS Shim Header**

#### MPLS Shim Header

The *MPLS* shim header contains the following fields:

- 20-bit label
- 3-bit experimental (EXP) field

The EXP field can be used to identify different traffic classes to support the DiffServ *QoS (Quality of Service)* model.

- 1-bit bottom-of-stack flag

The bottom-of-stack bit is set to 1 to indicate the last stack entry.

- 8-bit Time-To-Live (TTL) field.

The TTL field is used for loop mitigation, similar to the TTL field carried in IP headers.

#### MPLS Label Stack

The format of an *MPLS* label stack containing two MPLS shim header entries is shown in [Figure 120](#).

|         |     |                        |     |         |     |                        |     |
|---------|-----|------------------------|-----|---------|-----|------------------------|-----|
| Label 1 | EXP | bottom-of-stack<br>= 0 | TTL | Label 2 | EXP | bottom-of-stack<br>= 1 | TTL |
|---------|-----|------------------------|-----|---------|-----|------------------------|-----|

**Figure 120: MPLS Label Stack**

[Figure 121](#) illustrates the format of a unicast MPLS frame on an Ethernet link. The MAC addresses are those of the adjacent MPLS router interfaces. The x8847 Ethertype value indicates that the frame contains an MPLS unicast packet. A different Ethertype value (x8848) is used to identify MPLS multicast packets.

|        |        |                    |                     |                       |
|--------|--------|--------------------|---------------------|-----------------------|
| MAC DA | MAC SA | Ethertype<br>x8847 | MPLS<br>label stack | remainder<br>of frame |
|--------|--------|--------------------|---------------------|-----------------------|

**Figure 121: MPLS Unicast Frame on Ethernet**

[Figure 122](#) shows the format of a unicast MPLS frame that contains an 802.1Q *VLAN* tag. In both cases, the Ethertype values no longer identify the network layer protocol type. This implies that, generally, the protocol type must be inferable from the MPLS label value(s). For example, when only one type of protocol is carried on a given LSP.

|        |        |                    |          |                    |                     |                       |
|--------|--------|--------------------|----------|--------------------|---------------------|-----------------------|
| MAC DA | MAC SA | Ethertype<br>x8100 | VLAN tag | Ethertype<br>x8847 | MPLS<br>label stack | remainder<br>of frame |
|--------|--------|--------------------|----------|--------------------|---------------------|-----------------------|

**Figure 122: MPLS Unicast Frame on Tagged Ethernet VLAN**

**Note**

For more detailed information on MPLS encapsulations, see RFC 3032, MPLS Label Stack Encoding.

### Penultimate Hop Popping

Penultimate hop popping (PHP) is an LSR label stack processing optimization feature. When enabled, the LSR can pop (or discard) the remaining label stack and forward the packet to the last router along the LSP as a normal Ethernet packet.

By popping the label stack one hop prior to the LSP egress router, the egress router is spared having to do two lookups. After the label stack has been popped by the penultimate hop LSR, the LSP egress router must only perform an address lookup to forward the packet to the destination.

PHP label advertisements using implicit NULL labels can be optionally enabled. Support for receiving implicit NULL label advertisements by neighbor LSRs is always enabled. For example, if an LSR advertises implicit NULL labels for IP prefixes, the neighbor LSRs must support PHP.

### Label Binding

Label binding is the process of, and the rules used to, associate labels with FECs.

LSRs construct label mappings and forwarding tables that comprise two types of labels: labels that are locally assigned and labels that are remotely assigned.

Locally assigned labels are labels that are chosen and assigned locally by the LSR. For example, when the LSR assigns a label for an advertised direct interface. This binding information is communicated to neighboring LSRs. Neighbor LSRs view this binding information as remotely assigned.

Remotely assigned labels are labels that are assigned based on binding information received from another LSR.

### Label Space Partitioning

The Extreme implementation partitions its label space as described in the following illustration.

**Figure 123: MPLS Label Space Partitions**

Platforms that support *MPLS* divide the incoming (MPLS egress) label space into static, L3VPN, and dynamic label ranges. The static label range starts immediately after the reserved labels at 16 (0x10), and spans up through the configured maximum number of static labels. In ExtremeXOS 15.4, the `configure mpls label max-static` command is added to allow the static partition range to be changed. Any changes made to the static range affect subsequent ranges.

VRFs used for L3VPNs are allocated from a label range that immediately follows the static range. The remaining label space is called the dynamic label space, and is used by LDP and RSVP-TE. The `show mpls label usage` command displays the label ranges on a given system. The outgoing (MPLS ingress) label space spans the full 20-bit label range, and is used for all outgoing labels for both LSPs and PWs, static and signaled.

No hard limits are imposed on the maximum size of the label stack, other than the constraint of not exceeding the maximum frame size supported by the physical links comprising the LSP.

Jumbo frames should be enabled on all ports, and the jumbo frame size should be set to accommodate the addition of a maximally-sized label stack. For example, a jumbo frame size of at least 1530 bytes is needed to support a two-level label stack on a tagged Ethernet port, and a jumbo frame size of at least 1548 bytes is needed to support a VPLS encapsulated MPLS frame.

### *Routing Using Matching and Calculated LSP Next Hops*

Normally, a route table prefix is associated with a gateway or next hop IP address.

Using *MPLS*, a route table prefix can also be associated with an LSP that can be used as the next hop. There are two types of LSP next hops that can be used to route a packet to its destination:

- Matching LSP next hop

An LSP is considered matching with respect to an FEC if it has been associated with that FEC via LDP or RSVP-TE. An example of this is an IPv4 prefix for which a matching label mapping has been received by LDP. Matching LSPs are supported for all route origin types.

- Calculated LSP next hop

An LSP is considered calculated with respect to an FEC if it has been associated with that FEC through a routing protocol. Both *OSPF* and *BGP* can perform the calculations necessary to associate a route table prefix with an LSP next hop.

Figure 124 illustrates the concept of matching and calculated LSPs.

Figure 124: Matching and Calculated LSP Next Hops

Table 75 describes the label bindings in the MPLS forwarding table for LSR A that are maintained for FECs reachable via LSR A to LSR C, shown in Figure 124.

Table 75: Label Bindings for LSR A

| Destination | Next Hop | Matching LSP Next Hop Label | Calculated LSP Next Hop Label |
|-------------|----------|-----------------------------|-------------------------------|
| 10.1.1.1/32 | 10.2.1.1 | 31                          | 30                            |
| 10.0.1.0/24 | 10.2.1.1 | 32                          | 31                            |
| 10.0.2.0/24 | 10.2.1.1 | 33                          | 31                            |
| 10.0.3.0/24 | 10.2.1.1 | 34                          | 31                            |

Matching LSP Next Hops

A matching LSP next hop is always preferred over a calculated LSP next hop.

Matching LSP next hop entries are added to the route table when an LSP becomes operational. They are deleted when an LSP is no longer operational.

OSPF Calculated LSP Next Hops

Managing calculated LSP next hop entries is more involved.

The *OSPF* Shortest Path First (SPF) algorithm checks the availability of LSPs to remote *OSPF* routers during a calculation. The intra-area SPF algorithm begins with the calculating router as the root of a graph. The graph is expanded by examining the networks connected to the root and then examining the routers connected to those networks. Continuing in this manner, the graph is built as a series of parent and child nodes. A check is made for a matching LSP next hop as each entry is added. A check is also made for an LSP next hop that can be inherited from the parent node. These inherited LSP next hops are referred to as calculated LSP next hops. Thus, for each route table entry, the modified SPF algorithm determines whether a matching LSP next hop is available and whether a calculated LSP next hop is available for use whenever a matching LSP next hop is not present.

The modification to the SPF algorithm described above is important, because it enables the capabilities provided by LDP or RSVP-TE LSPs to be fully utilized, while minimizing the resources devoted to label management.

For example, in a network where all the LERs/LSRs implement this feature (such as an all-Extreme *MPLS* network), labels only need to be advertised for the router IDs of the LERs/LSRs. Yet, LSPs can still be used to route traffic destined for any *OSPF* route.

More specifically, LSPs can be used for all routes advertised by *OSPF*, with the possible exception of LDP LSPs to routes summarized by *OSPF* area border routers (ABRs). The problem with using routes summarized by *OSPF* ABRs is that route summarization can prevent label mappings from being propagated for the links internal to the area being summarized, since an LSR only propagates LDP labels for FECs that exactly match a routing table entry.

#### *BGP Calculated LSP Next Hops*

*BGP* can also calculate how to use LSPs to reach *BGP* next hops.

For example, an *IBGP* session is established across the *OSPF/MPLS* backbone, and the communicating routers run both *OSPF* and *IBGP*. When an *IBGP* route is installed, *BGP* determines whether a matching LSP next hop exists to the destination. If not, it checks for an LSP to the *BGP* next hop. If an LSP exists to the *BGP* next hop, that LSP is used as an LSP next hop for the *IBGP* route.

The recalculation requirements for *BGP* are similar to those for *OSPF*; when an LSP to a *BGP* next hop router changes state, the *BGP* routing table entries must be checked to ensure their LSP next hop information is still valid.

#### *LSP Precedence and Interaction*

A longest prefix match (LPM) is determined for all packets.

If an LSP next hop is available, routed IP traffic may be forwarded over an LSP using the LSP next hop. With respect to a given prefix, LSP next hops can be either matching or calculated, and can be based on LDP, RSVP-TE, or static LSPs. Matching LSP next hops are preferred over calculated LSP next hops. RSVP-TE LSPs are preferred over LDP LSPs, and LDP LSPs are preferred over static LSPs. Also, RSVP-TE LSPs and static LSPs can be individually configured to enable or disable their use as LSP next hops.

Therefore, if a more preferred LSP is established, routed IP traffic may begin to use a new LSP next hop. Likewise, if a preferred LSP is torn down, routed traffic may begin to use the next best LSP next hop. These changes can take place when there is an *OSPF* routing topology change, an LDP label advertisement event, or a RSVP-TE signaling action.

#### *Multivendor Support for Calculated LSPs*

Unfortunately, some *MPLS* implementations do not support the ability to forward packets received on an egress LSP to their *OSPF* router ID and/or *BGP* next hop address.

If your MPLS network includes equipment that does not support this type of IP forwarding, you can use configuration commands to explicitly control the use of calculated LSP next hops.

The following commands enable and disable all use of LSP next hops. No IP traffic is routed over an LSP when *mpls-next-hop* IP routing capability is disabled.

- `enable iproute mpls-next-hop`
- `disable iproute mpls-next-hop`

These commands enable and disable the calculation of LSP next hops by OSPF:

- `enable ospf mpls-next-hop {vr vrf_name}`
- `disable ospf mpls-next-hop {vr vrf_name}`

These commands enable and disable the calculation of LSP next hops by BGP:

- `enable bgp mpls-next-hop`
- `disable bgp mpls-next-hop`

## Layer 2 VPN over MPLS Overview (VPLS and VPWS)

Layer 2 virtual private networking (VPN) services over *MPLS* include Virtual Private LAN Services (VPLS) and Virtual Private Wire Services (VPWS).

These services enable Layer 2 VPN service offerings in a simple manner that is easy to deploy and operate. Layer-2 VPN services, based on a combination of Ethernet and MPLS/IP technologies, are designed to enable service providers to offer Business Ethernet private line services. These services use a simple Layer 2 interface at the customer edge and benefit from the resilience and scalability of an MPLS/IP core.

VPLS provides a virtual LAN between multiple locations. VPWS provides a virtual dedicated line between only two locations.

#### *Layer 2 VPN Support*

The LDP Layer 2 VPN implementation includes support for:

- LDP signaling support for pseudowire ID (PWid) FEC for pseudowire (PW) establishment.
- Use of LDP, RSVP-TE, or Static to establish transport LSPs.

- Tunnel endpoints, identified via configured IP addresses.
- Different VLAN IDs at each end of a PW, with the VLAN ID set by the egress switch to match that of the locally configured VLAN.
- Operations as VPLS, H-VPLS, or VPWS node.
- VLAN, VMAN, and port edge services (no port-qualified VLAN service).
- Flooding of Layer 2 packets to multiple PWs when operating as a VPLS or H-VPLS node.

**Note**

The implementation does not include support for pseudowire participation in running the Spanning Tree Protocol.

### *Layer 2 VPN Service Delimiters*

Service delimiters are used to define how the customer is identified to the Layer 2 VPN service.

There are multiple types of service delimiters. The ExtremeXOS software currently supports three types. The first is a VLAN service. This service transparently interconnects two or more VLAN segments together over an MPLS network. The configured VLAN IDs for the customer switch interfaces are not required to match, as long as the egress LSR overwrites the VLAN tag with the locally defined VLAN ID.

The second service is a VMAN service, which interconnects two or more VMAN segments. The service operates like the VLAN service but uses the VMAN tag instead of the VLAN tag to identify the service. As with the VLAN service, the interconnected VMAN segments do not need to have matching VMAN IDs.

The third service is a port service, which transparently interconnects two or more ports together over an MPLS network. Traffic is transported unmodified between ports.

The VLAN and VMAN services are configured by adding the service VLAN or a VMAN to a VPLS or VPWS. The port service is not explicitly configured but is emulated using a combination of Layer 2 VPN capabilities. First a VMAN must be configured and the port added untagged to the VMAN. The service VMAN is then added to the VPLS or VPWS. At this point all traffic received on the port is VMAN encapsulated for transmission across the Layer 2 VPN. To transmit the traffic across the Layer 2 VPN as it was received on the port, the VPLS or VPWS is configured to exclude the service tag. By excluding the service tag, the VMAN tag is stripped prior to being transmitted from the switch. This configuration provides port mode service and allows one or multiple ports to be associated with a Layer 2 VPN.

### *MPLS Pseudowires*

MPLS pseudowire (PW) tunnels are logical connections between two LERs over an LSP.

LDP Pseudowires are signaled based on the configured PW identifier (pwid). The signaled PW label is used to create a two-label-stack shim header on PW encapsulated packets. The outer label is the transport LSP label obtained from LDP or RSVP-TE and the inner label is the signaled PW label. LERs also signal the PW type when attempting

to establish a PW. The ExtremeXOS software supports only the PWid type FEC. The Generalized ID FEC type is currently not supported.

**Note**

MPLS PWs can also be configured with statically assigned labels.

**Transporting 802.1Q Tagged Frames**

When an 802.1Q Ethernet frame is encapsulated for transport over a VC tunnel, the entire frame is included, except for the preamble and FCS.

There is a configuration option that determines whether the 4-byte VLAN tag field is included in the transmitted packet. By default, the tag field is not included. If the tag field is not included, the egress LER may add one. If it is included, the tag service identifier may be overwritten by the egress LER. The ability to add a tag field or to overwrite the service identifier at the egress node allows two (possibly independently administered) VLAN segments with different VLAN IDs to be treated as a single VLAN.

The following command can be used to include the VLAN tag field:

```
configure l2vpn [vp1s vp1s_name | vpws vpws_name] {dot1q [ethertype
hex_number | tag [include | exclude]]} {mtu number}
```

This command can also be used to control the overwriting of the 802.1Q ethertype when the VLAN tag field is included. In this case, the ingress node prior to transmitting the encapsulated packet overwrites the ethertype. This allows devices with a configurable VLAN tag ethertype to interoperate.

**Establishing LDP LSPs to PW Endpoints**

Establishing a PW requires both an LSP and a targetted LDP session between the two endpoints.

The local PW endpoint is the MPLS LSR ID. The remote PW endpoint is identified using an IP address configuration parameter.

When using LDP to establish the LSPs, each endpoint needs to advertise a label mapping for an LSP to its local endpoint address. To ensure that its LDP peers use the label mapping, a corresponding IGP route should also be advertised for the address. The IGP route can come from any of the supported routing protocols, such as OSPF or IS-IS. For example, when using OSPF, an OSPF route with prefix length 32 should be advertised for the configured IP address.

We recommend that you configure a loopback VLAN using the IP address of the local endpoint (the MPLS LSR ID). Use prefix length 32 for the IP address configured for the loopback VLAN. When you configure a loopback VLAN, the IP address used to identify the endpoint remains active, even when one or more of the LSR VLAN interfaces go down. Should a remote peer normally use one of the down interfaces, the normal IGP and LDP recovery procedures allow the PW to use one of the remaining up interfaces to minimize the network outage.

You should also configure the loopback VLAN for MPLS using the `configure mpls add vlan vlan_name` command. The addition of the loopback VLAN to MPLS causes LDP to include the IP address in LDP address messages. Some implementations (including the ExtremeXOS software) require this information to determine the correct LDP session over which to advertise label mappings for VC FECs (see [Using LDP to Signal PW Label Mappings](#) on page 1049).

**Note**

Neither MPLS nor LDP have to be enabled on the loopback VLAN.

There are two options to initiate the LDP advertisement of an LSP to the local MPLS LSR ID when a loopback VLAN has been configured for that IP address:

- Configure MPLS LDP to advertise a direct interface whose IP address matches the LSR ID and has prefix length 32. Use the `configure mpls ldp advertise direct lsr-id` command to do this.
- Configure MPLS LDP to advertise direct interfaces using the `configure mpls ldp advertise direct all` command.

**Note**

This causes LDP to advertise label mappings for all VLANs that have an IP address configured and have IP forwarding enabled.

While both of the above methods initiate the advertisement of a label mapping for an LSP to the local endpoint, the first method is the preferred method.

### Using LDP to Signal PW Label Mappings

Just as LDP advertises label mappings for LSPs, it can also advertise label mappings for Layer 2 VPNs.

In this case, the signaled FEC information describes a particular Layer 2 VPN. This FEC is often called a Virtual Circuit FEC, or VC FEC. The VC FEC information includes a PWid that is a 32-bit numeric field. Unlike LSP label advertisements that are usually sent to all possible upstream peers, the VC FEC information is sent only to the configured remote endpoint.

When the first Layer 2 VPN is configured to a remote peer, *MPLS* automatically creates a targeted hello adjacency entity for establishing an LDP session. Once the session is established, LDP passes the VC FEC label mapping associated with the Layer 2 VPN. Once VC FECs for the same PW ID have been exchanged in each direction, MPLS is ready to associate the PW with an LSP to the remote endpoint as described in [Message Types](#) on page 1068.

To determine the correct LDP session over which to send a VC FEC, MPLS checks the IP addresses learned from its LDP peers via LDP address messages. The ExtremeXOS software MPLS expects to find the IP address of a remote PW peer among the addresses received over the LDP session to that peer.

To ensure that the local endpoint IP address is included in LDP address messages, it is highly recommended to configure MPLS on a loopback VLAN as described in [Establishing LDP LSPs to PW Endpoints](#) on page 1048.

Use the command `configure mpls add vlan vlan_name` to configure MPLS on the loopback VLAN. It is not required that LDP or MPLS be enabled on the VLAN for the associated IP address to be advertised in LDP address messages.

## LSP Selection

A PW can be configured to use any available LSP to the peer endpoint IP address, or the PW can be configured to use one or more specific named LSPs.

In either case, the LSP has to egress (terminate) at the remote endpoint. In the case of an LDP LSP, the LSP's FEC has to be a /32 prefix length to the endpoint IP address. In the case of an RSVP-TE LSP or static LSP, the destination address has to be that of the remote endpoint. When configured to use any available LSP, MPLS gives preference to RSVP-TE LSPs, then to LDP LSPs, and lastly, to static LSPs. As a single LSP is chosen to carry the PW traffic, if multiple LSPs of the chosen type exist, the decision of which LSP of this type to use is non-deterministic.

The `configure l2vpn [vpls vpls_name | vpws vpws_name] peer ipaddress [add | delete] mpls lsp lsp_name` command forces the PW to use the specified named LSP. If multiple named LSPs are configured, only one is used to carry the PW. The decision of which of the multiple configured LSPs to use is non-deterministic.

RSVP-TE can be configured to allow specific types of traffic on an LSP. By default, LSPs are used to transport all traffic. Optionally, named LSPs can be configured to allow only IP traffic or only VPN traffic. This can be used to control the LSP selection for specific types of packets. For example, if both LDP and RSVP-TE LSPs exist and the RSVP-TE LSPs are configured to transport only VPN traffic, all IP traffic is forwarded using LDP LSPs. Since RSVP-TE LSPs are preferred over LDP LSPs, VPN traffic flows over the RSVP-TE LSPs. The following command configures this behavior for the specified RSVP-TE LSP:

```
configure mpls rsvp-te lsp lasp_name transport ip-traffic deny
```

## Layer 2 VPN Domains

Layer 2 VPN domains are created by adding PWs to each peer LSR to build a fully-meshed interconnected VPLS.

For each peer added, a PW is signaled that is used to carry traffic from the local LSR to the remote peer LSR. Flood traffic from the local service (broadcast, multicast, and unknown unicast packets) is replicated and forwarded across all PWs in the VPLS. Each peer receives one copy of the packet for delivery to its locally attached service. As MAC learning occurs on PWs, unicast packets to a known destination MAC address are forwarded to the peer over the PW from which the MAC address was learned.

## MAC Learning

Learned MAC addresses are associated with the PWs from which the packets are received.

The learned MAC address is always inserted into the *FDB (forwarding database)* as though it was learned on the local service *VLAN* (and not the VLAN identified in the dot1q tag in the received PW packet). MAC addresses learned from PWs use a different FDB aging timer than those MAC addresses learned on Ethernet interfaces. Different FDB aging timers are maintained for Ethernet and pseudowire Layer 2 VPN FDB entries. By default, both aging timers are set to 300 seconds. However, the aging timers for each type of FDB entry can be configured to different values. Note that PW FDB entries are not refreshed; they age out based on the configured aging timer setting, unless you have disabled the aging timer. Ethernet FDB entries automatically refresh with use, and do not age out unless they are not used for the length of time configured for the aging timer. Any MAC address associated with a PW is automatically cleared from the FDB when the PW label is withdrawn.

**Note**

MAC learning is disabled for VPWS.

### Spanning Tree Protocols

There is some debate as to the benefit of supporting *STP (Spanning Tree Protocol)* within a Layer 2 VPN.

The idea is that STP protocols can be used to provide redundant VPN data paths that can be unblocked if the STP detects a spanning tree topology failure. In general, it is believed that introducing STP to VPLS increases network complexity with very little real benefit.

*MPLS* already provides a significant level of redundancy for the LSP over which a PW is carried. For example, if a PW is using an LDP established LSP, provided there are parallel routed paths to the PW endpoint, the PW automatically shifts from a withdrawn or failed LSP to the next best available LSP. For transport LSPs established using RSVP-TE, secondary LSPs can be configured that can be hot-swapped in the event of a primary LSP failure. Fast-reroute detour LSPs can also be used to protect RSVP-TE LSPs. Thus, even though the underlying transport LSP might have changed, the Layer 2 VPN data plane remains unaffected.

For these reasons, VPLS and STP are not normally enabled on the same *VLAN*. The exception is for local customer network redundancy such as shown in [VPLS STP Redundancy Overview](#) on page 1061.

When STP is not enabled on a VPLS VLAN, the BPDU functional address is not inserted into the *FDB* for this VLAN and all received BPDU packets are flooded across the Layer 2 VPN. In this scenario, a single large spanning tree topology spanning all interconnected Layer 2 VPN service sites is constructed. Note that this is not a recommended configuration for a Layer 2 VPN service. Depending on the packet latency within the backbone network, STP timers might need to be tuned to build and maintain reliable topologies.

Currently, most ExtremeXOS software Layer 2 protocols cannot be configured on MPLS Layer 2 VPN domains. Likewise, the following protocols cannot be enabled on a Layer 2 VPN service VLAN:

- *VRRP (Virtual Router Redundancy Protocol)*

- [\*ESRP \(Extreme Standby Router Protocol\)\*](#)
- [\*EAPS \(Extreme Automatic Protection Switching\)\*](#) control VLAN

### *IP Protocol Considerations*

The ExtremeXOS software allows an IP address to be configured for a Layer 2 VPN service [\*VLAN\*](#). This is permitted to allow the switch to use the IP ping and traceroute functions to and from other nodes on the VLAN. It is envisioned that any such IP address is configured temporarily to assist in network verification.

As such, the ExtremeXOS software does not allow IP forwarding to be enabled on a Layer 2 VPN service VLAN for either IPv4 or IPv6. Therefore, any higher-level protocol that requires IP forwarding to be enabled cannot be enabled on a Layer 2 VPN service VLAN. For example, [\*OSPF\*](#) cannot be enabled on a VPLS service VLAN at the PE router. However, OSPF routers can be attached to the service vlan transparently at the customer interfaces. In addition, [\*IGMP \(Internet Group Management Protocol\)\*](#) snooping cannot be enabled on a VPLS service VLAN.

### *MPLS Layer 2 VPN Characteristics*

Characteristics of a Layer 2 VPN include:

- Use of LDP or RSVP-TE to establish the underlying pseudowire transport LSPs.
- Pseudowire endpoints are identified through configured VPLS/VPWS peer IP addresses.
- Configuration of a Layer 2 VPN pseudowire ID doubles as VPN ID.
- Customer packet [\*VLAN\*](#) tags may be overwritten on egress from the pseudowire allowing local service VLANs or VMANs interconnected over the same Layer 2 VPN to have different IDs.
- Customer packet VLAN tags can be included or excluded from packets transmitted on the pseudowire.
- Customer packet VLAN tag ethertype value can be modified before packet is transmitted on the pseudowire, allowing local service VLANs or VMANs interconnected over the same VPLS to have different 802.1Q tag ethertype values.
- Support for full-mesh VPN architectures.
- Support for VLAN, VMAN, and port Layer 2 VPN services.
- Support for enabling and disabling VPLS and/or the VPLS service.
- Support for enabling and disabling VPWS and/or the VPWS service.

## Layer 3 VPN over MPLS Overview

Layer 3 VPN services over [\*MPLS\*](#) are supported using [\*BGP\*](#). For more information, see [Layer 3 VPN Configuration Overview](#) on page 2142.

## H-VPLS Overview

VPLS requires a full mesh of pseudowires between all Provider Edge (PE) peers.

As *MPLS* is pushed to the edge of the network, this requirement presents a number of problems. One problem is the increased number of pseudowires required to service a large set of VPLS peers. In a full-mesh VPLS, pseudowires must be established between all VPLS peers across the core. Full-mesh networks do not scale well due to the number of pseudowires that are required, which is  $p(p-1)$ , where  $p$  is the number of peer devices in the network. Hierarchical VPLS (H-VPLS) networks can dramatically increase network scalability by eliminating the  $p^2$  scaling problem.

In a hierarchical VPLS network, a spoke node (often a Multi-Tenant Unit—MTU) is only required to establish a pseudowire to a single core PE. Thus the number of pseudowires required in the provider's network is  $c(c-1) + s$ , where  $c$  is the number of core PE nodes and  $s$  is the number of spoke MTU edge devices. This is a significant reduction in the number of pseudowires that need to be established and maintained. For example, a 10-core PE network with 50 MTU devices per core PE requires almost 260,000 pseudowires using a full-mesh VPLS design. A hierarchical VPLS design requires only 590 pseudowires.

An example H-VPLS network is shown in [Figure 125](#).

**Figure 125: Example H-VPLS Network**

H-VPLS spokes allow VPLS domains to be constructed hierarchically in a partial-mesh or hub-and-spoke configuration. This is useful for increasing the scaling of VPLS domains that can be supported. Within the context of H-VPLS, a spoke is a VPLS connection between two VPLS peers. Typically, one spoke node provides connectivity to the customer *VLAN* or customer service while its peer, a core node, provides repeater connectivity to other VPLS peers.

The pseudowire hierarchy must be known because the forwarding rules for spoke and core pseudowires are different. Flood traffic received on a core pseudowire from another full-mesh core PE must not be transmitted over other core pseudowires to other PEs. However, flood traffic received on a core pseudowire is transmitted on all

spoke pseudowires in the VPLS. Unlike core pseudowires in a full-mesh VPLS, flood traffic received on a spoke pseudowire must be transmitted on all other pseudowires in the VPLS, including pseudowires to other core PEs.

H-VPLS introduces the definition of a pseudowire type. In previous ExtremeXOS releases, only core peers were supported in an interconnected full-mesh configuration. Therefore, all pseudowires were considered to be of the type core. A new spoke pseudowire type is introduced and is highlighted in [Figure 126](#) on page 1055. A VPLS core node that has multiple spoke pseudowires but no configured core pseudowires is informally referred to as a hub.

#### *Eliminating Packet Replication by the MTU*

A scaling problem inherent in a full-mesh VPLS network is packet replication.

In a full-mesh configuration, until a node learns over which pseudowire a MAC address is reachable, unknown unicast frames must be flooded on all pseudowires within the VPLS. Packet replication is always true for broadcast and multicast traffic. As the number of VPLS peers increase, the packet replication burden on a node increases. MTU devices attached to a full-mesh core most likely cannot maintain wire-speed forwarding as the number of VPLS peers increase. Hierarchical VPLS eliminates this MTU burden by requiring only a single pseudowire connection between a spoke and its core PE peer. Packet replication is pushed to the PEs, where it is more suitably handled.

#### *Simplifying Customer Service Provisioning*

Bandwidth provisioning between an MTU and a PE is extremely difficult with a full-mesh VPLS design.

Since each VPLS instance can require multiple tunnel LSPs, the bandwidth requirements for each tunnel LSP must be separately accepted and individually enforced by every PE a tunnel LSP traverses. Because the provider requirement is to manage the provisioned bandwidth for the VPLS and not each tunnel LSP, the MTU has the added responsibility of rate limiting the aggregate egress traffic across multiple tunnel LSPs on the uplink. Due to packet replication issues described previously, this is not practical.

Hierarchical VPLS designs simplify bandwidth provisioning and management. Because tunnel LSPs from the MTU are terminated at the PE, tunnel LSP resources are easily shared and managed between customers. Thus, traffic for multiple VPLS instances can be transported across a single tunnel LSP. In some cases only a single best-effort tunnel LSP is required between the MTU and the PE. Traffic for each customer is carried over a different pseudowire on the same tunnel LSP. This allows the tunnel LSP to be signaled once, with the desired bandwidth and priority parameters sufficient for providing best-effort service for customers connected to the spoke peer. If a customer upgrades their service or a new customer is connected that requires guaranteed bandwidth, a second tunnel LSP could be signaled with the SLA bandwidth parameters. Once established, the second tunnel LSP can carry traffic for a single customer as a premium service.

### Redundant Spoke Pseudowire Connections

Redundant spoke pseudowires to PE peers can be configured from an MTU to provide backup connectivity into a VPLS core.

The addition of a redundant spoke pseudowire is optional. By default, when the MPLS Feature Pack license has been applied to the switch, the spoke pseudowire to the primary peer is used to forward packets. In the event of a network failure over the primary pseudowire, the spoke pseudowire to the secondary peer is used to provide redundant VPLS connectivity. An example network is shown in [Figure 126](#).

**Figure 126: Example H-VPLS Network with Redundant Spokes**

When both the primary and secondary pseudowires are established, the MTU is responsible for blocking the secondary pseudowire. Any packets received on the secondary pseudowire while the primary pseudowire is active are discarded. This behavior prevents packet-forwarding loops within the L2 VPN.

Since the MTU is responsible for choosing which pseudowire to the VPLS is active, the MTU is uniquely responsible for preventing network loops. The MTU uses only one spoke pseudowire per VPLS and only the label stack associated with the active pseudowire is programmed into the hardware. If the active pseudowire fails, then the label stack for the active pseudowire is removed from hardware. The secondary pseudowire label stack is then installed in the hardware in order to use the redundant VPLS link from the MTU into the VPLS core. Customer connectivity through the MTU should experience minimal disruption.

*IETF RFC 6870* defines the "Preferential Forwarding" status bit to designate which pseudowire is active and can be used to forward user packets. The MTU sets this bit to indicate that a pseudowire is standby (not active) and should not be used to forward user packets.

When a failover occurs from a primary pseudowire to a secondary pseudowire, the MTU clears its *FDB* database of MAC addresses learned over the primary pseudowire. It then begins learning MAC addresses over the new active pseudowire. To inform other nodes to clear their learned MAC database, the MTU can send a MAC address-withdraw message (if this feature is enabled) to the peer PE node of the secondary pseudowire. This PE node can subsequently send its own MAC address-withdraw message to the other VPLS full-mesh core nodes. Upon receipt of the MAC address withdrawal message, each core node clears its database. In this manner, other core nodes re-learn MAC addresses from the correct pseudowire or port.

Packets can be received out-of-order by the VPLS destination device during certain pseudowire failover events. In the redundant VPLS spoke configuration, when the primary pseudowire fails, traffic is immediately switched to the secondary pseudowire. For a very short period of time, there may be packets that are in route via both pseudowires. No attempt to prevent mis-ordered packets from being received is made.

The command to configure the VPLS peer from an MTU to a PE and from a PE to an MTU is fundamentally the same. However, the optional primary and secondary pseudowire keywords are only applicable on the MTU since the MTU is responsible for preventing loops within the VPLS. A switch cannot be configured with a primary and a secondary pseudowire to the same peer within a VPLS. This is an invalid configuration since it provides no redundant protection for a failed PE node.

#### *MAC Address Withdrawal TLV Support*

MAC address withdrawal is a feature that is used to inform other nodes that certain FDB MAC address entries should be immediately unlearned, rather than waiting for them to age out. Traffic destined to these unlearned MAC addresses is then flooded until the MAC addresses are learned again. MAC address withdrawal is enabled by default when the MPLS Feature Pack License has been applied to the switch, but can be disabled. When this feature is disabled, traffic destined to MAC addresses previously learned over a now unusable pseudowire (PW) is not flooded until the FDB entries eventually age out. However, it can take the VPLS network longer to adjust than when MAC address withdrawal is enabled. This section describes how this feature operates when it is enabled.

After certain network recovery events, MAC addresses should be unlearned. For example, if the MTU's last usable transport LSP for the primary spoke pseudowire goes down, the MTU decides to activate and switch to the secondary pseudowire and send the primary and secondary core PE nodes an LDP notification message containing the appropriate PW status codes. The core PE node of the primary pseudowire flushes its FDB of any MAC addresses learned from the MTU, but does not send any MAC address-withdraw messages. It is the responsibility of the MTU to initiate the sending of MAC address-withdraw messages. If MAC address withdrawal is enabled, the MTU sends a MAC address-withdraw message to the core PE node of the secondary pseudowire. This node, in turn, sends its own MAC address-withdraw message to all the other core PE nodes in the VPLS causing each of these other core PE nodes to flush their FDB of any matching learned MAC addresses specified in the address-withdraw message. By withdrawing MAC addresses immediately, the other core PE nodes are forced to flood traffic destined to the MAC addresses specified in the address-withdraw message. If an

alternate VPLS path exists, the new path can be quickly learned without having to wait for the FDB MAC entry to age out.

When a node needs to withdraw a MAC address, it can signal the MAC withdrawal for a VPLS using an address-withdraw message in one of two ways: the MAC address is explicitly specified in a MAC TLV; or an empty MAC TLV is sent indicating that all MAC addresses not learned from that node should be unlearned. Because this information may be propagated to multiple VPLS nodes, a control plane processing trade-off exists. To reduce the processing load, ExtremeXOS sends an empty MAC TLV. Additionally, ExtremeXOS supports the processing of multiple withdraw messages per VPLS, since other vendors may choose not to send an empty MAC TLV.

#### *Event Log Messages*

MPLS has full EMS logging capabilities to capture error as well as debug information. Messages are logged with the MPLS component identifier.

#### *SNMP Support*

No SNMP (Simple Network Management Protocol) support is provided for H-VPLS.

## Protected VPLS and H-VPLS with ESRP Redundancy Overview

Protected VPLS Access enables redundant nodes at the entry to a VPLS or H-VPLS network.

This feature provides fault tolerant connectivity from the customer VLAN to the backbone VPLS. This could be implemented by running Layer 2 protocols across the VPLS to block switch ports, but this can lead to sub optimal spanning tree topologies across the VPLS backbone and relatively long outages while the STP converges. Instead, the ExtremeXOS software has been enhanced to provide the ability to configure redundant VPLS switches using a dual-homed design that provides fast failover for protected access points.

The first figure below shows fault-tolerant access in a full mesh core VPLS network while the second figure shows fault-tolerant access in a hierarchical VPLS network.

**Figure 127: Example Protected Access VPLS Network**

**Figure 128: Example Protected Access H-VPLS Network**

In the above figure, fault tolerance is provided at the customer site by MTU-A and MTU-B. A failure of either MTU-A or MTU-B does not result in any loss of customer connectivity beyond the failover time from one MTU to the other.

*ESRP* is employed to ensure that only one VPLS switch is active at any instant in time for a protected customer access point. Only the ESRP master switch forwards packets between the access network and the backbone VPLS network. This active primary switch retains this status based on a set of predefined tracking criteria. If the configured criteria can be better satisfied by the inactive secondary VPLS switch, the primary VPLS switch relinquishes control and the secondary switch assumes the active role. The secondary switch can also autonomously assume the active role if it detects that the primary switch has failed. This use of ESRP helps to prevent duplicate packet delivery and to prevent broadcast loops when the customer network is a loop topology.

*Fault Tolerant Access Points Assumptions and Limitations*

The following assumptions and limitations are associated with a fault tolerant access point network:

- This feature supports a maximum of two redundant VPLS switches per protected VLAN access point.
- This feature operates only with ESRP extended mode.
- For ESRP to communicate between neighbor switches, you must configure a separate control VLAN with the same network layout as the set of protected customer VLANs. For example, consider two customer VLANs, VLAN-X and VLAN-Y. Both require protected VPLS access. If both VLAN-X and VLAN-Y have the same network layout (for example, both are part of a single EAPS domain), you must create an ESRP control VLAN that has the same layout as VLAN-X and VLAN-Y. Conversely, if VLAN-X and VLAN-Y do not have the same layout, you must create two separate ESRP domains with each control VLAN following the layout of the associated service VLAN(s).
- All VPLS switches in the control VLAN need to have the same ESRP domain configured. VPLS switches that provide protected access to the VPLS network need to have ESRP enabled while other nodes in the control VLAN need to be ESRP aware.
- The software does not validate the configuration between switches to determine if all VPLS switches for a protected VLAN are configured to be part of the same ESRP.

*H-VPLS Redundant Edge Network*

In [Figure 129](#), PE-C still represents a single point of failure. To remove this exposure, the fault tolerant access points can be combined with the redundant spoke pseudowires to produce a redundant edge configuration, as shown below.

**Figure 129: Example Redundant Edge H-VPLS Network**

In the network shown in the above figure, only one of the pseudowires between the MTUs and their attaching PEs is active at any instant in time. This network provides fault tolerance for a failure at either MTU or at either of the attaching PEs, as well as for the active pseudowire in use between the MTUs and PEs.

### Fault Tolerant VPLS Operation

To provide the fault tolerance shown in the following figure through the following figure, the redundant network nodes communicate with each other to determine the active primary and inactive secondary status and elect an active master node.

For a VPLS domain type, [ESRP](#) considers election factors in the following order: standby, active ports, tracking information, stickiness, ESRP priority, and MAC. For more information on the ESRP election priority, see [ESRP](#).

For fault tolerant VPLS to function correctly, the ExtremeXOS software imposes restrictions on the configuration options on the VPLS redundancy type ESRP domain. [Table 76](#) lists the configuration restrictions on the control [VLAN](#).

**Table 76: ESRP Configuration Restrictions for VPLS Type Domains**

| No. | Parameter                  | Restrictions                         | Remarks                                                                                                                        |
|-----|----------------------------|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| 1   | <i>mode</i>                | Not configurable                     | Only extended mode is supported.                                                                                               |
| 2   | <i>elrp poll</i>           | Always enabled on control VLAN ports | Enabled because control VLANs can have loops. That is, a control VLAN is protecting an S-VLAN in an <a href="#">EAPS</a> ring. |
| 3   | <i>master VLAN</i>         | No restrictions                      | The ESRP control VLAN is configured as the master VLAN on the ESRP master and slave.                                           |
| 4   | <i>member VLAN</i>         | Not configurable                     | Member VLANs are not configured for the domain since we would need the slave node to perform L2 switching and L3 forwarding.   |
| 5   | <i>track-environment</i>   | Not configurable                     | Tracking is always done on pseudowires.                                                                                        |
| 6   | <i>track-VLAN</i>          | Not configurable                     | Tracking is always done on pseudowires.                                                                                        |
| 7   | <i>track-IProute</i>       | Not configurable                     | Tracking is always done on pseudowires.                                                                                        |
| 8   | <i>track-Ping</i>          | Not configurable                     | Tracking is always done on pseudowires.                                                                                        |
| 9   | <i>domain-id</i>           | None                                 |                                                                                                                                |
| 10  | <i>elrp-master-poll</i>    | No restrictions                      | Not configurable, disabled by default.                                                                                         |
| 11  | <i>elrp-premaster-poll</i> | No restrictions                      | Not configurable, disabled by default.                                                                                         |
| 12  | <i>election policy</i>     | Not configurable                     | Always set to: standby > ports > track > sticky > priority > mac.                                                              |
| 13  | <i>name</i>                | No restrictions                      |                                                                                                                                |

**Table 76: ESRP Configuration Restrictions for VPLS Type Domains (continued)**

| No. | Parameter       | Restrictions    | Remarks                                                                                                                                                                                                                  |
|-----|-----------------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14  | <i>priority</i> | No restrictions |                                                                                                                                                                                                                          |
| 15  | <i>timer</i>    | No restrictions | When the service VLAN is part of an EAPS ring, it is strongly recommended that the hello timer is always greater than the EAPS master health checkup timer because an ESRP switch before EAPS could cause traffic loops. |

The MTU nodes in the following figure signal the PE nodes about active/inactive state using the Status TLV defined in RFC 4447, Pseudowire Setup and Maintenance Using the Label Distribution Protocol (LDP). This operation is described in [Redundant Spoke Pseudowire Connections](#) on page 1055.

#### *Performance of Fault Tolerant VPLS Access Points*

Switching times for a VPLS type *ESRP* domain are the same as that for regular domains. Actual time depends on the configured hello timer values and is expected to be in the order of seconds.

#### *Deployment and Application Considerations*

The following configuration guidelines should be observed when deploying fault tolerant access points:

- When this feature is deployed with *EAPS* access rings, it is strongly recommended that the EAPS health check time is configured to a value that is less than or equal to the *ESRP* hello time. Current defaults are one second and two seconds for EAPS health check and ESRP hello, respectively.
- All nodes in the control *VLAN* other than the two VPLS enabled nodes are configured as ESRP-Aware.

#### *Event Log Messages*

*MPLS* has full EMS logging capabilities to capture error as well as debug information. Messages are logged with the MPLS component identifier.

#### *SNMP Support*

No *SNMP* support is provided for H-VPLS.

## VPLS STP Redundancy Overview

[Figure 130](#) shows an example network that uses *STP* to support redundant links to an H-VPLS network.

**Figure 130: Redundant Edge H-VPLS Network with STP Example**

This topology uses redundant VPLS spoke nodes (S1 and S2) and an STP customer network to protect customer access. The redundant VPLS nodes provide protection from the loss of a VPLS node, and STP provides protection from the loss of a node or link in the customer access network. Within the VPLS nodes, VPLS and STP work together to react to topology changes in the customer access VLAN.

This topology uses the restricted role feature on access switch ports to control path redundancy. In [Figure 130](#), the VPLS nodes S1 and S2 are the lowest priority STP bridges (STP prefers lower priority for root bridge election and shortest path calculation). The S1 ports connected to the R links are configured for STP restricted role mode. To prevent network loops, the restricted role mode in S1 blocks an STP enabled port when STP BPDUs with better information are received from the access network. As shown, the customer traffic uses S2 to access the VPLS network. Should one of the two restricted ports on S1 become unblocked due to a topology change, customer traffic could use both S1 and S2 to access the VPLS network.

The selection of primary and secondary PWs for this configuration is arbitrary. Therefore data paths traversing the spoke nodes S1 or S2 could use either or both core nodes C1 and C2.

In the network shown in [Figure 130](#), traffic destined to R1 from the VPLS core traverses C2, S2, and R1.

#### *Failure Recovery Scenario without VPLS STP Redundancy*

If VPLS STP redundancy is not configured on the network shown in the following figure and the S2-R1 link fails, S1 unblocks S1-R1 and S2 flushes its FDB on the S2-R1 port.

The VPLS core nodes C3 and C4 are unaware of this change and continue to forward any traffic destined for R1 to C2. C2 continues to forward traffic towards S2. This results in data loss because S2 is not able to reach R1 over the customer network.

This data loss continues until one of the following events occurs:

- The FDB entry for R1 ages out in the VPLS core nodes
- R1 sends traffic into the VPLS core allowing its MAC address to be relearned by the VPLS core nodes

Depending on the type of data traffic from R1, the latter scenario might not occur quickly.

#### *Failure Recovery Scenario with VPLS STP Redundancy*

If VPLS STP redundancy is configured on switches S1 and S2 in the following figure and the S2-R1 link fails, S1 unblocks S1-R1 and S2 flushes its FDB on the S2-R1 port.

When S2 flushes its FDB, it also sends a flush message to its core peer C2. Upon receipt of this flush message, C2 flushes its FDB entries learned over the PW to S2. C2 also sends flush messages to its core peers C1, C3, and C4. These core nodes then flush their FDB entries learned over their PWs to C2. Any traffic from the VPLS core destined for R1 is flooded until such time as traffic from R1 is forwarded into the VPLS core.

#### **Note**

In the example shown in [Figure 130](#) on page 1062, the core nodes are unaware that STP redundancy is configured on S1 and S2. There is no STP redundancy configuration on C1 and C2.

The following figure shows an H-VPLS configuration where the STP network directly connects to redundant spoke nodes. A similar configuration is possible where the STP network directly connects to redundant VPLS core nodes. In this case, the core nodes participating in STP are configured for STP redundancy and originate flush messages to their core peers whenever STP causes a flush on an STP port.

#### *Requirements and Limitations*

The solution shown in [VPLS EAPS Redundancy Overview](#) on page 1064 has the following requirements and limitations:

- The redundant VPLS nodes must be core nodes.
- An EAPS common link is required between the redundant VPLS nodes.
- The redundant VPLS nodes (Core 1 and Core 2) use PWs to connect to each other and the other core nodes (Core 3 and Core 4).
- The redundant VPLS nodes use PWs to support the EAPS-protected VLANs, not the EAPS common link.
- Works only with EAPS customer attachment ring.
- The EAPS master should *not* be on a VPLS node.
- EAPS state used by VPLS to control state of PWs (Active/Ready).
- EAPS monitors common link state and ring state.
- VPLS on controller node uses EAPS state to set Active/Ready PWs.
- EAPS blocks customer-facing ports as normal.

### Enabling and Disabling VPLS STP Redundancy

- To enable or disable VPLS *STP* redundancy, use the following commands:  

```
configure {l2vpn} vpls vpls_name redundancy [esrp esrpDomain | eaps | stp]
unconfigure {l2vpn} vpls vpls_name redundancy [eaps | esrp | stp]
```

## VPLS EAPS Redundancy Overview

To protect your customer access network from link and node failures, you can use the VPLS with Redundant *EAPS* configuration shown in [Figure 131](#).

**Figure 131: VPLS with Redundant EAPS Configuration Example**

This topology uses redundant VPLS core nodes and an EAPS ring to protect customer access. The redundant VPLS nodes provide protection from the loss of a VPLS node, and the EAPS ring provides protection from the loss of a node or link on the EAPS ring. Within the VPLS nodes, VPLS and EAPS work together to control the use of PWs so that no loops are created.

During normal operation, the Dist2 node is the EAPS ring master, and it blocks the port leading to the link at point 2. The protected VLANs on the EAPS ring do not include the EAPS common link at point 3. The protected VLANs on the EAPS ring use VPLS PWs between the redundant VPLS nodes to connect the two ring segments. This difference in normal EAPS operation is established during configuration by configuring an EAPS-protected VLAN on the core node with only one port on the ring.

To see the commands used to create the configuration shown above, see [VPLS with Redundant EAPS Configuration Example](#) on page 1111.

### Requirements and Limitations

The solution shown in [VPLS EAPS Redundancy Overview](#) on page 1064 has the following requirements and limitations:

- The redundant VPLS nodes must be core nodes.
- An [EAPS](#) common link is required between the redundant VPLS nodes.
- The redundant VPLS nodes (Core 1 and Core 2) use PWs to connect to each other and the other core nodes (Core 3 and Core 4).
- The redundant VPLS nodes use PWs to support the EAPS-protected VLANs, not the EAPS common link.
- Works only with EAPS customer attachment ring.
- The EAPS master should *not* be on a VPLS node.
- EAPS state used by VPLS to control state of PWs (Active/Ready).
- EAPS monitors common link state and ring state.
- VPLS on controller node uses EAPS state to set Active/Ready PWs.
- EAPS blocks customer-facing ports as normal.

### Failure Recovery Scenario 1

Suppose that a failure occurs at point 1 in the following figure.

The [EAPS](#) master detects the topology change (either through a failure notification from a node on the ring or through a hello timeout), and it unblocks the port on the protected [VLAN](#) at point 2. The Dist 2 node now connects to the VPLS through Core 2 instead of through Core 1.

When the topology changes either on an access ring or the shared port link, the path used to reach customer devices can change. For example, in the following figure, the path that Dist 2 takes to reach other parts of the VPLS network changes following the failure on the access ring at point 1. Prior to the failure, Dist 2 used Core 1 to reach the VPLS network. Following the failure, Dist 2 accesses the VPLS network using Core 2.

When the EAPS master detects a topology change, it sends a flush [FDB](#) message to its transit nodes. The transit nodes re-learn all the MAC addresses on the ring. However, this flush FDB message is not propagated over the VPLS network. As a result, Core 3 in the following figure still expects to find Dist 2 through the PW between Core 3 and Core 1. Any traffic destined for Dist 2 that is sent to Core 1 will not reach its destination.

To correct this problem, EAPS informs VPLS about any received EAPS flush FDB messages on both the controller and the partner nodes, and VPLS performs a local flush of any MAC addresses learned from the originating nodes. In this example, the EAPS processes in both Core 1 and Core 2 notify VPLS because neither node knows where the access ring is broken. The VPLS services in Core 1 and Core 2 send flush messages to the other VPLS nodes.

### Failure Recovery Scenario 2

The recovery scenario is more complicated when the common link fails between Core 1 and Core 2.

The common link is configured to be an *EAPS* common link, and this configuration requires that one node be designated as the EAPS controller node and the other node be designated as the EAPS partner node. As described below, the selection of which node is assigned which role must consider the overall customer topology.

If the shared port link fails, the EAPS master node unblocks its port, and VPLS on the EAPS controller node takes the additional action to remove the PWs (point 4 in the following figure) associated with the VPLS from hardware.

In this recovery mode, all traffic to and from the access ring and the rest of the VPLS instance passes through Core 2. When the EAPS controller node detects that the common link is repaired, it enters the preforwarding state as normal. When the controller node exits the preforwarding state, EAPS informs VPLS so that VPLS can reestablish the PWs.

### *Failure Recovery Scenario 3*

Now suppose there is a failure on the shared port link (point 3) and on the access ring at point 1.

The recovery actions for this double-failure need to be somewhat different. In this case, even though the core link has failed, both core nodes do not receive a copy of the ring traffic. For example, the only path to the VPLS network for Dist 1 is through the controller core node. In this case, the controller node does not take down its PWs.

It is possible that the customer access network could have parallel *EAPS* rings that attach to Core 1 and Core 2 as shown in [Figure 132](#). In this example, the network connections are broken at each point X and as long as any of the parallel EAPS rings are complete, there is a path to both core VPLS nodes. Thus, the controller node must take down its PWs as long as any of the parallel EAPS rings is complete.

**Figure 132: VPLS with Parallel Redundant EAPS Rings Configuration Example**

PW Management for Network Failures

Table 77 shows how the controller node responds to multiple failures in a network with parallel EAPS rings.

**Table 77: Controller Node Responses to EAPS Ring States**

| Ring State              | Common Link Up | Common Link Down |
|-------------------------|----------------|------------------|
| Any parallel ring Up    | PWs Active     | PWs Inactive     |
| All parallel rings Down | PWs Active     | PWs Active       |

RSVP-TE Overview

RSVP is a protocol that defines procedures for signaling *QoS* requirements and reserving the necessary resources for a router to provide a requested service to all nodes along a data path. This release supports inter-area RSVP tunnels.

**Note**  
Partial path computation for FRR over multiple *OSPF* areas is not supported.

RSVP is not a routing protocol. It works in conjunction with unicast and multicast routing protocols. An RSVP process consults a local routing database to obtain routing information. Routing protocols determine where packets get forwarded; RSVP is concerned with the QoS of those packets that are forwarded in accordance with the routing protocol.

Reservation requests for a flow follow the same path through the network as the data comprising the flow. RSVP reservations are unidirectional in nature, and the source initiates the reservation procedure by transmitting a path message containing a traffic specification (Tspec) object. The Tspec describes the source traffic characteristics in terms of peak data rate, average data rate, burst size, and minimum/maximum packet sizes.

RSVP-TE is a set of traffic engineering extensions to RSVP. RSVP-TE extensions enable RSVP use for traffic engineering in *MPLS* environments. The primary extensions add support for assigning MPLS labels and specifying explicit paths as a sequence of loose and strict routes. These extensions are supported by including label request and explicit route objects in the path message. A destination responds to a label request by including a label object in its reserve message. Labels are then subsequently assigned at each node the reserve message traverses. Thus, RSVP-TE operates in downstream-on-demand label advertisement mode with ordered LSP control.

The ExtremeXOS software implementation of RSVP-TE complies with RFC 3209 and includes support for:

- Configuration on a per *VLAN* interface.
- Operation as either edge or core MPLS router.
- Support for specifying explicitly routed paths.
- Support for both loose and strict route objects.
- Recording the route of an established path.
- Bandwidth reservation and policy per LSP.
- Signaling QoS along the RSVP path using the Tspec and Adspec objects.
- Fixed Filter (FF) and Shared Explicit (SE) reservation styles.
- Specifying RSVP-TE session attributes.
- Scaling enhancements using Refresh Overhead Reduction extensions.
- Improved link failure detection using the RSVP-TE Hello Message.
- Ability to reroute traffic over pre-configured backup LSPs.

## *RSVP Elements*

### **Message Types**

RSVP messages are passed between RSVP-capable routers to establish, remove, and confirm resource reservations along specified paths.

RSVP messages are sent as raw IP datagrams with protocol number 46. Each LSR along the path must process RSVP control messages so that it can maintain RSVP session state information. Therefore, most RSVP messages are transmitted with the IP Router Alert Option. Including the IP Router Alert provides a convenient mechanism allowing the IP routing hardware to intercept IP packets destined to a different IP address and deliver them to the RSVP control plane for processing. This is needed to set up and refresh RSVP-TE LSPs that follow an explicitly specified network path and thus may not use the normal routed next hop IP address. RSVP has two basic message types, path message and reserve message, as shown in the following figure.

MPLS\_27

**Figure 133: RSVP Messages**

RSVP has the following message types:

- Path message
- Reserve message
- Path tear message
- Reserve tear message
- Path error message
- Reserve error message
- Reserve confirm message

**Path Message:** The RSVP path message is used to store state information about each node in the path. Each RSVP sender transmits path messages downstream along routed paths to set up and maintain RSVP sessions. Path messages follow the exact same path as the data flow, creating path states in each LSR along the path. The IP source address of the path message must be an address of the sender it describes and the IP destination address must be the endpoint address for the session. The path message is transmitted with the IP Router Alert option since each router along the path must process the path message. Each LSR is responsible for refreshing its path status by periodically transmitting a path message to the downstream LSR.

In addition to the previous hop address, the path message contains the sender Tspec and Adspec. The reservation message carries the flowspec.

**Reserve Message:** Each receiver host transmits an RSVP reservation request to its upstream neighbor. Reserve messages carry reservation requests hop-by-hop along the reverse path. The IP destination address of a reserve message is the unicast address of the previous-hop LSR, obtained from the session's path state. The IP source address is the address of the node that originated the message. The reserve message creates and maintains a reserve state in each node on the path. Each LSR is responsible for refreshing its reserve status by periodically transmitting a reserve message to the upstream LSR.

<sup>6</sup> The routed path may be the best routed path or an explicitly specified routed path using EROs.

<sup>7</sup> IP Router Alert option is described in RFC 2113.

Reserve messages are eventually delivered to the sender, so that the sender can configure appropriate traffic control parameters for the first hop node.

**Path Tear Message:** Path tear messages delete path state information reserved along the path. The message is initiated by the path sender or by any LSR in which a path state time-out occurs or an LSP is preempted (due to bandwidth reservations), and is sent downstream to the session's path endpoint. Path tear messages are transmitted with the IP Router Alert option and are routed exactly the same as path messages. The IP destination address must be the path endpoint and the source IP address must be the sender address obtained from the session's path state for the path that is being torn down.

When a path state is deleted as the result of the path tear message, the related reservation state must also be adjusted to maintain consistency in the node. The adjustment depends on the reservation style.

**Reserve Tear Message:** Reserve tear messages delete reservation state information. The message is initiated by the path endpoint or any node along the path in which a reservation state has timed out or an LSP is preempted (due to bandwidth reservations), and is sent upstream to the session's path sender. Reserve tear messages are routed exactly the same as reserve messages. The IP destination address of a reserve message is the unicast address of the previous-hop node, obtained from the session's reservation state. The IP source address is the address of the node that originated the message.

If no reservation state matches the reserve tear message, the message is discarded. The reserve tear message can delete any subset of the filter specification in FF-style or SE-style reservation state. Reservation styles are described in the following table.

**Path Error Message:** Path error messages are used to report processing errors for path messages. These messages are sent upstream to the sender that issued the path message. The message is routed hop-by-hop using the path state information maintained in each node. Path error messages are informational and do not modify the path state within any node.

**Reserve Error Message:** Reserve error messages are used to report processing errors for reserve messages. In addition, reserve error messages are used to report the spontaneous disruption of a reservation. Reserve error messages travel downstream to the endpoint of the session. The message is forwarded hop-by-hop using the reservation state information maintained in each node. Reserve error messages are informational and do not modify the reservation state within any node.

**Reserve Confirm Message:** Reserve confirm messages are optionally transmitted to acknowledge a reservation request. These messages are transmitted from the sender to the endpoint. The destination IP address is the IP address of the endpoint and the source IP address is the address of the sender. Since none of the intermediate path nodes need to process a reserve confirm message, the message is transmitted without the IP Router Alert option.

## Reservation Styles

A reservation style is a set of options that is included in the reservation request.

One reservation style concerns how reservations requested by different senders within the same session are handled. This type of reservation style is handled in one of two ways: either create a distinct reservation for each sender in the session, or use a single reservation that is shared among all packets of the selected senders.

Another reservation style concerns how senders are selected. Again, there are two choices: an explicit list of all selected senders, or a wildcard that implies all senders in the session.

Table 78 describes the relationship between reservation attributes and styles.

**Table 78: Reservation Attributes and Styles**

| Sender Selection | Distinct Reservation Style | Shared Reservation Style |
|------------------|----------------------------|--------------------------|
| Explicit         | Fixed filter (FF)          | Shared explicit (SE)     |
| Wildcard         | Not defined                | Wildcard filter (WF)     |

**Fixed Filter:** The fixed filter (FF) reservation style uses a distinct reservation and an explicit sender selection. This means that each resource reservation is for a specific sender. The session resources are not shared with other senders' packets. Because each reservation is identified with a single sender, a unique label is assigned by the endpoint to each sender (i.e., point-to-point LSP reservation).

**Shared Explicit:** The shared explicit (SE) reservation style uses a shared reservation and an explicit sender selection. This means that a single resource reservation is created that is shared by multiple senders. The endpoint may specify which senders are to be included for the reservation. Because different senders are explicitly listed in the RESV message, different labels may be assigned to each sender. Thus, multiple shared-resource LSPs to the same endpoint can be created (i.e., multipoint-to-point LSP reservation). The Extreme *MPLS* implementation requests SE reservation style when signaling RSVP-TE LSPs.

**Wildcard:** The wildcard (WF) reservation style uses the shared reservation and wildcard sender options. A wildcard reservation creates a single reservation that is shared by data flows from all upstream senders.

The Extreme MPLS implementation does not support WF reservation style.

### *RSVP Traffic Engineering*

*MPLS* Traffic Engineering (TE) extends RSVP to support several unique capabilities.

By coupling RSVP and MPLS, LSPs can be signaled along explicit paths with specific resource reservations. Additional RSVP objects have been defined to provide TE extensions. These objects include the Label Request, Label, Explicit Route, Record Route, and Session Attribute. Extreme's RSVP-TE implementation supports all of these TE objects.

### **RSVP Tunneling**

An RSVP tunnel sends traffic from an ingress node through an LSP. The traffic that flows through the LSP is opaque (or tunneled) to the intermediate nodes along the

path. Traffic flowing through the tunnel to an intermediate node along the path is identified by the previous hop and is forwarded, based on the label value(s), to the downstream node.

RSVP-TE can:

- Establish tunnels with or without *QoS* requirements.
- Dynamically reroute an established tunnel.
- Observe the actual route traversed by a tunnel.
- Identify and diagnose tunnels.
- Use administrative policy control to preempt an established tunnel.
- Perform downstream-on-demand label allocation, distribution, and binding.

Some LSRs require their neighboring LSRs to include their Router ID in the Extended Tunnel ID field when sending RSVP-TE messages. The Extended Tunnel ID is a globally unique identifier present in the RSVP common header Session object (see RFC 3209). To provide maximum compatibility with other vendors' implementations, the ExtremeXOS *MPLS* implementation accepts RSVP-TE messages regardless of the Extended Tunnel ID value and always inserts the local Router ID into the Extended Tunnel ID field prior to transmission of an RSVP-TE message.

## RSVP Objects

This section describes the RSVP objects that are used to establish RSVP-TE LSPs:

- Label
- Label request
- Explicit
- Record route
- Session attribute

**Label:** The label object is carried in the reserve message and is used to communicate a next hop label for the requested tunnel endpoint IP address upstream towards the sender.

**Label Request:** To create an RSVP-TE LSP, the sender on the *MPLS* path creates an RSVP path message and inserts the label request object into the path message.

A label request object specifies that a label binding for the tunneled path is requested. It also provides information about the network layer protocol that is carried by the tunnel. The network layer protocol sent through a tunnel is not assumed to be IP and cannot be deduced from the Layer 2 protocol header, which simply identifies the higher layer protocol as MPLS. Therefore, the Layer 3 Protocol ID (PID) value must be set

in the Label Request Object, so that the egress node can properly handle the tunneled data.

**Note**

The ExtremeXOS RSVP-TE implementation supports only Label Request objects with no Label Range. Label Ranges are used to signal ATM VPI/VCI or Frame Relay DLCI information for the LSP. These types of Label Requests are not supported. In the ExtremeXOS RSVP-TE implementation, the L3 PID value, which identifies the Layer 3 protocol of the encapsulated traffic, is always set to 0x0800 (IP).

**Explicit Route:** The explicit route object specifies the route of the traffic as a sequence of nodes. Nodes may be loosely or strictly specified.

The explicit route object is used by the MPLS sender if the sender knows about a route that:

- Has a high likelihood of meeting the *QoS* requirements of the tunnel.
- Uses the network resources efficiently.
- Satisfies policy criteria.

If any of the above criteria are met, the sender can decide to use the explicit route for some or all of its sessions. To do this, the sender node adds an explicit route object to the path message.

After the session has been established, the sender node can dynamically reroute the session (if, for example, it discovers a better route) by changing the explicit route object.

**Record Route:** The record route object is used by the sender to receive information about the actual route traversed by the RSVP-TE LSP. It is also used by the sender to request notification if there are changes to the routing path. Intermediate or transit nodes can optionally use the RRO to provide loop detection.

To use the object, the sender adds the record route object to the path message.

**Session Attribute:** The session attribute object can also be added to the path message. It is used for identifying and diagnosing the session. The session attribute includes the following information:

- Setup and hold priorities
- Resource affinities
- Local protection

**ERO Exclude Option**

In order to allow more flexibility when traffic engineering redundant paths for RSVP-TE LSPs, this feature adds the “exclude” option to the “configure mpls rsvp-te path <path> add ero” command. An “include” option is also available, but is optional. If neither option is used, “include” will be used for backward compatibility.

A hop that is excluded is avoided when CSPF does path calculations. By adding an “exclude” hop to a path, LSPs can be set up to avoid certain links. An example of

this is to configure a secondary RSVP-TE LSP to avoid the hops that a primary LSP has been configured to traverse. This can allow the secondary LSP more freedom to route through other parts of the network. Often, without the “exclude” option, the secondary LSP must be configured more tightly than desired to ensure that its path never overlaps with the primary LSP’s path.

### *Establishing RSVP-TE LSPs*

Establishing LSPs requires every LSR along the path to support RSVP and the TE extensions defined in RFC 3209.

The LSP endpoints attempt to detect non-RSVP capable LSRs by comparing the time-to-live (TTL) value maintained in the RSVP common header with that of the IP TTL. If these values are different, it is assumed that a non-RSVP capable LSR exists along the path. By including the Label Request object in the path message, RSVP capable routers that do not support the TE extensions can be detected. RSVP routers that do not support TE extensions reply with the Unknown object class error.

RSVP-TE LSPs are referred to as named LSPs. These LSPs have configurable names that are used to identify the LSP within the CLI. The command `create mpls rsvp-te lsp lsp_name destination ipaddress` allocates the internal resources for the LSP. The newly created LSP is not signaled until the LSP has been configured. The LSP can be configured to take a specific path through the network or the administrator can let the switch choose the best path by specifying the path any. Up to three paths may be configured for an LSP to provide redundancy. The command `configure mpls rsvp-te lsp lsp_name add path` configures an LSP. Optionally, RSVP-TE profiles may be applied to an LSP to change its properties. An RSVP-TE profile is a specific CLI container used to hold configuration parameters associated with timers, bandwidth reservation, limits, and other miscellaneous properties.

Once the RSVP-TE LSP is configured, the LSP is immediately signaled. If signaled successfully, the LSP becomes active. The commands `disable mpls rsvp-te lsp lsp_name` and `enable mpls rsvp-te lsp lsp_name` are used to tear down and re-signal the LSP. Disabling the LSP causes the LER to send a path tear message to the destination, forcing the LSP down and all resources along the path to be freed. Enabling the LSP instructs the LER to send a path message to the destination re-establishing the LSP. The configuration of the LSP is not modified by the enable or disable LSP commands.

### *RSVP-TE Implementation*

#### **Explicit Route Path LSPs**

An explicit route is a specified path through a routed network topology.

The path can be strictly or loosely specified. If strictly specified, each node or group of nodes along the path must be configured. Thus, no deviation from the specified path is allowed.

Loosely specified paths allow for local flexibility in fulfilling the requested path to the destination. This feature allows for significant leeway by the LSR in choosing the next

hop when incomplete information about the details of the path is generated by the LER. Each node along the path may use other metrics to pick the next hop along the path, such as bandwidth available, class of service, or link cost. The command `configure mpls rsvp-te path path_name add ero` is used to add an Explicit Route Object to a path container.

An explicit routed path is encoded using the explicit route object (ERO) and is transmitted in the path message. The ERO consists of a list of subobjects, each of which describes an abstract node. By definition, an abstract node can be an IP prefix or an autonomous system (AS) number. The ExtremeXOS RSVP-TE implementation supports only IPv4 abstract nodes. The ExtremeXOS RSVP-TE implementation supports both strict and loose IPv4 abstract nodes. Received path messages with EROs that contain any other subobject type result in the transmittal of an Unknown object class error message. All LSRs along the specified path must support the inclusion of the ERO in the path message for an explicitly routed path to be successfully set up.

An LSR receiving a path message containing an ERO must determine the next hop for this path.

The steps for selection of the next hop are as follows:

1. The receiving LSR evaluates the first subobject. If the subobject type is not supported or there is no subobject, a Bad ERO error is returned. The abstract node is evaluated to ensure that this LSR was the valid next hop for the path message. If the subobject is a strict abstract node, the abstract node definition must match the local interface address. If it does, then this LSR is considered to be a member of the abstract node. Additionally, if the /32 address matches a local interface address, the path message must have been received on the direct interface corresponding to the /32 address. If the abstract node is an IP prefix, the subnet configured for the interface from which the path message was received must match the abstract node definition. In the event that this LSR is not part of the strict abstract node definition, a Bad initial subobject error is returned. If the subobject is a loose abstract node, the LSR determines if the abstract node definition corresponds to this LSR. If it doesn't, the path message is transmitted along the best-routed or constrained optimized path to the endpoint and the ERO is not modified. If it is, then processing of the ERO continues.
2. If there is no second subobject, the ERO is removed from the path message. If this LSR is not the end of the path, the next hop is determined by the constrained optimized path (through Constrained Shortest Path First—CSPF) to the path message endpoint.
3. If there is a second subobject, a check is made to determine if this LSR is a member of the abstract node. If it is, the first subobject is deleted and the second subobject becomes the first subobject. This process is repeated until either there is only one subobject or this LSR is not a member of the abstract node as defined by the second subobject. Processing of the ERO is then repeated with step 2. By repeating steps 2 and 3, any redundant subobjects that are part of this LSRs abstract node can be removed from the ERO. If this operation were not performed, the next hop LSR might reject the path message.
4. The LSR uses its CSPF to determine the next hop to the second subobject. If the first object is a /32 address, the first subobject is removed, since it would not be part of

the next hop's abstract node. The path message is then sent along the explicit path to the path message endpoint. No determination is made to verify that the abstract node defined in the subobject is topologically adjacent to this LSR. The next hop should verify this as part of its processing as defined in step 1.

If CSPF determines that a specific path needs to be taken through the network, additional EROs are inserted into the path message.

## Route Recording

The route a path takes can be recorded.

Recording the path allows the ingress LER to know, on a hop-by-hop basis, which LSRs the path traverses. Knowing the actual path of an LSP can be especially useful for diagnosing various network issues.

Network path recording is configurable per LSP. This feature is configured by enabling route recording for a specific RSVP-TE profile using the command `configure mpls rsvp-te lsp profile lsp_profile_name record enabled` and associating the profile to an LSP. The ExtremeXOS software sets the label recording desired flag in the path message if route recording has been enabled for the LSP.

If route recording is enabled, the record route object (RRO) is inserted into the path message using a single RRO subobject, representing the ingress LER. When a path message that contains an RRO is received by an Extreme LSR, an RRO IPv4 subobject representing the /32 address of the outgoing interface of the path message is pushed onto the top of the first RRO. The updated RRO is returned in the reserve message.

The label recording flag is supported by the ExtremeXOS software and is set automatically when route recording is enabled. The route-only option can be used when enabling route recording in the profile to prevent the label recording flag from being set. If an Extreme LSR receives a path message with the label recording flag set in the RRO, the LSR encodes the LSP label into a label subobject and pushes it onto the RRO.

If a path message is received that contains an RRO, the Extreme LSR uses the RRO to perform loop detection. The RRO is scanned to verify that the path message has not already traversed this LSR. If the RRO contains an IPv4 subobject that represents a local LSR interface, the path message is dropped and a Routing Problem error message is sent to the originating LER with an error value of Loop detected.

## LSP Session Attributes

Session attributes are signaled for configured RSVP-TE LSPs using the session attribute object without resource affinities (that is, LSP\_TUNNEL Type).

The ExtremeXOS software uses the setup and hold priority values to preempt established LSPs in order to satisfy bandwidth requests. Lower hold priority LSPs are preempted in order to satisfy the bandwidth request in a path message with a higher setup priority. LSP attributes are configured by setting the priorities for

---

<sup>8</sup> RRO is organized as a LIFO stack.

a specific RSVP-TE profile using the command `configure mpls rsvp-te lsp profile lsp_profile_name setup-priority priority hold-priority priority` and associating the profile to the configured LSP.

## Bandwidth Reservation

As mentioned previously, RSVP reservations are unidirectional in nature.

The source initiates the reservation procedure by transmitting a path message containing a sender Tspec object. The Tspec describes the source traffic characteristics in terms of peak data rate, average data rate, burst size, and minimum/maximum packet sizes. The path message can also contain an optional AdSpec object that is updated by network elements along the path to indicate information such as the availability of particular [QoS](#) services, the maximum bandwidth available along the path, the minimum path latency, and the path maximum transmission unit (MTU).

The ExtremeXOS software supports LSR bandwidth reservation requests per LSP. Only the Int-Serv Controlled-Load service request is supported. Bandwidth is always reserved on the physical ports that the LSP traverses. Depending on the platform, the bandwidth reservation may also be policed. The network administrator can verify that the requested bandwidth was actually reserved. In those cases when the bandwidth reserved is less than the requested bandwidth, the LSP can be manually torn down, re-signaled using a different path, or accepted. The LSR automatically attempts to find a path that best satisfies the bandwidth request. Constrained path selections are supported using [OSPF-TE](#). Best effort LSPs are provisioned by specifying a reserved bandwidth as best-effort. The reserved LSP bandwidth is configured by setting the bps rate for a specific RSVP-TE profile, using the `configure mpls rsvp-te lsp profile lsp_profile_name bandwidth` command and associating the profile to an LSP.

Accounting of bandwidth reserved through an Extreme LSR RSVP-TE enabled [VLAN](#) is supported. The maximum available bandwidth per physical port or trunk group is enforced. Thus, the available bandwidth specified in the Adspec object is not modified as the path message is forwarded to the LSP endpoint. As reserve messages are processed, the reserved bandwidth specified in the Flowspec is added to the total reserved bandwidth allocated for the physical ports.

Because LSP bandwidth is dynamically allocated, a configuration command is provided to reserve port bandwidth for use by [MPLS](#). The command **`configure mpls rsvp-te bandwidth committed-rate`** pre-reserves bandwidth from the specified MPLS enabled VLAN for RSVP-TE traffic only. This pre-allocation of bandwidth is useful since other applications may compete with MPLS for available bandwidth. By pre-reserving a portion of the MPLS interface's bandwidth capacity, MPLS is guaranteed to have that amount of the MPLS interface's bandwidth to meet RSVP-TE LSP reservation requests.

CIR bandwidth for the receive direction is not tracked by TE IGP, such as OSPF-TE, and configuring it is not required. Configuring CIR bandwidth for the receive direction does not prevent an LSP from going operational due to lack of receive bandwidth; however, it can be useful for tracking and informational purposes. An Info level log (MPLS.RSVPTE.IfRxBwdthExcd) is generated if the setup of a TE LSP requires receive bandwidth greater than that which is currently available for the receive direction on a particular interface. This generally happens only when TE LSPs with different previous

hops ingress the switch on the same interface (for example, from a multi-access link) and egress the switch on different interfaces.

### Bandwidth Management for RSVP-TE LSPs

If an RSVP-TE LSP is signaled through a switch with bandwidth parameters, the LSP bandwidth request is granted or rejected based on the availability of bandwidth resources on the physical ports that the LSP traverses.

Data traffic through these switches is not policed and there are no guarantees that the packets using the LSP are not dropped.

#### Note

Per LSP rate limiting is not supported in this release.

The available bandwidth for each *OSPF* interface is continually updated within the OSPF area. As RSVP-TE LSPs are established and torn down, the reserved bandwidth associated with these LSPs is used to update the total bandwidth available through each OSPF interface. RSVP-TE and CSPF can use the bandwidth information to determine the appropriate path that each LSP should take through the network based on the LSP's profile parameters. LSP parameters that can affect the CSPF TE path calculation include the LSP setup priority and bandwidth configuration.

Available bandwidth is calculated for eight *CoS (Class of Service)* levels. Each CoS uniquely maps to an LSP hold priority. Thus, when an LSP is set up through the switch, the reserved bandwidth consumed is associated with a CoS based on the signaled LSP hold priority. The available bandwidth is recalculated and is advertised to its OSPF neighbors. Advertised bandwidth is calculated using graduated bandwidth reporting methodology. Using this scheme, higher CoS levels advertise available bandwidth that includes allocated bandwidth for lower CoS levels. The reasoning for doing this is that higher priority LSPs can preempt lower priority LSP. Thus, even though the bandwidth has been allocated to a lower priority LSP, it is still available for use by higher priority LSPs.

In the following example, an interface is configured to reserve 250 Mbps for *MPLS* traffic.

The following LSPs are established through this interface. Remember, hold priority value of 0 is the highest priority and 7 is the lowest.

- LSP A, hold priority = 7, reserved = 50 Mbps
- LSP B, hold priority = 5, reserved = 100 Mbps
- LSP C, hold priority = 2, reserved = 25 Mbps
- LSP D, hold priority = 1, reserved = 25 Mbps

OSPF advertises the following available bandwidth for each CoS.

CoS 0 is the highest and CoS 7 is the lowest:

- CoS 0 (hold = 0): 250 Mbps (No LSPs; all bandwidth available)
- CoS 1 (hold = 1): 225 Mbps (LSP D)
- CoS 2 (hold = 2): 200 Mbps (LSP C & D)

- CoS 3 (hold = 3): 200 Mbps (LSP C & D)
- CoS 4 (hold = 4): 200 Mbps (LSP C & D)
- CoS 5 (hold = 5): 100 Mbps (LSP B, C & D)
- CoS 6 (hold = 6): 100 Mbps (LSP B, C & D)
- CoS 7 (hold = 7): 50 Mbps (LSP A, B, C & D)

CSPF calculations only use the available bandwidth for the desired CoS, as specified by the LSP hold priority. Thus in this example, if LSP E, with a configured setup priority of 6, requires 150 Mbps, CSPF calculates a path to the destination that does not go through the above interface, since only 100 Mbps worth of bandwidth is available.

### Redundant LSPs

There are three methods for provisioning redundant RSVP-TE LSPs at the ingress LER, also referred to as head-end LSP protection:

- Configured secondary (or backup) LSPs
- Fast reroute (detour) LSPs
- Multipath LSPs

Secondary RSVP-TE LSPs can be configured to provide backup LSPs in the event that the primary LSP fails. You can create up to two secondary LSPs for each primary LSP. The secondary LSPs are fully provisioned, pre-established RSVP-TE LSPs that are maintained as inactive until needed. If the primary LSP is torn down, the associated LSP next hop is removed from the route table, and a new LSP next hop representing one of the secondary LSPs is installed as the preferred LSP. If there are multiple secondary LSPs available, the secondary LSP is randomly selected. If the primary LSP is re-established, the primary LSP next hop information is re-installed and the secondary LSP returns to inactive state.

If both the primary and secondary paths for an LSP fail, and there are no other RSVP-TE LSPs active to the destination, an LDP LSP can be used if available.

Operation with L2 VPNs is similar. If a primary path fails, and a secondary LSP is available, VPLS uses the secondary LSP. When the primary LSP is re-established, VPLS again uses the primary LSP.

Specifying redundant LSPs is accomplished by assigning secondary paths to an LSP. The `configure mpls rsvp-te lsp lsp_name add path path_name secondary` command can configure the specified path as a backup LSP. A path different from the primary path must be specified. It is recommended that defined paths be configured using EROs to specify different paths through the network. Relying on the routing topology, by configuring the path to any, can create two LSPs that take the same path. It is important to understand that the configured LSP signals multiple LSPs, up to three (one primary and two secondary), but only one LSP can be used to forward traffic at any one time.

Fast Reroute LSPs are based on the on IETF RFC 4090, Fast Reroute Extensions to RSVP-TE for LSP Tunnels, which defines RSVP-TE extensions to establish backup LSP tunnels for local repair of LSP tunnels. To respond to failures, these mechanisms enable

the re-direction of traffic onto backup LSP tunnels in tens of milliseconds, and this meets the needs of real-time applications such as voice over IP (VoIP). This timing requirement is satisfied by computing and signaling backup LSP tunnels in advance of a failure and by re-directing traffic as close to the failure point as possible. In this way the time for redirection includes no path computation and no signaling delays, which include delays to propagate failure notification between label-switched routers (LSRs). Speed of repair is the primary advantage of using fast-reroute backup methods.

There are two backup methods; the detour LSP method (which is also called the one-to-one backup method) and the facility backup method (which is also called the by-pass tunnel method). The software supports only the detour LSP method.

Based on the RFC-4090 there are two different methods to uniquely identify a backup path:

1. Path-specific method
2. Sender template-specific method

The software supports only the path-specific method, which uses a new object, the DETOUR object, to distinguish between PATH messages for a backup path and the protected LSP.

Figure 134 illustrates the terminology used to describe fast-reroute configuration and operation.

**Figure 134: Fast-Reroute Terminology**

The primary LSP in Figure 134 is established between MPLS routers A and D. Router A is the ingress LER, and Router D is the egress LER. When used with fast-reroute protection, the primary LSP is also called the protected LSP, as it is protected by the detour LSP created by the fast-reroute feature. The detour LSP provides a route around a protected component. The link between Router B and Router C has failed. The detour LSP, which is indicated by the dashed line, provides a path around the failure.

Routers B and C are transit LSRs for the primary LSP. With respect to a specific LSP, any router that is not the ingress or egress LER is a transit LSR. Routers F and G are transit LSRs for the detour LSP.

The origin of the detour LSP is called the Point of Local Repair (PLR), and the termination of the detour LSP is called the Merge Point. A protected LSP is an explicitly-routed LSP that is provided with protection. A detour LSP is also an explicitly-routed LSP. If you configure a series of one or more hops (EROs), then based on the currently set DYNAMIC\_FULL option in the Constrained-based Shortest Path First (CSPF) routing component, the CSPF will calculate and try to fill in the gaps to build a complete list of EROs.

You can configure up to two secondary LSPs for each standard TE (non-FRR) LSP or for each protected FRR LSP. If a standard TE LSP fails, then one of the secondary LSPs becomes active. If that secondary LSP fails, the other secondary LSP becomes active. If a protected FRR LSP fails, its detour LSP becomes active. If the detour LSP fails, then one of the secondary LSPs becomes active, and if that secondary LSP fails, the other secondary LSP becomes active. If all configured backup and secondary paths for an LSP fail, a different active RSVP-TE LSP to the destination can be used. Otherwise, an LDP LSP can be used if available.

The primary advantage of detour LSPs is the repair speed. The cost of detour LSPs is resources. Each backup LSP reserves resources that cannot be used by other LSPs. Another cost is that currently there is no automatic way to redirect traffic from a detour LSP back to a primary LSP when the protected LSP recovers. Redirecting traffic from the detour LSP to the primary LSP requires a series of CLI commands.

Fast reroute protection is configured primarily on the ingress LER, however, it must be enabled on all transit LSRs and the egress LER also. After configuration is complete and fast-reroute protection is enabled on the primary LSP, the primary and detour LSPs are signalled. Provided that the resources are available, detour LSPs are set up at each transit LSP along the primary LSP.

Multiple RSVP-TE LSPs can exist or be configured to the same destination. The paths do not need to be equal cost; all that is required is that all the LSPs to the same destination must have IP transport enabled. In this scenario, LSP next hop information is communicated to the route table for up to eight different named RSVP-TE LSPs. Locally originated traffic is distributed across each LSP based on standard IP address hash algorithms. If one of the LSPs fails, the traffic is redistributed across the remaining active named LSPs. Unlike the backup LSP mechanism, all of the redundant multipath LSPs are unique named LSPs and in general have primary configured paths.

## Improving LSP Scaling

RSVP maintains path and reserve state by periodically sending refresh messages.

Refresh messages allow each LSR along the path to properly maintain reservation state information and to recover from network failures. Because refresh messages are periodically sent for each path reservation, scaling the number of RSVP-TE LSPs is an issue. Additionally, network requirements for faster failure detection and improved LSP recovery times further exacerbate the scaling issue.

Several techniques are described in RFC 2961 RSVP Refresh Overhead Reduction to improve the scalability of RSVP. These techniques include the bundle message, message ID extension, and summary refresh extension. Support for these extensions is signaled between RSVP peers via the refresh-reduction-capable bit in the flags field

of the common RSVP header. Additionally, the hello extension, described in RFC 3209, provides a fourth scaling mechanism for RSVP. The hello extension is designed so that either peer can use the mechanism regardless of how the other peer is configured. Therefore, support for the hello extension is not signaled between RSVP peers. The ExtremeXOS software supports and is compliant with the RSVP-TE scaling features described in RFC 2961.

These features include the following:

- Bundle message
- Summary refresh extension
- Message ID extension
- Hello extension

**Bundle Message:** RSVP bundle messages aggregate multiple RSVP messages within a single PDU. The messages are addressed directly to peer LSRs. Therefore, bundle messages are not sent with the IP Router Alert option. Bundling multiple RSVP messages into a single PDU reduces the per packet overhead associated with local delivery and local origination. Each bundle message must contain at least one RSVP message. Transmission of RSVP messages may be delayed up to the number of seconds configured for bundle time. The size of the bundle message is limited to the RSVP-TE interface MTU size. Bundle messaging is enabled using the `enable mpls rsvp-te bundle-message` command.

**Summary Refresh Extension:** A summary refresh message is used to refresh RSVP states along an LSP without having to explicitly send path and reserve refresh messages. This can substantially reduce the RSVP control bandwidth overhead. Summary refresh messages contain a list of `message_ID` objects. Each `message_ID` object identifies a path and reserve state to be refreshed. When summary refresh support is enabled, path and reserve refresh messages are suppressed. If the message identifier value indicates that the RSVP state has changed, the receiving LSR notifies the sender by transmitting a `message_ID_NACK` message. The summary refresh rate is enabled using the `enable mpls rsvp-te summary-refresh` command.

**Message ID Extension:** The message ID extension provides reliable delivery of RSVP messages. It also provides a simple mechanism for identifying refresh messages, which can greatly reduce refresh message processing on the receiving LSR. The message ID extension defines three new objects: `message_ID`, `message_ID_ACK`, and `message_ID_NACK`. The `message_ID` object contains a unique message identifier based on the sender's IP address. Only one `message_ID` object is inserted into an RSVP message. The receiving LSR can use the `message_ID` object to quickly refresh path and reserve states. If the message identifier value in the `message_ID` object is greater than the locally saved message identifier value, then the RSVP message represents a new or modified state. The receiving LSR must acknowledge an RSVP message using the `message_ID_ACK` object if the sender set the `ACK_desired` flag in the `message_ID` object, otherwise the `message_ID` acknowledgement is optional. The `message_ID_ACK` object may be included in any unrelated RSVP message or in an RSVP ACK message. Message ID extension is required for both bundle message and summary refresh, so this capability is automatically enabled if either of the other capabilities is enabled.

**Hello Extension:** The RSVP hello message provides a quick and simple mechanism for detecting the loss of a peer RSVP-TE LSR. The hello protocol is implemented using the RSVP soft-state model. RSVP hello messages may be enabled independently of each LSR peer. The hello protocol consists of two new objects: hello\_request and hello\_ACK. If configured, an LSR sends a hello\_request every hello interval. If a hello\_ACK is not received within a specified amount of time, the sending LSR assumes that its peer LSR is no longer active. Once a peer LSR is deemed inactive, all reservation states associated with LSPs established to or through the peer LSR must be freed and the LSPs torn down. The hello interval is configurable using the command `configure mpls rsvp-te timers session hello-time`.

You can improve LSP scaling by configuring the following RSVP-TE parameters:

- Refresh time
- Summary refresh time
- Bundle time

**Refresh Time:** The refresh time specifies the interval for sending refresh path messages. RSVP refresh messages provide soft state link-level keep-alive information for previously established paths and enable the switch to detect when an LSP is no longer active. RSVP sessions are torn down if an RSVP refresh message is not received from a neighbor within  $[(\text{keep-multiplier} + 0.5) * 1.5 * \text{refresh-time}]$  seconds. The valid refresh time may be set to any value between 1 and 36000 seconds. The default setting is 30 seconds. Configuring a longer refresh time reduces both switch and network overhead.

**Summary Refresh Time:** The summary refresh time, specified in tenths of a second, indicates the time interval for sending summary refresh RSVP messages. The summary refresh time must be less than the configured refresh time. The default summary refresh time is zero, indicating that no summary refresh RSVP messages are sent. The summary refresh time value may be set to any value between zero to 100 (or 10 seconds). If configured, the bundled and summary refresh RSVP messages are only sent to RSVP-TE peers supporting RSVP refresh reduction.

**Bundle Time:** The bundle time, specified in tenths of a second, indicates the maximum amount of time a transmit buffer is held so that multiple RSVP messages can be bundled into a single PDU. The default bundle time is zero, indicating that RSVP message bundling is not enabled. The bundle time value can be set to any value between zero and 30 (or 3 seconds).

## Supporting Quality of Service Features

QoS LSP support is an important attribute of MPLS.

MPLS supports the Differentiated Services (DiffServ) model of QoS. The DiffServ QoS model is supported by mapping different traffic classes to different LSPs, or by using the EXP bits in the MPLS shim header to identify traffic classes with particular forwarding requirements.

## Propagation of IP TTL

There are two modes of operation for routed IP packets: pipe TTL mode and uniform TTL mode.

Currently, switches that run Extreme OS support only the pipe TTL mode. In pipe TTL mode, the LSP is viewed as a point-to-point link between the ingress LSR and the egress LSR; intermediate LSRs in the [MPLS](#) network are not viewed as router hops from an IP TTL perspective. Thus, the IP TTL is decremented once by the ingress LSR, and once by the egress LSR.

In this mode, the MPLS TTL is independent of the IP TTL. The MPLS TTL is set to 255 on all packets originated by the switch and on all packets that enter a pseudowire.

## Configuring MPLS

[MPLS](#) has the following configuration constraints:

- **IP flow redirection**—IP flow redirection commands and MPLS are mutually exclusive functions. Both functions cannot be enabled simultaneously.
- **IGMP snooping**—[OSPF](#) and LDP session establishment require the switch to receive and process IP multicast frames. Therefore, IGMP snooping must be enabled to support MPLS.
- **VPLS**—VPLS requires that IGMP snooping be disabled on customer-facing VLANs.

## Configuration Overview

Do the following to configure MPLS:

1. If you want to use in a different VR (the default is VR-Default), move MPLS to the appropriate VR as described in [Moving MPLS From VR to VR](#).
2. Create and configure the VLANs that will use MPLS.
3. Configure an MPLS LSR ID for each switch that serves as an LSR in the network. (See [Configuring the MPLS LSR ID](#)).
4. Add MPLS support to the appropriate VLANs. (See [Adding MPLS Support to VLANs](#)).
5. Enable MPLS on each switch that serves as an LSR. (See [Enabling and Disabling MPLS on an LSR](#)).
6. Enable MPLS on the appropriate VLANs. (See [Enabling and Disabling MPLS on a VLAN](#)).
7. Enable LDP on each switch that serves as an LSR. (See [Enabling LDP on the Switch](#)).
8. Enable LDP on the appropriate VLANs. (See [Enabling and Disabling LDP on a VLAN](#)).
9. Configure an IGP, such as or IS-IS, for the appropriate switches and VLANs.

## Moving MPLS From VR to VR

By default, *MPLS* is enabled on the *VR-Default*. You can operate MPLS in VR-Default or in any user VR, but MPLS only operates in one VR. If you want to use MPLS in a user VR, you must delete it from VR-Default first.

- To delete MPLS from a VR, do the following:
  - a. Disable MPLS on the LSR as described in [Enabling and Disabling MPLS on an LSR](#) on page 1086.
  - b. Disable MPLS on all VLANs and reset the MPLS configuration as described in [Resetting MPLS Configuration Parameter Values](#) on page 1094.
  - c. Remove MPLS from the VR by entering the following command:

```
configure vr vr-name delete protocol protocol-name
```

### Note

When you enter the command to delete MPLS from a VR, the software displays a prompt to remind you that the MPLS configuration is lost when MPLS is deleted.

- To add MPLS to VR, do the following:
  - a. Use the following command:

```
configure vr name add protocol mpls
```
  - b. Add any other protocols that you want to use with MPLS.

After you add MPLS to a VR, you must configure and enable MPLS. MPLS commands operate only in the VR to which MPLS is added. An error message appears if you enter an MPLS command in a VR that does not support MPLS.

## Configuring the MPLS LSR ID

The *MPLS* LSR ID must be configured before MPLS can be used. The address chosen must be a routable IP address on the switch. It is suggested that this be set to the same IP address as a routing protocol ID (for example, the *OSPF* Router ID).

- To configure the MPLS LSR ID, use the following command:

```
configure mpls lsr-id ipaddress
```

### Note

The MPLS LSR ID must be configured before MPLS can be enabled. The LSR ID should be configured on a loopback *VLAN*.

## Adding MPLS Support to VLANs

To use *MPLS* on a *VLAN*, MPLS must first be configured on that VLAN.

- To configure a specific VLAN or all VLANs, use the following command:

```
configure mpls add {vlan} vlan_name
```

MPLS must be configured on a VLAN before it can be used to transmit or receive MPLS-encapsulated frames. By default, MPLS is not configured on a newly created VLAN.

If you have enabled MPLS on an *OSPF* interface that is used to reach a particular destination, make sure that you enable MPLS on all additional OSPF interfaces that can reach that same destination (for example, enable MPLS on all VLANs that are connected to the backbone network).

## Enabling and Disabling MPLS on an LSR

- To enable *MPLS* on an LSR, use the following command:

```
enable mpls
```

### Note

For SummitStacks, see the [Switch Engine v33.3.1 Command References](#) description for the `enable mpls` command for special requirements for SummitStacks.

By default, MPLS is disabled on the switch. This command starts the MPLS process, allowing MPLS protocols to run and MPLS packets to be forwarded.

- To disable MPLS on an LSR, use the following command:

```
disable mpls
```

When you disable MPLS, LDP and RSVP-TE are effectively disabled. The MPLS configuration remains intact.

## Enabling and Disabling MPLS on a VLAN

After *MPLS* is enabled globally, MPLS must be enabled on the MPLS configured *VLANs*. Configuring a VLAN for MPLS does not enable MPLS on the VLAN. The VLAN must be specifically MPLS enabled in order to send and receive MPLS packets over an interface.

- To enable MPLS on specific VLANs, use the following command:

```
enable mpls [{vlan} vlan_name | vlan all]
```

- To disable MPLS on specific VLANs, use the following command:

```
disable mpls [{vlan} vlan_name | vlan all]
```

MPLS must be enabled on all VLANs that transmit or receive MPLS-encapsulated frames. By default, MPLS and MPLS label distribution protocols are disabled when MPLS is first configured on a VLAN.

## Enabling LDP on the Switch

- To enable LDP on the switch, use the following command:

```
enable mpls protocol ldp
```

By default, LDP is disabled on the switch. This command enables *MPLS* to process LDP control packets and to advertise and receive LDP labels.

**Note**

Globally enabling the LDP protocol does not enable LDP on MPLS configured *VLANs*. See the next section for instructions on enabling LDP on a VLAN.

## Enabling and Disabling LDP on a VLAN

Each *VLAN* must be specifically LDP-enabled in order to set up LDP adjacencies over the interface. Before LDP can be enabled on a VLAN, the VLAN must be configured to support *MPLS* as described in [Adding MPLS Support to VLANs](#) on page 1085.

- To enable LDP on a VLAN, use the following command:

```
enable mpls ldp [{vlan} vlan_name | vlan all]
```

This command enables LDP on one or all VLANs for which MPLS has been configured.

**Note**

If you have enabled LDP and MPLS on an IGP interface that is used to reach a particular destination, make sure that you enable LDP and MPLS on all additional IGP interfaces that can reach that same destination (for example, enable LDP and MPLS on all *OSPF* VLANs that are connected to the backbone network).

- To disable LDP on a VLAN, use the following command:

```
disable mpls ldp [{vlan} vlan_name | vlan all]
```

This command disables LDP on one or all VLANs for which MPLS has been configured. This command terminates all LDP hello adjacencies and all established LDP LSPs that use the specified interface(s).

## Creating Static LSPs

Static LSPs are label switched paths that are manually configured at each LSR in the prospective path. Static LSPs are too labor intensive for building complex network topologies, but they can be useful for defining simple one-hop LSPs to MTUs that might not have the CPU power necessary to support routing and label distribution protocols.

[Figure 135](#) shows two static LSPs configured between VLAN A and VLAN B. The dashed line shows the static LSP for unidirectional communications from VLAN A to VLAN B. The solid line shows the static LSP for communications in the reverse direction.

**Figure 135: Static LSP Example**

The path that an LSP takes and the labels the LSP uses at every hop do not change when the network topology changes due to links and nodes going up or down. Once enabled, a static LSP remains administratively up until it is manually disabled.

Static LSP configuration is different for ingress, transit, and egress LSRs. At the ingress LER, only an egress label is defined. At transit LSRs, both ingress and egress labels must be defined, and at the egress LER, only the ingress label is defined. During configuration, you must ensure that the egress label number for each LSR matches the ingress label number for the downstream LSR.

When creating static LSPs, consider the following guidelines:

- It is your responsibility to ensure that the egress label of an LSR matches the ingress label of the downstream LSR. The software does not detect or report label mismatches. Mismatches result in dropped or mis-routed packets.
- The operational state of the LSP is set to down at the head-end on local failures. However, there is no mechanism to detect the LSP going down when a failure occurs on a downstream node. When a failure occurs at a downstream node, traffic may be black-holed for the duration of the failure.
- The traffic profile for static LSPs is not configurable in this release. All static LSPs are given best effort treatment.
- The maximum number of static LSPs configurable on any given node is 1024. The maximum number of ingress static LSPs that are used to forward traffic to a single destination is 16 (as limited by *ECMP*).
- When multiple LSPs exist for the same destination, unless forced otherwise, signaled LSPs are preferred to static LSPs. When choosing an LSP for a FEC, the software prefers RSVP-TE LSPs first, LDP next, and finally static LSPs.
- Since the software has no knowledge of the cost or hop-count associated with each static LSP, all static LSPs to the same destination are equally preferred by IP routing.
- We recommend that the same LSP name be used on every LSR along the path of the static LSP. The software does not check for naming consistency across LSRs. However the switch does report an error when the configured name is not unique to the LSP on that LSR.

To configure a static LSP, use the following procedure at each node on the path:

1. Create a namespace for the LSP using the following command:

```
create mpls static lsp lsp_name destination ipaddress
```

2. Configure the appropriate labels for the LSP using the following command:

```
configure mpls static lsp lsp_name [{egress [egress_label |
implicit-null] egress-vlan evlan_name next-hop ipaddress} {ingress
ingress_label {ingress-vlan ivlan_name}}]
```

3. Configure optional traffic restrictions for IP or VPN traffic as needed using the following command:

```
configure mpls static lsp lsp_name transport [ip-traffic [allow | deny] | vpn-traffic [allow {all | assigned-only} | deny]]
```

4. Enable the static LSP for operation using the following command:

```
enable mpls static lsp {lsp_name | all}
```

5. When the configuration is complete, you can view the static LSP configuration with the following command:

```
show mpls static lsp {summary | {lsp_name} {detail}}
```

6. Clear the counters for the static LSP using the command:

```
clear counters mpls static lsp {lsp_name | all}
```

7. Once the static LSP is created on all path nodes, you can configure a default route, an IP route, or a VPN route to use the LSP. To configure a default or IP route to use the LSP, use the following command:

```
configure iproute add default [{gateway {metric} {vr vr_name} {unicast-only | multicast-only}] | {lsp lsp_name {metric}}
```

8. To configure a VPN route to use the LSP, use the following command:

```
configure l2vpn [vpls vpls_name | vpws vpws_name] peer ipaddress [add | delete] mpls lsp lsp_name
```

9. To disable a static LSP, use the following command:

```
disable mpls static lsp {lsp_name | all}
```

10. To delete a static LSP, use the following command:

```
delete mpls static lsp [lsp_name | all]
```

## Configuring Penultimate Hop Popping

- To enable or disable PHP, use the following command:

```
enable mpls php [{vlan} vlan_name | vlan all]
```

This command enables or disables whether PHP is requested by the egress LER. If **vlan all** is selected, PHP is enabled on all VLANs on which MPLS has been configured. By default, PHP is disabled.

When PHP is enabled, PHP is requested on all LSPs for which the switch is the egress LER.

PHP is requested by assigning the Implicit Null Label in an advertised mapping. PHP is always performed when requested by a peer (for example, when acting as an intermediate LSR).

## Configuring QoS Mappings

The ExtremeXOS software provides examination and replacement services for the EXP field.

These services behave like the dot1p QoS commands. When EXP examination is enabled, the EXP value from the received frame is used to assign the packet to a QoS

profile. Once a packet is assigned to a QoS profile, the EXP value may be overwritten in hardware before being transmitted. By default, the QoS profile EXP value is equivalent to the QoS profile number one (QP1). To enable QoS for *MPLS* LSPs, use the following command: `enable mpls exp examination`

This command enables EXP examination for MPLS received packets. When EXP examination is enabled, the EXP field in the outer or top label of the label stack is used to assign the received packet to an internal switch qosprofile. If enabled, all MPLS packets are mapped to a qosprofile based on the configured EXP bit value. That is, a packet with an EXP value of 0 is mapped to qosprofile QP1, a packet with an EXP value of 1 is mapped to qosprofile QP2, and so on. By default, EXP examination is disabled and all received MPLS packets are sent to QP1.

Each EXP value can be assigned a qosprofile. Multiple EXP values can be assigned to the same qosprofile. The following command is used to configure the switch to route packets with a received EXP value to a specific qosprofile:

```
configure mpls exp examination {value} value {qosprofile} qosprofile
```

The switch can overwrite the EXP value in the outer label of an MPLS packet.

The following command is used to enable the switch to replace the EXP value:

```
enable mpls exp replacement
```

This command enables EXP replacement for MPLS transmitted packets. When EXP replacement is enabled, the EXP field in the outer or top label of the label stack is replaced with the EXP value configured for the QoS profile for which the packet was assigned. By default, EXP replacement is disabled and packets are propagated without modifying the EXP field value.

Each qosprofile can be assigned an EXP value used to overwrite the EXP bit field in the outer label of the transmitted packet.

All qosprofiles can be configured to overwrite the EXP bit field using the same EXP value. The following command is used to configure the switch to overwrite MPLS packets transmitted from a specific qosprofile with a new EXP value:

```
configure mpls exp replacement {qosprofile} qosprofile {value} value
```

## Mapping Dot1p to EXP Bits

The priority of Ethernet tagged packets can be mapped into the *MPLS* network and vice versa using the switch fabric qosprofile.

Ethernet packets are assigned to a qosprofile by enabling dot1p examination. MPLS packets are assigned to a qosprofile by enabling exp examination. When the packets egress the switch, the dot1p and exp bit fields can be overwritten.

Enabling EXP replacement instructs the switch to overwrite both the dot1p field and the exp field in the outer most label.

**Figure 136: Mapping Dot1p to EXP Bits**

By default, when dot1p examination and exp replacement are not enabled, all received packets are routed through qosprofile qp1 and the packets are transmitted with the dot1p and exp value of zero. As shown in [Figure 136](#), the switch can be configured to route packets to a specific qosprofile based on the dot1p value in the 802.1p bit field. In this example dot1p examination is enabled. By default, when dot1p examination is enabled, packets are sent to the qosprofile that corresponds dot1p type to qosprofile mapping.

This mapping can be viewed using `show dot1p type`. By default, MPLS exp replacement is disabled. By enabling MPLS exp replacement, MPLS packets are transmitted with the configured qosprofile dot1p and exp value. By default, these values correspond to the qosprofile. Qosprofile 1 overwrites the dot1p and exp fields with 0, qosprofile 2 overwrites the dot1p and exp fields with 1, and so on.

To configure the reverse packet flow, mpls exp examination and dot1p replacement must be configured. Enabling MPLS exp examination instructs the switch to route received MPLS packets to a qosprofile based on the EXP value. Enabling dot1p replacement instructs the switch to write the dot1p value in the transmitted packet.

## Enabling and Disabling LDP Loop Detection

There are two types of LDP loop detection. By default both are disabled. Enabling loop detection allows the switch to detect if a label advertisement loop exists within the network. Both hop count and path vector loop detection methods are used if loop detection is enabled.

- To enable LDP loop detection, use the following command:  
`enable mpls ldp loop-detection`
- To disable LDP loop detection, use the following command:  
`disable mpls ldp loop-detection`

These commands affect the LDP loop detection behavior for all LDP enabled VLANs.

## Configuring an LDP Label Advertisement Filter

- To configure an LDP label advertisement filter, use the following command:

```
configure mpls ldp advertise [{direct [all | lsr-id | none]} | {rip
[all | none] | {static [all | none]}
```

This command configures a filter to be used by LDP when originating unsolicited label mapping advertisements to LDP neighbors.

You can configure how the direct advertisement filter is applied, as follows:

- **direct**—The advertisement filter is applied to the FECs associated with direct routes.
- **rip**—The advertisement filter is applied to the FECs associated with *RIP* routes.
- **static**—The advertisement filter is applied to the FECs associated with static routes.

You can configure the advertisement filter, as follows:

- **all**—Unsolicited label mappings are originated for all routes of the specified type (direct, RIP, or static).
- **lsr-id**—An unsolicited label mapping is originated if a /32 direct route exists that matches the *MPLS* LSR ID. This filter is the default setting for direct routes and is only available for direct routes.
- **none**—No unsolicited label mappings are originated for all routes of the specified type. This is the default setting for RIP and static routes.

You can control the number of labels advertised using the `configure mpls ldp advertise` command. Advertising labels for a large number of routes can increase the required number of labels that must be allocated by LSRs. Care should be used to insure that the number of labels advertised by LERs does not overwhelm the label capacity of the LSRs.

## Configuring LDP Session Timers

- To configure LDP session timers, use the following command:

```
configure mpls ldp timers [targeted | link] [{hello-time
hello_hold_seconds] {keep-alive-time keep_alive_hold_seconds}]
```

This command configures the LDP peer session timers for the switch. The LDP peer session timers are separately configurable for link and targeted LDP hello adjacencies.

The `hello-time` *hello\_hold\_seconds* parameter specifies the amount of time (in seconds) that a hello message received from a neighboring LSR remains valid. The rate at which hello messages are sent is one third the configured hello-time. If a hello message is not received from a particular neighboring LSR within the specified hello-time *hello\_hold\_seconds* then the hello-adjacency is not maintained with that neighboring LSR. Should two peers have different configured hello-time values, they negotiate to use the lower value.

The session keep-alive time *keep\_alive\_hold\_seconds* parameter specifies the time (in seconds) during which an LDP message must be received for the LDP session to be maintained. The rate at which keep alive messages are sent, provided there are no LDP messages transmitted, is one sixth the configured keep-alive-time. If an LDP PDU is not received within the specified session keep-alive time *keep\_alive\_hold\_seconds* interval, the corresponding LDP session is torn down. Should two peers have different configured keep-alive-time values, they negotiate to use the lower value.

In the event that two peers have both a link and a targeted hello adjacency, the hello-time values for the two hello adjacencies are negotiated separately. The keep-alive-time value is established based on negotiations occurring when the LDP session is established following the first hello adjacency to be established.

The minimum and maximum values for both the hello-time *hello\_hold\_seconds* and keep-alive time *keep\_alive\_hold\_seconds* are 6 and 65,534, respectively. Changes to targeted timers only affect newly created targeted peers. Disabling and then enabling all VPLS instances causes all current targeted peers to be re-created.

The default values are as follows:

- link ldp hello-time *hello\_hold\_seconds* – 15
- targeted-ldp hello-time *hello\_hold\_seconds* – 45
- link ldp hello-time *interval\_time* – auto set to 1/3 the configured hello-time
- targeted-ldp hello-time *interval\_time* – auto set to 1/3 the configured hello-time
- link ldp keep-alive *keep-alive hold-seconds* – 40
- targeted-ldp keep-alive *keep-alive hold-seconds* – 60
- link ldp keep-alive *interval\_time* – auto set to 1/6 the configured keep-alive time
- targeted-ldp keep-alive *interval\_time* – auto set to 1/6 the configured keep-alive time

### Restoring LDP Session Timers

- To restore the default values for LDP session timers, use the following command:  
`unconfigure mpls`

This command can only be executed when *MPLS* is disabled, and it restores all MPLS configuration settings.

## Clearing LDP Protocol Counters

- To clear the LDP control protocol error counters, use the following command:  
`clear counters mpls ldp {{{vlan} vlan_name} | lsp all}`

Omitting the optional *vlan* parameter clears counters for all LDP enabled interfaces.

## Resetting MPLS Configuration Parameter Values

- To reset [MPLS](#) configuration parameters to their default values, disable MPLS (see [Enabling and Disabling MPLS on an LSR](#) on page 1086) and then use the following command:

```
unconfigure mpls
```

This command affects the following configuration parameters:

- All VLANs are removed from MPLS.
- All EXP (examination and replacement) QOS mappings are reset.
- LSR-ID is reset.
- LDP and RSVP-TE are globally disabled.
- MPLS Traps are disabled.
- LDP and RSVP-TE timers are reset.
- LDP Advertisement settings are reset.
- LDP Loop Detection settings are reset.
- All RSVP-TE LSPs are deleted.
- All RSVP-TE Paths are deleted.
- All RSVP-TE Profiles are deleted.
- The default RSVP-TE Profile is reset.

## Managing the MPLS BFD Client

Bidirectional Forwarding Detection (BFD) is introduced in [Bidirectional Forwarding Detection \(BFD\)](#) on page 1275.

The [MPLS](#) BFD client enables rapid detection of failures between MPLS neighbors on specific [VLANs](#). BFD detects forwarding path failures at a uniform rate, which makes the re-convergence time consistent and predictable and makes network profiling and planning easier for network administrators.

When BFD detects a communication failure, it informs MPLS, which treats the indication as an interface (VLAN) failure. This allows the MPLS protocols to quickly begin using alternate paths to affected neighbors (the methodology for selecting alternate paths is dependent upon the MPLS protocol in use and how it reacts to interface failure conditions). As MPLS connections (LSPs) are removed from the interface, BFD sessions are removed as well, and the interface returns to a state without BFD protection. The MPLS protocol might continue to attempt to reestablish LSP connections across the interface, and if successful, also attempt to establish a BFD session with the corresponding neighbor. MPLS does not process BFD state changes until the BFD

session is fully active in the UP state, at which point state changes are processed and the state for LSPs which cross the interface becomes BFD protected.

#### Note

BFD sessions are established only when both peers select the same LSP route. We recommend that BFD operate only on interfaces that have one peer.

- To enable the MPLS BFD client, use the following command:

```
enable mpls bfd [{vlan} vlan_name | vlan all]
```

#### Note

BFD must be enabled on the interface before sessions can be established. To enable BFD, use the command: `[enable | disable] bfd vlan vlan_name .`

- To disable the MPLS BFD client, use the following command:

```
disable mpls bfd [vlan all | {vlan} vlan_name] {delete-sessions}
```

- To display the MPLS BFD client information, use the following commands:

```
show mpls interface [{vlan} vlan_name] {detail}
```

```
show mpls bfd [{vlan} vlan_name | ip_addr]
```

## Displaying MPLS Configuration Information

### Displaying MPLS Basic Configuration Information

- To display basic MPLS configuration information, use the following command:

```
show mpls
```

This command displays the general configuration of all the MPLS components and system wide configuration.

The output, shown below, displays the switch MPLS, RSVP-TE, and LDP configuration status. It also shows the configuration status of SNMP trap, EXP examination, and EXP replacement settings. The configured LSR ID are also shown.

```
show mpls
Virtual Router Name : VR-Default
MPLS Admin Status : Enabled
MPLS Oper Status : Enabled
RSVP-TE Admin Status : Enabled
RSVP-TE Oper Status : Enabled
LDP Admin Status : Enabled
LDP Oper Status : Enabled
MPLS SNMP Traps : Disabled
L2VPN SNMP Traps : Disabled
EXP Examination : Enabled
EXP Replacement : Disabled
LSR ID : 192.99.1.5
```

## Displaying LDP Basic Configuration Information

- To display basic LDP configuration information, use the following command:

```
show mpls ldp
```

This command displays the general configuration of LDP.

Some settings are not configurable. These fields are identified with an asterisk (\*). The remaining fields can be modified using LDP configuration commands to change the behavior of LDP. A list of VLANs that have LDP enabled is shown at the bottom of the display output.

```
show mpls ldp
LDP Status : Enabled
Protocol Version : v1*
Label Retention Mode : Liberal*
Label Distribution Method : Downstream Unsolicited*
LDP Loop Detection
Status : Disabled
Hop-Count Limit : 255
Path-Vector Limit : 255
LDP Targeted Timers
Hello Hold : 45 seconds
Keep Alive Hold : 60 seconds
LDP Link Timers
Hello Hold : 15 seconds
Keep Alive Hold : 40 seconds
Label Advertisement
Direct : All
Rip : None
Static : None
LDP VLANs : loopback
 : blowingrock
 : boone
 : asheville
* Indicates parameters that cannot be modified
```

## Displaying MPLS Interface Information

- To display the *MPLS* interface information, use the following command:

```
show mpls interface {{vlan} vlan_name} {detail}
```

When the optional parameters are omitted, this command displays information for all the configured MPLS *VLAN* interfaces.

The summary MPLS interface information displayed includes the configured IP address, approximate time RSVP-TE and LDP have been up, number of neighbors or adjacencies, and a set of status flags.

When the *vlan\_name* parameter is specified, this command displays the current MPLS interface summary configuration and status for only the specified VLAN. If the optional detail keyword is specified, the summary information is displayed in the detail format.

## Displaying LDP Interface Information

- To display LDP interface information, use the following command:  
`show mpls ldp interface {{vlan} vlan_name} {detail | counters}`

This command displays the operational LDP interface information.

All the VLANs that have LDP enabled are listed. The negotiated LDP hello hold time is displayed. This is not the configured LDP hello hold time but represents the value that is negotiated between the local switch and the connected LDP peer. Hello messages are transmitted every 1/3 the negotiated hello hold time. In the following example, that would be every 5 seconds. The hello timer status information is displayed in milliseconds. The approximate LDP uptime and status flags are also shown.

```
show mpls ldp interface
VLAN Name #Adj NegHHldTm NxtHello UpTm Flags

loopback 0 15000 2230 16h MLU
blowingrock 1 15000 2200 14h MLU
boone 1 15000 2210 16h MLU
asheville 1 15000 2210 16h MLU
Flags: (M) MPLS Enabled, (L) LDP Enabled,
(U) LDP Operational
```

## Displaying MPLS Label Information

- To display MPLS label information, use the following commands:  
`show mpls {rsvp-te | static} label {summary | label_num | [advertised | received] {label_num} | received implicit-null}`  
`show mpls label l3vpn {summary | label_num | [advertised | received] {label_num}}`  
`show mpls {ldp} label {lsp} {summary | label_num | [advertised | received] {label_num} | received implicit-null}`  
`show mpls ldp label {lsp} advertised implicit-null {ipNetmask}`  
`show mpls {ldp} label l2vpn {summary | label_num | [advertised | received] {label_num}}`  
`show mpls ldp label l2vpn retained {ipaddress}`  
`show mpls ldp label lsp retained {ipNetmask}`  
`show mpls ldp label retained [l2vpn {ipaddress} | lsp {ipNetmask}]`

## Displaying MPLS Label Mapping Information

- To display MPLS label mapping information, use the following command:  
`show mpls ldp lsp {prefix ipNetmask} {ingress | egress | transit} {detail}`  
`show mpls rsvp-te lsp [egress | transit] {fast-reroute} {{lsp_name} [{destination | origin] ipaddress} {detail} | summary}`

This command displays information about how to forward packets that arrive labeled as MPLS packets. As such, it shows how labels advertised to upstream peers

are mapped to labels received from downstream peers. This mapping is sometimes referred to as the Incoming Label Map (ILM).

When the `label_number` parameter is omitted, summary information is displayed for all incoming label assignments that have been made by the switch. When the `label_number` is specified, summary information is displayed for the specified label.

As can be seen below, the output display differs for label mappings signaled by LDP and RSVP-TE. Please see the respective sections for additional information.

```
show mpls ldp lsp
Prefix Adv Label Peer Label Next Hop VLAN
192.168.0.4/32 0x80402 -- -- lpbk
192.168.0.2/32 0x00039 0x80400 11.0.2.2 vlan2
11.0.4.0/24 0x0003A 0x80401 11.0.2.2 vlan2
192.168.0.4/32 0x0003B 0x00013 11.0.2.2 vlan2
* BD-10K.6 # show mpls rsvp-te lsp
Ingress LSP Name Path Name Destination Transmit I/F UpTm
Flags

LSR1-LSR4 path1-2-4 192.168.0.4 vlan2 47m
UEP--OIV
Egress LSP Name Source IP Destination Receive I/F UpTm

LSR4-LSR1 192.168.0.4 192.168.0.1 vlan1 47m
Transit LSP Name Source IP Destination Receive I/F Transmit I/F UpTm

LSR2-LSR3 192.168.0.2 192.168.0.3 vlan2 vlan1 47m
Flags: (U) Up, (E) Enabled, (P) Primary LSP, (S) Secondary LSP,
(R) Redundant Paths, (B) Bandwidth Requested, (O) ERO Specified,
(I) IP Traffic Allowed, (V) VPN Traffic Allowed,
(v) VPN Assigned Traffic Allowed
```

## Displaying MPLS QoS Mapping Information

- To display *MPLS QoS* mapping information, use the following command:

```
* BD-10K.10 # show mpls exp examination
EXP --> QoS Profile mapping:
00 --> QP1
01 --> QP2
02 --> QP3
03 --> QP4
04 --> QP5
05 --> QP6
06 --> QP7
07 --> QP8
EXP Examination is disabled
* BD-10K.11 # show mpls exp replacement
QoS Profile --> EXP mapping:
QP1 --> 00
QP2 --> 01
QP3 --> 02
QP4 --> 03
QP5 --> 04
QP6 --> 05
QP7 --> 06
QP8 --> 07
EXP Replacement is disabled
* BD-10K.12 #
```

Configured mappings for both dot1p-to-exp and exp-to-dot1p are displayed.

## Displaying LDP Peer Session Information

- To display *MPLS* LDP peer session information, use the following command:  
`show mpls ldp peer {ipaddress} {detail}`

This command displays information about the status of LDP peer sessions. Summary information is displayed for all known LDP peers and LDP peer sessions. If you specify the *ipaddress* of an LDP peer, information for the single LDP peer is displayed. If you specify the detail keyword, additional information is displayed in a comprehensive detailed format.

By default the information displayed includes:

- Peer sessions
- Peer state
- Uptime
- Number of hello adjacencies

If you specify the detail keyword, the following additional information is displayed:

- Discontinuity time
- Negotiated label distribution
- Next hop address
- Keep-Alive hold timer
- Hello adjacency details

## Displaying LDP Protocol Counters

LDP control protocol packet error counters are maintained per interface.

- To view these counters, use the following command:  
`show mpls ldp interface {{vlan} vlan_name} {detail | counters}`

These counters may be useful in determining LDP issues between peers.

Error counters that continually increment should be investigated.

```
show mpls ldp interface vlan blowingrock counters
VLAN: blowingrock (192.60.40.5)
Link Targeted
Counter Adjacencies Adjacencies

Shutdown Notifications (Rcvd) 0 0
Shutdown Notifications (Sent) 0 0
Failed Session Attempts (NAKs) 0 0
Hello Errors 0 0
Parameters Advertised Errors 0 0
Max PDU Length Errors 0 0
Label Range Errors 0 0
Bad LDP ID Errors 0 0
Bad PDU Length Errors 0 0
Bad Msg Length Errors 0 0
Bad TLV Length Errors 0 0
```

|                           |   |   |
|---------------------------|---|---|
| Bad TLV Value Errors      | 0 | 0 |
| Keep-Alive Timeout Errors | 0 | 0 |

Omitting the optional vlan parameter displays counters for all LDP enabled interfaces.

## Displaying LDP LSP Forwarding Database

- To display information about LDP LSPs, use the following command:  

```
show mpls ldp lsp {prefix ipNetmask} {egress | ingress | transit} {detail}
```

This command displays the LDP LSPs established to, from, and through this switch. By default, ingress, egress, and transit LSPs are all displayed. By optionally specifying the LSP type, the output display is filtered to show only the type of LSPs specified.

When all LSP types are being displayed, LSPs that show only an advertised label represent egress LSPs from the network perspective or incoming LSPs from the switch perspective. LSPs that show only a received label represent ingress LSPs from the network perspective or outgoing LSPs from the switch perspective. LSPs that show both an incoming and an outgoing label represent transit LSPs. As Extreme switches are merge-capable, all LDP transit LSPs can also be used as ingress LSPs.

The significance of the VLAN information shown depends on the LSP type. For ingress and transit LSPs, the indicated VLAN is the MPLS interface used to reach the next hop peer. For egress LSPs, there is no associated MPLS next hop interface. When the prefix being advertised is associated with a local (direct) VLAN, that VLAN name is displayed. When the advertised prefix is associated with a static or an RIP route, the VLAN field is empty.

Advertised labels have switch-wide significance and are generally advertised out multiple interfaces.

```
* BD-10K.15 # show mpls ldp lsp
Prefix Adv Label Peer Label Next Hop VLAN
192.99.1.5/32 0x80402 -- -- loopback
192.80.40.0/24 0x80403 -- -- asheville
192.100.40.0/24 0x80404 -- -- boone
192.60.40.0/24 0x8040b -- -- blowingrock
192.24.100.0/24 0x00015 0x80401 192.100.40.3 boone
192.99.1.3/32 0x00016 0x80403 192.100.40.3 boone
192.10.50.0/24 0x00018 0x80405 192.100.40.3 boone
10.20.30.0/24 0x0001c 0x00013 192.100.40.3 boone
11.136.96.0/24 0x0001d 0x00014 192.100.40.3 boone
```

Specifying the optional detail keyword displays each LSP in detail format.

Additionally, received packets and bytes are maintained for transit and egress (or incoming) LSPs. Specifying the keyword prefix and a matching ipNetmask restricts the display to a single entry.

```
*BD-X8.17 # show mpls ldp lsp prefix 11.108.96.0/24 detail
FEC IP/Prefix: 11.108.96.0/24:
Advertised Label: 0 (0)
Received Label : 0x18 (24)
Next Hop IP : 192.100.40.3
```

```
VLAN Name : boone
Packets received : 489
Bytes received : 46944
```

## Displaying RSVP-TE LSP Configuration Information

- To display RSVP-TE LSP configuration information, use the following command:

```
show mpls rsvp-te
```

This command displays summary configuration and status information for RSVP-TE. Global status of RSVP-TE and the configured standard and rapid-retry LSP timer values are included in the display output.

## Displaying the RSVP-TE Paths

- To display RSVP-TE paths, use the following command:

```
show mpls rsvp-te path {path_name} {detail}
```

This command displays the configuration and status information for *MPLS* RSVP-TE paths. Information is listed in tabular format and includes the path name, number of configured ERO objects, number of LSPs configured to use this path, the list of EROs and their type. Optionally specifying the detail keyword displays the path information in verbose format, including all LSPs that are configured to use the path.

## Displaying the RSVP-TE Path Profile

- To display RSVP-TE path profiles, use the following command:

```
show mpls rsvp-te profile {profile_name} {detail}
```

By default, this command displays all configured profile parameters for the specified profile. If the profile name is omitted, the profile parameter values for all configured LSP profiles are displayed. Optionally specifying the keyword detail displays the profile information in verbose format. When the detail keyword is specified, all LSPs that are configured to use this profile are also displayed.

## Displaying the RSVP-TE LSP

- To display the RSVP-TE LSP, use the following command:

```
show mpls rsvp-te lsp {[destination | origin] ipaddress} {fast-reroute} {detail} | summary}
```

This command displays the LSP information associated with RSVP-TE that is used to forward packets within the *MPLS* network. If no options are specified, summary information for all RSVP-TE LSPs is displayed. This information includes the LSP name, LSP direction relative to the MPLS network (i.e., ingress, egress, or transit), incoming and or outgoing interface, configured destination, and uptime. If the optional LSP name parameter is specified, only the LSP information for the specified ingress LSP name is displayed. Optionally, the LSPs displayed can be further

qualified by the keywords ingress, egress, and transit. These keywords qualify the LSPs displayed from the perspective of the switch.

Ingress LSPs identify LSPs that originate from the switch into the MPLS network. Egress LSPs identify LSPs that terminate at the switch from the MPLS network. Transit LSPs represent LSPs that traverse the switch.

The optional destination keyword limits the display to only those LSPs that terminate at the specified IP address. The optional origin keyword limits the display to only those LSPs that originate at the specified IP address. Optionally specifying the detail keyword displays the LSP information in verbose format. Additional information displayed includes the configured path and profile, transmit and/or receive labels, failure and retry counts, packet and byte counters, and recorded routes.

## MPLS Configuration Example

The network configuration, shown in [Figure 137](#), illustrates how to configure a BlackDiamond switch to support a routed MPLS network.

**Figure 137: MPLS Configuration Example**

The four switches, labeled LSR 1, LSR 2, LSR 3, and LSR 4, have the same physical hardware configuration. Each switch contains two 8900-G48T-x1 and an 8900-MSM128 module. The switches are all interconnected via Gigabit Ethernet to form the *OSPF* backbone area and the MPLS domain. In this example, two directly connected OSPF-disabled VLANs are shown: unc and duke. Traffic between unc and duke follows routed paths over calculated LSPs established between LSR 1 and LSR 4.

The commands used to configure LSR 1 are described below. The remaining LSRs are configured similarly.

The following commands configure the module types for specific slots:

```
configure slot 2 module 8900-G48T-x1
configure slot 2 module 8900-G48T-x1
```

The following command sets the maximum jumbo frame size for the switch chassis to 1600:

```
configure jumbo-frame-size size 1600
enable jumbo-frame ports all
```

The following commands create the VLANs:

```
create vlan lpbk
create vlan vlan1
create vlan vlan2
create vlan unc
```

The following commands configure the VLAN IP address and assign ports participating in each VLAN:

```
configure vlan lpbk ipaddress 192.168.0.1/32
enable ipforwarding lpbk
enable loopback-mode lpbk
configure vlan default delete ports all
configure vlan vlan1 ipaddress 11.0.1.1/24
configure vlan vlan1 add port 3:2 untagged
configure vlan vlan2 ipaddress 11.0.2.1/24
configure vlan vlan2 add port 3:3 untagged
configure vlan unc ipaddress 9.9.9.1/24
configure vlan unc add port 3:4 untagged
```

The following commands enable IP forwarding on the configured VLANs.

The MTU size is increased on the MPLS VLANs to accommodate the MPLS shim header:

```
enable ipforwarding vlan vlan1
configure ip-mtu 1550 vlan vlan1
enable ipforwarding vlan vlan2
configure ip-mtu 1550 vlan vlan2
enable ipforwarding vlan unc
```

The following command configures the MPLS LSR ID:

```
configure mpls lsr-id 192.168.0.1
```

The following commands add MPLS support to VLANs lpbk, vlan1, and vlan2:

```
configure mpls add vlan lpbk
configure mpls add vlan vlan1
configure mpls add vlan vlan2
```

The following commands enable MPLS on VLANs lpbk, vlan1, and vlan2 and LDP on VLANs vlan1 and vlan2:

```
enable mpls lpbk
enable mpls vlan1
enable mpls vlan2
enable mpls ldp vlan1
enable mpls ldp vlan2
```

The following command allows LDP to advertise a label mapping for the LSR ID:

```
configure mpls ldp advertise direct lsr-id
```

The following commands globally enable LDP and MPLS on the switch:

```
enable mpls protocol ldp
enable mpls
```

The following commands add lpbk, vlan1, and vlan2 to the backbone area.

The 0.0.0.0 (backbone) area does not need to be created because it exists by default:

```
configure ospf add vlan lpbk area 0.0.0.0
configure ospf add vlan vlan2 area 0.0.0.0
configure ospf add vlan vlan1 area 0.0.0.0
```

The following command enables distribution of local (direct) interfaces into the OSPF area:

```
enable ospf export direct cost 10 type ase-type-1
```

The following command configures the OSPF router ID on the switch and enables the distribution of a route for the OSPF router ID in the router LSA.

Originating the router ID as a host route allows other routers in the same OSPF area to establish calculated LSPs for external routes to this router:

```
configure ospf routerid 192.168.0.1
```

It also allows this router to be a peer in a L2 VPN.

The following command enables OSPF:

```
enable ospf
```

## Configuring MPLS Layer-2 VPNs (VPLS and VPWS)

### Note

ELRP should not be used to protect VPLS service VLANs because ELRP is not aware of VPLS pseudowires.

## Configuring MPLS for Establishing Layer 2 VPN Instances

As described in [Using LDP to Signal PW Label Mappings](#) on page 1049, [MPLS](#) and LDP must be properly configured in order to establish the PWs that make up a Layer 2 VPN.

MPLS should be enabled using the `enable mpls` command and LDP should be enabled using the `enable mpls protocol ldp` command.

Since the MPLS LSR ID is used as the local endpoint for PWs, it is highly desirable to create a loopback [VLAN](#) whose associated IP address is that of the MPLS LSR ID. The configured prefix length should be 32. As described in [Establishing LDP LSPs to PW Endpoints](#) on page 1048, configuring this loopback VLAN for MPLS causes the address to be included in LDP address messages. Use the `configure mpls add vlan`

*vlan\_name* command for this. It is not required that LDP or MPLS be enabled on the VLAN for the address to be advertised by LDP. Use the `configure mpls ldp advertise direct lsr-id` command to initiate an LDP label mapping for an LDP LSP to the local endpoint.

## Creating or Deleting a Layer 2 VPN Domain

- To create a Layer 2 VPN, use the following command:  

```
create l2vpn [vppls vppls_name | vpws vpws_name] fec-id-type pseudo-wire pwid
```

This command creates a named Layer 2 VPN instance. Multiple domains can be created, each representing a different L2 VPN. The *pwid* is a number that is used to signal and identify which Layer 2 VPN is associated with each pseudowire. All of the pseudowires carrying traffic for a specific Layer 2 VPN are signaled with the same *pwid*. No Layer 2 VPN traffic is forwarded over the Layer 2 VPN until at least one peer is added to the Layer 2 VPN and a service is associated with the Layer 2 VPN. The configured *pwid* also doubles as the Layer 2 VPN ID.

- To delete a Layer 2 VPN, use the following command:  

```
delete l2vpn [vppls [vppls_name | all] | vpws [vpws_name | all]]
```

This command deletes the named Layer 2 VPN instance or all Layer 2 VPN instances, depending on the keyword. All Layer 2 VPN peers and services associated with the deleted Layer 2 VPN instance(s) are also deleted.

## Enabling or Disabling a Layer 2 VPN Domain

- To enable a Layer 2 VPN, use the following command:  

```
enable l2vpn [vppls [vppls_name | all] | vpws [vpws_name | all]]
```

This command enables a named Layer 2 VPN instance. By default, a newly created Layer 2 VPN is enabled.

- To disable a Layer 2 VPN, use the following command:  

```
disable l2vpn [vppls [vppls_name | all] | vpws [vpws_name | all]]
```

This command disables the named Layer 2 VPN instance. When a Layer 2 VPN is disabled, no traffic flows across the Layer 2 VPN. The pseudowires connecting this peer to all other configured peers are also terminated, so the remote peers no longer see this LSR as an active peer.

## Adding or Deleting a Layer 2 VPN Peer

- To add a peer to the Layer 2 VPN, use the following command:  

```
configure l2vpn [vppls vppls_name | vpws vpws_name] add peer ipaddress {{core {full-mesh | primary | secondary} | spoke}}
```

For each new peer added, a pseudowire is signaled to carry traffic for this Layer 2 VPN. Up to 64 peers can be added to a VPLS; and only one peer can be added to a VPWS. For each peer added, that remote peer must also configure this local LSR as a

peer for the Layer 2 VPN. For VPLS configurations, this insures that the VPLS core is configured as a full mesh of VPLS peers.

The Layer 2 VPN names on each peer do not have to match since the pseudowire ID is used to define the Layer 2 VPN to which each pseudowire is associated.

- Delete a peer from the Layer 2 VPN, use the following command:

```
configure l2vpn [vppls vppls_name | vpws vpws_name] delete peer
[ipaddress | all]
```

Once the peer is deleted, that specified peer is no longer a member of the Layer 2 VPN. For VPLS configurations, the peer must also be removed from all other VPLS peers to insure a proper full mesh and to prevent connectivity issues.

## Add or Delete a Layer 2 VPN Service

- To add a service to a Layer 2 VPN, use the following command:

```
configure l2vpn [vppls vppls_name | vpws vpws_name] add service [{vlan}
vlan_name | {vman} vman_name]
```

Only one service can be added to each Layer 2 VPN. Traffic associated with the service is transported over the Layer 2 VPN. Three basic types of services are supported: VLAN, VMAN, and port. Both the VLAN and VMAN services are specified by adding the VLAN or VMAN name to the Layer 2 VPN. The port service is configured by adding a VMAN name to the Layer 2 VPN, configuring the Layer 2 VPN to strip the VMAN tag, and adding the port as untagged to the VMAN. This allows incoming service traffic to be transported across the Layer 2 VPN exactly as it was received. See [Managing Layer 2 VPN Packet Forwarding Options](#) on page 1107 for information about configuring a Layer 2 VPN to strip the VMAN tag.

- To delete a service from a Layer 2 VPN, use the following command:

```
configure l2vpn [vppls vppls_name | vpws vpws_name] delete service
[{vlan} vlan_name | {vman} vman_name]
```

Since there is no local service that needs to be connected to the Layer 2 VPN, the pseudowires to each of the configured peers for this Layer 2 VPN are terminated.

### Note

Ports added to Layer 2 VPN service VPLS/VMAN should not be part of PVLAN or VLAN aggregation or VLAN translation.

## Enabling or Disabling a Layer 2 VPN Service

- To enable a Layer 2 VPN service, use the following command:

```
enable l2vpn [vppls [vppls_name | all] | vpws [vpws_name | all]] service
```

By default, any configured Layer 2 VPN service is enabled.

- To disable a service from the Layer 2 VPN, use the following command:

```
disable l2vpn [vppls [vppls_name | all] | vpws [vpws_name | all]]
service
```

When the service is disabled, the service is disconnected from the Layer 2 VPN and disabled such that no packets are sent to or received from the service. The pseudowires to each of the configured peers for this Layer 2 VPN are terminated.

## Managing Layer 2 VPN Packet Forwarding Options

- To configure Layer 2 VPN packet forwarding options, use the following command:

```
configure l2vpn [vppls vppls_name | vpws vpws_name] {dot1q [ethertype hex_number | tag [include | exclude]]} {mtu number}
```

The options should be configured the same for every LSR for this Layer 2 VPN in order to prevent connectivity issues. Specifying the dot1q ethertype forces the switch to overwrite the dot1q ethertype value in the service packet. This can be used to interconnect two customer segments over the Layer 2 VPN that are using different configured ethertype values. By default, the dot1q tag in the service packet is not included. The switch can be configured to strip or exclude the dot1q tag. This can be used to emulate port services or for interoperability with equipment that may require tags.

- To unconfigure Layer 2 VPN packet forwarding options, use the following command:

```
unconfigure l2vpn [vppls vppls_name | vpws vpws_name] dot1q ethertype
```

This command resets the dot1q ethertype for the specified Layer 2 VPN to the default ethertype configured for the switch.

## Configuring the Layer 2 VPN MTU

The Maximum Transmission Unit (MTU) is the maximum packet size (excluding the data link header) that an interface can transmit. The Layer 2 VPN MTU defines the MTU for the customer facing interface. By default, the MTU size is set to 1500 bytes, which is the MTU size for standard Ethernet frames.

The frame size of the customer packet also includes the data link header and FCS field. The Ethernet data link header includes a minimum of a destination MAC address (six bytes), a source MAC address (six bytes), and an ethertype field (two bytes). The FCS field is four bytes. For a 1500-byte customer payload, the minimum customer frame size is 1518 bytes.

The Layer 2 frame, minus the FCS field, is encapsulated to form an *MPLS* packet to be transmitted to a Layer 2 VPN peer. This encapsulation adds another Ethernet header, an MPLS shim header, and a FCS field. The MPLS shim header usually includes two four-byte MPLS labels. Therefore, this encapsulation adds a minimum of 26 bytes.

The total frame size includes the customer payload, the Ethernet header on the customer facing interface (minimum 14 bytes), and the MPLS encapsulation (minimum 26 bytes). For a 1500-byte customer payload, the minimum Layer 2 VPN frame size is 1540 bytes.

The total frame size is restricted by the jumbo frame size. The maximum jumbo frame size that can be configured is 9216 bytes. If the customer payload in the above example

is increased to 9176 bytes, the resulting Layer 2 VPN encapsulated frame size is 9216 bytes. Therefore, the maximum practical value of the Layer 2 VPN MTU is 9176 bytes.

There are additional considerations that can lower the maximum practical value of the Layer 2 VPN MTU setting. If the Layer 2 VPN is configured to include the VLAN tag of the customer interface, this increases the total frame size by four bytes. If the MPLS interface used to transmit the encapsulated Layer 2 VPN packet is a tagged VLAN, this also increases the total frame size by four bytes. If either of these configuration options is present, the maximum practical Layer 2 VPN MTU size is reduced accordingly.

- To configure the Layer 2 VPN MTU size, use the **mtu** option in the following command:

```
configure l2vpn [vppls vppls_name | vpws vpws_name] {dot1q [ethertype
hex_number | tag [include | exclude]]} {mtu number}
```

The Layer 2 VPN MTU value is signaled to peers as part of the VC FEC information during PW setup. The local value must match the value received from the PW peer. If the two values do not match, the PW is not established.

## Managing VPLS Redundancy Options

- To configure VPLS redundancy options, use the following command:

```
configure {l2vpn} vppls vppls_name redundancy [esrp esrpDomain | eaps |
stp]
```

- To unconfigure VPLS redundancy options, use the following command:
- ```
unconfigure {l2vpn} vppls vppls_name redundancy [eaps | esrp | stp]
```
- To display the configured VPLS redundancy option, use the following command:
- ```
show l2vpn vppls {vppls_name} {peer ipaddress} detail
```

## Displaying Layer 2 VPN Status

- To display the status of all Layer 2 VPNs, a configured Layer 2 VPN, or a specific peer within a specific Layer 2 VPN, use the following command:

```
show [{l2vpn} vppls {vppls_name} | l2vpn vpws {vpws_name} | l2vpn]
{peer ipaddress} {detail} | summary }
```

## Displaying Layer 2 VPN Statistics

- To display statistics for Layer 2 VPNs, use the following command:

```
show mpls statistics l2vpn {vppls_name | vpws_name } {detail}
```

## Managing Layer 2 VPN SNMP Traps

- To enable or disable Layer 2 VPN SNMP traps, use the following commands:

```
enable snmp traps l2vpn
disable snmp traps l2vpn
```

- To configure or remove a text-string identification for traps from a Layer 2 VPN, use the following command:

```
configure vpls vpls_name snmp-vpn-identifier identifier
unconfigure vpls vpls_name snmp-vpn-identifier
```

- To view the configured state for Layer 2 VPN SNMP traps, use the following command:

```
show mpls
```

## VPLS VPN Configuration Examples

### Basic Point-to-Point VPLS Configuration Example

This [MPLS](#) VPLS network configuration shown [Figure 138](#), builds upon the routed MPLS network configuration example shown in [MPLS Configuration Example](#) on page 1102.

**Figure 138: MPLS VPLS Configuration Example**

Assuming that the routed MPLS network has already been configured as in the previous example, the commands used to create the VPLS on LSR1 and LSR4 follow. The nc-university-vpn is a point-to-point VPLS, since only two peers are participating.

The following command creates the VPLS with VPN ID 35. This command must be issued on both LSR1 and LSR4:

```
create l2vpn vpls nc-university-vpn fec-id-type pseudo-wire 35
```

The following command enables the VPLS instance specified by the *vpls\_name*:

```
enable l2vpn [vpls [vpls_name | all]
```

On LSR1, configure the local VLAN service and the VPLS peer:

```
configure l2vpn vpls nc-university-vpn add service vlan unc-charlotte
configure l2vpn vpls nc-university-vpn add peer 192.168.0.4
```

On LSR4, configure the local VLAN service and the VPLS peer:

```
configure l2vpn vpls nc-university-vpn add service vlan unc-wilmington
configure l2vpn vpls nc-university-vpn add peer 192.168.0.1
```

## Multipoint Full Mesh VPLS Configuration Example

The example shown in [Figure 139](#) configures a four node full-mesh MPLSVPLS configuration by adding two additional peers to the previous example.

**Figure 139: Full Mesh Configuration Example**

*LSR1*

```
configure vpls nc-university-vpn add peer 192.168.0.2
configure vpls nc-university-vpn add peer 192.168.0.3
```

*LSR2*

```
create vpls nc-university-vpn fec-id-type pseudo-wire 35
configure vpls nc-university-vpn add peer 192.168.0.1
configure vpls nc-university-vpn add peer 192.168.0.3
configure vpls nc-university-vpn add peer 192.168.0.4
configure vpls nc-university-vpn add service vlan unc-asheville
```

*LSR3*

```
create vpls nc-university-vpn fec-id-type pseudo-wire 35
configure vpls nc-university-vpn add peer 192.168.0.1
```

```
configure vpls nc-university-vpn add peer 192.168.0.2
configure vpls nc-university-vpn add peer 192.168.0.4
configure vpls nc-university-vpn add service vlan unc-greensboro
```

#### LSR4

```
configure vpls nc-university-vpn add peer 192.168.0.2
configure vpls nc-university-vpn add peer 192.168.0.3
```

## VPLS with Redundant EAPS Configuration Example

The following sections provide examples of how to configure switches to support the configuration described in [VPLS EAPS Redundancy Overview](#) on page 1064:

- [Core 1 Router Configuration](#) on page 1111
- [Core 2 Router Configuration](#) on page 1111

### Core 1 Router Configuration

The following example shows the [EAPS](#) and VPLS configuration for the Core 1 router.

```
//create the EAPS protected VLAN and the VPLS service vlan
create vlan v1
configure v1 add ports 2:3 // port 2:3 is the port connected to dist 1
create eaps eaps2
configure eaps eaps2 mode transit
configure eaps eaps2 primary port 2:1 // port going to core 2
configure eaps eaps2 secondary port 2:3
configure eaps eaps2 add control vlan ctrl2 // eaps control vlan
configure eaps eaps2 add protected vlan v1
create eaps shared-port 2:1
configure eaps shared-port 2:1 mode controller
configure eaps shared-port 2:1 link-id 888
enable eaps2
create vpls vpls1 fec-id-type pseudo-wire 2
configure vpls vpls1 add service vlan v1
configure vpls vpls1 redundancy eaps
configure vpls vpls1 add peer <core2>
configure vpls vpls1 add peer <core3>
configure vpls vpls1 add peer <core4>
```

### Core 2 Router Configuration

The following example shows the [EAPS](#) and VPLS configuration for the Core 2 router.

```
//create the EAPS protected VLAN and the VPLS service vlan
create vlan v1
configure v1 add ports 2:9 // port 2:9 is the port connected to dist 5
create eaps eaps2
configure eaps eaps2 mode transit
configure eaps eaps2 primary port 2:1 // port going to core 1
configure eaps eaps2 secondary port 2:9
configure eaps eaps2 add control vlan ctrl2
configure eaps eaps2 add protected vlan v1
create eaps shared-port 2:1
configure eaps shared-port 2:1 mode partner
configure eaps shared-port 2:1 link-id 888
enable eaps2
create vpls vpls1 fec-id-type pseudo-wire 2
configure vpls vpls1 add service vlan v1
configure vpls vpls1 redundancy eaps
```

```
configure vpls vpls1 add peer <core1>
configure vpls vpls1 add peer <core3>
configure vpls vpls1 add peer <core4>
```

## Configuring H-VPLS

H-VPLS is configured at the edge of the network. The core of the network supports H-VPLS and is configured as described in [Configuring MPLS Layer-2 VPNs \(VPLS and VPWS\)](#) on page 1104. To configure H-VPLS, you need to configure the H-VPLS spoke nodes and the PE core nodes that peer with the spoke nodes.

### Configuring H-VPLS Spoke Nodes

- To configure an MTU as an H-VPLS spoke node, use the following command:

```
configure l2vpn [vpls vpls_name | vpws vpws_name] add peer ipaddress
{{core {full-mesh | primary | secondary} | spoke}
```

Use the core primary and core secondary command options as needed. The core primary option specifies that the spoke node peer is a core node and that the link between the peers is the primary spoke. The core secondary option specifies that the spoke node peer is a core node and that the link between the peers is the secondary spoke.

- To delete an H-VPLS spoke node, use the following command:

```
configure l2vpn [vpls vpls_name | vpws vpws_name] delete peer
[ipaddress | all]
```

### Configuring H-VPLS Core Nodes

- To configure a VPLS core node as an H-VPLS core node, use the following command:

```
configure l2vpn [vpls vpls_name | vpws vpws_name] add peer ipaddress
{{core {full-mesh | primary | secondary} | spoke}
```

Use the spoke command option to specify that the peer is an H-VPLS spoke node. When the H-VPLS spoke and core peers are configured, VPLS communications can be established between them.

#### Note

To enable communications from the H-VPLS spoke across the VPLS network, the H-VPLS core node must also be configured to peer with the other VPLS nodes.

- To delete an H-VPLS core node, use the following command:

```
configure l2vpn [vpls vpls_name | vpws vpws_name] delete peer
[ipaddress | all]
```

## Configuring the MAC Address Withdrawal Feature

The MAC address withdrawal feature is enabled by default.

- To disable this feature, use the following command:  
`disable l2vpn vpls peer [ipaddress | all] fdb send-mac-withdrawal`
- To enable this feature after it has been disabled, use the following command:  
`enable l2vpn vpls peer [ipaddress | all] fdb send-mac-withdrawal`

## Displaying H-VPLS Configuration Information

- To display H-VPLS configuration information, use the following command:  
`show [ {l2vpn} vpls {vpls_name} | l2vpn vpws {vpws_name} | l2vpn ]  
 {peer ipaddress} {detail} | summary }`

## Configuring Protected VPLS

- To configure a protected VPLS, use the following command:  
`create esrp esrp_domain {type [vpls-redundancy | standard]}`  
`configure {l2vpn} vpls vpls_name redundancy [esrp esrpDomain | eaps | stp]`
- To unconfigure a protected VPLS, use the following command:  
`unconfigure {l2vpn} vpls vpls_name redundancy [eaps | esrp | stp]`
- To display information about the protected VPLS, use the following command:  
`show esrp { {name} | {type [vpls-redundancy | standard]} }`

## Configuring RSVP-TE

### Enabling and Disabling RSVP-TE on the Switch

- To enable RSVP-TE on a switch, use the following command:  
`enable mpls protocol rsvp-te`
- To disable RSVP-TE on a switch, use the following command:  
`disable mpls protocol rsvp-te`

#### Note

*MPLS* must be globally enabled before RSVP-TE can become operational. For more information, see [Enabling and Disabling MPLS on an LSR](#) on page 1086.

### Enabling and Disabling RSVP-TE on a VLAN

- To enable RSVP-TE on one or all VLANs, use the following command:  
`enable mpls rsvp-te [{vlan} vlan_name | vlan all]`

- To disable RSVP-TE on one or all VLANs, use the following command:

```
disable mpls rsvp-te te [{vlan} vlan_name | vlan all]
```

Disabling RSVP-TE on a VLAN causes all TE LSPs using that interface to be released, and prevents TE LSPs from being established or accepted on the specified VLAN.

## Configuring RSVP-TE Protocol Parameters

- To configure RSVP-TE protocol parameters, use the following command:

```
configure mpls rsvp-te timers session [{bundle-message-time bundle_message_milliseconds} {hello-keep-multiplier hello_keep_number} {hello-time hello_interval_seconds} {refresh-keep-multiplier refresh_keep_number} {refresh-time refresh_seconds} {summary-refresh-time summary_refresh_milliseconds}] [{vlan} vlan_name | vlan all]
```

This command configures the RSVP-TE protocol parameters for the specified *VLAN*. The RSVP-TE keyword *all* indicates that the configuration changes apply to all RSVP-TE enabled VLANs.

The hello-interval time specifies the RSVP hello packet transmission interval. The RSVP hello packet is used by the switch to detect when an RSVP-TE peer is no longer reachable. If an RSVP hello packet is not received from a peer within [hello-interval \* keep-multiplier] seconds, the peer is declared down and all RSVP sessions to and from that peer are torn down. The default hello-interval time is zero, indicating that RSVP hellos are not enabled. The hello-interval can be set to any value between zero and 60 seconds.

The refresh-time parameter specifies the interval for sending refresh path messages. RSVP refresh messages provide soft state link-level keep-alive information for previously established paths and enable the switch to detect when an LSP is no longer active. RSVP sessions are torn down if an RSVP refresh message is not received from a neighbor within [(keep-multiplier + 0.5) \* 1.5 \* refresh-time] seconds. The default refresh-time is 30 seconds and the default keep-multiplier value is three. The minimum and maximum refresh-time values are one and 36,000 seconds (or ten hours), respectively. The minimum and maximum keep-multiplier values are one and 255, respectively.

The bundle-time, specified in tenths of a second, indicates the maximum amount of time a transmit buffer is held so that multiple RSVP messages can be bundled into a single PDU. The default bundle-time is zero, indicating that RSVP message bundling is not enabled. The bundle-time value can be set to any value between zero and 30 (or 3 seconds).

The summary-refresh-time, specified in tenths of a second, indicates the time interval for sending summary refresh RSVP messages. The summary-refresh-time must be less than the configured refresh-time. The default summary-refresh-time is zero, indicating that no summary refresh RSVP messages are sent. The summary-refresh-time value may be set to any value between zero to 100 (or 10 seconds).

If configured, the bundled and summary refresh RSVP messages are only sent to RSVP-TE peers supporting RSVP refresh reduction.

## Creating or Deleting an RSVP-TE LSP

- To create an RSVP-TE LSP, use the following command:

```
create mpls rsvp-te lsp lsp_name destination ipaddress
```

The *lsp\_name* parameter is a character string that identifies the LSP within the switch. The *lsp\_name* string must begin with an alphabetic character and can contain up to 31 additional alphanumeric characters. The LSP is not signaled until at least one path is added. See [Adding a Path to an RSVP-TE LSP](#) on page 1119.

- To delete an RSVP-TE LSP, use the following command:

```
delete mpls rsvp-te lsp [lsp_name | all]
```

Deleting an LSP name disassociates all configured paths with this LSP and all configuration information for the LSP name is deleted. If the LSP has been specified for use by a static route or a VPLS, that configuration information is also deleted. If you specify the **all** keyword, all LSPs are deleted.

## Creating an RSVP-TE Path

- To create an RSVP-TE routed path resource, use the following command:

```
create mpls rsvp-te path path_name
```

The *path\_name* parameter is a character string that is used to identify the path within the switch. The *path\_name* string must begin with an alphabetic character, and can contain up to 31 additional alphanumeric characters. The RSVP-TE LSP is not signaled along the path until an LSP adds the specified path name. The maximum number of configurable paths is 1000.

- To delete an RSVP-TE path, use the following command:

```
delete mpls rsvp-te path [path_name | all]
```

This command deletes a configured MPLS RSVP-TE routed path with the specified *path\_name*. All associated configuration information for *path\_name* is deleted. A path cannot be deleted as long as the *path\_name* is associated with an LSP. If the **all** keyword is specified, all paths not associated with an LSP are deleted.

## Configuring an Explicit Route

The routed path for an RSVP-TE LSP can be described by a configured sequence of the LSRs and/or subnets traversed by the path. Each defined LSR or subnet represents an ERO subobject. Up to 64 subobjects can be added to each path name. LSRs and/or subnets can be either included or excluded.

- To add an RSVP-TE explicit route, use the following commands:
  - To specify an LSR or subnet to be included in the path calculation:

```
configure mpls rsvp-te path path_name add ero {include} ipNetmask
[strict|loose] {order number}
```

- To specify an LSR or subnet to be excluded from the path calculation:

```
configure mpls rsvp-te path path_name add ero exclude ipNetmask
{order number}
```

These commands add an IP address to the explicit route object (ERO) for the specified path name. The include keyword is optional and the default behavior is to define an ERO that must be included in the path. The exclude keyword allows a path to be created that must avoid certain subnets. This can be useful when defining redundant LSPs or paths that must avoid the path of other LSPs or paths.

The ipaddress keyword identifies an LSR using either a /32 address, which may represent an LSR router ID, loopback address, or direct router interface, or an IP prefix, which represents a directly connected subnet. Each IP address or prefix is included in the ERO as an IPv4 subobject.

For EROs that are configured to be included in the path calculation, if the IP address is specified as strict, the strict subobject must be topologically adjacent to the previous subobject as listed in the ERO. If the IP address is specified as loose, the loose subobject is not required to be topologically adjacent to the previous subobject as listed in the ERO. If omitted, the default subobject attribute is loose.

For EROs that are configured to be excluded in the path calculation, a given subnet is avoided if any address on that subnet is specified.

If the subobject matches a direct router interface or a directly attached subnet, the switch verifies that the path message is received on the matching router interface. The LSR path order is optionally specified using the order keyword. The order number parameter is an integer value from 1 to 65535. IP prefixes with a lower order number are sequenced before IP prefixes with a higher number. You can specify multiple addresses and assign them an order number. The order number determines the path that the LSP follows. Thus, the LSP follows the configured path of the IP prefix with the order value from low to high. If the order keyword is not specified, the number value for the LSR defaults to a value 100 higher than the current highest number value. For excluded nodes, the order is not important. Any excluded ERO will be always be avoided no matter where it is in the list of ERO objects.

If the list of IP prefixes added to the path does not reflect an actual path through the network topology, the path message is returned with an error from a downstream LSR and the LSP is not established.

The order of a configured subobject can not be changed. The ERO subobject must be deleted and re-added using a different order. If a subobject is added to or deleted from the ERO while the associated LSP is established, the path is torn down and is resigaled using the new ERO. Duplicate ERO subobjects are not allowed. Defining an ERO for the path is optional. If you do not configure an ERO, the path is signaled along the best CSPF calculated path and the ERO is not included in the path message. When the last subobject in the ERO of the path message is reached and the egress IP node of the path has not been reached, the remaining path to the egress node is signaled along

the best CSPF calculated path. Specification of an ERO could lead to undesirable routed paths, so care should be taken when terminating the ERO routed-path definition prior to the configured path egress node.

To delete an RSVP-TE explicit route, use the following command:

```
configure mpls rsvp-te path path_name delete ero [all | ipNetmask |
order number]
```

This command deletes an LSR or subnet from the ERO for the specified path name. The LSR is specified using the *ipaddress*, or *order* parameter. If an LSR is deleted from an ERO while the associated LSP is established, the path is torn down and is resigaled using a new ERO. Use the *all* keyword to delete the entire ERO from the path name. When there is no configured ERO, the path is no longer required to take an explicit routed path. The path is then signaled along the best CSPF calculated path and no ERO is included in the path message.

## Reserving Bandwidth for MPLS

In order to manage the bandwidth used by *MPLS* RSVP-TE LSPs, a configured amount of bandwidth must be reserved for MPLS. Bandwidth in the transmit direction must be reserved on all MPLS interfaces which will be used as egress interfaces for RSVP-TE LSPs requesting bandwidth. Bandwidth in the receive direction can be optionally reserved on all MPLS interfaces that will be used as ingress interfaces for RSVP-TE LSPs requesting bandwidth. Note that the receive bandwidth reservation can be exceeded, and is provided only for tracking and informational purposes.

- The following command is used to reserve bandwidth for MPLS:

```
configure mpls rsvp-te bandwidth committed-rate committed_bps [Kbps |
Mbps | Gbps] [{vlan} vlan_name | vlan all] {receive | transmit | both}
```

The *committed\_rate\_unit* must be specified in Kbps, Mbps, or Gbps. Choosing the **vlan all** option reserves the specified amount of bandwidth on all MPLS interfaces.

The default reserved value is zero. Therefore, no LSPs requesting bandwidth can be established until the bandwidth has been configured.

## Creating and Deleting an RSVP-TE Profile

- To create a traffic engineered LSP profile, use the following command:

```
create mpls rsvp-te profile profile_name {standard}
```

This command creates a configured RSVP-TE profile with the specified profile name. The default profile cannot be deleted. If a profile is associated with a configured LSP, the profile cannot be deleted.

- To delete a traffic engineered LSP profile, use the following command:

```
delete mpls rsvp-te profile [profile_name | all]
```

## Configuring an RSVP-TE Profile

- To configure an RSVP-TE profile, use the following command:

```
configure mpls rsvp-te profile profile_name {bandwidth [best-effort |
[committed-rate committed_bps [Kbps | Mbps | Gbps]] {max-burst-size
burst_size [Kb | Mb]} {peak-rate peak_bps [Kbps | Mbps | Gbps]]}
{hold-priority hold_priority} {mtu [number | use-local-interface]}
{path-computation [full | partial]} {record [enabled {route-only} |
disabled]} {setup-priority setup_priority}
```

A profile is a set of attributes that are applied to the LSP when the LSP is configured using the `create mpls rsvp-te lsp` command. A default profile is provided which cannot be deleted, but can be applied to any configured LSP. The profile name for the default profile is `default`. The default profile parameter values are initially set to their respective default values. The maximum number of configurable profiles is 1000 (one of which is reserved for the default profile).

The `bandwidth` parameter specifies the desired reserved bandwidth for the LSP. Any positive integer value is valid. You must append the characters `k` for kilobits, `m` for megabits, or `g` for gigabits, to the `bps` value to specify the unit of measure. The default bandwidth `bps` value is zero, which indicates that the *QoS* for the LSP is best effort.

The `max-burst-size` and `peak-rate` parameters are signaled in the sender Tspec object and add further definition of the expected traffic. The `mtu` parameter is also signaled in the sender Tspec object and defines the expected maximum packet size that is sent over the LSP.

The `setup-priority` and `hold-priority` are optional parameters indicating the LSP priority. During path set up, if the requested bandwidth cannot be reserved through the LSR, the `setup-priority` parameter is compared to the `hold-priority` of existing LSPs to determine if any of the existing LSPs need to be preempted to allow a higher priority LSP to be established. Lower numerical values represent higher priorities. The `setup-priority` range is 0 to 7 and the default value is 7. The `hold-priority` range is also 0 to 7 and the default value is 0.

The `path-computation` keyword specifies computation strategy for calculating a path to the LSP destination. "full" requires the ingress node to full calculate a path to the LSP destination. "partial" allows the ingress node to calculate only part of the path to the LSP destination.

### Note

Inter area RSVP fast reroute (FRR) is not supported.

The `record` keyword is used to enable hop-by-hop path recording. The `enabled` keyword causes the record route object (RRO) to be inserted into the path message. The RRO is returned in the reserve message and contains a list of IPv4 subobjects that describe the RSVP-TE path. Path recording by default is disabled. When disabled, no RRO is inserted into the path message.

- To delete an RSVP-TE path profile, use the following command:

```
delete mpls rsvp-te profile [profile_name | all]
```

This command deletes a configured RSVP-TE profile with the specified profile name. The default profile cannot be deleted. If a profile is associated with a configured LSP, the profile cannot be deleted. If you specify the **all** keyword, all profiles not associated with an LSP are deleted (except for the default profile).

## Adding a Path to an RSVP-TE LSP

- To add a path to an RSVP-TE LSP, use the following command:

```
configure mpls rsvp-te lsp lsp_name add path [path_name | any]
{profile profile_name} {primary {frr_profile_name} | secondary}
```

This command adds a configured path to the specified RSVP-TE LSP. The LSP name parameter is a character string that is to be used to identify the LSP within the switch and must have been created previously. The LSP is not signaled until a path is added to the LSP. Up to three paths can be defined for the LSP: one primary and two secondary. All paths are signaled, but only one path is used to forward traffic at any one time. The switch chooses the local *MPLS VLAN* interface from which to signal the LSP. To force an LSP to use a specific local MPLS interface, configure the peer's interface IP address as the first ERO in the associated path. The profile name is optional. If omitted, the default profile is applied to the LSP. The path name can be specified or the LSP can be configured to take any path. For a given LSP, only one path can be configured to take any path through the MPLS network.

The specified path defaults to primary when no primary path has been configured for the LSP and defaults to secondary if the primary path has been previously configured for the LSP.

Each *path\_name* added to an *lsp\_name* must be unique, but a *path\_name* can be associated with multiple LSP names.

All configured primary and secondary paths for the *lsp\_name* must have the same endpoint IP address. For example, three paths can be configured for the *lsp\_name*, but all paths should represent different topological paths through the network to the same LSP endpoint.

Adding a secondary *path\_name* designates a path as a hot-standby redundant path, used in the event that the primary or the other secondary path cannot be established or fails. Provided the *path\_name* has not already been established, all paths are signaled as soon as they are associated with an *lsp\_name*. If the primary *path\_name* fails, is not configured, or cannot be established after the specified LSP retry-timeout, one of the configured secondary paths becomes the active path for *lsp\_name*. All of the secondary paths have equal preference; the first one available is chosen. If at any time the primary path is reestablished, *lsp\_name* immediately switches to using the primary path. If a secondary path fails while in use, the remaining configured secondary path can become the active path for *lsp\_name*.

- To delete a path from an RSVP-TE LSP, use the following command:

```
configure mpls rsvp-te lsp lsp_name delete path [path_name | any |
all]
```

When you issue this command, the LSP associated with the path is immediately torn down. If the deleted path represents the in-use LSP for *lsp\_name* and another secondary path is configured, the LSP immediately fails over to an alternate LSP. Because at least one path must be defined for each LSP, the last configured path cannot be deleted from the LSP.

## Setting up Fast-Reroute Protection for an LSP

To create a protected LSP, do the following:

1. Create the LSP as described in [Creating or Deleting an RSVP-TE LSP](#) on page 1115.
2. Enable the fast-reroute feature on the LSP using the following command: `configure mpls rsvp-te lsp lsp_name fast-reroute [enable | disable]`
3. Create a path for the LSP as described in [Creating an RSVP-TE Path](#) on page 1115.
4. Define the path route as described in .
5. If you want to use a custom profile instead of the default profile, create a profile for the protected LSP as described in [Creating and Deleting an RSVP-TE Profile](#) on page 1117.
6. If you want to configure the custom profile created in the previous step, configure the profile as described in [Configuring an RSVP-TE Profile](#) on page 1118.
7. If you want to use a custom fast-reroute profile instead of using the default fast-reroute profile, create the profile using the following command at the ingress LER:  
`create mpls rsvp-te profile profile_name fast-reroute`
8. If you want to configure the custom fast-reroute profile created in the previous step, use the following command at the ingress LER:  
`configure mpls rsvp-te profile frr_profile_name {bandwidth  
bandwidth_rate_bps bandwidth_rate_unit} {detour {hop-limit  
hop_limit_value} {bandwidth-protection [enabled | disabled]} {node-  
protection [enabled | disabled]}} {hold-priority hold_priority_value  
{setup-priority setup_priority_value}`
9. Add the path to the protected LSP and select the standard and fast-reroute profiles using the following command:  
`configure mpls rsvp-te lsp lsp_name add path [path_name | any]  
{profile profile_name} {primary {frr_profile_name} | secondary}`

## RSVP-TE Configuration Example

RSVP-TE LSPs comprise profiles, paths, and the actual LSP. This section describes how to configure an RSVP-TE LSP.

Configuring RSVP LSPs is a multi-step process with some optional steps, depending on the specific requirements of the LSP. Conceptually, a number of mandatory elements must be configured to create an RSVP-TE LSP. In addition, you can also configure optional elements. In certain configurations, there are also order dependencies.

The profile contains constraints that you might wish to apply to the LSP. These constraints can affect the path selected across the *MPLS* domain in order to meet those constraints. Examples of profile parameters include bandwidth, setup, and hold priority relative to other configured LSPs.

The path can be used to specify the explicit path across the MPLS domain that the LSP should follow. This is done using EROs. An ERO is an object, sent as part of the LSP setup request (path message) that explicitly specifies the part of the path across the MPLS domain the setup request should follow. You can configure both loose and strict EROs in a path.

Certain elements of configuration are order dependent. For example if you specify a profile or path when creating an LSP, those path or profile definitions must already exist. Similarly a path must exist before an ERO is created, as the ERO is added explicitly to the path.

The typical steps used to configure and verify an RSVP-TE LSP are as follows:

1. Create and configure a path (optional).
2. Reserve bandwidth for the LSP (optional).
3. Create and configure a profile (optional).
4. Create an LSP (mandatory).
5. Add a primary/secondary path to the LSP (mandatory).
6. Add a secondary path to the LSP (optional).
7. Verify LSP status (recommended).

**Figure 140: RSVP-TE Configuration Example**

The configuration example, shown in [Figure 140](#), creates primary and secondary LSPs between the node Glasgow and the node Birmingham. The steps specifically create an LSP between Glasgow and Birmingham based on an explicitly routed path via London with bandwidth, setup priority, and hold priority profile requirements.

A secondary path is also created which, in the event of failure of a link or node on the primary path, activates the secondary LSP from Glasgow to Liverpool to Birmingham.

**Note**

Before configuring RSVP-TE LSPs, you need to enable the protocol on the switch, and an initial step of adding RSVP-TE to a VLAN must be carried out for all VLANs over which the user wishes RSVP-TE LSPs to be signaled. This is a one-time operation.

A loopback VLAN with the LSR-ID should be added to MPLS to allow RSVP-TE LSPs to be established to the LSR-ID.

The following commands configure RSVP-TE for the switch and add RSVP signaling capabilities to the specified VLANs:

```
enable mpls
enable mpls protocol rsvp-te
configure mpls add vlan loopback
configure mpls add vlan gla-lon
enable mpls rsvp-te vlan gla-lon
enable mpls vlan gla-lon
configure mpls add vlan gla-liv
enable mpls rsvp-te vlan gla-liv
enable mpls vlan gla-liv
```

The following commands reserve bandwidth for RSVP-TE LSPs on these MPLS interfaces:

```
configure mpls rsvp-te bandwidth committed-rate 20 Mbps gla-lon
configure mpls rsvp-te bandwidth committed-rate 20 Mbps gla-liv
```

The following commands create and configure an LSP profile named Glasgow-Birmingham-pro.

LSPs that use the Glasgow-Birmingham-pro profile are signaled with a reserved bandwidth of 10 Mbps and an LSP setup and hold priority of 5.

```
create mpls rsvp-te profile Glasgow-Birmingham-pro
configure mpls rsvp-te profile Glasgow-Birmingham-pro bandwidth committed-rate 10 m
configure mpls rsvp-te profile Glasgow-Birmingham-pro setup-priority 5 hold-priority 5
```

The following commands define the primary and secondary paths between Glasgow and Birmingham:

```
create mpls rsvp-te path Glasgow-Birmingham-pri-path
create mpls rsvp-te path Glasgow-Birmingham-sec-path
```

The following commands pin each path to an LSR, such that each path takes a different route to the endpoint 4.0.0.0.

Path Glasgow-Birmingham-pri-path is routed through LSR 1.0.0.0 and path Glasgow-Birmingham-sec-path is routed through LSR 5.0.0.0.

```
configure mpls rsvp-te path Glasgow-Birmingham-pri-path add ero 1.0.0.0/32 loose
configure mpls rsvp-te path Glasgow-Birmingham-sec-path add ero 5.0.0.0/32 loose
```

The following commands create one RSVP-TE LSP with one primary and one secondary or backup path.

Each path uses the same profile.

```
create mpls rsvp-te lsp Glasgow-Birmingham-lsp destination 4.0.0.0
configure mpls rsvp lsp Glasgow-Birmingham-lsp add path Glasgow-Birmingham-pri-path
profile Glasgow-Birmingham-pro primary
configure mpls rsvp lsp Glasgow-Birmingham-lsp add path Glasgow-Birmingham-sec-path
profile Glasgow-Birmingham-pro secondary
```

#### Note

The secondary LSP is signaled, however it remains in a standby state unless the primary path becomes unavailable.

By default, a VPLS pseudowire flows over any available LSP.

However, a VPLS pseudowire can be specifically directed to use a configured RSVP-TE based LSP. Configuration is no different from configuring an LDP-based VPLS pseudowire, except that the RSVP-TE LSP is explicitly specified. The following command specifically directs a VPLS pseudowire to use a previously configured RSVP-TE LSP:

```
configure vpls Glasgow-Birmingham-cust1 peer 4.0.0.0 add mpls lsp Glasgow-Birmingham-lsp
```

## Troubleshooting MPLS

The ExtremeXOS software includes multiple mechanisms for detecting and reporting problems.

Many failures generate an [SNMP](#) trap or log an error message. To find out more about a problem, you can enter show commands and review the flag states in the command output. The software also includes some [MPLS](#) troubleshooting tools, which are described in the following sections.

### Using LSP Ping

To assist with problem determination in an [MPLS](#) network, LSP ping support is included as a CLI ping option in the ExtremeXOS software. The LSP ping support is based on draft-ietf-mpls-lsp-ping-13.txt. This draft includes support for both connectivity verification and fault isolation for transport LSPs. Connectivity verification is supported using a modified ping packet that is sent over the specified transport LSP.

LSP ping is designed to catch failures where a transport LSP appears to be operational but is actually not functioning correctly. LSP data plane corruption is far less likely to occur than an LSP control plane failure, but the LSP ping is also useful for detecting possible latency issues.

- To send MPLS ping packets over an LSP, enter the following command:  

```
ping mpls lsp [lsp_name | any host | prefix ipNetmask] {reply-mode
[ip | ip-router-alert]} {continuous | count count} {interval interval}
{start-size start-size {end-size end-size}} {ttl ttl} {{from from}
{next-hop hopaddress}}
```

MPLS pings are sent to the well-known UDP port number 3503 with an IP in the 127.0.0.0/8 IP subnet. The source IP address is set to the sender.

The time stamp field is supported for calculating round trip times and is accurate to 1/100 of a second. When replying to a ping, the LSP ping response (MPLS echo reply) sequence number and time-stamp fields are set to the LSP ping request (MPLS echo request) values. One MPLS echo response is sent for each MPLS echo request received. An MPLS echo reply is sent out-of-band as a natively IP routed IPv4 UDP packet. The normal IP routed path might or might not use an LSP.

To reduce the possibility of fragmentation problems on the return path, MPLS echo reply packets do not include any padding that was sent in the MPLS echo request. Because each LSP is unidirectional, the return path is not directly relevant for verification of the LSP's functionality. What is important is that the LSP ping results are returned to the source of the MPLS echo request.

## Using LSP Trace

Transport LSP fault isolation is supported using the LSP trace feature. When the control plane detects a transport LSP failure, the LSR can switch to another LSP if one is available. When the failure is detected by LSP ping, you can use LSP trace to try to isolate the fault.

- To start an LSP trace, use the following command:

```
traceroute mpls lsp [lsp_name | any host | prefix ipNetmask]
 {reply-mode [ip | ip-router-alert]} {{from from} {ttl t1} {next-hop
hopaddress}}
```

## Using the Health Check VCCV Feature

Health check Virtual Circuit Connectivity Verification (VCCV) can be used as a network diagnostic tool or as a network fault-alert tool, and can be configured on up to 16 VPLS domains. Connectivity between VPLS peers can be verified using the health check VCCV feature, which is defined in RFC 5085, Pseudowire Virtual Circuit Connectivity Verification (VCCV).

This implementation uses the following components defined in that RFC:

- VCCV Control Channel Type: MPLS Router Alert Label
- VCCV Control Verification Type: LSP Ping

Health check uses the LSP ping capability to verify connectivity. When the PW is set up, the two peers negotiate the VCCV capabilities, and if they establish a common set, health check becomes operational. If the VCCV capabilities do not match, health check cannot operate.

Health check operates in a single direction, so health checking should be enabled on the LSRs at both ends of the pseudowire in order to verify that traffic can flow bi-directionally between two VPLS peers. For multi-peer full-mesh or hierarchical VPLS networks, VCCV should be enabled on all VPLS peers to verify the entire VPLS network.

VCCV sends health check packets at regular intervals (the default interval is 5 seconds). If health check reaches the threshold for missed responses (the default fault-multiplier is 4), health check logs a message in EMS at the Warning level. Note that this log is not seen with the default log settings and no *SNMP* traps are sent. A health check failure does not change the state of the PW, which could remain operationally up and continue to support traffic, depending on the actual problem.

- To enable health check, use the following commands:

```
enable l2vpn [vppls vppls_name | vpws vpws_name] health-check vccv
```

- To configure health check, use the following command:

```
configure l2vpn [vppls [vppls_name | all] | vpws [vpws_name | all]] health-check vccv {interval interval_seconds} {fault-multiplier fault_multiplier_number}
```

- View VPLS configuration information, including the health check feature configuration.

```
show [{l2vpn} vppls {vppls_name} | l2vpn vpws {vpws_name} | l2vpn]
{peer ipaddress} {detail} | summary }
```

- To disable health check, use the following command:

```
disable l2vpn [vppls [vppls_name | all] | vpws [vpws_name | all]]
health-check vccv
```

This chapter introduces MSDP (Multicast Source Discovery Protocol), an interdomain multicast protocol used to connect multiple multicast routing domains that run PIM-SM (Protocol Independent Multicast-Sparse Mode). This chapter discusses the features and configuration for PIM border, MSDP peers, mesh groups, anycast RP, SA cache, redundancy, and [\*SNMP \(Simple Network Management Protocol\)\*](#) MIBs.

## Note

For more information about MSDP, refer to RFC 3618.

## MSDP Overview

---

[\*MSDP \(Multicast Source Discovery Protocol\)\*](#) is an interdomain multicast protocol used to connect multiple multicast routing domains that run Protocol Independent Multicast-Sparse Mode (PIM-SM).

MSDP speakers are configured on each PIM-SM domain. These speakers establish a peering relationship with other MSDP speakers through secured TCP connections. When the source sends traffic, the MSDP speaker learns about the source through its Rendezvous Point (RP). In turn, the RP advertises the source to its peers through Source Active (SA) messages. The peers receive these advertisements and inform their RPs about the presence of the active source in the other PIM-SM domain, which triggers the normal PIM operation in the corresponding domains.

For example, as businesses expand and networks grow in size, it might become necessary to connect PIM domains to allow multicast applications to reach other offices across the network. MSDP simplifies this process by providing a mechanism to connect those multicast routing domains without reconfiguring existing domains. Each PIM domain remains separate and has its own RP. The RP in each domain establishes an MSDP peering relationship over a TCP connection either with RPs in other domains or with border routers leading to other domains. When an RP learns about a new multicast source in its own domain (using the normal PIM registration process), it then

sends a SA message to all of its MSDP peers, letting them know about the new stream. In this way, the network can receive multicast traffic from all over the network without having to reconfigure each existing PIM domain.

## Supported Platforms

*MSDP* is supported on all platforms running a minimum software version of ExtremeXOS 12.0 with the Premier or Extreme Platform ONE license.

Our implementation of MSDP is compliant with RFC 3618 and RFC 3446, and compatible with other devices that are compliant with these standards.

## Limitations

The limitations of are as follows:

- There is no support for MSDP operating with SA cache disabled (transit node). MSDP will always cache/store received SA messages.
- There is no support for logical RP.
- There is no support for MSDP on user-created virtual routers (VRs).
- routes are not used for peer-RPF checking. So, our implementation of MSDP does not exactly conform to rule (iii) in section 10.1.3 of RFC 3618. However, our implementation of MSDP uses / for peer-RPF checking as per rule (iii) in section 10.1.3.
- Read-write/read-create access is not supported on MSDP MIB objects.

## PIM Border Configuration

To create a PIM-SM domain for *MSDP*, you must restrict the reach of Bootstrap Router (BSR) advertisements by defining a *VLAN (Virtual LAN)* border. BSR advertisements are not sent out of a PIM interface configured as a VLAN border, thereby defining a PIM domain for MSDP.

To configure a PIM VLAN border, use the command:

```
configure pim vlan_name border
```

## MSDP Peers

*MSDP* peers exchange messages to advertise active multicast sources. The peer with the higher IP address passively listens to a well-known port number and waits for the side with the lower IP address to establish a Transmission Control Protocol (TCP) connection on port 639. When a PIM-SM RP that is running MSDP becomes aware of a new local source, it sends an SA message over the TCP connection to its MSDP peer. When the SA message is received, a peer-RPF check is performed to make sure the peer is toward the originating RP. If so, the RPF peer floods the message further. If not, the SA message is dropped and the message is rejected.

- Configure an MSDP peer using the command:  

```
create msdp peer remoteaddr {remote-as remote-AS} {vr vrname}
```

- Delete an MSDP peer using the command:  
`delete msdp peer [all | remoteaddr] {vr vr_name}`
- Display configuration and run-time parameters about an MSDP peer using the command:  
`show msdp [peer {detail} | {peer} remoteaddr] {vr vr_name}`

## MSDP Default Peers

You can configure a default peer to accept all SA messages. Configuring a default peer simplifies the peer-RPF checking of SA messages. If no policy is specified, the current peer is the default RPF peer for all SA messages.

When configuring a default peer, you can also specify an optional policy filter. If the peer-RPF check fails, and a policy filter is configured, the default peer rule is applied to see if the SA message should be accepted or rejected.

You can configure multiple default peers with different policies. However, all default peers must either be configured with a default policy or not. A mix of default peers, with a policy and without a policy, is not allowed.

- Configure an MSDP default peer, and optional policy filter using the command:  
`configure msdp peer [remoteaddr | all] default-peer {default-peer-policy filter-name} {vr vrname}`
- Remove the default peer using the command:  
`configure msdp peer [remoteaddr | all] no-default-peer {vr vrname}`
- Verify that a default peer is configured using the command:  
`show msdp [peer {detail} | {peer} remoteaddr] {vr vr_name}`

## Peer Authentication

MSDP supports TCP RSA Data Security, Inc. MD5 (Message-Digest algorithm 5) Message-Digest Algorithm authentication (RFC 2385) to secure control messages between MSDP peers. You must configure a secret password for an MSDP peer session to enable TCP RSA Data Security, Inc. MD5 Message-Digest Algorithm authentication. When a password is configured, MSDP receives only authenticated MSDP messages from its peers. All MSDP messages that fail TCP RSA Data Security, Inc. MD5 Message-Digest Algorithm authentication are dropped.

- Configure TCP RSA Data Security, Inc. MD5 Message-Digest Algorithm authentication on an MSDP peer using the command:  
`configure msdp peer [remoteaddr | all] password [none | {encrypted tcpPassword}] {vr vrname}`
- Remove the password using the command:  
`configure msdp peer {all | remoteaddr} password none`  
 The password displays in encrypted format and cannot be seen as simple text. Additionally, the password is saved in encrypted format.
- Display the password in encrypted format using the command:  
`show msdp [peer {detail} | {peer} remoteaddr] {vr vr_name}`

## Policy Filters

You can configure a policy filter to control the flow of SA messages going to or coming from an *MSDP* peer. For example, policy filters can help mitigate state explosion during denial of service (DoS) or other attacks by limiting what is propagated to other domains using MSDP.

You can use the following policy attributes in an SA filter policy. All other attributes are ignored:

- Match:
  - multicast-group
  - multicast-source
  - pim-rp
- Set:
  - permit
  - deny

The following shows some examples of policy files taking into account multicast-source with permit/deny action:

```
entry policy2 {
 if match any{
 nlri 10.10.10.0/24;
 }
 then {
 deny;
 }
}

entry policy1 {
 if match any{
 nlri 10.10.10.0/24;
 nlri 20.20.20.0/24 ;
 }
 then {
 permit;
 }
}
```

- To configure an incoming or outgoing policy filter for SA messages:
 

```
configure msdp peer [remoteaddr | all] sa-filter [in | out] [filter-name | none] {vr vr_name}
```
- To remove a policy filter for SA messages, use the none keyword:
 

```
configure msdp [{peer} remoteaddr | peer all] sa-filter [in | out] none
```
- To verify that a policy filter is configured on an MSDP peer:
 

```
show msdp [peer {detail} | {peer} remoteaddr] {vr vr_name}
```

## SA Request Processing

You can configure the router to accept or reject SA request messages from a specified *MSDP* peer or all peers. If an SA request filter is specified, only SA request messages from those groups permitted are accepted. All others are ignored.

- Configure the router to accept SA request messages from a specified MSDP peer or all peers using the command:

```
enable msdp [{peer} remoteaddr | peer all] process-sa-request {sa-request-filter filter-name} {vr vr_name}
```

- Configure the router to reject SA request messages from a specified MSDP peer or all peers using the command:

```
disable msdp [{peer} remoteaddr | peer all] process-sa-request {vr vrname}
```

- Display configuration and run-time parameters about MSDP peers using the command:

```
show msdp [peer {detail} | {peer} remoteaddr] {vr vr_name}
```

## MSDP Mesh-Groups

*MSDP* can operate in a mesh-group topology. A mesh-group limits the flooding of SA messages to neighboring peers. In a mesh-group, every MSDP peer must be connected to every other peer in the group. In this fully-meshed topology, when an SA message is received from a member of the mesh-group, the SA message is always accepted, but not flooded to other members of the same group. Because MSDP peers are connected to every other peer in the mesh-group, an MSDP peer is not required to forward SA messages to other members of the same mesh-group. However, SA messages are flooded to members of other mesh-groups. An MSDP mesh-group is an easy way to implement inter-domain multicast, as it relaxes the requirement to validate looping of MSDP control traffic (that is, peer-RPF checking is not required). Consequently, SA messages do not loop in the network.

### Note

We recommend that you configure anycast RP peers in a mesh topology.

- Configure an MSDP mesh-group using the command:

```
create msdp mesh-group mesh-group-name {vr vrname}
```

- Remove an MSDP mesh-group using the command:

```
delete msdp mesh-group mesh-group-name {vr vrname}
```

- Display information about an MSDP mesh-group using the command:

```
show msdp [mesh-group {detail} | {mesh-group} mesh-group-name] {vr vrname}
```

- Configure a peer to be a member of an MSDP mesh-group using the command:

```
configure msdp peer [remoteaddr | all] mesh-group [mesh-group-name | none] {vr vrname}
```

- Remove a peer from an MSDP mesh-group using the command:

```
configure msdp [{peer} remoteaddr | peer all] mesh-group none {vr vrname}
```

## Anycast RP

Anycast RP is an application of *MSDP* that allows multiple RPs to operate simultaneously in a PIM-SM domain. Without anycast RP, multiple routers can be configured as candidate RPs, but at any point in time, only one router can serve as RP. Because anycast RP allows multiple RPs to be simultaneously active, anycast RP provides both load sharing and redundancy, as each RP serves the receivers that are closest to it in the network and can take over for additional receivers if another RP fails.

**Note**

Starting with ExtremeXOS 31.1, you can use Anycast RP without MSDP using the Anycast RP Using PIM (*RFC 4610*) feature.

In an anycast RP topology, all RPs in a PIM-SM domain are configured with the same IP address on a loopback *VLAN*. The loopback VLAN IP address should have a 32-bit mask, so that it specifies a host address. All the routers within the PIM-SM domain select the nearest RP for each source and receiver. If the senders and receivers within the PIM-SM domain are distributed evenly, the number of senders that register with each RP is approximately equal.

Another requirement of the anycast RP topology is that MSDP must run on all RPs in the PIM-SM domain, so all RPs are also MSDP peers. We recommend that you configure an MSDP mesh connection between all MSDP peers in the domain.

Whenever any multicast source becomes active, this information is sent in an MSDP SA message to the other MSDP peers in the domain, announcing the presence of the source. If any RP within the domain fails, the IP routing protocol mechanism ensures that next available RP is chosen. If a sender registers with one RP and a receiver joins another RP, the information shared through MSDP enables PIM-SM to establish an SPT between the receiver and the source.

**Note**

We recommend that you configure anycast RP peers in a mesh topology.

The exchange of information in an anycast RP process works as follows:

- When the first-hop router sends a PIM Register message to the nearest RP, the PIM router checks to see if the nearest RP is the RP for the group.
- If the nearest RP is the RP for the group, an MSDP SA message is created and forwarded to the other MSDP peers.
- The MSDP SA message includes the configured originator ID, which is a mandatory configuration component.
- Each remote peer checks the RPF of the originator ID address and informs the PIM process on that remote router about active multicast sources.
- Remote receivers get data packets through the remote shared tree, and can then switch over to the SPT by sending join messages directly towards the source.

To configure anycast RP, do the following at each anycast RP router:

1. Create and configure a loopback VLAN using the commands:

```
create vlan vlan_name {tag tag } {description vlan-description } {vr
name }
```

```
enable loopback-mode vlan vlan_name
```

2. Assign the anycast RP address to the loopback VLAN with a 32 bit subnet mask using the command:

```
configure {vlan} vlan_name ipaddress [ipaddress {ipNetmask} | ipv6-
link-local | {eui64} ipv6_address_mask]
```

#### Note

The anycast RP address must be unique to the loopback VLAN and be the same on all anycast RP peers. It must not match the router IP address, the PIM BSR address, or any other IP addresses used by the router or any other network devices.

3. Enable IP forwarding and IP multicast forwarding on the loopback VLAN using the commands:

```
enable ipforwarding {ipv4 | broadcast} {vlan vlan_name}
```

```
enable ipmcforwarding {vlan name}
```

4. Add the loopback VLAN into the unicast routing domain using the appropriate command for your unicast routing protocol:

```
configure ospf add vlan vlan-name area area-identifier link-type [auto
| broadcast | point-to-point] {passive}
```

```
configure rip add vlan [vlan_name | all]
```

```
configure isis add [vlan all | {vlan} vlan_name] area area_name {ipv4
| ipv6}
```

5. Add the loopback VLAN into the PIM-SM domain and configure it as an RP using the commands:

```
configure pim {ipv4 | ipv6} add vlan [vlan-name | all] {dense |
sparse} {passive}
```

```
configure pim {ipv4 | ipv6} crp static ip_address [none | policy]
{priority [0-254]}
```

6. Enable MSDP and establish a peering relationship with similar anycast RP neighbors using the commands:

```
create msdp peer remoteaddr {remote-as remote-AS} {vr vrname}

configure msdp peer [remoteaddr | all] password [none | {encrypted}
tcpPassword] {vr vrname}

configure msdp peer remoteaddr description {peer-description} {vr
vrname}

enable msdp [{peer} remoteaddr | peer all] {vr vr_name}

enable msdp {vr vrname}
```

7. Configure a unique originator ID for each anycast RP peer using the command:

```
configure msdp originator-id ip-address {vr vrname}
```

## SA Cache

As an *MSDP* router learns of new sources either through a PIM-SM Source-Register (SR) message or SA message from its RPF peer, it creates an entry in SA cache (or refreshes the entry if it is already there) and forwards this information to its peers. These entries are refreshed by periodic SA messages received from the MSDP peers. If these entries are not refreshed within six minutes, they will time out. When a PIM-SM RP detects that the source is no longer available it informs MSDP, which in turn removes the SA information from the local database.

Caching makes it easy for local receivers to know immediately about inter-domain multicast sources and to initiate building a source tree towards the source. However, maintaining a cache is heavy both in CPU processing and memory requirements.

### Note

Our implementation of MSDP does not support operating with local cache disabled.

- Remove an SA cache server.

```
unconfigure msdp sa-cache-server {vr vrname}
```

As MSDP uses the flood-and-join model to propagate information about sources, there is a restriction that no more than two advertisements per cache entry will be forwarded per advertisement interval. This is helpful in reducing an SA message storm and unnecessarily forwarding them to peers.

By default, the router does not send SA request messages to its MSDP peers when a new member joins a group and wants to receive multicast traffic. The new member simply waits to receive SA messages, which eventually arrive.

- Configure the MSDP router to send SA request messages immediately to the MSDP peer when a new member becomes active in a group.

```
configure msdp sa-cache-server remoteaddr {vr vr_name}
```

- Purge all SA cache entries.

```
clear msdp sa-cache {{peer} remoteaddr | peer all} {group-address grp-addr} {vr vrname}
```

- Display the SA cache database.

```
show msdp [sa-cache | rejected-sa-cache] {group-address grp-addr} {source-address src-addr} {as-number as-num} {originator-rp originator-rp-addr} {local} {peer remoteaddr} {vr vrname}
```

## Maximum SA Cache Entry Limit

You can configure a limit on the maximum number of SA cache entries that can be stored in the cache database. Once the number of SA cache entries exceeds the pre-configured limit, any newly received cache entries are discarded. You can configure the limit on a per-peer basis. By default, no SA message limit is set. The router can receive an unlimited number of SA entries from an *MSDP* peer.

- Configure a limit on the number of SA entries that can be stored in cache.

```
configure msdp peer [remoteaddr | all] sa-limit max-sa {vr vr_name}
```

To allow an unlimited number of SA entries, use 0 (zero) as the value for *max-sa*.

- Display the SA cache limit.

```
show msdp [peer {detail} | {peer} remoteaddr] {vr vr_name}
```

## SNMP MIBs

*SNMP* MIB access is not supported for *MSDP*.

## Multicast Routing Overview

---

Multicast routing and switching is the functionality of a network that allows a single host (the multicast server) to send a packet to a group of hosts. With multicast, the server is not forced to duplicate and send enough packets for all the hosts in a group. Instead, multicast allows the network to duplicate packets for all of the hosts in a group. Multicast greatly reduces the bandwidth required to send data to a group of hosts. IP

multicast routing is a function that allows multicast traffic to be forwarded from one subnet to another across a routing domain.

IP multicast routing requires the following functions:

- A router that can forward IP multicast packets
- A router-to-router multicast routing protocol (for example, Protocol Independent Multicast (PIM)) to discover multicast routes
- A method for the IP host to communicate its multicast group membership to a router (for example, *IGMP (Internet Group Management Protocol)*)

**Note**

You should configure IP unicast routing before you configure IP multicast routing.

## Multicast Table Management

---

The ExtremeXOS software uses the following tables to support IP multicast traffic:

- IPv4 multicast route table
- L3 hash table
- IP multicast group table
- FDB table (L2 table)
- L2 multicast table (L2MC table)

### IP Multicast Hardware Lookup Modes

Extreme platforms support various hardware forwarding lookup modes by using a combination of L3 hash table and L2 (*FDB (forwarding database)*) table. Refer to Multicast Table Management for details on these tables. The scalability limits vary based on the lookup mode used.

#### *Configuration Options*

Configuration options allow you to choose the hardware forwarding lookup mode for multicast forwarding. Here is a list of options:

- `source-group-vlan` -- Uses L3 hash table with S,G,V lookup. This is the default mode for all platforms.
- `group-vlan` -- Uses L3 hash table with \*,G,V lookup.
- `mac-vlan` -- Uses L2 table with DMAC, *VLAN (Virtual LAN)* lookup.
- `mixed-mode` -- Uses both L2 and L3 tables for multicast. In this mode, the following logic is applied on installing the cache entries in the hardware:

Multicast cache entries requiring forwarding across VLANs would be installed in the L3 IP multicast table. This includes PIM, MVR, and PVLAN cache entries.

Multicast cache entries requiring L2 forwarding within a VLAN are installed in the L2 table. This includes entries corresponding to *IGMP* Snooping, PIM snooping, and MLD snooping.

Any IPv4/v6 reserved multicast addresses (for example, 224.0.0.x or IPv6 equivalent) are installed in the L3 IP multicast table as needed. These reserved

addresses map to the following multicast MAC addresses: 01:00:5e:00:00:xx, 33:33:00:00:00:xx, 33:33:00:00:01:xx, or 33:33:ff:xx:xx:xx.

#### Note

Any change in the lookup key configuration causes all cache entries to be cleared, and traffic is temporarily dropped until the system re-learns the multicast caches and associated subscriptions.

#### Note

mac-vlan mode helps increase scaling. This mode is supported on all platforms.

#### Note

mac-vlan and mixed-mode are not supported prior to ExtremeXOS 15.3.1.

The ExtremeXOS multicast process continues to maintain the cache entries as "S,G,V", and interacts with HAL the same way as today. ExtremeXOS hardware abstraction layer (HAL) applies the logic explained above and installs the cache entries in the appropriate hardware table. If the cache entry needs to be installed in the L2 multicast table, HAL derives the MAC address based on the standard logic and installs the MAC entry in the L2 table.

The IP multicast address to MAC address mapping is not validated for the received/forwarded multicast packets in ExtremeXOS to date. If the lookup mode is configured either as "mac-vlan" or "mixed-mode", the multicast kernel module is modified to validate this mapping and, if a packet does not use the standard mapping, the packet is dropped.

#### *IPMC Compression*

In order to increase the scaling of multicast entries, ExtremeXOS implements a feature called IPMC compression which allows multiple <S,G,V> (or <\*,G,V>) IP multicast FDB entries to utilize the same IP multicast group table entry when the associated egress port lists are the same. The base IP multicast compression implementation will be reused for achieving L2 multicast entry reuse. In this case, multiple <MAC,VLAN> multicast FDB entries can use a single L2MC index if the egress port lists of the cache entries are the same.

#### *Interactions with Static FDBs*

ExtremeXOS allows you to create FDB entries for multicast MAC address using:

```
create fdb mac_addr {vlan} vlan_name ports port_list
```

These entries also get installed in the L2 table and use the L2MC table for hardware forwarding. If there is a dynamic <MAC,VLAN> entry from MCMGR and a static entry from FDB manager, the static entry takes precedence and the dynamic entry would get deleted in hardware. Compression of L2MC indices is not supported on these types of entries. Each newly created static multicast FDB will cause the allocation of a new L2MC index.

### *Interactions with Dynamic FDBs*

When IP multicast forwarding entries are utilizing the L2 MAC table, the multicast entries are installed as static in the hardware L2 table to avoid undesirable interactions with L2 protocol or user administered FDB flushing. These multicast L2 entries also take precedence over dynamic unicast L2 MAC entries. If there is a hash bucket collision upon inserting an L2 multicast entry, it will replace another dynamic unicast L2 entry if one exists in the same hash bucket.

### *Virtual Router Support*

Current IPMC cache hardware entries stored as <S,G,V> additionally include the VRID associated with the ingress . In this feature, <MAC, VLAN> cache entries are stored in the L2 table which does not additionally include the VRID. However, user VRs are still supported since the VLAN portion of the lookup key is unique across all VRs.

### *IPMC Cache Rate Limiting*

Based on the number of cache entries supported on each platform, there is a software cache limiting implementation present in ExtremeXOS multicast. The HAL module informs MCMGR about the supported limit, MCMGR creates cache entries up to MAX supported limit, and the remaining traffic is dropped in software.

### *Flood to VLAN Filters for mDNS, LLMNR, and UPnP protocols*

Version 32.2 introduces support for flood to VLAN Filters for mDNS, LLMNR, and UPnP protocols. This feature enables you to create filters that forward to VLAN for these three protocol packets on both standalone switches and stacks. When flood to VLAN is enabled, an ACL filter is installed, and one ACL entry is consumed for each of the three protocols. When in learn mode, no ACL filters are installed, and no ACL resources are consumed. The default mode is learn.

### *Supported Platforms*

This feature is implemented on all platforms.

### *Limitations*

The following limitations exist for the L2MC table feature:

- When using the "mac-vlan" configuration option:
  - PIMv4/V6, MVR features cannot be used.
  - IGMPv3 should not be used in conjunction with this mode
  - Private VLAN multicast should not be used.
  - Issues with IP multicast address to MAC address mapping:

All IPv4 multicast frames use multicast mac addresses starting with 01:00:5e:xx:xx:xx. The lower order 23 bits of the IP multicast address is used in the MAC address derivation. As only 23 bits of MAC addresses are available for mapping layer 3 IP multicast addresses to layer 2 MAC addresses, this mapping results in 32:1 address ambiguity.

When traffic is received for 1 out of these 32 overlapping address, then the MAC, Vlan entry is installed in hardware based on the IGMP group membership of received

traffic's destination multicast IP address. After this installation, traffic to any of the remaining 31 addresses is delivered based on the existing cache entry and the actual receiver list of the remaining 31 addresses will not be honored.

IPv6 multicast streams use multicast MAC addresses in the form 33:33:xx:xx:xx:xx. The lower 24 bits of the IPv6 multicast address are used to derive the MAC address. So, the address ambiguity issue is also applicable to IPv6 with more severity. Given this condition, we do not recommend using overlapping IP multicast addresses with this mode.

This limitation applies to "mixed-mode", too.

- IPv4 multicast addresses consist of a block of addresses (224.0.0.x) used for network control traffic. Packets having IP destination addresses from the LNCB are always flooded to all ports of the VLAN. The address ambiguity issue discussed above is applicable for the addresses in this block too. For example, 224.0.0.5 (address used for *OSPF (Open Shortest Path First)*) and 225.0.0.5 would use the same MAC address 01:00:5e:00:00:05. If a mac based multicast FDB entry is installed on the hardware for 01:00:5e:00:00:05 based on the 225.0.0.5 join list, it would break OSPF functionality. Hence, MAC addresses mapping to the LNCB block will not be installed in the L2 table, resulting in software forwarding for those streams. We recommend that you avoid using multicast addresses that map to the 01:00:5e:00:00:xx MAC address range.
- As per RFC 3307, IANA assigned reserved IPv6 multicast addresses could be in the group Id range of 0x00000001 to 0x3FFFFFFF. As a result, ExtremeXOS switches flood traffic addressed to ff02::/98 to all ports of the VLAN. Since the lower 32 bits of IPv6 multicast addresses are mapped to the multicast mac address, not installing all of the addresses in this range would make it too restrictive. So, installing entries for 33:33:00:00:00:xx in hardware would be avoided, and the traffic would be software forwarded.

In addition, the following important IPv6 multicast addresses cannot be installed as hardware forwarding entries:

*DHCP (Dynamic Host Configuration Protocol)*: All-dhcp-agents address  
FF02:0:0:0:0:1:2

All-dhcp-servers address FF05:0:0:0:0:1:3

Neighbor Discovery (ND): Solicited-node-address FF02::1:FF00:0000/104

Therefore, the following multicast MAC addresses are not programmed in hardware, and the corresponding packets are handled in slowpath: 33:33:00:00:01:xx , 33:33:ff:xx:xx:xx

- Given the issues with IP multicast address to MAC address mapping, no attempt is made to merge subscriber lists of multiple overlapping IP groups.
- The following limitation regarding IPMC compression is also applicable for this feature, because this feature uses the same L2MC entry for multiple I2 multicast entries with same egress ports.

- When IP multicast forwarding entries are installed as <MAC,VLAN>, ICMP or MLD packets which have a MAC-DA=<group> will cause the refresh of the IP multicast cache, preventing timely entry age-out.
- The L2MC table is limited to 1K entries on all platforms. This means that only up to 1K unique port lists can be addressed from the <MAC,VLAN> IP multicast forwarding entries that are stored in the L2 table. Additionally, statically created multicast FDB entries do not perform L2MC index compression.

## IPv4 Multicast Route Table

Beginning with Release 12.1, all IP multicast routes are stored and maintained in the software multicast route table. Routes are added to the multicast route table from the following sources:

- Multicast static routes (configured manually by the network administrator)
- Multicast dynamic routes (learned through protocols such as MBGP and MISIS)

The multicast route table is used for reverse path forwarding (RPF) checks, not for packet forwarding. The switch uses RPF checks to avoid multicast forwarding loops. When a multicast packet is received, the switch does an RPF lookup, which checks the routing tables to see if the packet arrived on the interface on which the router would send a packet to the source. The switch forwards only those packets that arrive on the interface specified for the source in the routing tables.

The RPF lookup uses the multicast routing table first, and if no entry is found for the source IP address, the RPF lookup uses the unicast routing table.

### Note

Because the multicast routing table is used only for RPF checks (and not for routing), IP route compression and *ECMP (Equal Cost Multi Paths)* do not apply to multicast routes in the multicast routing table.

Beginning with ExtremeXOS software version 12.1, the route metric is no longer used to select between multicast and unicast routes. If the RPF lookup finds a route in the multicast table, that route is used. The unicast routing table is used only when no route is found in the multicast table.

The advantage to having separate routing tables for unicast and multicast traffic is that the two types of traffic can be separated, using different paths through the network.

## L3 Hash Table

The L3 hash table is introduced in [Introduction to Hardware Forwarding Tables](#) on page 879. The L3 hash table stores entries for IPv4 routes, IPv4 and IPv6 hosts, and IPv4 and IPv6 multicast groups. For multicast, L3 hash table supports <S,G,V> and <\*,G,V> lookups. The entry from this table provides an index to IP Multicast Group table.

To make more space available in the L3 hash table for IPv4 and IPv6 multicast groups, you can do the following:

- Configure the extended IPv4 host cache feature to move IPv4 local and remote routes to the LPM table as described in [Extended IPv4 Host Cache](#) on page 879.
- For more information, see the description for the **configure iproute reserved-entries** command.

## IP Multicast Group Table

The IP multicast group table specifies the egress ports for Layer 2 and Layer 3 multicast traffic groups. To make more space available in the IP multicast group table, you can leave IP multicast compression enabled (it is enabled by default). This allows multiple L3 hash entries to share the same IP multicast group entry if the egress list is the same.

## PIM Overview

Protocol Independent Multicast (PIM) is the de-facto standard for routing multicast traffic over the Internet. Other multicast routing protocols such as DVMRP and MOSPF are sometimes used in controlled environment, but are not widely deployed. PIM does not depend on a particular unicast routing protocol for its operation. Also, it does not have any mechanism of its own for route discovery. PIM operation is based on the routing table being populated by another routing protocol, or by the user. This provides flexibility in routing unicast and multicast traffic based on a common database.

PIM has two flavors, sparse and dense mode, that are deployed in different topologies. These two flavors, called PIM-SM and PIM-DM, are different in operation. PIM-SM is based on a "join protocol", where traffic is not forwarded on a segment unless an explicit request originates (typically through [IGMP](#)) from the network segment. PIM-DM is based on a "flood and prune" mechanism, where every one receives traffic until they explicitly inform (through the PIM-DM prune mechanism) that they do not want that particular stream. Thus, PIM-DM is typically deployed in topologies where listeners are densely populated. And PIM-SM is typically deployed where the receivers are sparsely populated over the network, so that most of the network segments' bandwidth is conserved.

You can configure dense mode or sparse mode on a per-interface basis. After they are enabled, some interfaces can run dense mode, while others run sparse mode. The switch supports both dense mode and sparse mode operation.

The switch also supports PIM snooping.

## PIM Edge Mode

PIM Edge Mode is a subset of PIM that operates with the following restrictions:

- The switch does not act as a candidate rendezvous point (CRP).
- The switch does not act as a candidate bootstrap router (CBSR).

- At most, four active PIM-SM interfaces are permitted. There is no restriction on the number of passive interfaces (within the limit of the maximum IP interfaces).
- Only PIM Sparse Mode (PIM-SM) is supported.

**Note**

This feature is supported at and above the license level listed for this feature in the license tables in the [Switch Engine v33.3.1 Licensing Guide](#) document.

Active PIM interfaces can have other PIM enabled routers on them. Passive interfaces should only have hosts sourcing or receiving multicast traffic. If another PIM router is connected to a multi-access VLAN, then passive mode should not be enabled for that respective VLAN. *OSPF* passive mode should not be enabled for a VLAN when a PIM neighbor is present.

## PIM Dense Mode

Protocol-Independent Multicast - Dense Mode (PIM-DM) is a multicast routing protocol. PIM dense-mode is a flood and prune-based protocol. Convergence is based on the downstream routers' response for the traffic received. The downstream router in turn floods the traffic to its own downstream interfaces. Each router sends prune to the interface on which it received the traffic under the following conditions:

- Traffic was not received on RPF interface towards the source.
- The PIM router is a leaf router, and there are no *IGMP*/MLD members.
- All the downstream PIM routers have pruned the stream, and there are no IGMP/MLD members.

A feature called PIM-DM state refresh creates two PIM-DM operating modes, which are described in the following sections:

**Note**

For additional information on PIM-DM, see RFC 3973, Protocol Independent Multicast - Dense Mode (PIM-DM): Protocol Specification.

### *PIM-DM Without State Refresh*

PIM-DM is a broadcast and prune protocol, which means that multicast servers initially broadcast traffic to all destinations, and then switches later prune paths on which there are no receivers. [Figure 141](#) shows a dense mode multicast tree with an active branch and a pruned branch.

**Figure 141: PIM-DM Operation**

Multicast traffic is flowing from VLAN V1 connected to switch S1. S1 floods multicast traffic to both neighbors S2 and S3 which in turn flood multicast traffic to S4 and S5. S4 has IGMP members, so it floods multicast traffic down to VLAN V6. S5, which has no multicast members, sends a prune upstream towards the source. The green line shows the flow of traffic on the active branch, and the red line shows the prune sent upstream for the pruned branch. After outgoing interface V2 is pruned from the multicast tree, subsequent multicast traffic from S1 flows only through S2 and S4 and is not forwarded to S3.

After S3 sends a prune upstream, S3 starts a prune hold time timer on outgoing interface V5. When this timer expires, S3 adds V5 back to the multicast egress list and sends a graft upstream to pull multicast traffic down again. When multicast traffic arrives from S1, it is forwarded to S5, which repeats the upstream prune message because it still has no members. This prune, time-out, and flood process repeats as long as the traffic flow exists and no members are on the pruned branch, and this process consumes bandwidth during every cycle.

**Note**

This feature is supported at and above the license level listed for this feature in the license tables in the [Switch Engine v33.3.1 Licensing Guide](#) document.

PIM-DM routers perform reverse path multicasting (RPM). However, instead of exchanging its own unicast route tables for the RPM algorithm, PIM-DM uses the existing unicast routing table for the reverse path. As a result, PIM-DM requires less system memory.

### *PIM-DM with State Refresh*

The PIM-DM State Refresh feature keeps the PIM-DM prune state from timing out by periodically sending a state refresh control message down the source tree. These control messages reset the prune hold time timer on each pruned interface and prevent the bandwidth waste that occurs with each prune, time-out, and flood cycle.

When a topology change occurs, the PIM-DM State Refresh feature improves network convergence. For example, suppose that an S, G entry on S5 in the following figure is removed due to non-availability of a route. Without PIM-DM State Refresh, multicast traffic is blocked for minutes (due to a time-out on the upstream routers). In the meantime if an *IGMP* member or a PIM-DM neighbor joins S5, there is no way to pull traffic down immediately because S5 does not have any S, G information. State refresh control messages solve this problem by indicating S, G state information periodically to all downstream routers. When S5 receives a state refresh from S3, it scans the S, G information and all pending requests from PIM-DM neighbors and IGMP members. If there are pending requests for the group in the state refresh message, S5 can immediately send a graft message upstream to circumvent the upstream timers and pull multicast traffic to its members and neighbors.

- To enable, configure, and disable the PIM-DM State Refresh feature, use the following commands:

```
configure pim state-refresh {vlan} [vlanname | all] [on | off]
configure pim state-refresh timer origination-interval interval
configure pim state-refresh timer source-active-timer interval
configure pim state-refresh ttl ttlvalue
```

## PIM Sparse Mode

Unlike PIM-DM, Protocol-Independent Multicast - Sparse Mode (PIM-SM) is an explicit join protocol, which means that multicast receivers, and the routers that support them, must join multicast groups before they receive multicast traffic. When all receivers on a network branch leave a multicast group, that branch is pruned so that the multicast traffic does not continue to consume bandwidth on that branch. PIM-SM supports shared trees as well as shortest path trees (SPTs). PIM-SM is beneficial for large networks that have group members that are sparsely distributed.

### Note

This feature is supported at and above the license level listed for this feature in the license tables in the [Switch Engine v33.3.1 Licensing Guide](#) document.

Using PIM-SM, the router sends a join message to the rendezvous point (RP). The RP is a central multicast router that is responsible for receiving and distributing the initial multicast packets. You can configure a dynamic or static RP.

When a router has a multicast packet to distribute, it encapsulates the packet in a unicast message and sends it to the RP. The RP decapsulates the multicast packet and distributes it among all member routers.

When a router determines that the multicast rate has exceeded a configured threshold, that router can send an explicit join to the originating router. When this occurs, the receiving router gets the multicast directly from the sending router and bypasses the RP.

### Note

You can run either PIM-DM or PIM-SM per VLAN.

## PIM Mode Interoperation

An Extreme Networks switch can function as a PIM multicast border router (PMBR). A PMBR integrates PIM-SM and PIM-DM traffic.

When forwarding PIM-DM traffic into a PIM-SM network, the PMBR acts as a virtual first hop and encapsulates the initial traffic for the RP. The PMBR forwards PIM-DM multicast packets to the RP, which, in turn, forwards the packets to those routers that have joined the multicast group.

The PMBR also forwards PIM-SM traffic to a PIM-DM network, based on the (\*,RP) entry. The PMBR sends a (\*,RP) join message to the RP, and the PMBR forwards traffic from the RP into the PIM-DM network.

No commands are required to enable PIM mode interoperation. PIM mode interoperation is automatically enabled when a dense mode interface and a sparse mode interface are enabled on the same switch.

## PIM Source Specific Multicast

PIM-SM works well in many-to-many multicasting situations. For example, in video conferencing, each participating site multicasts a stream that is sent to all the other participating sites. However, PIM-SM is overly complex for one-to-many multicast situations, such as multimedia content distribution or streaming stock quotes. In these and similar applications, the listener is silent and can know the source of the multicast in advance, or can obtain it. In these situations, there is no need to join an RP, as the join request can be made directly towards the source.

### Note

This feature is supported at and above the license level listed for this feature in the license tables in the [Switch Engine v33.3.1 Licensing Guide](#) document.

### Note

(\*;G)s are created for groups inside the SSM range if SSM is not enabled.

PIM Source Specific Multicast (PIM-SSM) is a special case of PIM-SM, in which a host explicitly sends a request to receive a stream from a specific source, rather than from any source.

IGMPv3 hosts can use PIM SSM directly, because the ability to request a stream from a specific source first became available with IGMPv3. The PIM-SSM capable router interprets the IGMPv3 message to initiate a PIM-SM join towards the source.

### Note

IGMPv1 and IGMPv2 hosts can use PIM SSM if [IGMP-SSM](#) mapping is enabled and configured on the ExtremeXOS switch. For more information, see [Using IGMP-SSM Mapping](#).

Table 79 describes PIM-SSM behavior while sending IGMPv3 joins in the SSM range and outside the SSM range for IPv4:

**Table 79: Using PIM-SSM While Sending IGMPv3 Joins (IPv4)**

| SSM Enabled | SSM range | Mode | Include Src | ExtremeXOS 15.4                   |                                                                  | ExtremeXOS 15.5                   |                                                                  |

| Yes            | No           | Excl | Yes            | Send<br>MLDv2 join                        | -the group<br>is learned<br>-(*;G) is<br>created                              | Send<br>MLDv2 join                        | -the group<br>is learned<br>-(*;G) is<br>created            |

PIM-SSM has the following advantages:

- No overhead of switching to the source-specific tree and waiting for the first packet to arrive
- No need to learn and maintain an RP
- Fewer states to maintain on each router
- No need for the complex register mechanism from the source to the RP
- Better security, as each stream is forwarded from sources known in advance

PIM-SSM has the following requirements:

- Any host that participates directly in PIM-SSM must use IGMPv3. For PIM IPv6 host must use MLDv2.
- To support IGMPv1 and IGMPv2 hosts, IGMP-SSM mapping must be enabled and configured. To support MLDv1 hosts, MLD-SSM mapping must be enabled and configured.

PIM-SSM is designed as a subset of PIM-SM and all messages are compliant with PIM-SM. PIM-SSM and PIM-SM can coexist in a PIM network; only the last hop router need to be configured for PIM-SSM if both source and receivers are present all the time. However, to avoid any JOIN delay, it is recommended that you enable all routers along the (s,g) path for PIM-SSM.

#### *Configuring the PIM-SSM Address Range*

A range of multicast addresses is used for PIM-SSM. Within that address range, non-IGMPv3 messages are ignored, and any IGMPv3 exclude messages are ignored. These messages are ignored for all router interfaces, even those not configured for PIM-SSM. By default there is no PIM-SSM range specified on the router. If you choose the default keyword in the CLI when specifying the PIM-SSM range, you configure the range 232.0.0.0/8 and default PIM-SSM range for IPv6 is FF3x::/96. You can also choose to specify a different range for PIM-SSM by using a policy file.

To configure the PIM-SSM address range, use the following command:

```
configure pim ssm range [default | policy policy-name]
```

## PIM Snooping

PIM snooping provides a solution for handling multicast traffic on a shared media network more efficiently. In networks where routers are connected to a L2 switch, multicast traffic is essentially treated as broadcast traffic (see [Figure 142](#)).

**Figure 142: Multicast Without PIM Snooping**

*IGMP* snooping does not solve this flooding issue when routers are connected to a L2 switch. Switch ports are flooded with multicast packets. PIM snooping addresses this flooding behavior by efficiently replicating multicast traffic only onto ports which routers advertise the PIM join requests (see [Figure 143](#)).

**Figure 143: Multicast With PIM Snooping**

PIM snooping does not require PIM to be enabled. However, IGMP snooping must be disabled on VLANs that use PIM snooping. PIM snooping and MVR cannot be enabled on the same VLAN.

To enable PIM snooping on one or all VLANs, use the following command:

```
enable pim snooping [{vlan} name]
```

To disable PIM snooping on one or all VLANs, use the following command:

```
disable pim snooping [{vlan} name]
```

#### Note

PIM snooping can be enabled only between PIM SM enabled switches. It should not be enabled between PIM DM enabled switches.

## PIM Register Policy

This feature allows you to filter register messages based on the policy file configured at the First Hop Router (FHR) and Rendezvous Point (RP) in PIM-SM domain. You can use the register policy to filter out specific PIM register messages that have encapsulated specific (S,G) packets. This feature allows you to detect and deny malicious multicast packets from flowing into a multicast shared tree, and causing a potential service blackout. The PIM Register Policy feature is supported in both the PIM IPv4 and PIM IPv6 mode.

*Filtering at FHR*

- FHR receives the source multicast packet and sends a register message towards the RP. Before it sends the register message to the RP, the FHR checks the configured register filter policy. If the (S,G) is denied by the policy, the register will not send a message to the RP. The FHR adds the L3 entries to stop the packet from arriving at the CPU. An EMS message is logged.
- The FHR checks the register policy before generating a NULL register packet. If the policy is denied by the filter then the NULL register is not sent to the RP.
- If the cache's Group is in the SSM range, or is received in the PIM dense circuit, then this filtering is not applicable. The cache miss packet will go thru the normal processing.
- If a non-SSM (S,G) cache already exists but is denied by the filter policy, then (S,G) cache is removed. The cache miss comes to the CPU for register processing if the traffic is still flowing.

The PIM filtering policy is configured at the FHR using the `configure pim {ipv4 | ipv6} register-policy [policy | none]` command.

*Filtering at RP*

- When an encapsulated PIM register packet or PIM NULL register is received by the RP, and is denied by the registering filter policy, the register message is discarded. Additionally, no (S,G) cache is created in the PIM cache.
- The register drop counter is incremented, and the EMS message is logged.
- If a register is received from the *MSDP (Multicast Source Discovery Protocol)*, it also goes through the RP filtering policy.

The PIM filtering policy is configured at RP using the following command:

```
configure pim {ipv4 | ipv6} register-policy rp [rp_policy_name | none]
```

*Example*

PIM Register policy rules can be created only on the Source IP address and group address, as shown in the following.

*SAMPLE POLICY 1:*

If the matching entry is not found, then the entry permission is considered as denied. Need wildcard entries to permit the unmatched entries. The following policy file permits the matched entries and wildcard entries deny the unmatched source:

```
entry policy1 {
 if match any{
 nlri 10.10.10.0/24;
 nlri 20.20.20.0/24 ;
 } <= Permit these sources for group
 then {
 nlri 226.1.1.0/24;
 nlri 227.1.1.0/24;
 permit;
 }
}
```

```

entry policy2 {
 if match any{
 nlri 10.10.10.0/24;
 }
 then {
 nlri 228.1.1.0/24;
 permit;
 }
}

entry policy3 {
 if match any{
 }
 then {
 deny;
 }
}

```

*SAMPLE POLICY 2:*

The following policy file denies the matched entries and wildcard entry permits the unmatched source:

```

entry policy1 {
 if match any{
 nlri 10.10.10.0/24;
 nlri 20.20.20.0/24 ;
 }
 then {
 nlri 226.1.1.0/24;
 nlri 227.1.1.0/24;
 deny;
 }
}

entry policy2 {
 if match any{
 nlri 10.10.10.0/24;
 }
 then {
 nlri 228.1.1.0/24;
 deny;
 }
}

entry policy3 {
 if match any{
 }
 then {
 permit;
 }
}

```

*SAMPLE POLICY 3:*

The following policy file denies the matched entries and unmatched entries. Since the wildcard permit entry is not present in this policy file, by default all the unmatched entries are denied:

```

entry policy1 {
 if match any{
 nlri 10.10.10.0/24;
 }
}

```

```

 nlri 20.20.20.0/24 ;
 } <= deny these sources for group
 then {
 nlri 226.1.1.0/24;
 nlri 227.1.1.0/24;
 deny;
 }
}

entry policy2 {
 if match any{
 nlri 10.10.10.0/24;
 }
 then {
 nlri 228.1.1.0/24;
 deny;
 }
}

```

## PIM DR Priority

The DR\_Priority option allows a network administrator to give preference to a particular router in the DR election process by giving it a numerically larger DR Priority. The DR\_Priority option is included in every Hello message, even if no DR Priority is explicitly configured on that interface. This is necessary because priority-based DR election is only enabled when all neighbors on an interface advertise that they are capable of using the DR\_Priority Option. The default priority is 1.

DR Priority is a 32-bit unsigned number, and the numerically larger priority is always preferred. A router's idea of the current DR on an interface can change when a PIM Hello message is received, when a neighbor times out, or when a router's own DR Priority changes. If the router becomes the DR or ceases to be the DR, this will normally cause the DR Register state machine to change state. Subsequent actions are determined by that state machine.

The DR election process on the interface consists of the following:

- If any one of the neighbors on the interface is not advertised, the DR priority (not DR capable) will not be considered for all the neighbors in the circuit and the primary IP address will be considered for all the neighbors.
- Higher DR priority or higher primary address will be elected as DR.

Use the following command to configure PIM DR Priority:

```
configure pim {ipv4 | ipv6} {vlan} [vlan_name] dr-priority priority
```

## PIM ECMP Load Splitting

The PIM *ECMP* feature allows downstream PIM routers to choose multiple ECMP paths to source via hash from one of the following selections without affecting existing unicast routing algorithm:

- Source
- Group

- Source-Group
- Source-Group-Next Hop

This feature operates on a per (S,G) basis splitting the load onto available equal-cost paths by hashing according to the selection criteria configured by the user. It does not operate by counting the flows. Load splitting need not balance the traffic on the available paths. PIM ECMP load splitting uses a hash algorithm based on the selected criteria to pick up the path to use and will result in load-sharing the traffic when there are many multicast streams that utilize approximately the same amount of bandwidth.

#### *PIM ECMP Load Splitting Based on Source Address*

When you enable PIM ECMP load splitting based on source address, the RPF interface for each (\*, G) or (S,G) state is selected among the equal cost paths based on the hash derived from the source address. For an (S, G) state, the address considered for hashing is the source address of the state. For a (\*, G) state, the address considered for hashing is the address of the RP that is associated with the state's group address. There is no randomization applied when calculating the hash value. The same hash value is generated on all the ExtremeXOS routers for a given source address. If there are two equal cost paths ("left" and "right") available at the last hop router and at each of the intermediate routers for a given source, each of these routers pick the same hash, and the traffic flows can get skewed (to either "left" or "right" paths).

#### *PIM ECMP Load Splitting Based on Group Address*

When you enable PIM ECMP load splitting based on group address, the RPF interface for each (\*, G) or (S,G) state is selected among the equal cost paths based on the hash derived from the group address. If multiple equal cost common paths exist to the multicast source and the RP that is associated with the state's group address, the same hash will be chosen for both (\*, G) and (S, G) states as the same group address is used in deriving the hash. There is no randomization applied when calculating the hash value. The same hash value is generated on all the ExtremeXOS routers for a given group address. If there are two equal cost paths ("left" and "right") available at the last hop router and at each of the intermediate routers for a given group, each of these routers pick the same hash and the traffic flows can get skewed (to either "left" or "right" paths).

#### *PIM ECMP Load Splitting Based on Source-Group Addresses*

When you enable PIM ECMP load splitting based on source-group address, the RPF interface for each (\*, G) or (S,G) state is selected among the equal cost paths based on the hash derived from the source and group addresses. For an (S, G) state, the address considered for hashing is the source address of the state. For a (\*, G) state, the address considered for hashing is the address of the RP that is associated with the state's group address. There is no randomization applied when calculating the hash value. The same hash value is generated on all the ExtremeXOS routers for a given source-group address. If there are two equal cost paths ("left" and "right") available at the last hop router and at each of the intermediate routers for a given source-group, each of these routers pick the same hash and the traffic flows can get skewed (to either "left" or "right" paths).

### *PIM ECMP Load Splitting Based on Source-Group-Next Hop Addresses*

When you enable PIM ECMP load splitting based on source-group-next hop address, the RPF interface for each (\*, G) or (S,G) state is selected among the equal cost paths based on the hash derived from the source, group and next hop addresses. The hash value derived after introducing the next hop address is still predictable as there is no randomization applied when calculating the hash value. However, since the next hop address used at each of the routers vary, the hash value generated on each of the ExtremeXOS routers is different. As the hash value is different on each of the routers, the problem of traffic path skew present in the above mentioned schemes does not exist in this scheme.

### *Reconvergence Due to Unicast Routing Changes*

When a unicast route to a source or RP address changes (when a path goes down or a new path becomes available), all the (\*, G) and (S, G) states change based on the available unicast route information provided by Route Manager process. If one of the paths goes down and comes back up, multicast forwarding will reconverge to same RPF path that was used before the path went down. The hash function based on Source-Group-Next Hop avoids skewing of traffic flows because it introduces the actual next-hop IP address of PIM neighbors into the calculation resulting in different hash value being computed for each router. The Source-Group-Next Hop based hash function doesn't take the total number of available paths into consideration and so it increases stability of the paths chosen during path failures. During path failures, the multicast states that were using the failed path would need to reconverge onto the remaining paths. All other states using the unaffected paths are not affected.

### *Limitations*

- Cannot be used along with static multicast routes.
- Not supported for ExtremeXOS Multicast Tools (mtrace and mrinfo) in current release.
- Load splitting is not applied for configured static multicast routes and multicast routes present in the multicast routing table.
- Load splitting is only effective when the equal cost paths are upstream PIM neighbors on different interfaces. When the equal cost paths are PIM neighbors on the same shared VLAN, PIM assert mechanism chooses one path to avoid traffic duplication. The path chosen by PIM assert mechanism overrides the path selected by Multicast ECMP load splitting.

## IPv6 Specific Features

Apart from adding support for IPv6 addresses, PIMv6 adds the following functionality to existing PIM implementation:

- Secondary address list - This is a new option which will be added to the V6 Hello messages sent. The list includes all addresses assigned to an interface, including the link local addresses. The receiving router must process these addresses and must associate the same with the neighbor that sent the message.
- Tunnel interface - This is similar to a VLAN interface. APIs are now added to get callbacks from VLAN manager client for IP address configuration for a tunnel, etc.

### *Secondary address list*

The Address List Option, in a Hello message, advertises all the secondary addresses associated with the source interface of the router originating the message. These addresses are associated with the neighbor, and are used to compute the neighbor's primary address. The function NBR uses information gathered through PIM Hello messages to map the IP address A of a directly connected PIM neighbor on interface I to the primary IP address of the same router. The primary IP address of a neighbor is the address that it uses as the source of its PIM Hello messages.

### *Tunnel interfaces*

Two PIMv6 domains can be connected through an IPv4 network. In this case, PIMv6 routers across the domains communicate over the IPv4 network by tunneling the IPv6 packets inside IPv4 headers. To enable such communication, PIMv6 provides support for Tunnel interfaces.

The following tunnel types are supported:

- 6-in-4
- 6-to-4

### *Configuration details*

PIMv6 is incorporated into all CLI commands that currently support the PIM implementation. New keywords are added to support IPv6, and show command output is modified to display IPv6 related information. For specific configuration details, refer to the [Switch Engine v33.3.1 Command References](#).

## Anycast Rendezvous Point (RP) Using PIM (RFC 4610)

Anycast Rendezvous Point (RP) Using PIM (*RFC 4610*) provides fast convergence when RP routers fail using PIM protocol without using the source discovery protocol Multicast Source Discovery Protocol (MSDP) for both IPv4 and IPv6 address families.

This feature is useful when:

- Need support for IPv6 address family, which MSDP does not support.
- Interdomain connection is not required.
- Do not wish to deploy MSDP protocol.

The feature requires a Premier or Core license. For more information about licensing, see the [Switch Engine v33.3.1 Licensing Guide](#).

**Figure 144: Anycast RP Operation**

Anycast RP is a mechanism that provides fast convergence when a PIM RP node fails. Receivers and sources connect to the closest RP. The packets from a source need to get to all RPs to find joined receivers.

A unicast address is selected as the RP address. Multicast groups supported by the RP are configured using a policy file. This RP is configured either statically, or is dynamically distributed to the PIM domain using BSR protocol. To achieve the load balancing between the RPs, the same RP address is configured to multiple devices in a PIM domain. Sources and receivers connect to the nearest router selected by the L3 unicast routing protocols.

In the above topology, three RP nodes are configured with the same RP address. Receiver1 and Receiver2 choose RP1 as the nearest router. Receiver3 connects to RP2. When Source1 starts transmitting, Source1 node starts sending the register requests to RP1. The same sources should be known to other receivers, such as Receiver3. Typically, in IPv4, MSDP protocol is used to propagate the learned sources from RP1 to other RPs (RP2 and RP3) through MSDP messages.

In the above topology, each node configured with an Anycast RP address and a unique unicast IP address can communicate with other Anycast RP peers configured using the policy file (see [Anycast RP Using PIM Policy File Information](#)). Anycast RP addresses and the group of nodes' unique address bindings are called an Anycast RP set. Each RP communicates with other nodes in the same RP set.

#### *Anycast RP Using PIM Policy File Information*

The policy file contains a list of Anycast RP peer addresses, and should be in the following format. This same policy must be attached to all the RP Anycast RP peers participating in the Anycast RP set.

### Sample Policy File

```
entry policy1 {
 if match any{
 nlri 10.10.10.1/32;
 nlri 20.20.20.1/32;
 nlri 30.30.30.1/32;
 }
 then {
 permit;
 }
}
```

### Supported Platforms

This feature is available on platforms that support the appropriate license for the PIM feature. For complete information about software licensing, including how to obtain and upgrade your license and which licenses support the PIM feature, see the [Switch Engine v33.3.1 Licensing Guide](#).

### Limitations

The following limitation apply to this feature:

- Configuring MSDP peers between the Anycast RPs might not work as expected. Anycast RP Using PIM removes the dependence on using MSDP by removing MSDP peering between the Anycast-RPs.
- Register policy on an RP will reject the register source or groups mentioned in the policy file. If Anycast RP is configured on the same node, register policy takes precedence over the Anycast RP. Register policy filter is applied on all the PIM-Register messages received from either first hop router (FHR) or other Anycast RP peers.
- If RP is configured on an MLAG node, the peer node must not be configured as Anycast RP peer.

For information about:

- Configuring Anycast RP, see [Configuring Anycast RP Using PIM \(RFC 46010\)](#) on page 1169.
- Viewing Anycast RP information, see [Displaying Anycast Rendezvous Point \(RP\) Using PIM \(RFC 4610\)](#) on page 1189.

## PIM Multicast Routing Over GRE Tunnels

Version 32.3 adds the ability to configure IPv4 Protocol Independent Multicast (PIM) traffic over GRE tunnels. PIM control packets are exchanged between GRE tunnel endpoints, forming a PIM neighborhood across the GRE tunnel. Similar to IPv4 unicast support on GRE tunnels, multicast data packets are routed from a tenant interface to the far end of the IPv4 GRE tunnel. The IPv4 next-hop for the multicast packets is the IPv4 tunnel IP of the BGP neighbor.

### Supported Platforms

ExtremeSwitching 5520, 5720, 7520, and 7720 series switches

### Limitations

This feature has the following limitations:

- The maximum number of GRE tunnels supported is 64.
- The maximum number of VRs supported is 32.
- Routing across VRs is not supported.
- IPv6 multicast routing over tunnel is not supported.
- MSDP is not supported with this feature.
- Stacking is not supported with this feature.

## IGMP Overview

*IGMP* is a protocol used by an IP host to register its IP multicast group membership with a router. A host that intends to receive multicast packets destined for a particular multicast address registers as a member of that multicast address group. Periodically, the router queries the multicast group to see if the group is still in use. If the group is still active, a single IP host responds to the query, and group registration is maintained.

IGMPv2 is enabled by default on the switch, and the ExtremeXOS software supports IGMPv3. However, the switch can be configured to disable the generation of periodic IGMP query packets. IGMP should be enabled when the switch is configured to perform IP multicast routing.

IETF standards require that a router accept and process IGMPv2 and IGMPv3 packets only when the router-alert option is set in received IGMP packets.

By default, the ExtremeXOS software receives and processes all IGMP packets, regardless of the setting of the router-alert option within a packet. When the switch will be used with third-party switches that expect IETF compliant behavior, use the following command to manage this feature:

```
configure igmp router-alert receive-required [on | off] {{vlan}
vlan_name}
```

```
configure igmp router-alert transmit [on | off] {{vlan} vlan_name}
```

By default, IGMP report/leave message for the local multicast address (224.0.0.x/24 groups) will always have the router-alert option set, regardless of IGMP router-alert transmit option (on and off) setting by the user.

IGMPv3, specified in RFC 3376, adds support for source filtering. Source filtering is the ability for a system to report interest in receiving packets only from specific source addresses (filter mode include) or from all sources except for specific addresses (filter mode exclude). IGMPv3 is designed to be interoperable with IGMPv1 and IGMPv2.

### Note

The ExtremeXOS software supports IGMPv3 source include mode filtering, but it does not support IGMPv3 specific source exclude mode filtering.

## IGMP Snooping

IGMP snooping is a Layer 2 function of the switch; it does not require multicast routing to be enabled. In IGMP snooping, the Layer 2 switch keeps track of IGMP reports and only forwards multicast traffic to that part of the local network that requires it. IGMP snooping optimizes the use of network bandwidth and prevents multicast traffic from being flooded to parts of the local network that do not need it. The switch does not reduce any IP multicast traffic in the local multicast domain (224.0.0.x).

IGMP snooping is enabled by default on all VLANs and VMANs in the switch. If IGMP snooping is disabled on a VLAN or VMAN, all IGMP and IP multicast traffic floods within the VLAN or VMAN. IGMP snooping expects at least one device on every VLAN to periodically generate IGMP query messages.

To enable or disable IGMP snooping, use the following command:

```
enable igmp snooping {forward-mcrouter-only | {vlan} name | with-proxy
vr vrname}
```

```
disable igmp snooping {forward-mcrouter-only | {vlan} name | with-proxy
vr vrname}
```

### Note

IGMP snooping is not supported on SVLANs on any platform.

The IGMP snooping proxy feature represented by "with-proxy" in the above commands is enabled by default. This feature optimizes the forwarding of IGMPv1 and IGMPv2 reports. The following is true for each group:

- Only the first received IGMP join is forwarded upstream.
- Only the IGMP leave for last host is forwarded upstream.

When a switch receives an IGMP leave message on a port, it sends a group-specific query on that port if proxy is enabled (even if it is a non-querier). The switch removes the port from the group after leave timeout (The timeout value is configurable, with a default value of 1000 ms., and a range from 0 to 175000 ms). If all the ports are removed from the group, the group is deleted and the IGMP leave is forwarded upstream. If IGMP snooping proxy is disabled, then all the IGMP reports are forwarded upstream.

### Note

IGMP snooping proxy does not apply to IGMPv3 reports.

IGMP snooping is implemented primarily through ACLs, which are processed on the interfaces. These special purpose ACLs are called IGMP snooping hardware filters. The software allows you to choose between two types of IGMP snooping hardware filters: per-port filters (the default) and per-VLAN filters.

The two types of IGMP snooping hardware filters use switch hardware resources in different ways. The two primary hardware resources to consider when selecting the IGMP snooping hardware filters are the Layer 3 multicast forwarding table, and the interface ACL (Access Control List)s. The size of both of these hardware resources is determined by the switch model. In general, the per-port filters consume more

resources from the multicast table and less resources from the ACL table. The per-VLAN filters consume less space from the multicast table, and more from the ACL table.

Using the per-port filters can fill up the multicast table and place an extra load on the CPU. To avoid this, configure the switch to use the per-VLAN filters.

#### Note

The impact of the per-VLAN filters on the ACL table increases with the number of VLANs configured on the switch. If you have a large number of configured VLANs, we suggest that you use the per-port filters.

## IGMP Snooping Filters

*IGMP* snooping filters allow you to configure a policy file on a port to allow or deny IGMP report and leave packets coming into the port. (For details on creating policy files, see [Policy Manager](#) on page 1409.) The IGMP snooping filter feature is supported by IGMPv2 and IGMPv3.

#### Note

Do not confuse IGMP snooping filters with IGMP snooping hardware filters explained in previous section. IGMP snooping filters are software filters, and the action is applied at the software level by the ExtremeXOS multicast manager.

For the policies used as IGMP snooping filters, all the entries should be IP address type entries, and the IP address of each entry must be in the class-D multicast address space but should not be in the multicast control subnet range (224.0.0.x/24).

1. Use the following template to create a snooping filter policy file that denies IGMP report and leave packets for the 239.11.0.0/16 and 239.10.10.4/32 multicast groups:

```
#
Add your group addresses between "Start" and "end"
Do not touch the rest of the file!!!!
entry igmpFilter {
 if match any {
 #----- Start of group addresses -----
 nlri 239.11.0.0/16;
 nlri 239.10.10.4/32;
 #----- end of group addresses -----
 } then {
 deny;
 }
}
entry catch_all {
 if {
 } then {
 permit;
 }
}
```

2. After you create a policy file, use the following command to associate the policy file and filter to a set of ports:

```
configure igmp snooping vlan vlanname ports portlist filter [policy | none]
```

3. To remove the filter, use the **none** option.

4. To display the IGMP snooping filters, use the following command:

```
show igmp snooping {vlan} name filter
```

## Static IGMP

To receive multicast traffic, a host must explicitly join a multicast group by sending an *IGMP* report; then, the traffic is forwarded to that host. In some situations, you might like multicast traffic to be forwarded to a port where a multicast-enabled host is not available (for example, when you test multicast configurations).

Static IGMP emulates a host or router attached to a switch port, so that multicast traffic is forwarded to that port, and the switch sends a proxy join for all the statically configured IGMP groups when an IGMP query is received. You can emulate a host to forward a particular multicast group to a port; and you may emulate a router to forward all multicast groups to a port. Static IGMP is only available with IGMPv2.

- To emulate a host on a port, use the following command:

```
configure igmp snooping {vlan} vlan_name {ports port_list} add static
group ip_address
```

- To emulate a multicast router on a port, use the following command:

```
configure igmp snooping {vlan} vlan_name {ports port_list} add static
router
```

- To remove these entries, use the corresponding commands:

```
configure igmp snooping {vlan} vlan_name {ports port_list } delete
static group [ip_address | all]
configure igmp snooping vlan vlan_name {ports port_list } delete
static router
```

- To display the IGMP snooping static groups, use the following command:

```
show igmp snooping {vlan} vlan_name static [group | router]
```

## IGMP Loopback

Prior to ExtremeXOS 15.3.2, you could configure static groups, but it was necessary to specify port(s). As of ExtremeXOS Release 15.3.2, the configuration of dynamic groups is supported. The *IGMP* Loopback feature, along with the existing static group feature, supports the configuration of static and/or dynamic groups with or without ports.

A *VLAN* in loopback mode may not have ports associated with it, but its operational status is up. However, it is not possible to have multicast receivers on a VLAN without having a port. Sometimes there is a need to pull the multicast traffic from upstream to the loopback VLAN for troubleshooting. The traffic need not always be forwarded to any ports/receivers. The IGMP Loopback feature allows you to configure groups on a VLAN without specifying a port, so the traffic is pulled from upstream but not forwarded to any port.

The loopback (Lpbk) port is the logical port on a VLAN in the application context. If you configure a group on a VLAN but do not specify the port, the switch forms an IGMPv2 join and assumes it to be received on the Lpbk port. A dynamic group ages out after

the membership timeout if there are no other receivers. Membership joins refresh the dynamic group. The static group remains until it is removed from the configuration.

The following command is used to configure static or dynamic group entry :

```
configure igmp snooping {vlan} vlan_name {ports port_list} add [static |
dynamic] group ip_address
```

## Limiting the Number of Multicast Sessions on a Port

The default configuration places no limit on the number of multicast sessions on each VLAN port. To place a limit on the number of learned MLD reports, or remove the limit, use the command:

```
configure mld snooping {vlan} vlan_name ports port_list join-limit
[num_joins | no-limit]
```

## Enabling and Disabling IGMP Snooping Fast Leave

When the fast leave feature is enabled and the last host leaves a multicast group, the router immediately removes the port from the multicast group. The router does not query the port for other members of the multicast group before removing the group, and/or the port.

The default setting for IGMP snooping fast leave is disabled.

- To enable the fast leave feature, use the following command:

```
enable igmp snooping {vlan} name fast-leave
```

- To disable the fast leave feature, use the following command:

```
disable igmp snooping {vlan} name fast-leave
```

## IGMP-SSM Mapping

The IGMP-SSM Mapping feature allows IGMPv1 and IGMPv2 hosts to participate in SSM functionality, and eliminates the need for IGMPv3. You can configure SSM map entries that specify the sources used for a group/group range for which SSM functionality has to be applied. You also have the option to configure the domain name and DNS server to use to obtain the source list.

When a IGMPv1 or IGMPv2 report is received, the configured sources are provided to PIM so that it can send source specific joins. When the host leaves or when the membership times out, PIM is informed so that it can consider sending prunes.

In a multi-access network (where more than one router is receiving IGMP messages from the hosts), only the designated router sends joins towards the source, so it is desirable to have same configuration for SSM group range and SSM Mapping range on all routers in a VLAN.

### Limitations

The following limitations apply:

- A single group address or range can be mapped to a maximum of 50 sources. If more than 50 sources are configured, the switch uses the 50 longest-matching prefixes.
- We recommend a maximum of 500 mappings per switch, but no limit is imposed by the software.

### Limitations

The following features of Change-of-Authorization (RFC5176) are not implemented in ExtremeXOS:

- Reverse Path Forwarding Check—Typically this is used in a proxy scenario. This check is used to determine if the IP address indicated by the *RADIUS (Remote Authentication Dial In User Service)* attributes is a routable destination address for a request sent by the switch software.
- IPSEC encryption—End-to-end encryption of both the RADIUS requests and responses.
- Disconnect-Request and Change-of-Authorization packets identifying sessions with anything other than the Calling-Station-Id attribute containing a properly formatted MAC address. In addition to the Calling-Station-ID attribute, you can also use a NAS-Port attribute, which indicates the index of the specific port the session is connected to.
- Acct-Session-Id attribute—This is an alternate means of session identification. Sessions are currently uniquely identified by port and MAC address pair.
- Retransmissions of Disconnect-Request or Change-of-Authorization ACK and NAK packets—Retransmissions of packets is the responsibility of the device initiating the dynamic authorization transactions.

### Configuring IGMP-SSM Mapping

To support PIM-SSM for IGMPv1 and IGMPv2 clients, a PIM-SSM range must be configured, and that range should include all groups to which the clients want access. If IGMPv1 and IGMPv2 clients request group addresses outside the PIM-SSM range, those addresses are ignored by PIM-SSM and forwarded to PIM as (\*, G) requests.

- To enable *IGMP-SSM* mapping, first configure a PIM-SSM range, and then enable IGMP-SSM mapping using the following commands:

```
configure pim ssm range [default | policy policy-name]
enable igmp ssm-map {vr vr-name}
```

- To configure an IGMP-SSM mapping, use the following command:

```
configure igmp ssm-map add group_ip [prefix | mask] [source_ip | src_domain_name] {vr vr-name}
```

- To remove a single IGMP-SSM mapping, use the following command:

```
configure igmp ssm-map delete group_ip [prefix } | mask] [source_ip | all] vr vr-name }
```

- To remove all IGMP-SSM mappings on a , use the following command:  
`unconfigure igmp ssm-map {vr vr-name}`
- To disable IGMP-SSM mapping on a virtual router, use the following command:  
`disable igmp ssm-map {vr vr-name}`

#### Displaying IGMP-SSM Mappings

To see whether or not IGMP-SSM mapping is enabled or disabled and to view the configured mappings for a multicast IP address, use the following command:

```
show igmp ssm-map {group_ip} {vr vr-name}
```

## IGMP Statistics

To view IGMP counters, use the following command:

```
show igmp counters
```

To clear IGMP counters, use the following command:

```
clear igmp counters
```

## Configuring EAPS Support for Multicast Traffic

The ExtremeXOS software provides several commands for configuring how EAPS (Extreme Automatic Protection Switching) supports multicast traffic after an EAPS topology change. For more information, see the descriptions for the following commands:

```
configure eaps multicast add-ring-ports [on | off]
```

```
configure eaps multicast send-query [on | off]
```

```
configure eaps multicast temporary-flooding [on | off]
```

These commands apply for both IGMP and MLD.

#### Note

Using the `configure eaps multicast send-query` command applies to both IGMP and MLD. This also replaces the `configure eaps multicast send-igmp-query` command.

## Configuring IP Multicast Routing

### Enabling Multicast Forwarding

To enable IP multicast forwarding:

1. Configure the system for IP unicast routing.
2. Enable multicast forwarding on the interface.

```
enable ipmcforwarding {vlan name}
```

## Configuring PIM

To configure PIM multicast routing, enable multicast forwarding as described in [Enabling Multicast Forwarding](#) on page 1167 and do the following:

1. Configure PIM on all IP multicast routing interfaces using the following command:  

```
configure pim {ipv4 | ipv6} add vlan [vlan-name | all] {dense | sparse} {passive}
```
2. To enable and configure the PIM-DM state refresh feature on one or all VLANs, use the following commands:  

```
configure pim {ipv4 | ipv6} state-refresh {vlan} [vlan_name | all] [on | off]
```

```
configure pim { ipv4 | ipv6 } state-refresh timer origination-interval interval
```

```
configure pim {ipv4 | ipv6} state-refresh timer source-active-timer interval
```

```
configure pim {ipv4 | ipv6} state-refresh ttl ttlvalue
```
3. For PIM-SSM, specify the PIM-SSM range, enable IGMPv3, and enable PIM-SSM on the interfaces using the following commands:  

```
configure pim {ipv4 | ipv6} ssm range [default | policy policy-name]
```

```
enable igmp {vlan vlan name } {IGMPv1 | IGMPv2 | IGMPv3}
```

```
enable pim {ipv4 | ipv6} ssm vlan [vlan_name | all]
```
4. Enable PIM on the router using the following command:  

```
enable pim
```

## Configuring Multicast Static Routes

### Note

Multicast static routes are supported in the IPv4 address family, but not the IPv6 address family.

Static routes are used to reach networks not advertised by routers, and are manually entered into the routing table.

- You can use either of two commands to create multicast static routes. The recommended command is the following:

```
configure iproute add [ipNetmask | ip_addr mask] gateway {bfd} {metric} {multicast | multicast-only | unicast | unicast-only} {vr vrname}
```

For example:

```
configure iproute add 55.1.10.0/24 44.1.12.33 multicast
```

- The following command is still supported for backward compatibility with earlier ExtremeXOS software releases:

```
configure ipmroute add [source-net mask-len | source-net mask] {{protocol} protocol} rpf-address {metric} {vr vr-name}
```

In the following example, the `configure ipmroute add` command is used to specify protocol information for a route:

```
configure ipmroute add 58.1.10.0/24 ospf 44.1.12.33
```

**Note**

Ipmroute not supported for IPv6.

When a static route is configured with protocol information, the route is shown as UP only when the protocol route is available. Otherwise, the route is Down. In the example above, the multicast static route 58.1.10.0/24 is shown as UP only when the *OSPF* route is available to reach the network 58.1.10.0/24.

Static routes are stored in the switch configuration and can be viewed with the `show configuration` command. Static multicast routes that do not include protocol information are displayed using the `configure iproute` command format, even if they were created using the `configure ipmroute` command. Static routes that are created with a protocol field are displayed using the `configure ipmroute` command format.

## Disabling IP Multicast Compression

The IP multicast compression feature is enabled by default. You should only disable this feature if you suspect that switch processing resources are limited or if you think this feature is causing problems on the switch.

- To disable or enable IP multicast compression, use the following command:

```
configure forwarding ipmc compression {group-table | off}
```

## Configuring Anycast RP Using PIM (RFC 46010)

To configure or remove Anycast RPs, use the following command:

```
configure pim {ipv4 | ipv6} anycast-rp ip_address [policy | none]
```

## Multicast Over MLAG Configuration

For sample topology for , see [Layer 3 IP Multicast using PIM-SM](#).

## PIM Configuration Examples

### *PIM-DM Configuration Example*

In [Figure 145](#), the system labeled IR 1 is configured for IP multicast routing, using PIM-DM.

**Figure 145: IP Multicast Routing Using PIM-DM Configuration Example**

**Note**

The above figure is used in the [the OSPF section](#) to describe the *OSPF* configuration on a switch.

The router labeled IR1 has the following configuration:

```
configure vlan HQ_10_0_1 ipaddress 10.0.1.2 255.255.255.0
configure vlan HQ_10_0_2 ipaddress 10.0.2.2 255.255.255.0
configure ospf add vlan all area 0.0.0.0
enable ipforwarding
enable ospf
enable ipmcforwarding
configure pim add vlan all dense
enable pim
configure pim state-refresh vlan all on
```

### *PIM-SM Configuration Example*

In [Figure 146](#), the system labeled ABR1 is configured for IP multicast routing using PIM-SM.

**Figure 146: IP Multicast Routing Using PIM-SM Configuration Example**

**Note**

The above figure is used in [the OSPF section](#) to describe the *OSPF* configuration on a switch.

The router labeled ABR1 has the following configuration:

```
configure vlan HQ_10_0_2 ipaddress 10.0.2.1 255.255.255.0
configure vlan HQ_10_0_3 ipaddress 10.0.3.1 255.255.255.0
configure vlan LA_161_48_2 ipaddress 161.48.2.2 255.255.255.0
configure vlan CHI_160_26_26 ipaddress 160.26.26.1 255.255.255.0
configure ospf add vlan all area 0.0.0.0
enable ipforwarding
enable ipmcforwarding
configure pim add vlan all sparse
tftp TFTP_SERV -g -r rp_list.pol
configure pim crp HQ_10_0_3 rp_list 30
configure pim cbsr HQ_10_0_3 30
```

The policy file, `rp_list.pol`, contains the list of multicast group addresses serviced by this RP. This set of group addresses are advertised as candidate RPs. Each router then elects the common RP for a group address based on a common algorithm. This group to RP mapping should be consistent on all routers.

The following is a policy file that configures the CRP for the address ranges 239.0.0.0/24 and 232.144.27.0:

```
entry extremel {
 if match any {
 }
 then {
 nlri 239.0.0.0/24 ;
 }
}
```

```

 nlri 232.144.27.0/24 ;
 }
}

```

### PIM-SSM Configuration Example

In the following example, the default PIM-SSM range of 232.0.0.0/8 is configured. For all interfaces, non-IGMPv3 messages and IGMPv3 exclude messages are ignored for addresses in this range. Hosts that use IGMPv3 on VLAN v13 can request and receive source specific multicast streams for addresses in the PIM-SSM range.

```

create vlan v12
create vlan v13
configure v12 add port 1
configure v13 add port 2
configure v12 ipaddress 12.1.1.1/24
configure v13 ipaddress 11.1.1.1/24
configure pim add vlan all sparse
enable ipforwarding
enable ipmcforwarding
enable igmp IGMPv3
configure pim ssm range default
enable pim ssm vlan v13
enable pim

```

#### Note

(\*;G)s are created for groups outside the SSM range. SSM may not be enabled for the ingress VLAN (see [Table 79](#) on page 1146).

### PIM Snooping Configuration Example

[Figure 147](#) shows a network configuration that supports PIM snooping.

**Figure 147: PIM Snooping Configuration Example**

In [Figure 147](#) Layer 3 switches S2, S3, S4, and S5 are connected using the Layer 2 switch S1 through the VLAN comm\_vlan. Switches S3, S4, and S5 are multicast capable switches, and switch S2 is a non-multicast capable switch, which has no multicast routing protocol running.

Without PIM snooping, any ingress multicast data traffic on comm\_vlan is flooded to all the switches, including switch S2, which does not support multicast traffic. *IGMP* snooping does not reduce flooding because it floods the multicast traffic to all router ports.

The network design calls for most multicast traffic to egress switch S5. PIM snooping helps by intercepting the PIM joins received from the downstream routers and forwarding multicast traffic only to those ports that received PIM joins.

### Switch S1 (PIM Snooping Switch) Configuration Commands

The following is an example configuration for the PIM snooping switch S1:

```
create vlan comm_vlan
configure vlan comm_vlan add port 1,2,3,4
disable igmp snooping
disable igmp_snooping comm_vlan
enable pim snooping
enable pim snooping comm_vlan
```

### Switch S3 Configuration Commands

The following is an example configuration for switch S3, which also serves as an RP:

```
create vlan comm_vlan
configure vlan comm_vlan add port 1
configure comm_vlan ipa 10.172.168.4/24
enable ipforwarding comm_vlan
enable ipmcforwarding comm._vlan
configure pim add vlan comm_vlan sparse
configure ospf add vlan comm._vlan area 0.0.0.0

create vlan sender_vlan
configure vlan sender_vlan add port 2
configure sender_vlan ipa 10.172.169.4/24
enable ipforwarding comm_vlan
enable ipmcforwarding comm._vlan
configure pim add vlan comm._vlan sparse
configure ospf add vlan comm_vlan area 0.0.0.0

enable pim
enable ospf

configure pim crp static 10.172.169.4 pim_policy // RP is configured using the policy
pim_policy for the group 224.0.0.0/4
```

### Switch S5 Configuration Commands

The following is an example configuration for switch S5, which serves as the last hop router for multicast traffic:

```
create vlan comm_vlan
configure vlan comm_vlan add port 1
configure comm_vlan ipa 10.172.168.2/24
enable ipforwarding comm_vlan
enable ipmcforwarding comm._vlan
configure pim add vlan comm_vlan sparse
configure ospf add vlan comm._vlan area 0.0.0.0

create vlan receiver_vlan
configure vlan sender_vlan add port 1
configure sender_vlan ipa 10.172.170.4/24
```

```

enable ipforwarding comm_vlan
enable ipmcforwarding comm._vlan
configure pim add vlan comm._vlan sparse
configure ospf add vlan comm_vlan area 0.0.0.0

enable pim
enable ospf

configure pim crp static 10.172.169.4 pim_policy // RP is configured using the policy
pim_policy for the group 224.0.0.0/4

```

### Switch S4 Configuration Commands

The following is an example configuration for switch S4, which is neither an LHR nor a RP:

```

create vlan comm_vlan
configure vlan comm_vlan add port 1
configure comm_vlan ipa 10.172.168.3/24
enable ipforwarding comm_vlan
enable ipmcforwarding comm._vlan
configure pim add vlan comm_vlan sparse
configure ospf add vlan comm._vlan area 0.0.0.0

enable pim
enable ospf

configure pim crp static 10.172.169.4 pim_policy // RP is configured using the policy
pim_policy for the group 224.0.0.0/4

```

### Switch S2 Configuration Commands

The following is an example configuration for switch S2, which is not enabled for PIM:

```

create vlan comm_vlan
configure vlan comm_vlan add port 1
configure comm_vlan ipa 10.172.168.6/24
enable ipforwarding comm_vlan
enable ipmcforwarding comm._vlan
configure ospf add vlan comm._vlan area 0.0.0.0

enable ospf

```

### PIM Snooping Example Configuration Displays

After the example configuration is complete, multicast receivers connect to the network through switch S5 and multicast sources connect through switch S3.

When switch S5 receives an IGMP request from the receiver\_vlan for group 225.1.1.1, it sends a PIM (\*, G) join towards switch S3, which is the RP. The PIM snooping feature on switch S1 snoops the (\*, G) join, and the resulting entry can be viewed by entering the following command at switch S1:

```

show pim snooping vlan comm_vlan
PIM Snooping ENABLED
Vlan comm_vlan(3971) Snooping ENABLED
Source Group RP UpPort DownPort Age HoldTime
* 225.1.1.1 10.172.169.4 1 2 15 210
Neighbor IP DR Port Age Hold Time
10.1272.168.4 YES 1 2 105
10.1272.168.2 NO 2 2 105
10.1272.168.3 NO 3 2 105

```

Once multicast traffic arrives from the sender\_vlan, the LHR (switch S2) sends the (S, G) join message, which is snooped by the PIM snooping switch, switch S1. The resulting entries can be viewed by entering the following command at switch S1:

```
show pim snooping vlan comm_vlan
PIM Snooping ENABLED
Vlan comm_vlan(3971) Snooping ENABLED
Source Group RP UpPort DownPort Age HoldTime
* 225.1.1.1 10.172.169.4 1 2 15 210
10.172.169.10 225.1.1.1 10.172.169.4 1 2 15 210
Neighbor IP DR Port Age Hold Time
10.1272.168.4 YES 1 2 105
10.1272.168.2 NO 2 2 105
10.1272.168.3 NO 3 2 105
```

Multicast traffic is forwarded only to those ports that have received (\*, G) or (S, G) joins and designated router (DR) ports.

## Configuring PIM Multicast Routing Over GRE Tunnels

The following commands support this feature:

To configure a PIM tunnel, use `configure pim {ipv4} add {tunnel} [tunnel_name | tunnel all] {sparse | dense} {passive}`

To delete a PIM tunnel, use `configure pim {ipv4} delete tunnel [tunnel_name | tunnel all]`

To configure a PIM timer, use `configure pim {ipv4} timer hello_interval jp_interval [{tunnel} tunnel_name | tunnel all]`

To configure a PIM dr-priority, use `configure pim {ipv4} [{tunnel} tunnel_name | tunnel all] dr-priority priority`

To disable IPMC forwarding tunnels, use `disable ipmcforwarding {tunnel tunnel_name}`

To disable a PIM SSM, use `disable pim {ipv4} ssm tunnel [tunnel_name | tunnel all]`

To enable IPMC forwarding tunnels, use `enable ipmcforwarding {tunnel tunnel_name}`

To enable a PIM SSM tunnel, use `enable pim {ipv4} ssm tunnel [tunnel_name | tunnel all]`

To display PIM tunnel information, use `show pim tunnel`

To unconfigure a PIM tunnel, use `unconfigure pim {ipv4}{tunnel tunnel_name}`

## Multicast VLAN Registration

Multicast VLAN Registration (MVR) is designed to support distributing multicast streams for IPTV to subscribers over a Layer 2 network. In a standard Layer 2 network, a multicast stream received on a VLAN is not forwarded to another VLAN. The streams are confined to the Layer 2 broadcast domain. In an *IGMP* snooping environment, streams are forwarded only to interested hosts on a VLAN. For inter-VLAN forwarding (routing) a multicast routing protocol, such as PIM/DVMRP must be deployed.

MVR breaks this basic rule, so that a stream received over Layer 2 VLANs is forwarded to another VLAN, eliminating the need for a Layer 3 routing protocol. It simplifies the multicast stream distribution and is a better solution for IPTV-like services. With MVR, a multicast stream is forwarded to all VLANs containing interested hosts.

**Figure 148: Standard VLAN Compared to an MVR VLAN**

In the above figure, the left side shows a standard VLAN carrying a multicast stream.

The host H1 receives the multicast stream because it resides on VLAN Vlan1, but host H2 does not receive the multicast traffic because no IP multicast routing protocol forwards the stream to VLAN Vlan2. On the right side of the figure, H2 does receive the multicast stream. Because Vlan1 was configured as an MVR VLAN, the multicast stream is forwarded to the other VLANs on the switch, containing hosts that have requested the stream. To configure a VLAN as an MVR VLAN, use the following command:

```
configure mvr add vlan vlan-name
```

Typically, IGMP snooping is enabled, so only hosts that have requested a stream can see the multicast traffic. For example, another host on VLAN2 cannot receive the traffic unless it has sent an IGMP request to be included in the group.

Notice that only VLAN1 is MVR enabled. Configure MVR only on the ingress VLAN. To enable MVR on the switch, use the following command: `enable mvr`

## Basic MVR Deployment

Because MVR is primarily targeted for IPTV and similar applications, a basic deployment for that application is shown [Figure 149](#). In the figure, an IPTV server is

connected through a router to a network of switches. Switch 1 has three customer VLANs, Vlan2, Vlan3, and Vlan4. The multicast streams are delivered through the network core (Metro Ethernet), which often use a ring topology and some kind of redundant protection to provide high availability. For example, McastVlan forms a ring through switches Switch1 through Switch4. The link from Switch2 to Switch4 is shown as blocked, as it would be if some form of protection (such as *EAPS*) is used.

**Figure 149: Basic MVR Deployment**

Without MVR, there are two ways to distribute multicast streams in this topology:

- Extend subscriber *VLANs* (Vlan2, Vlan3, and Vlan4) to the network core, by tagging the ports connecting the switches.
- Configure all VLANs with an IP address and run PIM or DVMRP on each switch.

There are problems with both of these approaches. In the first approach, multiple copies of the same stream (IPTV channel) would be transmitted in the core, wasting bandwidth. In the second approach, all switches in the network core would have to be Layer 3 multicast aware, and would have to run a multicast protocol. Typical network cores are Layer 2 only.

MVR provides a simple solution to this problem. If McastVlan in Switch1 is configured with MVR, it leaks the traffic into the local subscriber VLANs that contain hosts that request the traffic. For simple cases, perform these configuration steps:

- Configure MVR on McastVlan.
- Configure an IP address and enable *IGMP* and IGMP snooping on the subscriber VLANs (by default IGMP and IGMP snooping are enabled on Extreme Networks switches).

- For all the multicast streams (IPTV channels), configure static IGMP snooping membership on the router on McastVlan.
- Enable MVR on the switches in the network.

**Note**

MVR works best with IGMPv1 and IGMPv2. We recommend that you do not use MVR with IGMPv3.

The strategy above conserves bandwidth in the core and does not require running PIM on the subscriber switches.

In this topology, a host (for example, a cable box or desktop PC) joins a channel through an IGMP join message. Switch1 snoops this message and adds the virtual port to the corresponding cache's egress list. This is possible because an MVR enabled VLAN can leak traffic to any other VLAN. When the user switches to another channel, the host sends an IGMP leave for the old channel and a join for the new channel. The corresponding virtual port is removed from the cache for the old channel and is added to the cache for the new channel.

As discussed in [Static and Dynamic MVR](#) on page 1178, McastVlan also proxies IGMP joins learned on other VLANs to the router. On an MVR network it is not mandatory to have a router to serve the multicast stream. All that is required is to have a designated IGMP querier on McastVlan. The IPTV server can also be directly connected to McastVlan.

### *Static and Dynamic MVR*

#### **Static MVR**

In a typical IPTV network, there are several high demand basic channels. At any instant there is at least one viewer for each of these channels (streams), and they should always be available at the core (ring). When a user requests one of these channels, it is quickly pulled locally from the multicast VLAN. You have the option to use the static router configuration in each of the switches in the core. But this will cause all the channels to be available in the core, which may not be desired. For example, on an Extreme Networks router, you can use the following commands:

```
configure igmp snooping {vlan} vlan_name ports port_list add static
router
```

You can use the static MVR configuration and choose the groups for which the multicast stream should be flooded. If a multicast stream for a group in the static MVR range is received on an MVR enabled VLAN, it is always flooded on the MVR VLAN. This allows the neighbor switch in the ring to receive all the static MVR streams.

#### **Dynamic MVR**

In contrast, since a video content provider would like to provide a variety of on-demand and other premium channels, there are often many lower demand (fewer viewers) premium channels that cannot all be made available simultaneously at the core network. These should be streamed from the router only if requested by a host.

IGMP is the standard method used by a host to request a stream. However, IGMP packets are constrained to a VLAN. Thus, subscribers' IGMP join requests on the VLAN cannot be forwarded onto other VLANs. You can use a dynamic MVR configuration, and choose the groups for which the IGMP join requests should be proxied over the MVR VLAN. Thus, in [Figure 1](#), McastVlan sends join and leave messages on behalf of Vlan2, Vlan3, and Vlan4. The router receives the messages on McastVlan and streams corresponding channels onto the core network. This provides on-demand service, and an administrator does not need to configure static IGMP on the router for each of these channels.

### Configuring MVR Address Range

By default, all multicast groups belong to MVR address range. Use the following command to specify the MVR address range:

```
configure mvr vlan vlan-name mvr-address {policy-name | none}
```

- Only the groups listed in the policy with "allow" action belong to MVR address range.
- For non-MVR groups, snoop cache is created and join requests are not proxied over MVR VLAN.

### Configuring Static and Dynamic MVR

By default, all MVR streams are static.

- Use the following command to specify which groups are static:  

```
configure mvr vlan vlan-name static group {policy-name | none}
```

  - Only the groups listed in policy with "allow" action are static. Any other groups in MVR address range are dynamic.
  - The groups in policy with "deny" action are dynamic. Any other groups in MVR address range are also dynamic, unless explicitly configured in the policy with "allow" action.
  - A group should not be configured to be both static and dynamic.

### MVR Configuration Example

The following example configuration is a two DUT scenario, in L2 mode, with no routing protocol or PIM configured.

- DUT-1 is sender
- DUT-2 is receiver
- VLAN v1 spans over DUT-1 and DUT-2, DUT-2 also has v2 where IGMP joins are coming IN (225.1.1.1)
- DUT-2 has a VLAN v3, which also has a receiver connected sending IGMP join for same group as v2 (225.1.1.1)
- VLAN v1 in the DUT-2 has another port apart from the trunk port, no joins are being sent on this port.

Configure MVR on vlan v1 on DUT-2

```
show config "mcmgr"
#
Module mcmgr configuration.
#
```

```
enable mvr vr VR-Default
configure mvr add vlan v1
configure mvr vlan v1 mvr-address none
configure mvr vlan v1 static group none*
*5420F-48P-4XE.158 #
```

The traffic will be flooded for the group only on MVR vlan (v1).

Since there are IGMP joins coming in on v2 and v3, v2, v3, and the second port in the MVR vlan v1 will receive traffic.

Configure the following policy file;

```
vi mvrPolicy.polentry policy1 {
if match any {
 nlri 225.1.1.1/24;
} then {
 permit;
}
}

```

When applying this policy file under static group on DUT-2

```
configure mvr vlan v1 static group mvrPolicy
#configure mvr vlan v1 mvr-address none
```

When the policy file contains "permit", the traffic flows to v2, v3, and the second port in MVR VLAN.

When the policy file is changed to "deny", the second port in the MVR VLAN v1 will stop receiving the traffic.

If you configure static policy (by default – permit), traffic for that group range will always be available in the MVR VLAN, that is, it will be forwarded to all the ports in MVR VLAN.

When applying this policy file under mvr-address (Dynamic) on DUT-2:

```
configure mvr vlan v1 static group none
configure mvr vlan v1 mvr-address mvrPolicy
```

When the policy file contains "permit", the traffic flows to v2,v3 and the second port in MVR vlan.

When the policy file is changed to "deny", the second port in MVR VLAN v1 continues receiving traffic, but VLAN v2 and v3 stop receiving traffic, in spite of IGMP groups being learned. This is because the join on v2 and v3 will not be leaked to MVR VLAN.

Essentially, the dynamic policy does not directly apply on traffic, but it affects the joins, based on which traffic is forwarded or blocked.

Dynamic means only if the join is sent then traffic is forwarded.

The join is leaked to MVR VLAN so traffic from MVR VLAN will be received by other VLANs (v2 and v3).

To confirm if a join was leaked to MVR VLAN use the `show igmp group` command. It should have the group learned on MVR VLAN (v1) with port as "MVR".

### MVR Forwarding

The goal for MVR is to limit the multicast traffic in the core Layer 2 network to only the designated multicast VLAN. If the backbone Layer 2 port is tagged with multiple VLANs, as shown in [Figure 150](#) on page 1181, a set of rules is needed to restrict the multicast streams to only one VLAN in the core.

**Figure 150: Multiple VLANs in the Core Network**

The core network has 2 more VLANs, vc1 and vc2, to provide other services. With MVR, multicast traffic should be confined to McastVlan, and should not be forwarded to vc1 and vc2. It should be noted that MVR is configured only on the ingress VLAN (McastVlan). MVR is not configured on any other VLANs.

In the same way as the IGMP snooping forwarding rules, the multicast stream is forwarded onto member ports and router ports on the VLAN. For a stream received on MVR enabled ports, this rule is extended to extend membership and router ports to all other VLANs. This rule works well on the topology in [Figure 150](#). However, in a tagged core topology, this rule forwards traffic onto VLANs, such as vc1 and vc2, on ports PC1 and PC2. This results in multiple copies of same stream on the core network, thus reintroducing the problem that MVR was intended to solve.

To avoid multiple copies of the same stream, MVR forwards traffic with some special restrictions. MVR traffic is not forwarded to another VLAN unless a host is detected on the port. On the ingress MVR VLAN, packets are not duplicated to ports belonging to MVR VLANs. This is to prevent duplicate multicast traffic streams on ingress ports. Streams belonging to static MVR groups are always forwarded on MVR VLANs so that any host can join such channels immediately. However, dynamic groups are streamed from the server only if some host is interested in them. A command is provided to receive traffic on a port which is excluded by MVR. However, regular IGMP rules still apply to these ports, so the ports must have a router connected or an IGMP host to receive the stream.

These rules are to prevent multicast packets from leaking into an undesired virtual port, such as p2 on VLAN pc2 in [Figure 150](#). These rules also allow that, in most topologies, MVR can be deployed with minimal configuration. However, unlike EAPS and STP

(*Spanning Tree Protocol*), MVR is not intended to be a Layer 2 protocol to solve packet looping problems. Since multicast packets leak across VLANs, one can misconfigure and end up with a multicast storm. MVR does not attempt to solve such problems.

#### Note

If a port is blocked by Layer 2 protocols, that port is removed from the egress list of the cache. This is done dynamically per the port state.

For most situations, you do not need to manually configure ports to receive the MVR multicast streams. But if one of the forwarding rules denies forwarding to a port that requires the streams, you can manually receive the MVR multicast streams by using the following command:

```
configure mvr vlan vlan_name add receiver port port-list
```

## Inter-Multicast VLAN Forwarding

In [Basic MVR Deployment](#), only simple topologies are considered, in which subscribers on different VLANs access a multicast VLAN. There are topologies where streams need to be forwarded onto another multicast VLAN, as shown in [Figure 151](#). In this figure, a Multicast Service Provider (MSP) multicast VLAN is attached to ports 1:1-2 on both switches, SW1 and SW2. On the customer side, another multicast VLAN, delivers multicast streams to other MSP switches around the ring.

**Figure 151: Inter-Multicast VLAN Forwarding**

In this topology, a multicast stream can be leaked into the customer multicast network through either switch SW1 or SW2. However, as described in [MVR Forwarding](#) on page 1181, packets are not forwarded to router ports (ports 1:4 and 1:5 can be router ports if SW2 is an *ICMP* querier). To get around this, MVR needs to be configured on CustVlan either on SW1 or SW2. Since the forwarding rules apply only to non-MVR VLANs, traffic from one MVR VLAN is leaked into the router ports of another VLAN, if MVR is enabled on that.

In the topology above, the MSP multicast VLAN is carried on two switches that also carry the customer multicast VLAN. When multiple switches carry both multicast VLANs, it is imperative that MVR is configured on only one switch. Only that switch should be used as the transit point for multicast streams from one multicast ring into another. Otherwise, duplicate packets are forwarded. Also on the non-MVR switches, the ring ports should be configured as static router ports, so that ring ports are excluded from forwarding packets onto the customer ring. There is no mechanism to elect a designated MVR forwarder, so it must be configured correctly.

## MVR Configurations

MVR enables Layer 2 network installations to deliver bandwidth intensive multicast streams. It is primarily aimed at delivering IPTV over Layer 2 networks, but it is valuable in many existing [EAPS](#) or [STP](#) installations. This section explores a few possible deployment scenarios and configuration details. Of course, real world networks can be lot different from these examples. This section is meant to present some ideas on how to deploy MVR over existing networks, as well as to design new networks that support MVR.

### *MVR with EAPS*

Since MVR is designed with a Layer 2 ring topology in mind, it is strongly recommended that it should be deployed with [EAPS](#). The MVR plus EAPS combination provides a superior solution for any triple play network, where the service provider intends to provide data, voice, and video services. EAPS is a proven solution for providing sub-second SONET-like protection to Layer 2 rings. For more detail on EAPS refer to [EAPS](#).

Consider a typical EAPS topology in [Figure 152](#), where 3 VLANs on the core ring serve various clients on each switch. To provide video service, one of the VLANs on the EAPS ring is designated as a multicast VLAN. MVR is enabled only on this VLAN (mcastvlan). V1 is the control VLAN, and V2 is another protected VLAN. A router serving the multicast feed would typically run PIM on mcastvlan, to support the static and dynamic [IGMP](#) membership on the VLAN.

**Figure 152: MVR on an EAPS Ring**

The following is a typical configuration for the router and switches.

**Router1:**

```
create vlan mcastvlan
configure mcastvlan add port 1:1
create vlan server
configure server add port 1:2
configure mcastvlan ipaddress 10.1.1.1/24
configure server ipaddress 11.1.1.1/24
configure igmp snooping mcastvlan port 1:1 add static group 239.1.1.1
enable ipforwarding
enable ipmcforwarding
configure igmp snooping leave-timeout 2000
configure pim add vlan all
enable pim
```

**Switch1:**

```
create vlan mcastvlan
create vlan v1
create vlan v2
create vlan vlan2
configure vlan vlan2 add port 1:3
configure vlan vlan2 ipaddress 10.20.1.1/24
configure mcastvlan tag 20
configure mcastvlan add port 1:1,1:2 tag
configure mvr add vlan mcastvlan
configure vlan v1 tag 30
configure v1 add port 1:1,1:2 tag
configure vlan v2 tag 40
configure v2 add port 1:1,1:2 tag
```

```

create eaps e1
configure eaps e1 mode transit
configure eaps e1 add control vlan v1
configure eaps e1 add protect vlan mcastvlan
configure eaps e1 add protect vlan v2
configure eaps port primary port 1:1
configure eaps port secondary port 1:2
enable eaps
enable mvr

```

**Switch3:**

```

create vlan McastVlan
create vlan v1
create vlan v2
configure mcastvlan tag 20
configure mcastvlan add port 1:2,1:3 tag
configure mcastvlan add port 1:1
configure mvr add vlan mcastvlan
configure vlan v1 tag 30
configure v1 add port 1:2,1:3 tag
configure vlan v2 tag 40
configure v2 add port 1:2,1:3 tag

create eaps e1
configure eaps e1 mode master
configure eaps e1 add control vlan v1
configure eaps e1 add protect vlan mcastvlan
configure eaps e1 add protect vlan v2
configure eaps port primary port 1:3
configure eaps port secondary port 1:2
enable eaps
enable mvr

```

**Note**

In this example, Switch3 is the EAPS master, but any of the other switches in the ring could have been configured as the master.

*MVR with STP*

In a Layer 2 ring topology, MVR works with STP as it works with [EAPS](#). However, in other Layer 2 topologies, additional configuration steps may be needed to make sure that multicast feeds reach all network segments. Extra configuration is required because all ports in the [VLAN](#) are part of an [STP](#) domain, so that solely by examining the configuration it is not clear whether a port is part of bigger ring or is just serving a few hosts. In EAPS this problem is solved by distinguishing between configured primary or secondary ports from other VLAN ports. Consider a simplified Layer 2 STP network as shown in [Figure 153](#).

**Figure 153: MVR with STP**

In this topology, subscribers are in a Layer 2 cloud on VLAN V1.

STP is configured for all ports of V1. Since V1 spans on the ring as well, multicast cannot be forwarded on V1 blindly. Forwarding rules (described in [MVR Forwarding](#) on page 1181), dictate that multicast traffic is not forwarded on STP enabled ports. This is to make sure that multiple copies of multicast packets are not forwarded on the ring. However, since other STP enabled ports on V1 (1:3,1:4) are not part of the ring multicast stream, they need to be configured so that they get the packets. To configure the ports to receive packets, use the following command (mentioned in [MVR Forwarding](#) on page 1181):

```
configure mvr vlan vlan-name add receiver port port-list
```

**Note**

If the Layer 2 cloud is connected back to ring ports, traffic may end up leaking into VLAN V1 in the ring. There is no way to avoid that. So, such topologies must be avoided.

The following is a typical configuration for Switch 1:

```
create vlan v1
configure v1 tag 200
configure v1 add port 1:1, 1:2 tag
configure v1 add port 1:3, 1:4
create vlan mvlan
configure mvlan add port 1:1, 1:2
configure mvr add vlan mvlan
create stpd stp1
configure stp1 add vlan v1 port all
enable stpd stp1 port all
```

```
configure mvr vlan vl add receiver port 1:3,1:4
enable mvr
```

### *MVR in a VMAN Environment*

In the case of a VMAN, a packet is tagged with a VMAN tag in addition to a possible VLAN tag. This is to provide VLAN aggregation for all customer traffic in the VMAN ring. Each customer is given its own VLAN, and traffic from all customers can be tunneled on a single VMAN tag into the metro ring to an outside Broadband Remote Access Server (BRAS). In a VMAN network, multicast traffic can be distributed over a separate VLAN in the metro core. These packets are not subjected to VMAN tunneling. Thus, IPTV service can be provided on this multicast VLAN on a VMAN network.

MVR deployment in a VMAN environment is not any different from that in an EAPS environment, since a separate multicast VLAN on the metro ring is used for multicasting. However, it provides interesting capabilities to MSPs for their video offerings. Different service bundles can be offered on separate VLANs. Packets are not forwarded to any metro link segments where a stream is not required.

[Figure 154](#) illustrates an example design for MVR in a VMAN environment. Any multicast packet entering on MVlan is forwarded on MVlan to the next switch. These multicast packets are not tunneled.

With MVR, switches on the VMAN do not have to run any routing protocol. If MVR is enabled on the multicast VLAN, MVlan, traffic is pulled from the IPTV server. Such multicast packets egressing from the CE port are always untagged. The downstream DSLAM distributes untagged multicast packets to the respective subscriber VLANs.

**Figure 154: MVR in a VMAN Environment**

The following is a typical configuration for Switch 1 in the above figure:

```
create vman vman2
configure vman vman2 tag 300
configure vman vman2 add port 2:2-2:3 untagged
configure vman vman2 add port 1:1,1:2 tagged
enable port 2:*
enable port 1:*
create vlan mvlan
configure vlan mvlan tag 200
configure vlan mvlan add port 1:1,1:2 tag
configure mvr add vlan mvlan
enable mvr
```

## Displaying Multicast Information

### Displaying the Multicast Routing Table

- To display part or all of the entries in the multicast routing table, use the following command:

```
show iproute {ipv4} {{vlan} name | [ipaddress netmask | ipNetmask]
| origin [direct | static | mbgp | imbgp | embgp]} multicast {vr
vr_name}
```

## Displaying the Multicast Cache

- The multicast cache stores information about multicast groups. To display part or all of the entries in the multicast cache, use the following command:

```
show mcast cache {{vlan} vlan_name} {{[[group grpaddressMask |
grpaddressMask] {source sourceIP | sourceIP}} {type [snooping | pim |
mvr]}| {summary}}
```

## Looking Up a Multicast Route

- To look up the multicast route to a specific destination, use the following command with the **multicast** option:

```
rtlookup [ipv4_address | ipv6_address] { unicast | multicast | rpf }
{vr vr_name}
```

## Looking Up the RPF for a Multicast Source

- To look up the RPF for a multicast source, use the following command with the **rpf** option:

```
rtlookup [ipv4_address | ipv6_address] { unicast | multicast | rpf }
{vr vr_name}
```

## Displaying the PIM Snooping Configuration

- To display the PIM snooping configuration for a VLAN, use the following command:

```
show pim snooping {vlan} vlan_name
```

## Displaying Anycast Rendezvous Point (RP) Using PIM (RFC 4610)

To display rendezvous point (RP) for Anycast RP using PIM (RFC 4610) information, use the following command:

```
show pim {ipv4 | ipv6} anycast-rp {ip_address}
```

## Troubleshooting PIM

### Multicast Trace Tool

The multicast trace tool is the multicast equivalent of unicast trace route mechanism and is an effective tool for debugging multicast reachability problems. This tool is based on an IETF draft and uses IGMP. Because it is harder to trace a multicast path from the source to the destination, a multicast trace is run from the destination to the source.

The multicast trace can be used to do the following:

- Locate where a multicast traffic flow stops
- Identify sub-optimal multicast paths

A multicast trace is used for tracing both potential and actual multicast forwarding tree paths. When the multicast tree is established and traffic is flowing, this tool traces the

actual traffic flow. If there is no traffic while executing the command, this tool displays the potential path for the group and source being traced.

You can direct a multicast trace to any network destination, which can be a multicast source or destination, or a node located between a source and destination. After you initiate the trace, a multicast trace query packet is sent to the last-hop multicast router for the specified destination. The query packet contains the source address, group address, destination/receiver address, response address, maximum number of hops, and TTL to be used for the multicast trace response.

The previous hop router selection is based on the multicast routing protocol and the state for the S,G entry in the processing router.

For example:

- If there is no S,G state in the router, the parent closest to the RP is chosen as the previous hop.
- If the S,G state exists in the router, the parent closest to the source is chosen as the previous hop.

The last hop router converts the multicast trace query into a unicast traceroute request by appending response data (for the last hop router) into the received query packet, and the last hop router forwards the request packet to the router that it believes is the proper previous hop for the given source and group.

Each multicast router adds its response data to the end of the request packet, and then forwards the modified unicast request to the previous hop.

The first hop router (the router that determines that packets from the source originate on one of its directly connected networks) changes the packet type to response packet and sends the completed response to the query generator. If a router along the multicast route is unable to determine the forwarding state for a multicast group, that router sends a response back to the originator with NO ROUTE forwarding code.

To initiate a multicast trace, use the following command:

```
mtrace source src_address {destination dest_address} {group grp_address}
{from from_address} {gateway gw_address} {timeout seconds} {maximum-hops
number} {router-alert [include | exclude] } {vr vrname}
```

## Multicast Router Information Tool

The multicast router information tool is an ExtremeXOS command that allows you to request information from a specific multicast router. For more information, see the command description for the following command:

```
mrinfo {router_address} {from from_address} {timeout seconds} {multiple-
response-timeout multi_resp_timeout} {vr vrname}
```

# Network Login

---

[Network Login Overview](#) on page 1191  
[Configuring Network Login](#) on page 1206  
[Authenticating Users](#) on page 1209  
[Local Database Authentication](#) on page 1209

[Web-Based Authentication](#) on page 1223  
[MAC-Based Authentication](#) on page 1231  
[Additional Network Login Configuration Details](#) on page 1237

This chapter offers information about Network Login procedures. This section provides an overview, specific configuration information, and specific information about Local Database Authentication, 802.1X Authentication, Web-based Authentication, and MAC-based Authentication.

## Network Login Overview

---

Network login controls the admission of user packets into a network by allowing MAC addresses from users that are properly authenticated. Network login is controlled on a per-port basis.

When network login is enabled on a port, that port does not forward any packets until authentication takes place.

Unknown broadcast/unicast/multicast (BUM) traffic is not allowed on the egress side of network login-enabled ports until authentication is successful. To allow BUM traffic to egress on network login-enabled, unauthenticated ports, use `configure netlogin ports [port_list | all] allow egress-traffic [none | unicast | broadcast | all_cast]` .

Network login is capable of three types of authentication: web-based, MAC-based, and 802.1X. In addition, network login has two different modes of operation: campus mode and ISP mode. The authentication types and modes of operation can be used in any combination.

When web-based network login is enabled on a switch port, that port is placed into a non-forwarding state until authentication takes place. To authenticate, a user must open a web browser and provide the appropriate credentials. These credentials are either approved, in which case the port is placed in forwarding mode, or not approved,

in which case the port remains blocked. You can initiate user logout by submitting a logout request or closing the logout window.

The following capabilities are included with network login:

- Web-based login using HTTP available on each port.
- Web-based login using HTTPS—if you install SSL—available on each port.
- Multiple supplicants for web-based, MAC-based, and 802.1X authentication on each port.

ExtremeXOS *NetLogin* provides the *AAA (Authentication, Authorization, and Accounting)* functionality, which is an important block of the network infrastructure and security and provides a model or framework to determine who is requesting network access, network resources that can be accessed by the requesting party, and when the resources are used. NetLogin supports all popular methods of authentication: MAC-based, Web-based, and IEEE 802.1X. NetLogin can help network administrators to control access into the network; it also provides flexibility to configure specific backend resources to which user access is allowed.

Together with IP Security, administrators can enhance security in the network by controlling access to upstream network and resources by the hosts or clients. IP Security is a collection of powerful features that allow network administrators to design security in combination with standard authentication and authorization techniques. IP Security features as ExtremeXOS 15.2 include:

- *DHCP (Dynamic Host Configuration Protocol)* Snooping and concept of trusted DHCP Servers
- Source IP Lockdown
- ARP Learning and Validation
- Gratuitous ARP Protection

When NetLogin and IP Security features are enabled on a port, NetLogin performs the first or the basic function of authenticating and authorizing the user. Further course of

action is determined by IP Security in case a violation is detected. The violation action will then determine further access to the network.

| Scenario                                                                                                                                                                                | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Expected Behavior                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <p>NetLogin + DHCP Snooping and trusted DHCP Servers/Ports.</p> <p>Violation: DHCP Server Packets seen on netlogin enabled ports (i.e. a host is masquerading post authentication).</p> | <p>We recommend that you enable NetLogin on the client-facing ports. Enabling DHCP Snooping on all ports, including client/host facing ports and ports connected to the upstream network automation and provisioning infrastructure, ensures that all DHCP messages are processed by the switch and a DHCP binding database is maintained.</p> <p>For the combination of NetLogin and DHCP Security to work correctly, we recommend that you configure at least one uplink (or server facing port) as a trusted port. This ensures that all other ports (normally client-facing ports) automatically become untrusted, and can be monitored for any violations that might occur. You can configure more than one uplink port as "trusted" as this allows flexibility in network design.</p> <p>In addition to controlling which DHCP Servers can communicate with the downstream clients, the trusted DHCP Server configuration can be used.</p> | <p>Action: None</p> <p>NetLogin authenticates the client, and IP Security flags a violation. No action is taken because of configuration.</p> <p>Action: Drop-packet</p> <p>The packet is dropped, and an EMS event is logged.</p> <p>Action: block-mac</p> <p>NetLogin initially authenticates the client, and subsequently when the violation occurs, IP Security reports violation, which causes the MAC address to be blocked either permanently or for a configured duration on the switch. The <i>FDB (forwarding database)</i> will be flushed after FDB entry ages out and the netlogin entry is unauthenticated and removed from the switch.</p> <p>Action: block-port</p> <p>NetLogin initially authenticates the client, and subsequently when the violation occurs, IP Security reports the violation, which causes the port to be administratively disabled. As a result, all authenticated clients on the ports are immediately unauthenticated and removed from the switch. This can occur either for a certain configured duration or permanently.</p> <p>We do not recommend that you use this configuration if there are multiple supplicants on the port (for example, conference rooms, groups of users, etc. accessing the network through an intermediate port extender, or hub).</p> <p>In addition, for network troubleshooting and debugging purposes, an <i>SNMP (Simple Network Management</i></p> |

| NetLogin + Source IP Lockdown<br>Violation: After a client/host successfully authenticates to the network, it performs a source IP address violation. | <p>The Source IP lockdown feature can determine if a client/host should be allowed access to the network based on inspection of the source IP address used in the packets. If a client is not using an IP address present in DHCP binding database, a violation is flagged for the client and further action is determined by configuration. This helps prevent clients from using source addresses not assigned by a centralized network automation and provisioning infrastructure.</p> <p>By default the switch denies all IP traffic from clients when source IP lockdown is enabled. In order for the clients to get a valid IP address, DHCP packets are allowed to be forwarded through the switch. NetLogin authentication (all three forms) will still proceed, and clients presenting the valid credentials (per authentication scheme) are authenticated. Post authentication (and authorization - for membership to a <i>VLAN (Virtual LAN)</i>), once a valid DHCP binding is found for the client, access control lists are automatically (dynamically) applied to permit traffic from the client.</p> | <p>It is not mandatory to configure specific violation actions in DHCP Snooping (which is a prerequisite to this feature).</p> <p>If configured, DHCP Snooping filters and violation actions take precedence over source IP lockdown. This is to ensure that successfully authenticated clients (with NetLogin) do not masquerade as rogue DHCP servers post authentication. In this case, DHCP violation is detected and actions are determined per configuration for violation-action.</p> |

| Scenario                    | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Expected Behavior                                                                                                                                                                                                                                                            |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NetLogin + DHCP Secured ARP | <p>DHCP Secured ARP allows administrators to control how the ARP table is populated. By default, the switch learns IP ARP bindings and builds the ARP table by tracking the ARP requests and replies. When DHCP Secured ARP is used for design, IP ARP learning method can be disabled. This is recommended for security purposes.</p> <p>When combined with NetLogin, this feature ensures that a client (even after success authentication) cannot override the ARP entry on the switch, thereby preventing duplicate addresses and ensuring proper network operation.</p> <p>ARP entries populated from DHCP are known as Secure ARP entries and are flushed/removed only when the address is released.</p> | <p>Same behavior as expected in the case of "NetLogin + DHCP Snooping and Trusted Ports/Server". Apart from securing the IP ARP table, in this case, violations detected as part of DHCP Snooping and validation is flagged and actions are determined by configuration.</p> |

| Scenario                             | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Expected Behavior                                                                                                                                                                                                                                                                                              |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NetLogin + ARP Validation            | <p>ARP Validation helps check different fields in the ARP packet. Source MAC, Destination MAC, and Source IP addresses can be checked for validity.</p> <p>For a complete reference to the different checks performed, please refer to <a href="#">ARP Validation Options</a>.</p> <p>All checks are performed post authentication.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | <p>Violation actions are same as the options presented in the DHCP Snooping and Validation Cases.</p> <p>Same expected behavior and functionality as in the case of "NetLogin + DHCP Snooping and Trusted Ports/Server".</p>                                                                                   |
| NetLogin + Gratuitous ARP Protection | <p>Gratuitous ARP is a method by which a client/host can resolve its own IP address, and is useful in scenarios where duplicate addresses need to be detected, or a host can announce that it has either used an IP address on a different NIC card, or even if a client has moved from one location to another.</p> <p>While ExtremeXOS supports Gratuitous ARP, protection can also be enabled to mitigate any risk or threats that can arise because of any m-i-m attacks. The switch will automatically send ARP packets to not only protect its own IP address but to also safeguard addresses of any NetLogin authenticated clients on the switch. For this, it is recommended that both DHCP Secured ARP and Gratuitous ARP protection be enabled on the switch.</p> <p>It is not mandatory that DHCP Snooping be enabled for this feature, but becomes a prerequisite if DHCP Secured ARP is also configured.</p> | <p>ARP Packets are sent out when a violation is detected.</p> <p>For all other violations detected by DHCP Snooping and Trust, the corresponding violation actions are determined by configuration, and expected behavior is the same as the case of "NetLogin + DHCP Snooping and Trusted Servers/Ports".</p> |

## Web-Based, MAC-Based, and 802.1X Authentication

Authentication is handled as a web-based process, MAC-based process, or as described in the IEEE 802.1X specification.

Web-based network login does not require any specific client software and can work with any HTTP-compliant web browser. By contrast, 802.1X authentication may require additional software installed on the client workstation, making it less suitable for a user walk-up situation, such as a cybercafé or coffee shop. A workstation running Windows 7

or Windows 8 supports 802.1X natively, and does not require additional authentication software. Extreme Networks supports a smooth transition from web-based to 802.1X authentication.

#### Note

When both HTTP and HTTPS are enabled on the switch and sending HTTP requests from the Netlogin client, HTTPS takes preference and the switch responds with a HTTPS response.

MAC-based authentication is used for supplicants that do not support a network login mode, or supplicants that are not aware of the existence of such security measures, for example an IP phone.

If a MAC address is detected on a MAC-based enabled network login port, an authentication request is sent once to the AAA application. AAA tries to authenticate the MAC address against the configured Remote Authentication Dial In User Server (*RADIUS (Remote Authentication Dial In User Service)*) server and its configured parameters (timeout, retries, and so on) or the configured local database.

The credentials used for this are the supplicant's MAC address in ASCII representation and a locally configured password on the switch. If no password is configured, the MAC address is also used as the password. You can also group MAC addresses together using a mask (configure netlogin add mac-list [*mac {mask} | default*] {**encrypted** {*encrypted\_password* | *password*} {**ports** *port\_list*} ).

*DHCP* is required for web-based network login because the underlying protocol used to carry authentication request-response is HTTP. The client requires an IP address to send and receive HTTP packets before the client is authenticated; however, the only connection that exists is to the authenticator. As a result, the authenticator must be furnished with a temporary DHCP server to distribute the IP address.

The switch responds to DHCP requests for unauthenticated clients when DHCP parameters such as *dhcp-address-range* and *dhcp-options* are configured on the network login *VLAN*. The switch can also answer DHCP requests following authentication if DHCP is enabled on the specified VLAN. If network login clients are required to obtain DHCP leases from an external DHCP server elsewhere on the network, DHCP should not be enabled on the VLAN.

Also, enabling DHCP on post authentication VLANs is not be saved in the switch configuration, since the port movement is dynamic. The following warning message appears when enabling DHCP on post authentication VLAN and network login VLAN:

```
Warning: DHCP server configuration will not be saved for netlogin-enabled ports: 1
```

```
After reboot/port removal the dhcp config should be reconfigured again
```

The DHCP allocation for network login has a short time duration of 10 seconds and is intended to perform web-based network login only. The Netlogin lease timer can be extended using the command: `configure vlan vlan_name netlogin-lease-timer seconds` . As soon as the client is authenticated, it is deprived of this address. The client must obtain an operational address from another DHCP server in the network. DHCP is

not required for 802.1X, because 802.1X uses only Layer 2 frames (EAPOL) or MAC-based network login.

URL redirection (applicable to web-based mode only) is a mechanism to redirect any HTTP request to the base URL of the authenticator when the port is in unauthenticated mode. In other words, when the user tries to log in to the network using the browser, the user is first redirected to the network login page. Only after a successful login is the user connected to the network. URL redirection requires that the switch is configured with a DNS client.

Web-based, MAC-based, and 802.1X authentication each have advantages and disadvantages, as summarized in Advantages of Web-Based Authentication.

*Advantages of Web-Based Authentication:*

- Works with any operating system that is capable of obtaining an IP address using DHCP. There is no need for special client side software; only a web browser is needed.

*Disadvantages of Web-Based Authentication:*

- The login process involves manipulation of IP addresses and must be done outside the scope of a normal computer login process. It is not tied to a Windows login. The client must bring up a login page and initiate a login.
- Supplicants cannot be re-authenticated transparently. They cannot be re-authenticated from the authenticator side.
- This method is not as effective in maintaining privacy protection.

*Advantages of MAC-Based Authentication:*

- Works with any operating system or network enabled device.
- Works silently; the user, client, or device does not know that it gets authenticated.
- Ease of management - set of devices can easily be grouped by the vendor part of the MAC address.

*Disadvantages of MAC-Based Authentication:*

- Security is based on the MAC address of the client, so the network is more vulnerable to spoofing attacks.

*Advantages of 802.1X Authentication:*

- In cases where the 802.1X is natively supported, login and authentication happens transparently.
- Authentication happens at Layer 2. It does not involve getting a temporary IP address and subsequent release of the address to obtain a permanent IP address.
- Allows for periodic, transparent re-authentication of supplicants.

*Disadvantages of 802.1X Authentication:*

- 802.1X native support is available only on newer operating systems, such as Windows 7 or Windows 8.

- 802.1X requires an EAP-capable RADIUS Server. Most current RADIUS servers support EAP, so this is not a major disadvantage.
- Transport Layer Security (TLS) and Tunneled TLS (TTLS) authentication methods involve Public Key Infrastructure (PKI), which adds to the administrative requirements.

## Multiple Supplicant Support

An important enhancement over the IEEE 802.1X standard is that ExtremeXOS supports multiple supplicants (clients) to be individually authenticated on the same port.

This feature makes it possible for two or more client stations to be connected to the same port, with some being authenticated while others are not. A port's authentication state is the logical "OR" of the individual MAC's authentication states. In other words, a port is authenticated if any of its connected clients is authenticated. Multiple clients can be connected to a single port of authentication server through a hub or Layer 2 switch.

Multiple supplicants are supported in ISP mode for web-based, 802.1X, and MAC-based authentication. In addition, multiple supplicants are supported in Campus mode if you configure and enable network login MAC-based VLANs. For more information, see [Configuring Network Login MAC-Based VLANs](#) on page 1237.

The choice of web-based versus 802.1X authentication is again on a per-MAC basis. Among multiple clients on the same port, it is possible that some clients use web-based mode to authenticate, and some others use 802.1X, but the restriction is that they must be in the same untagged [VLAN](#). This restriction is not applicable if you configure network login MAC-based VLANs. For more information, see [Configuring Network Login MAC-Based VLANs](#).

### Note

With multiple supplicant support, after the first MAC is authenticated, the port is transitioned to the authenticated state and other unauthenticated MACs can listen to all data destined for the first MAC. Be aware of this as unauthenticated MACs can listen to all broadcast and multicast traffic directed to a network login-authenticated port.

## Network Login Multiple Authentication Support

The client or supplicant connected to the NetLogin-enabled port(s) are authenticated by only one authentication protocol. If enabled globally and at the port, MAC-based authentication takes precedence if enabled globally and at the port. Dot1x takes precedence over MAC-based authentication if Dot1x is supported by the supplicant. In this case the MAC-based authentication information is cleared as the client gets authenticated via Dot1x. Web-based authentication happens only when the port belongs to the NetLogin [VLAN](#). The final authentication method used with its associated actions is applied while any previous authenticated protocol information is cleared.

This feature supports multiple authentication protocols on a NetLogin-enabled port. The user must specify the authentication protocol priority or order per port which dictates the action for the client or supplicant that is getting authenticated on this port. Use the CLI to configure the authentication protocol order (`configure netlogin authentication protocol-order [[dot1x [web-based | mac | cep]] | [mac [dot1x | web-based | cep]] | [web-based [dot1x | mac | cep]] | [cep [dot1x | web-based | mac]]]`). By default the protocol precedence order for a NetLogin-enabled port is:

1. Dot1x
2. Web-based
3. MAC
4. CEP

For example, if the following is the authentication protocol order configured on a NetLogin-enabled port in which three authentication protocols are enabled:

1. Dot1x
2. MAC
3. Web-based

#### Note

Precedence order does not work when MAC and web-based are enabled on the same port. If you want to authenticate by web-based, do not use MAC and other protocols.

When user “john” tries to authenticate with his login credentials through Dot1x-enabled supplicant or client, it sends the EAPOL packet to the ExtremeXOS switch or authenticator. Upon receipt of the EAPOL packet, the ExtremeXOS kernel *FDB* module informs the user interface FDBMgr about the new MAC detection. The FDBMgr in turn informs the NetLogin process about the new MAC or client. The NetLogin process tries to authenticate the client/MAC through *RADIUS*. On receiving the authentication result from AAA process, the NetLogin process checks for the protocol precedence configured by the user for that port and also finds if this client is being authenticated by any other authentication protocol. In this case, no other authentication protocol has authenticated this MAC address yet and the NetLogin process applies the action (VLAN movement, UPM security profile, etc.;;) corresponding to MAC-based authentication.

The ExtremeXOS switch or authenticator then sends the credentials of user “john” to the authentication server (RADIUS) a second time for Dot1x protocol authentication. After the authentication result is received, the NetLogin process again checks the protocol precedence to find that the user “john's” host/MAC is already authenticated using MAC-based authentication. Since Dot1x is configured as the highest precedence protocol for this port the NetLogin process remove MAC-based authentication actions for this client and apply the Dot1x protocol action for “john” on this port. The MAC-based authenticated client continues to exist and performs the periodic re-authentication for the configured time. The `show netlogin` output shows the client's highest precedence protocol or action applied authentication protocol details only.

When another user “sam” tries to authenticate from the same host or MAC through web-based authentication method (provided the NetLogin-enabled port is still

present in NetLogin VLAN) the user “sam” gets authenticated, but the web-based authentication protocol action is not applied, since user “john” is already authenticated from this MAC address with user-configured highest precedence Dot1x protocol on this port.

**Note**

After changing the protocol precedence, the action for the current highest precedence protocol (if client is authenticated by this protocol) takes effect immediately.

**Note**

After disabling the highest precedence protocol on this port, the next precedence protocol (if client is authenticated by this protocol) action takes effect immediately.

### *Support for Attaching and Detaching the UPM profile*

When the user or device gets authenticated the netlogin process will check for the protocol precedence configured by the user in this port and apply or remove the action accordingly. From the previous example when the user “john” tries to authenticate using Dot1x the ExtremeXOS switch or authenticator will authenticate the MAC using MAC based authentication and apply the action corresponding to the MAC based authentication protocol which includes applying UPM profile, creating VLAN (if netlogin dynamic VLAN is enabled on this port), VLAN movement etc.; when the user “john” then gets authenticated through Dot1x the ExtremeXOS switch or authenticator determines that Dot1x is the highest precedence protocol configured by the user in this port and removes the actions of MAC based authentication protocol and applies the Dot1x authentication protocol action that includes applying UPM profile, creating VLAN (if netlogin dynamic VLAN is enabled on this port), VLAN movement etc.; the MAC based authenticated client details still remains and continues to get reauthenticated for the configured time.

The netlogin process does the following when the user or MAC is being unauthenticated:

1. Sends accounting stop message to RADIUS through AAA.
2. Logs unauthentication EMS message for this client for this authentication protocol.
3. Sends “extremeNetloginUserLogout” SNMP trap message for this authentication protocol.
4. Informs IDM about unauthentication of this client for this authentication protocol.
5. Informs UPM about the client’s unauthentication for this protocol.

After performing the above actions, the netlogin process applies the highest precedence authentication protocol action configured for this port.

## Campus and ISP Modes

Network login supports two modes of operation, Campus and ISP.

Campus mode is intended for mobile users who tend to move from one port to another and connect at various locations in the network. ISP mode is meant for users who connect through the same port and VLAN each time (the switch functions as an ISP).

In Campus mode, the clients are placed into a permanent VLAN following authentication with access to network resources. For wired ports, the port is moved from the temporary to the permanent VLAN.

In ISP mode, the port and VLAN remain constant. Before the supplicant is authenticated, the port is in an unauthenticated state. After authentication, the port forwards packets.

You do not explicitly configure the mode of operation; rather, the presence of any Extreme Networks Vendor Specific Attribute (VSA) that has a VLAN name or VLAN ID (any VLAN attribute) in the RADIUS server determines the mode of operation. If a VLAN attribute is present, it is assumed to be Campus mode. If a VLAN attribute is not present, it is assumed to be ISP mode.

**Note**

When a client is authenticated in multiple VLANs using campus mode: 1) If any of the authenticated VLANs are deleted manually from a port or globally, the client is unauthenticated from all VLANs; and 2) If traffic is not seen on a particular VLAN then the FDB entry ages out and is deleted; the client itself remains authenticated and the FDB entry is reinstalled either when traffic is detected on that VLAN or when the client reauthenticates. For additional information on Campus and ISP mode operation on ports that support network login and STP (Spanning Tree Protocol), see [Exclusions and Limitations](#).

### *Spanning Tree Protocol (STP) Support with NetLogin Campus Mode*

ExtremeXOS provides support for STP with NetLogin campus mode.

If NetLogin is authenticating a client in campus mode on a port, then that port is moved/added to list of authentication VLANs (provided in VLAN VSA), and as a consequence the port could be removed from the VLANs where it is currently present. Due to this constant port/VLAN movement in campus mode, any STP configuration on the port could be lost; so to protect the port by STP, autobind needs to be configured on the list of authentication VLANs provided in VLAN VSA.

For example, configure RSTP with autobind on VLANs V1, V2, and V3 assuming that there are no ports associated to any of those VLANs. NetLogin moves the ports to the VLANs as when clients get authenticated. As the ports are added to the VLAN, RSTP inherits only tagged ports or untagged ports, depending on the default encapsulation configured for the S1 domain. If S1 is configured with default-encapsulation PVST+ or EMISTP, and if NetLogin adds port P1 to V1 (tagged), then RSTP inherits port P1. This occurs dynamically, and if port P1 is removed from VLAN V1, then port P1 is automatically removed from S1.

This feature is generic and applicable to all STP operational modes.

### Supported Platforms

All ExtremeSwitching switches.

## Network Login and Hitless Failover

When redundancy is available in a SummitStack, one node assumes the role of primary and the another node assumes the role of backup node.

The primary node executes the switch's management functions, and the backup node acts in a standby role. Hitless failover transfers switch management control from the primary node to the backup node.

#### Note

Not all platforms support hitless failover in the same software release. To verify if the software version you are running supports hitless failover, see [Protocol Support for Hitless Failover](#) on page 89. For more information about protocol and platform support for hitless failover, see [Understanding Hitless Failover Support](#) on page 88.

Network login supports hitless failover by relaying current client authentication information from the master node to the backup node. For example, if a client moves to the authenticated state, or moves from an authenticated state to an unauthenticated state, the primary node conveys this information to the backup node. If failover occurs, your authenticated client continues to operate as before the failover.

Backup nodes do not show reauthentication timer in the output of the show netlogin command as in master. Only the authenticated clients details appear in show netlogin in backup.

#### Note

If you use 802.1X network login, authenticated clients remain authenticated during failover; however, shortly after failover, all authenticated clients automatically re-authenticate themselves. Re-authentication occurs without user intervention.

If failover occurs during the authentication or re-authentication of a client, the client must repeat the authentication process.

#### Note

Before initiating failover, review the section [Synchronizing Nodes](#) on page 1656 to confirm that your switch (or SummitStack) and both (or all) nodes are running software that supports the [synchronize](#) command.

### Initial Hitless Failover

To initiate hitless failover on a network that uses network login:

1. Confirm that the nodes are synchronized and have identical software and switch configurations using the `show switch {detail}` command.  
If the primary and backup nodes, are not synchronized and both nodes are running a version of ExtremeXOS that supports synchronization, proceed to the next step.  
If the primary and backup nodes, are synchronized, proceed to Step 3 on page 1204.  
The output displays the status of the primary and backup nodes, with the primary node showing MASTER and the backup node showing BACKUP (InSync).
2. If the primary and backup nodes, are not synchronized, use the `synchronize` command to replicate all saved images and configurations from the primary to the backup.  
After you confirm that the nodes are synchronized, proceed to Step 3.
3. If the nodes are synchronized, use the `show ports tdm information` command to initiate failover.

For more detailed information about verifying the status of the nodes and system redundancy, see [Understanding System Redundancy](#) on page 83. For more information about hitless failover, see [Understanding Hitless Failover Support](#) on page 88.

## Network Login over LAG

When NetLogin is enabled on a sharing group, user credentials for the LAG (Link Aggregation Group) are forwarded to AAA server for authentication. Once authenticated, the LAG is moved to the VLAN configured as the destination VLAN for NetLogin, and the learned MAC address is installed over the LAG in the FDB on the NetLogin's destination VLAN.

All NetLogin configurations should be done on the LAG master port. For example:

```
enable sharing 24 grouping 24, 25, 26

enable netlogin ports 24 mac
```

For MAC-based authentication (see [MAC-Based Authentication](#) on page 1231), when NetLogin is enabled on a sharing group, software-based learning is enabled for each

member port of the sharing group. Similarly, when member ports are removed from the sharing group, software-based learning is disabled on that member port.

**Note**

- When a LAG is removed, all the NetLogin configurations related to that LAG are removed. Before deleting a sharing group, disable NetLogin on the LAG port.
- The master port cannot be removed from the LAG.
- The maximum number of authenticated users per LAG group is 1,024.
- If OnePolicy is enabled, NetLogin global protocol configurations and NetLogin VLAN configurations are lost, and then the LAG port is authenticated using OnePolicy by enabling NetLogin protocols globally.

## Network Login over MLAG

Starting with ExtremeXOS 22.4, NetLogin MAC-based authentication and 802.1X authentication are supported in policy mode (NetLogin web-based authentication is not supported) over ports. If an MLAG peer goes down, supplicants remain authenticated on the other MLAG peers and continue to send data traffic thereby providing redundancy.

After successful authentication, NetLogin passes the necessary information to the policy module (such as the port, MAC address, policy profile, and authentication result) for further processing, such as movement of the port to VLAN and insertion of MAC address in the FDB.

**Note**

ISC port must be added to the destination VLAN for all dynamic VLANs on the switch.

### *Limitations*

- Web-based authentication is not supported.
- Supported in policy mode only.

### *MLAG Support for Change of Authentication (CoA)*

Starting with ExtremeXOS 30.4, MLAG support for Netlogin is extended for dynamic authorization and disconnect (CoA). CoA support (introduced in ExtremeXOS 22.1), which was implemented directly in the policy module, now moves to NetLogin.

The CoA messages that were previously handled directly by the policy module are now handled by the NetLogin module. With ExtremeXOS 30.4, the AAA module, on receiving the CoA messages from the RADIUS server, passes the data to NetLogin. Netlogin checks for the availability of the client, and the mode of authentication. If it finds a valid client, the CoA message is passed to policy for further processing. Additionally, NetLogin takes care of updating the MLAG peer about the dynamic authorization changes or disconnect. The NetLogin module on the MLAG peer passes the message to the policy module of that switch.

### Limitations

- CoA support is not provided for web-based clients.
- The CoA server is aware of only the MLAG authenticator, so if the ISC link is down, one MLAG peer might have a client in a different profile with respect to the other MLAG node. This is resolved after the ISC link becomes active. This is a limitation of the CoA server.

## Configuring Network Login

---

This section provides a general overview of the commands used for:

- [Enabling or Disabling Network Login on the Switch](#) on page 1206
- [Enabling or Disabling Network Login on a Specific Port](#) on page 1207
- [Configuring the Move Fail Action](#) on page 1207
- [Displaying Network Login Settings](#) on page 1207
- [Exclusions and Limitations](#) on page 1208

This section also describes information about Network Login's [Exclusions and Limitations](#) on page 1208.

For more detailed information about a specific mode of network login, including configuration examples, see the following sections:

- [802.1X Authentication](#) on page 1213
- [Web-Based Authentication](#) on page 1223
- [MAC-Based Authentication](#) on page 1231

### Note

When *STP* with Edge-safeguard and the Network login feature are enabled on same port, the port moves to a disabled state when it detects a loop in the network.

## Enabling or Disabling Network Login on the Switch

By default, network login is disabled. To enable or disable network login and specify the authentication method, use the following commands:

- `configure netlogin vlan vlan_name`
- `enable netlogin [{dot1x} {mac} {web-based}]`
- `disable netlogin [{dot1x} {mac} {web-based}]`

## Enabling or Disabling Network Login on a Specific Port

Network login must be disabled on a port before you can delete a VLAN that contains that port. By default, all methods of network login are disabled on all ports.

- To enable network login on a port to specify the ports and the authentication method, use the following command:

```
enable netlogin ports ports [{dot1x} {mac} {web-based}]
```

### Note

When network login and STP are enabled on the same port, network login operates only when the STP port is in the forwarding state.

- To disable network login, use the following command:

```
disable netlogin ports ports [{dot1x} {mac} {web-based}]
```

## Configuring the Move Fail Action

If network login fails to perform Campus mode login, you can configure the switch to authenticate the client in the original VLAN or deny authentication even if the user name and password are correct. For example, this may occur if a destination VLAN does not exist.

To configure the behavior of network login if a VLAN move fails, use the following command:

```
configure netlogin move-fail-action [authenticate | deny]
```

By default, the setting is deny.

The following describes the parameters of this command if two clients want to move to a different untagged VLAN on the same port:

- **authenticate**—Network login authenticates the first client that requests a move and moves that client to the requested VLAN. Network login authenticates the second client but does not move that client to the requested VLAN. The second client moves to the first client's authenticated VLAN.
- **deny**—Network login authenticates the first client that requests a move and moves that client. Network login does not authenticate the second client.

The dot1x client is not informed of the VLAN move-fail because it always receives EAP-Success or EAP-Fail directly based on the authentication result, not based on both authentication and the VLAN move result.

## Displaying Network Login Settings

To display the network login settings and parameters, use the following command:

```
show netlogin {port portlist vlan vlan_name} {dot1x {detail}}
```

## Setting Netlogin Traps

To set NetLogin trap setting for ports, use the following command:

```
configure netlogin ports [all | port_list] [allowed-users allowed_users
| authentication mode [optional | required] | trap [all-traps | no-traps
| [{success} {failed} {terminated} {max-reached}]]]
```

To set NetLogin system traps, use the following command:

```
configure netlogin trap max-users [enable | disable]
```

## Exclusions and Limitations

The following are limitations and exclusions for network login:

- When using *NetLogin* MAC-based *VLAN* mode, moving a port as untagged from a pre-authentication VLAN to a post-authentication VLAN is not supported when both VLANs are configured with Protocol Filter IP.
- All unauthenticated MACs will be seeing broadcasts and multicasts sent to the port if even a single MAC is authenticated on that port.
- Network login must be disabled on a port before that port can be deleted from a VLAN.
- In Campus mode on all switches with untagged VLANs and the network login ports' mode configured as port-based-VLAN, after the port moves to the destination VLAN, the original VLAN for that port is not displayed.
- A network login VLAN port should not be a part of following protocols:
  - *EAPS (Extreme Automatic Protection Switching)*
  - *ESRP (Extreme Standby Router Protocol)*
- Network login and *STP* operate on the same port as follows:
  - At least one VLAN on the intended port should be configured both for network login and STP.
  - When STP blocks a port, network login does not process authentication requests and BPDUs are the only traffic in and out of the port. All user data forwarding stops.
  - When STP places a port in forwarding state, network login operates and BPDUs and user data flow in and out of the port. The forwarding state is the only STP state that allows network login and user data forwarding.
  - If a network login client is authenticated in ISP mode and STP blocks one of the authenticated VLANs on a given port, the client is unauthenticated only from the port or VLAN which is blocked.
  - All clients that are going through authentication and are learned on a blocked port or VLAN are cleared.

### Note

When STP with edge-safeguard and network login feature is enabled on the same port, the port goes into the disabled state after detecting a loop in the network. NetLogin campus mode and STP can be configured together on a port with the autobind feature.

- The maximum re-authentication period configured using CLI commands is 86,400 seconds for MAC and Dot1x authentication methods. There is no limitation for the

re-authentication period (session timeout) sent using RADIUS server for Netlogin authentication.

- When in non-policy mode, NetLogin is not supported on user VRs. In non-policy mode, it is supported only on VR-Default.

Enabling NetLogin on ports that are not part of VR-default produces the following error

```
WARNING: Ports that are not part of the current Virtual Router were ignored.
```

- When in policy mode, system-wide, only one NetLogin base VLAN can be configured and this VLAN can be part of any VR.
- If you want to scale to 65,000 authenticated users, use a session timeout value of at least 300 minutes.
- NetLogin is not supported on user VRs in non-policy mode. NetLogin is supported only on VR-Default in non-policy mode.

## Authenticating Users

---

There are three methods to authenticate users who log in to the switch: [RADIUS](#) client, TACACS+, and a local database of accounts and passwords.

### Note

You cannot configure RADIUS and TACACS+ at the same time.

## Local Database Authentication

---

You can configure the switch to use its local database for web-based and MAC-based network login authentication.

802.1X network login does not support local database authentication. Local authentication essentially mimics the functionality of the remote [RADIUS](#) server locally. This method of authentication is useful in the following situations:

- If both the primary and secondary (if configured) RADIUS servers timeout or are unable to respond to authentication requests.
- If no RADIUS servers are configured.
- If the RADIUS server used for network login authentication is disabled.

If any of the above conditions are met, the switch checks for a local user account and attempts to authenticate against that local account.

For local authentication to occur, you must configure the switch's local database with a user name and password for network login. We recommend a maximum of 64 local accounts. If you need more than 64 local accounts, we recommend using RADIUS for authentication. You can also specify the destination [VLAN](#) to enter upon a successful authentication. You can also specify a UPM profile in the local database when creating a local user.

You can also use local database authentication in conjunction with network login MAC-based VLANs. For more detailed information about network login MAC-based VLANs, see [Configuring Network Login MAC-Based VLANs](#) on page 1237.

## Creating a Local Network Login Account--User Name and Password Only

We recommend creating a maximum of 64 local accounts. If you need more than 64 local accounts, we recommend using [RADIUS](#) for authentication. For information about RADIUS authentication, see [Configuring the RADIUS Client](#) on page 1556.

User names are not case-sensitive. Passwords are case-sensitive. User names must have a minimum of one character and a maximum of 32 characters. Passwords must have a minimum of zero characters and a maximum of 32 characters. If you use RADIUS for authentication, we recommend that you use the same user name and password for both local authentication and RADIUS authentication.

- To create a local network login user name and password, use the following command and specify the parameter: *user-name*

```
create netlogin local-user user-name {encrypted} {password} {vlan-vsa
[[{tagged | untagged} [vlan_name] | vlan_tag]]} {security-profile
security_profile}
```

If you attempt to create a user name with more than 32 characters, the switch displays the following messages:

```
%% Invalid name detected at '^' marker.
%% Name cannot exceed 32 characters.
```

If you attempt to create a password with more than 32 characters, the switch displays the following message after you re-enter the password:

```
Password cannot exceed 32 characters
```

The encrypted option is used by the switch to encrypt the password. Do not use this option through the command line interface (CLI).

- After you enter a local network login user name, press **[Enter]**. The switch prompts you twice to enter the password.

The following example:

- Creates a new local network login user name.
- Creates a password associated with the local network login user name.

```
create netlogin local-user megtest
password: <Enter the password. The switch does not display the password.>
Reenter password: <Re-enter the password. The switch does not display the password.>
```

For information about specifying the destination [VLAN](#), see the section [Specifying a Destination VLAN](#) on page 1210.

### Note

If you do not specify a password or the keyword **encrypted**, you are prompted for one.

## Specifying a Destination VLAN

If you configure a local network login account with a destination [VLAN](#), upon successful authentication, the client transitions to the permanent, destination VLAN.

You can specify the destination VLAN when you initially create the local network login account or at a later time.

### Adding VLANs when Creating a Local Network Login Account

- To specify the destination VLAN when creating the local network login account, use the following command and specify the **vlan-vsa** option with the associated parameters:

```
create netlogin local-user user-name {encrypted} {password} {vlan-vsa
[[{tagged | untagged} [vlan_name] | vlan_tag]]} {security-profile
security_profile}
```

Where the following is true:

- **tagged**—Specifies that the client be added as tagged.
- **untagged**—Specifies that the client be added as untagged.
- **vlan\_name**—Specifies the name of the destination VLAN.
- **vlan\_tag**—Specifies the VLAN ID, tag, of the destination VLAN.

The following example:

- Creates a new local network login user name.
- Creates a password associated with the local network login user name.
- Adds the VLAN test1 as the destination VLAN.

The following is a sample display from this command:

```
create netlogin local-user megtest vlan-vsa "test1"
password: <Enter the password. The switch does not display the password.>
Reenter password: <Re-enter the password. The switch does not display the password.>
```

### Adding VLANs at a Later Time

To specify the destination VLAN after you created the local network login account, use the following command:

```
configure netlogin local-user user-name {vlan-vsa [[{tagged | untagged}
[vlan_name | vlan_tag]] | none]}
```

Where the following is true:

- **tagged**—Specifies that the client be added as tagged
- **untagged**—Specifies that the client be added as untagged
- **vlan\_name**—Specifies the name of the destination VLAN
- **vlan\_tag**—Specifies the VLAN ID, tag, of the destination VLAN
- **none**—Specifies that the VSA 211 wildcard (\*) is applied, only if you do not specify tagged or untagged

The following example:

- Modifies a previously created local network login account.
- Specifies that clients are added as tagged to the VLAN.
- Adds the VLAN blue as the destination VLAN.

```
configure netlogin local-user megtest vlan-vsa tagged "blue"
```

## Modifying an Existing Local Network Login Account

After you create a local network login user name and password, you can update the following attributes of that account:

- Password of the local network login account.
- Destination VLAN attributes including: adding clients tagged or untagged, the name of the VLAN, and the VLAN ID.

If you try modifying a local network login account that is not present on the switch, or you incorrectly enter the name of the account, output similar to the following appears:

```
* Switch # configure netlogin local-user purplenet
^
%% Invalid input detected at '^' marker.
```

To confirm the names of the local network login accounts on your switch, use the following command:

```
show netlogin local-users
```

### Updating the Local Network Login Password

Passwords are case-sensitive. Passwords must have a minimum of zero characters and a maximum of 32 characters.

1. Update the password of an existing local network login account with the following command:

```
configure netlogin local-user user_name
```

where *user\_name* specifies the name of the existing local network login account.

2. After you enter the local network login user name, press **[Enter]**.

The switch prompts you to enter a password.

3. At the prompt, enter the new password and press **[Enter]**.

The switch then prompts you to reenter the password.

If you attempt to create a password with more than 32 characters, the switch displays the following message after you re-enter the password:

```
Password cannot exceed 32 characters
```

The following example modifies the password for the existing local network login account megtest. The following is a sample display from this command:

```
configure netlogin local-user megtest
password: <Enter the new password. The switch does not display the password.>
Reenter password: <Re-enter the new password. The switch does not display the password.>
```

After you complete these steps, the password has been updated.

### Updating VLAN Attributes

You can add a destination VLAN, change the destination VLAN, or remove the destination VLAN from an existing local network login account.

To make any of these VLAN updates, use the following command:

```
configure netlogin local-user user-name {vlan-vsa [{tagged | untagged}
[vlan_name | vlan_tag]] | none}}
```

Where the following are true:

- *user\_name*—Specifies the name of the existing local network login account
- **tagged**—Specifies that the client be added as tagged
- **untagged**—Specifies that the client be added as untagged
- *vlan\_name*—Specifies the name of the destination VLAN
- *vlan\_tag*—Specifies the VLAN ID, tag, of the destination VLAN
- **none**—Specifies that the VSA 211 wildcard (\*) is applied, only if you do not specify tagged or untagged

## Displaying Local Network Login Accounts

To display a list of local network login accounts on the switch, including VLAN information, use the following command:

```
show netlogin local-users
```

## Deleting a Local Network Login Account

To delete a local network login user name and password, use the following command:

```
delete netlogin local-user user-name
```

### Note

You cannot mass delete all local users. You can only remove them one at a time by specifying each name.

## 802.1X Authentication

802.1X authentication methods govern interactions between the supplicant (client) and the authentication server.

The most commonly used methods are Transport Layer Security (TLS); Tunneled TLS (TTLS), which is a Funk/Certicom standards proposal; and PEAP.

TLS is the most secure of the currently available protocols, although TTLS is advertised to be as strong as TLS. Both TLS and TTLS are certificate-based and require a Public Key Infrastructure (PKI) that can issue, renew, and revoke certificates. TTLS is easier to deploy, as it requires only server certificates, by contrast with TLS, which requires client and server certificates. With TTLS, the client can use the RSA Data Security, Inc. MD5 (Message-Digest algorithm 5) Message-Digest Algorithm mode of user name/password authentication.

If you plan to use 802.1X authentication, refer to the documentation for your particular *RADIUS* server and 802.1X client on how to set up a PKI configuration.

**Note**

If you do not configure the reauthentication timer in non-policy mode, or the reauthentication or idle timer for policy mode, Dot1x clients remain active and are not removed when switching between machine authentication and user authentication (by logging out of a VM, and then logging back into the VM) or when switching between two users using the same VM.

## Interoperability Requirements

For network login to operate, the user (supplicant) software and the authentication server must support common authentication methods. Not all combinations provide the appropriate functionality.

### *Supplicant Side*

The supported 802.1X supplicants (clients) are Windows 7 and Windows 8 native clients, and Meetinghouse AEGIS.

A Windows 7 or Windows 8 802.1X supplicant can be authenticated as a computer or as a user. Computer authentication requires a certificate installed in the computer certificate store, and user authentication requires a certificate installed in the individual user's certificate store.

By default, the Windows 7 or Windows 8 machine performs computer authentication as soon as the computer is powered on, or at link-up when no user is logged into the machine. User authentication is performed at link-up when the user is logged in.

Windows 7 or Windows 8 also supports guest authentication, but this is disabled by default. Refer to relevant Microsoft documentation for further information. You can configure a Windows 7 or Windows 8 machine to perform computer authentication at link-up even if a user is logged in.

### *Authentication Server Side*

The *RADIUS* server used for authentication must be EAP-capable. Consider the following when choosing a RADIUS server:

- Types of authentication methods supported on RADIUS, as mentioned previously.
- Need to support VSAs. Parameters such as *Extreme-Netlogin-Vlan-Name* (destination vlan for port movement after authentication) and *Extreme-NetLogin-Only* (authorization for network login only) are brought back as VSAs.

- Need to support both EAP and traditional user name-password authentication. These are used by network login and switch console login respectively.

**Note**

For information on how to use and configure your RADIUS server, refer to [Configuring the RADIUS Client](#) on page 1556 and to the documentation that came with your RADIUS server.

## Enabling and Disabling 802.1X Network Login

Network Login must be disabled on a port before you can delete a VLAN that contains that port. You can set a reauthentication maximum counter value to indicate the number of reauthentication trials after which the supplicant is denied access or given limited access.

- To enable 802.1X network login on the switch, use the following command:  
`enable netlogin dot1x` Any combination of types of authentication can be enabled on the same switch. At least one of the authentication types must be specified on the CLI.
- To disable 802.1X network login on the switch, use the following command:  
`disable netlogin dot1x`
- To enable 802.1X network login on one or more ports, use the following command:  
`enable netlogin ports portlist dot1x`
- To disable 802.1X network login on one or more ports, use the following command:  
`disable netlogin ports portlist dot1x`
- To configure the reauthentication counter values, use the following command:  
`configure netlogin dot1x timers`

## 802.1X Network Login Configuration Example

The following configuration example shows the Extreme Networks switch configuration needed to support the 802.1X network login example.

**Note**

In the following sample configuration, any lines marked (Default) represent default settings and do not need to be explicitly configured.

```
create vlan "temp"
create vlan "corp"
configure vlan "default" delete ports 4:1-4:4
Configuration Information for VLAN corp
No VLAN-ID is associated with VLAN corp.
configure vlan "corp" protocol "ANY" (Default)
configure vlan "corp" ipaddress 10.203.0.224 255.255.255.0
Configuration Information for VLAN Mgmt
configure vlan "Mgmt" ipaddress 10.10.20.30 255.255.255.0
Network Login Configuration
configure netlogin vlan "temp"
enable netlogin dot1x
enable netlogin ports 1:10-1:14, 4:1-4:4 dot1x
```

```
RADIUS Configuration
configure radius netlogin primary server 10.0.1.2 1812 client-ip 10.10.20.30 vr "VR-Mgmt"
configure radius netlogin primary shared-secret purple
enable radius
```

The following example is for the FreeRADIUS server; the configuration might be different for your *RADIUS* server:

```
#RADIUS Server Setting, in this example the user name is eaptest
eaptest Auth-Type := EAP, User-Password == "eaptest"
Session-Timeout = 120,
Termination-Action =1
```

For information about how to use and configure your RADIUS server, refer to [Configuring the RADIUS Client](#) on page 1556 and the documentation that came with your RADIUS server.

## Configuring Guest VLANs

Ordinarily, a client that does not respond to 802.1X authentication remains disabled and cannot access the network.

802.1X authentication supports the concept of “guest *VLANs*” that allow such a supplicant (client) limited or restricted network access. If a supplicant connected to a port does not respond to the 802.1X authentication requests from the switch, the port moves to the configured guest VLAN. A port always moves untagged into the guest VLAN.

### Note

The supplicant does not move to a guest VLAN if it fails authentication after an 802.1X exchange; the supplicant moves to the guest VLAN only if it does not respond to an 802.1X authentication request.

When the authentication server sends an 802.1X request to the supplicant, there is a specified time interval for the supplicant to respond. By default, the switch uses the supplicant response timer to authenticate the supplicant every 30 seconds for a maximum of three tries. If the supplicant does not respond within the specified time, the authentication server sends another request. After the third 802.1X request without a supplicant response, the port is placed in the guest VLAN, if the guest VLAN feature has been configured for the port. The number of authentication attempts is not a user-configured parameter.

If a supplicant on a port in the guest VLAN becomes 802.1X-capable, the switch starts processing the 802.1X responses from the supplicant. If the supplicant is successfully authenticated, the port moves from the guest VLAN to the destination VLAN specified by the *RADIUS* server. If the RADIUS server does not specify a destination VLAN, the port moves to the VLAN it belonged to before it was placed in the guest VLAN. After a port has been authenticated and moved to a destination VLAN, it is periodically

re-authenticated. If the port fails authentication, it moves to the VLAN it belonged to originally.

#### Note

A guest VLAN is not a normal network login VLAN. A guest VLAN performs authentication only if authentication is initiated by the supplicant.

#### Using Guest VLANs

Suppose you have a meeting that includes company employees and visitors from outside the company.

In this scenario, your employees have 802.1X enabled supplicants but your visitors do not. By configuring a guest VLAN, when your employees log into the network, they are granted network access (based on their user credentials and 802.1X enabled supplicants). However, when the visitors attempt to log into the network, they are granted limited network access because they do not have 802.1X enabled supplicant. The visitors might be able to reach the Internet, but they are unable to access the corporate network.

For example, in [Figure 155](#) Host A has 802.1x capability and Host B does not. When Host A is authenticated, it is given full access to the network. Host B does not have 802.1X capability and therefore does not respond to 802.1X requests from the switch. If port B is configured with the guest VLAN, port B is moved to the guest VLAN. Then Host B will be able to access the Internet but not the corporate network. After Host B is equipped with 802.1X capability, it can be authenticated and allowed to be part of the corporate network.

**Figure 155: Guest VLAN for Network Login**

#### Guidelines for Configuring Guest VLANs

Keep in mind the following guidelines when configuring guest VLANs:

- You must create a VLAN and configure it as a guest VLAN before enabling the guest VLAN feature.
- Configure guest VLANs only on network login ports with 802.1x enabled.

- Movement to guest VLANs is not supported on network login ports with MAC-based or web-based authentication.
- 802.1x must be the only authentication method enabled on the port for movement to guest VLAN.
- No supplicant on the port has 802.1x capability.

### Creating Guest VLANs

If you configure a guest VLAN, and a supplicant has 802.1X disabled and does not respond to 802.1X authentication requests from the switch, the supplicant moves to the guest VLAN. Upon entering the guest VLAN, the supplicant gains limited network access.

#### Note

You can configure guest VLANs on a per port basis, which allows you to configure more than one guest VLAN per VR. In ExtremeXOS 11.5 and earlier, you can only configure guest VLANs on a per VR basis, which allows you to configure only one guest VLAN per VR.

To create a guest VLAN, use the following command:

```
configure netlogin dot1x guest-vlan vlan_name {ports port_list}
```

### Enabling Guest VLANs

To enable the guest VLAN, use the following command:

```
enable netlogin dot1x guest-vlan ports [all | ports]
```

### Modifying the Supplicant Response Timer

The default supplicant response timeout is 30 seconds, and the range is 1-120 seconds. The number of authentication attempts is not a user-configured parameter.

To modify the supplicant response timer, use the following command and specify the **supp-resp-timeout** parameter:

```
configure netlogin dot1x timers [{server-timeout server_timeout}
{quiet-period quiet_period} {reauth-period reauth_period {reauth-max
max_num_reauths}} {supp-resp-timeout supp_resp_timeout}]
```

### Disabling Guest VLANs

To disable the guest VLAN, use the following command:

```
disable netlogin dot1x guest-vlan ports [all | ports]
```

### Unconfiguring Guest VLANs

To unconfigure the guest VLAN, use the following command:

```
unconfigure netlogin dot1x guest-vlan {ports port_list | vlan_name}
```

### Displaying Guest VLAN Settings

To display the guest VLAN settings, use the following command:

```
show netlogin guest-vlan {vlan_name}
```

If you specify the `vlan_name`, the switch displays information for only that guest VLAN.

The output displays the following information in a tabular format:

- Port—Specifies the 802.1X enabled port configured for the guest VLAN.
- Guest-vlan—Displays guest VLAN name and status: enable/disable.
- Vlan—Specifies the name of the guest VLAN.

## Post-authentication VLAN Movement

After the supplicant has been successfully authenticated and the port has been moved to a VLAN, the supplicant can move to a VLAN other than the one it was authenticated on.

This occurs when the switch receives an Access-Accept message from the RADIUS server with a VSA that defines a new VLAN. The supplicant remains authenticated during this transition. This occurs on both untagged and tagged VLANs. For example, suppose a supplicant submits the required credentials for network access; however, it is not running the current, approved anti-virus software or it does not have the appropriate software updates installed. If this occurs, the supplicant is authenticated but has limited network access until the problem is resolved. After you update the supplicant's anti-virus software, or install the software updates, the RADIUS server re-authenticates the supplicant by sending ACCESS-ACCEPT messages with the accompanying VLAN attributes, thereby allowing the supplicant to enter its permanent VLAN with full network access.

This is normal and expected behavior; no configuration is necessary.

## 802.1X Authentication and Network Access Protection

802.1X authentication in combination with Microsoft's Network Access Protection (NAP) provide additional integrity checks for end users and supplicants that attempt to access the network.

NAP allows network administrators to create system health policies to ensure supplicants that access or communicate with the network meet administrator-defined system health requirements. For example, if a supplicant has the appropriate software updates or anti-virus software installed, the supplicant is deemed healthy and granted network access. On the other hand, if a supplicant does not have the appropriate software updates or anti-virus software installed, the supplicant is deemed unhealthy and is placed in a quarantine VLAN until the appropriate update or anti-virus software is installed. After the supplicant is healthy, it is granted network access. For more information about NAP, please refer to the documentation that came with your Microsoft Windows or Microsoft Server software.

To configure your network for NAP, the minimum required components are:

- Extreme Networks switches running ExtremeXOS 11.6 or later.
- *RADIUS* server that supports NAP (Microsoft Windows Vista operating system refers to this as a network policy server (NPS), formerly known as the internet authentication server (IAS)).
- Remediation servers that receive unhealthy supplicants. The remediation servers contain the appropriate software updates, anti-virus software, and so on to make a supplicant healthy.

In addition to the required hardware and software, you must configure NAP-specific VSAs on your RADIUS server. By configuring these VSAs, you ensure supplicant authentication and authorization to the network and the switch creates dynamic Access Control Lists (ACLs) to move unhealthy supplicants to the quarantine VLAN for remediation. For more information see, [Using NAP-Specific VSAs to Authenticate 802.1X Supplicants](#) on page 1222.

Figure 156 displays a sample network that uses NAP to protect the network.

**Figure 156: Sample Network Using NAP to Provide Enhanced Security**

#### *Example Scenarios Using NAP*

Using the following figure, the following two scenarios describe some sample actions taken when an 802.1X-enabled supplicant initiates a connection to the network.

The scenarios assume the following:

- Scenario 1 has a healthy 802.1X-enabled supplicant.
- Scenario 2 has an unhealthy 802.1X-enabled supplicant.

- 802.1X network login has been configured and enabled on the switch.
- The *RADIUS* server has been configured using the NAP-specific VSAs for authenticating supplicants.
- The remediation servers have been configured with the appropriate software updates, anti-virus software, and so on.
- *VLANs* Production and Quarantine have already been created and configured.

**Note**

You can dynamically create the quarantine VLAN if you configure dynamic VLAN creation on the switch. For more information see, [Configuring Dynamic VLANs for Network Login](#) on page 1240.

**Scenario 1--Healthy Supplicant**

The steps to authenticate a healthy supplicant are:

1. The 802.1X supplicant initiates a connection to the 802.1X network access server (NAS), which in this scenario is the Extreme Networks switch.
2. The supplicant passes its authentication credentials to the switch using PEAP and an inner authentication method such as MS-CHAPv2.
3. The *RADIUS* server requests a statement of health (SoH) from the supplicant. Only NAP-capable supplicants create an SoH, which contains information about whether or not the supplicant is compliant with the system health requirements defined by the network administrator.
4. If the SoH indicates that the supplicant is healthy, the RADIUS server sends an Access-Accept message with a RADIUS VSA indicating which *VLAN* the healthy supplicant is moved to (in this example, the Production VLAN).
5. The switch authenticates the supplicant and moves it into the Production VLAN.
6. The switch sends a trap to the NMS indicating that the supplicant has been successfully authenticated and the VLAN into which it has been moved.

**Scenario 2--Unhealthy Supplicant**

The steps to authenticate an unhealthy supplicant are:

1. The 802.1X supplicant initiates a connection to the 802.1X network access server (NAS), which in this scenario is the Extreme Networks switch.
2. The supplicant passes its authentication credentials to the switch using PEAP and an inner authentication method such as MS-CHAPv2.
3. The *RADIUS* server requests a statement of health (SoH) from the supplicant. Only NAP-capable supplicants create an SoH, which contains information about whether or not the supplicant is compliant with the system health requirements defined by the network administrator.
4. If the SoH indicates that the supplicant is unhealthy, the RADIUS server sends an Access-Accept message with RADIUS VSAs indicating which:
  - *VLAN* the unhealthy supplicant is moved to (in this example, the Quarantine VLAN).
  - the remediation server(s) from which the supplicant can get software updates, anti-virus software and so on to remediate itself.

5. When the switch receives the VLAN and remediation server information from the RADIUS server, the switch:
  - Moves the supplicant into the Quarantine VLAN.
  - Applies ACLs to ensure the supplicant in the Quarantine VLAN can access only the remediation servers
  - Drops all other traffic not originating/destined from/to the remediation servers
  - .
6. The supplicant connects to the remediation server to get software updates, anti-virus software, and so on to get healthy.
7. After the supplicant is healthy, it restarts the authentication process and is moved to the Production VLAN, as a healthy supplicant with full network access.

#### Using NAP-Specific VSAs to Authenticate 802.1X Supplicants

**Table 81** contains the VSA definitions for 802.1X network login in conjunction with devices and servers that support NAP.

The Microsoft Vendor ID is 311.

#### Note

For more information about NAP and the VSAs supported by NAP, please refer to the documentation that came with your Microsoft operating system or server.

**Table 81: NAP-Specific VSA Definitions for 802.1X Network Login**

| VSA                         | Vendor Type | Type    | Sent-in       | Description                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------|-------------|---------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MS-Quarantine-State         | 45          | Integer | Access-Accept | Indicates the network access level that the <i>RADIUS</i> server authorizes the user. The network access server (the switch) also enforces the network access level. A value of "0" gives the user full network access. A value of "1" gives the user limited network access. A value of "2" gives the user full network access within a specified time period. |
| MS-IPv4-Remediation-Servers | 52          | Integer | Access-Accept | Indicates the IP address(es) of the remediation server(s) that an unhealthy supplicant moves to in order to get healthy.                                                                                                                                                                                                                                        |

#### ACLs for Remediation Servers

The NAP VSA, MS-IPv4-Remediation-Servers, contains a list of IP addresses that an unhealthy and therefore quarantined supplicant should be allowed access to so that it can remediate itself and become healthy.

The way a quarantine is implemented on the switch is simply by moving the client/port to a user-designated 'quarantine' *VLAN* whose VLANID/Name is sent in the Access-

Accept message. It is up to the user to ensure that the quarantine VLAN does indeed have limited access to the rest of the network. Typically, this can be done by disabling IP forwarding on that VLAN so no routed traffic can get out of that VLAN. Also, with dynamic VLAN creation, the quarantine VLAN being supplied by *RADIUS* could be dynamically created on the switch, once dynamic VLAN creation is enabled on it. The remediation server(s) would need to be accessible via the uplink port, regardless of whether the quarantine VLAN is pre-configured or dynamically created, since IP forwarding is not enabled on it.

To get around this restriction, network login has been enhanced so when a MS-Quarantine-State attribute is present in the Access-Accept message with extremeSessionStatus being either 'Quarantined' or 'On Probation,' then a 'deny all traffic' dynamic *ACL (Access Control List)* will be applied on the VLAN. If such an ACL is already present on that VLAN, then no new ACL will be applied.

When the last authenticated client has been removed from the quarantine VLAN, then the above ACL will be removed.

Additionally, if the MS-IPv4-Remediation-Servers VSA is present in the Access-Accept message, for each IP address present in the VSA a 'permit all traffic to/from this IP address' ACL will be applied on the quarantine VLAN. This will allow traffic to/from the remediation servers to pass unhindered in the Quarantine VLAN while all other traffic will be dropped.

## Web-Based Authentication

---

This section describes web-based network login.

For web-based authentication, you need to configure the switch DNS name, default redirect page, session refresh, and logout-privilege. URL redirection requires the switch to be assigned a DNS name. The default name is network-access.com. Any DNS query coming to the switch to resolve switch DNS name in unauthenticated mode is resolved by the DNS server on the switch in terms of the interface (to which the network login port is connected).

### Note

When both HTTP and HTTPS are enabled on the switch and sending HTTP requests from the Netlogin client, HTTPS takes preference and the switch responds with a HTTPS response.

## Enabling and Disabling Web-Based Network Login

- To enable web-based network login on the switch, use the following command:

```
enable netlogin web-based
```

Any combination of types of authentication can be enabled on the same switch. At least one of the authentication types must be specified on the CLI.

- To disable web-based network login on the switch, use the following command:

```
disable netlogin web-based
```

- To enable web-based network login on one or more ports, use the following command:

```
enable netlogin ports portlist web-based
```

Network Login must be disabled on a port before you can delete a [VLAN](#) that contains that port.

- To disable web-based network login on one or more ports, use the following command:

```
disable netlogin ports portlist web-based
```

## Configuring the Base URL

- To configure the network login base URL, use the following command:

```
configure netlogin base-url url
```

where *url* is the DNS name of the switch.

For example, configure netlogin base-url network-access.com makes the switch send DNS responses back to the network login clients when a DNS query is made for network-access.com.

## Configuring the Redirect Page

To configure the network login redirect page, use the following command:

```
configure netlogin redirect-page url
```

Where *url* defines the redirection information for the users after they have logged in. You must configure a complete URL starting with http:// or https://. By default, the redirect URL value is "<http://www.extremenetworks.com>" and default re-direction will take maximum of 20 seconds i.e default netlogin-lease-timer + 10 seconds. Re-direct time can be changed by tuning netlogin-lease-timer.

You can also configure the redirect value to a specific port number, such as 8080. For example, you can configure the network login redirect page to the URL value "http://www.extremenetworks.com:8080". The default port value is 80.

This redirection information is used only in case the redirection info is missing from [RADIUS](#) server. For example, configure netlogin base-url http://www.extremenetworks.com redirects all users to this URL after they get logged in.

For more information about SSH2, see [Secure Shell 2](#) on page 1589.

## Configuring Proxy Ports

To configure the ports to be hijacked and redirected, use the following command:

```
configure netlogin add proxy-port tcp_port {http | https}
```

```
configure netlogin delete proxy-port
```

For each hijacked or proxy port, you must specify whether the port is to be used for HTTP or HTTPS traffic. No more than five hijack or proxy ports are supported for HTTP in addition to port 80 (for HTTP) and port 443 (for HTTPS), both of which cannot be deleted.

## Configuring Session Refresh

To enable or disable the network login session refresh, use the following commands:

```
enable netlogin session-refresh {refresh_minutes}
```

```
disable netlogin session-refresh
```

Where *minutes* ranges from 1 - 255. The default setting is 3 minutes. The commands `enable netlogin session-refresh` and `configure netlogin session-refresh` make the logout window refresh itself at every configured time interval. Session refresh is enabled by default. When you configure the network login session refresh for the logout window, ensure that the *FDB* aging timer is greater than the network login session refresh timer.

### Note

If an attempt is made to authenticate the client in a non-existent *VLAN*, and the move fail action setting is `authenticate`, then the client is successfully authenticated in the port's original VLAN, but subsequent session refreshes fail and cause the client to become unauthenticated.

When web-based Network Login is configured with proxy ports and session-refresh are also enabled, you must configure the web browser to bypass the web proxy server for the IP address of the VLAN into which the client moves after authentication.

## Configuring Logout Privilege

- To enable or disable network login logout privilege, use the following commands:

```
enable netlogin logout-privilege
```

```
disable netlogin logout-privilege
```

These commands turn the privilege for network login users to logout by popping up (or not popping up) the logout window. Logout-privilege is enabled by default.

- You can configure the number of times a refresh failure is ignored before it results in the client being unauthenticated by using the following commands:

```
configure netlogin allowed-refresh-failures
```

```
unconfigure netlogin allowed-refresh-failures
```

You can set the number of failures to be from between 0 and 5. The default number of logout failures is 0.

## Configuring the Login Page

You can fully customize the HTML login page and also add custom embedded graphical images to it. This page and the associated graphics must be uploaded to

the switch so that they can be served up as the initial login page at the base URL. Both HTTP and HTTPS are supported as a means of authenticating the user via the custom page.

In general, the steps for setting up a custom login page and graphical images (if any) are as follows:

1. Write the custom webpage.
2. TFTP the page and any embedded JPEG or GIF graphical images that it references onto the switch.
3. Enable and configure web-based Network Login on the switch. When the custom page is present on the switch, it will override the configured banner.

### *Configuring a Network Login Banner*

- To configure a banner on a network login screen, use the following command:  
`configure netlogin banner banner`
- To display configured banners from the network login screen, use the following command:  
`show netlogin banner`
- To clear configured network login banners, use the following command:  
`unconfigure netlogin banner`

### *Login Page Contents*

The customized web-page must have the file name `netlogin_login_page.html`.

While the contents of the page are left up to the customer, they must contain the following elements:

- An HTML submit form with `action="/hello"` and `method="post"` that is used to send the Network Login username and password to the switch. The form must contain the following:
  - A username input field with `name="extremenetloginuser"`
  - A password input field with `name="extremenetloginpassword"`
- Optionally, one or more graphical images embedded using the tags

`` or

`` or

``

where `<xxx>` is user-configurable.

The following is a sample custom page, where the embedded graphical image is named `netlogin_welcome.jpg`:

```
<html lang="en">

<head>
<title>Network Login Page</title>
</head>
```

```
<body>
<form action="/hello" method="post">

Please log in:

User:

<input type="text" name="extremenetloginuser" />

Password:

<input type="password" name="extremenetloginpassword" />

<input type="submit" value="Submit" />
</form>
</body>
</html>
```

### *Uploading the Login File to the Switch*

To upload the page and the JPEG/GIF files, the switch TFTP command must be used.

For example, assuming the page resides on a TFTP server with IP address 10.255.49.19, the command used would be:

```
BD-8810.1 # tftp get 10.255.49.19 netlogin_login_page.html
```

### *General Guidelines*

The following general guidelines are applicable to the login page:

- When the custom web page is not present on the switch, the system falls back to the using the default banner. The web page may be added (or removed) from the switch at any time, at which point the switch will stop (or start) using the banner.
- The graphical image file names referenced in the web page must not have any path information prepended.
- Both uppercase and lowercase names (or a mixture) for the graphical image filenames are supported, but the user and password tag names should be either all uppercase or all lowercase, not a mixture of the two.
- More than one form may exist on the page. This can be useful when, for example, in addition to the main username and password that is typed in by the user, an additional special username and password needs to be auto-filled and sent. This could be used when end users without a valid username or password need to be given restricted access to the network.

### *Limitations*

The following limitations apply to the login page:

- When the client is in the unauthenticated state, any embedded URLs in the custom page are inaccessible to it.
- Only JPEG and GIF graphical images are supported.

- It is the web page writer's responsibility to write the HTML page correctly and without errors.
- Only TFTP is supported as a method to upload the web-page and graphical images to the switch.

## Customizable Authentication Failure Response

In the event of web-based network login authentication failure, you can use a custom authentication failure page to recover.

When a customized login page is in effect, by default, any authentication failure results in the following failure response being delivered to the browser:

Login Incorrect. [Click here to try again.](#)

Clicking on the indicated link will bring the user back to the initial custom login page.

You may choose to override the above default response with a custom one. This custom failure response page must be uploaded to the switch using TFTP with the name `netlogin_login_fail_page.html`. When authentication fails, the switch responds with this page. If the page is deleted from the switch, the response reverts back to the default.

The same graphical images that are uploaded to the switch for the custom login page can also be embedded in the custom authentication failure page.

### Note

The custom authentication failure page can be used only when authentication is being done via the custom login page.

## Customizable Graphical Image in Logout Popup Window

You can embed a graphical image in the logout popup window.

This image appears in the window in addition to the text that is displayed. The image must be TFTPed to the switch in the same manner as the custom login image, and must have the filename `netlogin_logout_image.jpg` or `netlogin_logout_image.gif` (depending on whether the image is JPEG or GIF). If no such image is present on the switch, then the logout popup contains only text.

## Web-Based Network Login Configuration Example

The following configuration example shows both the Extreme Networks switch configuration and the RADIUS server entries needed to support the example.

VLAN corp is assumed to be a corporate subnet which has connections to DNS, WINS servers, network routers, and so on. VLAN temp is a temporary VLAN and is created to provide connections to unauthenticated network login clients. Unauthenticated ports belong to the VLAN temp. This kind of configuration provides better security as unauthenticated clients do not connect to the corporate subnet and will not be able to

send or receive any data. They have to get authenticated in order to have access to the network.

- **ISP Mode**—Network login clients connected to ports 1:10–1:14, VLAN corp, will be logged into the network in ISP mode. This is controlled by the fact that the VLAN in which they reside in unauthenticated mode and the RADIUS server Vendor Specific Attributes (VSA), Extreme-Netlogin-Vlan, are the same, corp. So there will be no port movement. Also if this VSA is missing from RADIUS server, it is assumed to be ISP Mode.
- **Campus Mode**—On the other hand, clients connected to ports 4:1–4:4, VLAN temp, will be logged into the network in Campus mode since the port will move to the VLAN corp after getting authenticated. A port moves back and forth from one VLAN to the other as its authentication state changes.

Both ISP and Campus mode are not tied to ports but to a user profile. In other words, if the VSA Extreme:Extreme-Netlogin-Vlan represents a VLAN different from the one in which the user currently resides, then VLAN movement will occur after login and after logout. In following example, it is assumed that campus users are connected to ports 4:1–4:4, while ISP users are logged in through ports 1:10–1:14.

#### Note

In the following sample configuration, any lines marked (Default) represent default settings and do not need to be explicitly configured.

```
create vlan "temp"
create vlan "corp"
configure vlan "default" delete ports 4:1-4:4
enable ipforwarding
Configuration Information for VLAN temp
No VLAN-ID is associated with VLAN temp.
configure vlan "temp" ipaddress 198.162.32.10 255.255.255.0
Configuration Information for VLAN corp
No VLAN-ID is associated with VLAN corp.
configure vlan "corp" ipaddress 10.203.0.224 255.255.255.0
configure vlan "corp" add port 1:10 untagged
configure vlan "corp" add port 1:11 untagged
configure vlan "corp" add port 1:12 untagged
configure vlan "corp" add port 1:13 untagged
configure vlan "corp" add port 1:14 untagged
Network Login Configuration
configure vlan "temp" dhcp-address-range 198.162.32.20 - 198.162.32.80
configure vlan "temp" dhcp-options default-gateway 198.162.32.1
configure vlan "temp" dhcp-options dns-server 198.162.32.10
configure vlan "temp" dhcp-options wins-server 10.0.1.85
configure netlogin vlan "temp"
enable netlogin web-based
enable netlogin ports 1:10-1:14,4:1-4:4 web-based
configure netlogin base-url "network-access.com" (Default)
configure netlogin redirect-page http://www.extremenetworks.com (Default)
enable netlogin logout-privilege (Default)
disable netlogin session-refresh 3 (Default)
DNS Client Configuration
configure dns-client add name-server 10.0.1.1
configure dns-client add name-server 10.0.1.85
#RADIUS Client Configuration
configure radius netlogin primary server 10.0.1.2 1812 client-ip 10.10.20.30 vr "Vr-Mgmt"
configure radius netlogin primary shared-secret purple
enable radius
```

For this example, the following lines (for a FreeRADIUS server) should be added to the RADIUS server users file for each user:

```
Extreme:Extreme-Netlogin-Only = Enabled (if no CLI authorization)
Extreme:Extreme-Netlogin-Vlan = "corp" (destination vlan for CAMPUS mode network login)
```

**Note**

For information about how to use and configure your RADIUS server, refer to [Configuring the RADIUS Client](#) on page 1556 and the documentation that came with your RADIUS server.

## Web-Based Authentication User Login

To use web-based authentication:

1. Set up the Windows IP configuration for DHCP.
2. Plug into the port that has web-based network login enabled.
3. Log in to Windows.
4. Release any old IP settings and renew the DHCP lease.

This is done differently depending on the version of Windows the user is running:

- **Windows 9x**—Use the winipcfg tool. Choose the Ethernet adapter that is connected to the port on which network login is enabled. Use the buttons to release the IP configuration and renew the DHCP lease.
- **Windows 7 or Windows 8**—Use the ipconfig command line utility. Use the command ipconfig/release to release the IP configuration and ipconfig/renew to get the temporary IP address from the switch. If you have more than one Ethernet adapter, specify the adapter by using a number for the adapter following the ipconfig command. You can find the adapter number using the command ipconfig/all. At this point, the client will have its temporary IP address. In this example, the client should have obtained an IP address in the range 198.162.32.20–198.162.32.80.

**Note**

The idea of explicit release/renew is required to bring the network login client machine in the same subnet as the connected VLAN. When using web-based authentication, this requirement is mandatory after every logout and before login again as the port moves back and forth between the temporary and permanent VLANs.

5. Bring up the browser and enter any URL as `http://www.123.net` or `http://1.2.3.4` or switch IP address as `http://<IP address>/login` (where IP address could be either temporary or Permanent VLAN Interface for Campus mode).  
URL redirection redirects any URL and IP address to the network login page. This is significant where security matters most, as no knowledge of VLAN interfaces is required to be provided to network login users, because they can login using a URL or IP address.

**Note**

URL redirection requires that the switch be configured with a DNS client.

A page opens with a link for Network Login.

6. Click the Network Login link.

A dialog box opens requesting a user name and password.

7. Enter the user name and password configured on the *RADIUS* server. After the user has successfully logged in, the user will be redirected to the URL configured on the RADIUS server. During the user login process, the following takes place:
  - a. Authentication is done through the RADIUS server.
  - b. After successful authentication, the connection information configured on the RADIUS server is returned to the switch:
    - The permanent VLAN
    - The URL to be redirected to (optional)
    - The URL description (optional)
  - c. The port is moved to the permanent VLAN.
  - d. You can verify this using the `show vlan` command. For more information on the `show vlan` command, see [Displaying VLAN Information](#) on page 2160.

After a successful login has been achieved, there are several ways that a port can return to a non-authenticated, non-forwarding state:

- The user successfully logs out using the logout web browser window.
- The link from the user to the switch's port is lost.
- There is no activity on the port for 20 minutes.
- An administrator changes the port state.

**Note**

Because network login is sensitive to state changes during the authentication process, we recommend that you do not log out until the login process is complete. The login process is complete when you receive a permanent address.

## MAC-Based Authentication

MAC-based authentication is used for supplicants that do not support a network login mode, or supplicants that are not aware of the existence of such security measure (for example, an IP phone).

If a MAC address is detected on a MAC-based enabled network login port, an authentication request is sent once to the AAA application. AAA tries to authenticate the MAC address against the configured *RADIUS* server and its configured parameters (timeout, retries, and so on) or the local database.

In a MAC-based authentication environment, the authentication verification is done only after at MAC address detection. However, forced re-authentication is allowed through the Session-Timeout VSA when supplied along with Termination-Action attribute “RADIUS-Request” by RADIUS. When this VSA with Termination-Action attribute “RADIUS-Request” is present the switch, re-authenticates the client based on the value supplied by the VSA. If no VSA is present, there is no re-authentication. If Session-Timeout VSA is supplied and no Termination-Action attribute or “Default” Termination-Action attribute is specified, the client is unauthenticated. You can also force re-authentication by configuring the MAC re-authentication timers using the CLI (see [Configuring Reauthentication Period](#) on page 1235). If MAC re-authentication timers are configured using the CLI and RADIUS sends a different session timeout value, the RADIUS session timeout has higher precedence.

The credentials used for this are the MAC address of the supplicant in ASCII representation, and a locally configured password on the switch. If no password is configured, the MAC address is used as the password. ExtremeXOS 30.3 provides an option to send the MAC address in either uppercase or lowercase for the user name or password to provide compatibility with the requirements of the RADIUS server (see [Configuring MAC Authentication Case Option for User Name and Password](#) on page 1234). You can also group MAC addresses together using a mask.

You can configure a MAC list or a table of MAC entries to filter and authenticate clients based on their MAC addresses. If a match is found in the table of MAC entries, authentication occurs. If no match is found in the table of MAC entries, and a default entry exists, the default will be used to authenticate the client. All entries in the list are automatically sorted in longest prefix order. All passwords are stored and showed encrypted.

You can associate a MAC address with one or more ports. By learning a MAC address, the port confirms the supplicant before sending an authorization request to the RADIUS server. This additional step protects your network against unauthorized supplicants because the port accepts only authorization requests from the MAC address learned on that port. The port blocks all other requests that do not have a matching entry.

**Note**

When ONEPolicy is enabled and authentication required mode is configured with a static macsource rule applied, even if a MAC address fails authentication, traffic is forwarded.

**Note**

With ONEPolicy enabled, admin-profile port rule configured, and authentication required mode set, traffic is not forwarded by the admin profile VLAN when MAC authentication fails.

## Limitations

Web-based authentication is not supported on Extended Edge Switching extended ports.

## Enabling and Disabling MAC-Based Network Login

Network Login must be disabled on a port before you can delete a VLAN that contains that port.

- To enable MAC-based network login on the switch, use the following commands:

```
configure netlogin vlan vlan_name
```

```
enable netlogin mac
```

Any combination of types of authentication can be enabled on the same switch. At least one of the authentication types must be specified on the CLI.

If **enable netlogin mac** is entered, **configure netlogin add mac-list default** configuration is added by default. This added mac-list config will not be removed if **disable netlogin mac** is entered. Instead, **configure netlogin delete mac-list default** must be entered to remove the mac-list config.

- To disable MAC-based network login on the switch, use the following command:

```
disable netlogin mac
```

- To enable MAC-based network login on one or more ports, use the following command:

```
enable netlogin ports portlist mac
```

- To disable MAC-based network login on one or more ports, use the following command:

```
disable netlogin ports portlist mac
```

## Associating a MAC Address to a Specific Port

You can configure the switch to accept and authenticate a client with a specific MAC address. Only MAC addresses that have a match for the specific ports are sent for authentication. For example, if you associate a MAC address with one or more ports, only authentication requests for that MAC address received on the port(s) are sent to the configured RADIUS server or local database. The port(s) block all other authentication requests that do not have a matching entry. This is also known as secure MAC.

- To associate a MAC address with one or more ports, specify the **ports** option when using the following command:

```
configure netlogin add mac-list [mac {mask} | default] {encrypted}
{password} {ports port_list}
```

You must enable MAC-based network login on the switch and the specified ports.

If MAC-based network login is not enabled on the specified port(s), the switch displays a warning message similar to the following:

```
WARNING: Not all specified ports have MAC-Based NetLogin enabled.
```

For a sample configuration, see [Securing MAC Configuration Example](#) on page 1235.

## Adding and Deleting MAC Addresses

- To add a MAC address to the table, use the following command:  

```
configure netlogin add mac-list [mac {mask} | default] {encrypted}
{password} {ports port_list}
```
- To remove a MAC address from the table, use the following command:  

```
configure netlogin delete mac-list [mac {mask} | default]
```

## Displaying the MAC Address List

To display the MAC address table, use the following command:

```
show netlogin mac-list
```

When a client needs authentication the best match will be used to authenticate to the server.

MAC-based authentication is VR aware, so there is one MAC list per VR.

Assume we have a supplicant with MAC address 00:04:96:05:40:00, and the switch has the following table:

| MAC Address/Mask     | Password (encrypted) | Port(s)  |
|----------------------|----------------------|----------|
| 00:00:00:00:00:10/48 | <not configured>     | 1:1-1:5  |
| 00:00:00:00:00:11/48 | <not configured>     | 1:6-1:10 |
| 00:00:00:00:00:12/48 | <not configured>     | any      |
| 00:01:30:70:0C:00/48 | yaqu                 | any      |
| 00:01:30:32:7D:00/48 | ravdqsr              | any      |
| 00:04:96:00:00:00/24 | <not configured>     | any      |

The user name used to authenticate against the RADIUS server would be "000496000000," as this is the supplicant's MAC address with the configured mask applied. Although this is the default, ExtremeXOS 16.1 allows for a hyphenated mac address to be sent - `configure netlogin mac username format hyphenated`.

Note that the commands are VR aware, and therefore one MAC list table exists per VR.

## Configuring MAC Authentication Case Option for User Name and Password

If a RADIUS server is case-sensitive and it expects the user name and password only in lowercase, then MAC Authentication will fail due to the case mismatch, since whenever a MAC address is used as user name and password, by default the MAC address is sent only in uppercase.

ExtremeXOS 30.3 provides an option to send the Network Login (NetLogin) MAC Authentication MAC address in either upper or lower case for the user name or password.

To change the MAC case, use the following command:

```
configure netlogin mac username case {lower | upper}
```

## Configuring Reauthentication Period

The reauthentication timer is applicable for all the cases when session timeout is not sent by [RADIUS](#). Clients moved to authentication success, authentication failure VLAN, and service unavailable VLANs can be reauthenticated using this timer. If the switch receives the session-timeout attribute during authentication, the switch uses that value to set the reauthentication period.

To configure the reauthentication period for network login MAC-based authentication, use the following command:

```
configure netlogin mac timers reauth-period
```

For more information about RADIUS server attributes, see [Configuring the RADIUS Client](#) on page 1556.

## Securing MAC Configuration Example

The following configuration example shows how to configure secure MAC on your Extreme Networks switch. To configure secure MAC:

1. Create a [VLAN](#) used for network login.
2. Configure the VLAN for network login.
3. Enable MAC-based network login on the switch.
4. Enable MAC-based network login on the ports used for authentication.
5. Specify one or more ports to accept authentication requests from a specific MAC address.

In the following example, authentication requests from MAC address:

- 00:00:00:00:00:10 are only accepted on ports 1:1 through 1:5
- 00:00:00:00:00:11 are only accepted on ports 1:6 through 1:10
- 00:00:00:00:00:12 are accepted on all other ports

```
create vlan nlvlan
configure netlogin vlan nlvlan
enable netlogin mac
enable netlogin ports 1:1-1:10 mac
configure netlogin add mac-list 00:00:00:00:00:10 ports 1:1-1:5
configure netlogin add mac-list 00:00:00:00:00:11 ports 1:6-1:10
configure netlogin add mac-list 00:00:00:00:00:12
```

To view your network login configuration, use the following commands:

```
show netlogin {port portlist vlan vlan_name} {dot1x {detail}} {mac}
{web-based}
```

```
show netlogin mac-list
```

## MAC-Based Network Login Configuration Example

The following configuration example shows the Extreme Networks switch configuration needed to support the MAC-based network login example.

```
create vlan "temp"
create vlan "corp"
configure vlan "default" delete ports 4:1-4:4
Configuration Information for VLAN corp
No VLAN-ID is associated with VLAN corp.
configure vlan "corp" ipaddress 10.203.0.224 255.255.255.0
Network Login Configuration
configure netlogin vlan "temp"
enable netlogin mac
enable netlogin ports 4:1-4:4 mac
configure netlogin add mac-list default <password>
RADIUS Client Configuration
configure radius netlogin primary server 10.0.1.2 1812 client-ip 10.10.20.30 vr "VR-Mgmt"
configure radius netlogin primary shared-secret purple
enable radius
```

The following example is a user's file entry for a specific MAC address on a FreeRADIUS server:

```
00E018A8C540 Auth-Type := Local, User-Password == "00E018A8C540"
```

### Note

For information about how to use and configure your *RADIUS* server, refer to [Configuring the RADIUS Client](#) on page 1556 and the documentation that came with your RADIUS server.

## MAC-Based Authentication Delay

Prior to ExtremeXOS 21.1, the default behavior was to authenticate the client with all enabled authentication methods on that port for backward compatibility. To delay MAC authentication the user must configure the MAC authentication delay period using the CLI. The MAC authentication delay period's default value is 0 seconds for backward compatibility. The MAC authentication delay period configurable range is 0 to 120 seconds.

The following example explains both the pre-ExtremeXOS 21.1 behavior and the added MAC Authentication Delay feature:

Assume MAC, dot1X and Web-based authentication methods are enabled on a port. When the client is connected to the port the first packet from the client triggers ExtremeXOS to do MAC authentication, authenticates the client using *RADIUS*, and applies the action. When the user "Adam" tries to do the dot1X authentication, ExtremeXOS triggers the dot1X authentication, authenticates "Adam" using RADIUS, and applies the high preferred authentication method's action. If dot1X authentication is configured as preferred over MAC authentication, then the MAC authentication action is unapplied and the dot1X authentication action is applied. In this case the switch authenticates the client using both MAC and dot1X authentication method. This is the existing behavior in which the MAC authentication delay interval is 0 second.

If the customer requirement is to delay/bypass the MAC authentication then the the MAC authentication delay period must be configured on a per port basis. In this case, the moment ExtremeXOS detects the first packet from the client connected port it will wait for the MAC authentication delay period for other authentication methods to be triggered to authenticate the client. In this case the user “Adam” will do dot1X authentication to authenticate himself. The time ExtremeXOS waits for the dot1X authentication to trigger is termed as MAC authentication delay period and it is user configurable.

## Additional Network Login Configuration Details

---

This section describes additional, optional network login configurations. These configurations are not required to run network login; however, depending on your network settings and environment, you can use the commands described in this section to enhance your network login settings.

Review the earlier sections of this chapter for general information about network login and information about MAC-based, web-based, and 802.1X authentication methods.

### Configuring Network Login MAC-Based VLANs

Currently, network login allows only a single, untagged VLAN to exist on a port. This limits the flexibility for untagged supplicants because they must be in the same VLAN.

ExtremeSwitching series switches support network login MAC-based VLANs. Network login MAC-based VLANs allow a port assigned to a VLAN to operate in a MAC-based fashion. This means that each individual untagged supplicant, identified by its MAC address, can be in different VLANs.

Network login MAC-based VLAN utilizes VSA information from both the network login local database and the RADIUS server. After successfully performing the Campus mode operation, the supplicant is added untagged to the destination VLAN.

To support this feature, you must configure the network login port's mode of operation.

#### *Network Login MAC-Based VLANs Rules and Restrictions*

This section summarizes the rules and restrictions for configuring network login MAC-based VLANs:

- You must configure and enable network login on the switch and before you configure network login MAC-based VLANs.

If you attempt to configure the port's mode of operation before enabling network login, the switch displays an error message similar to the following:

```
ERROR: The following ports do not have NetLogin enabled; 1
```

- If you attempt to configure network login MAC-based VLANs on 10 Gigabit Ethernet ports, the switch displays an error message similar to the following:

```
ERROR: The following ports do not support the MAC-Based VLAN mode; 1, 2, 10
```

In ExtremeXOS version 12.0 and later, you can configure MAC-based-VLANs on 10 Gigabit Ethernet ports.

- You can have a maximum of 1,024 MAC addresses per switch.

### Configuring the Port Mode

To support network login MAC-based VLANs on a network login port, you must configure that port's mode of operation.

Specify MAC-based operation using the following command and specifying mac-based-vlans:

```
configure netlogin ports [all | port_list] mode [mac-based-vlans | port-based-vlans]
```

By default, the network login port's mode of operation is port-based-vlans. If you modify the mode of operation to mac-based-vlans and later disable all network login protocols on that port, the mode of operation automatically returns to port-based-vlans.

When you change the network login port's mode of operation, the switch deletes all currently known supplicants from the port and restores all VLANs associated with that port to their original state. In addition, by selecting mac-based-vlans, you are unable to manually add or delete untagged VLANs from this port. Network login now controls these VLANs.

With network login MAC-based operation, every authenticated client has an additional *FDB* flag that indicates a translation MAC address. If the supplicant's requested VLAN does not exist on the port, the switch adds the requested VLAN.

### Configuring Ingress Filtering

Ingress filtering is disabled by default when MAC-based VLANs are enabled on the port. To toggle the ingress filtering setting for MAC-based VLANs, use the following command:

- `configure ports port_list mac-based-vlans ingress-filtering [on|off]`

The configuration is specific to MAC-based VLANs, and only takes effect if MAC-based VLANs are enabled on the port. If the command is executed on a port that does not have MAC-based VLANs enabled, the command will be accepted, but it will not be applied until MAC-based VLANs are enabled.

### Displaying Network Login MAC-Based VLAN Information

The following commands display important information for network login MAC-based *VLANs*.

#### FDB Information

To view *FDB* entries, use the following command:

```
show fdb netlogin [all | mac-based-vlans]
```

By specifying netlogin, you see only FDB entries related to network login or network login MAC-based *VLANs*.

The flags associated with network login include:

- v—Indicates the FDB entry was added because the port is part of a MAC-Based virtual port/VLAN combination
- n—Indicates the FDB entry was added by network login

### VLAN and Port Information

- To view the VLANs that network login adds temporarily in MAC-based mode, use the following command:

```
show ports port_list information detail
```

By specifying **information** and **detail**, the output displays the temporarily added VLANs in network login MAC-based mode.

This command will also show port information for ingress filtering for MAC-based VLANs.

- To confirm this, review the following output of this command:

VLAN cfg—The term "MAC-based" appears next to the tag number.

Netlogin port mode—This output was added to display the port mode of operation. "Mac-based" appears and the network login port mode of operation.

- To view information about the ports that are temporarily added in MAC-based mode for network login, due to discovered MAC addresses, use the following command:

```
show vlan detail
```

By specifying **detail**, the output displays detailed information including the ports associated with the VLAN.

The flags associated with network login include:

- a—Indicates that egress traffic is allowed for network login
- u—Indicates that egress traffic is not allowed for network login.
- m—Indicates that the network login port operates in MAC-based mode.

#### Note

If network login is enabled together with STP, the 'a' and 'u' flags are controlled by network login only when the STP port state is 'Forwarding.'

### Network Login MAC-Based VLAN Example

The following example configures the network login MAC-based VLAN feature:

```
create vlan users12
create vlan nlvlan
configure netlogin vlan nlvlan
enable netlogin mac
enable netlogin ports 1:1-1:10 mac
configure netlogin ports 1:1-1:10 mode mac-based-vlans
configure netlogin add mac-list default MySecretPassword
```

Expanding upon the previous example, you can also utilize the local database for authentication rather than the *RADIUS* server:

```
create netlogin local-user 000000000012 vlan-vsa untagged default
create netlogin local-user 000000000010 vlan-vsa untagged users12
```

For more information about local database authentication, see [Local Database Authentication](#) on page 1209.

## Configuring Dynamic VLANs for Network Login

During an authentication request, network login receives a destination *VLAN* (if configured on the *RADIUS* server) to put the authenticated user in.

The VLAN must exist on the switch for network login to authenticate the client on that VLAN.

You can configure the switch to dynamically create a VLAN after receiving an authentication response from a RADIUS server. A dynamically created VLAN is only a Layer 2 bridging mechanism; this VLAN does not work with routing protocols to forward traffic. If configured for dynamic VLAN creation, the switch automatically creates a supplicant VLAN that contains both the supplicant's physical port and one or more uplink ports. After the switch unauthenticates all of the supplicants from the dynamically created VLAN, the switch deletes that VLAN.

### Note

Dynamically created VLANs do not support the session refresh feature of web-based network login because dynamically created VLANs do not have an IP address.

By dynamically creating and deleting VLANs, you minimize the number of active VLANs configured on your edge switches. In addition, the dynamic VLAN name can be stored on the RADIUS server and supplied to the switch during authentication, simplifying switch management. A key difference between dynamically created VLANs and other VLANs is that the switch does not save dynamically created VLANs. Even if you use the save command, the switch does not save a dynamically created VLAN.

After you configure network login on the switch, the two steps to configure dynamic VLANs are:

- [Specifying the tagged uplink port\(s\)](#) to be added to each dynamically created VLAN.
- [Enabling the switch](#) to create dynamic VLANs.

### *Specifying the Uplink Ports*

The uplink ports send traffic to and from the supplicants from the core of the network. Uplink ports should not be configured for network login (network login is disabled on uplink ports).

To specify one or more ports as tagged uplink ports that are added to the dynamically created *VLAN*, use the following command:

```
configure netlogin dynamic-vlan uplink-ports [port_list | none]
```

By default, the setting is none.

If you specify an uplink port with network login enabled, the configuration fails and the switch displays an error message similar to the following:

```
ERROR: The following ports have NetLogin enabled: 1, 2
```

If this occurs, select a port with network login disabled.

### *Enabling Dynamic VLANs for Network Login*

By default, the setting is disabled.

To enable the switch to create dynamic VLANs, use the following command:

```
configure netlogin dynamic-vlan [disable | enable]
```

When enabled, the switch dynamically creates VLANs. Remember, dynamically created VLANs are not permanent nor are user-created VLANs. The switch uses the VLAN ID supplied by the RADIUS attributes (as described below) to create the VLAN. The switch only creates a dynamic VLAN if the requested VLAN, indicated by the VLAN ID, does not currently exist on the switch.

The RADIUS server uses VSAs to forward VLAN information. The forwarded information can include only a VLAN ID (no VLAN name). The following list specifies the supported VSAs for configuring dynamic VLANs:

- Extreme: Netlogin-VLAN-ID (VSA 209)
- Extreme: Netlogin-Extended-VLAN (VSA 211)
- IETF: Tunnel-Private-Group-ID (VSA 81)

Extreme-specific VSAs have greater precedence than IETF Tunnel-Private-Group-Id attribute if both are sent using RADIUS Access-Accept. For example, if Extreme-Netlogin-Extended-Vlan 211: Uv1;Tcorp and Tunnel-Private-Group-Id:200 are both sent, MAC is authenticated on VLAN v1 and corp, and not on vlanid 200.

#### **Note**

If the ASCII string contains only numbers, it is interpreted as the VLAN ID. Dynamic VLANs support only numerical VLAN IDs; VLAN names are not supported.

The switch automatically generates the VLAN name in the following format: SYS\_VLAN\_TAG where *TAG* specifies the VLAN ID. For example, a dynamic VLAN with an ID of 10 has the name SYS\_VLAN\_0010.

#### **Note**

Like all VLAN names, dynamic VLAN names are unique. If you create a VLAN and use the name of an existing dynamic VLAN, the switch now sees the dynamic VLAN as a user-created VLAN and will save this VLAN to the switch configuration. If this occurs, the switch does not delete the VLAN after the supplicants are authenticated and moved to the permanent VLAN.

For more information on Extreme Networks VSAs, see [Extreme Networks VSAs](#) on page 1564.

#### *Dynamic VLAN Example with Web-Based Network Login*

After you finish the web-based network login configuration as described in [Web-Based Network Login Configuration Example](#) on page 1228, complete the dynamic [VLAN](#) configuration by:

- Assigning one or more non-network-login ports as uplink ports

#### **Note**

Do not enable network login on uplink ports. If you specify an uplink port with network login enabled, the configuration fails and the switch displays an error message.

- Enabling the switch to dynamically create VLANs

Whether you have MAC-based, web-based, or 802.1X authentication, you use the same two commands to configure dynamic VLANs on the switch.

The following example configures dynamic VLANs on the switch:

```
configure netlogin dynamic-vlan uplink ports 2:1-2:2
configure netlogin dynamic-vlan enable
```

#### *Displaying Dynamic VLAN Information*

- To display summary information about all of the [VLANs](#) on the switch, including any dynamically VLANs currently operating on the switch, use the following command:

```
show vlan
```

If the switch has dynamically created VLANs, the VLAN name begins with `SYS_NLD_`.

- To display the status of dynamic VLAN configuration on the switch, use the following command:

```
show netlogin
```

The switch displays the current state of dynamic VLAN creation (enabled or disabled) and the uplink port(s) associated with the dynamic VLAN.

## Configuring Network Login Port Restart

You can configure network login to restart specific network-login-enabled ports when the last authenticated supplicant unauthenticates, regardless of the configured authentication methods on the port.

This feature, known as *network login port restart*, is available with all network login authentication methods although is most practical with web-based network login. This section describes how this feature behaves with web-based network login; MAC-based and 802.1X network login do not experience any differences in behavior if you enable network login port restart.

Currently with web-based network login, if you have an authenticated supplicant and log out of the network, you must manually release the IP address allocated to you by the [DHCP](#) server. The DHCP server dynamically manages and allocates IP addresses

to supplicants. When a supplicant accesses the network, the DHCP server provides an IP address to that supplicant. DHCP cannot renegotiate their leases, which is why you must manually release the IP address.

For example, if the idle timer expires on the switch, the switch disconnects your network session. If this occurs, it may be unclear why you are unable to access the network. After you manually renew the IP address, you are redirected to the network login page and can log back into the network. To solve this situation in a single supplicant per port environment, port restart triggers the DHCP client on the PC to restart the DHCP address assignment process.

#### *Guidelines for Using Network Login Port Restart*

Configure network login port restart on ports with directly attached supplicants.

If you use a hub to connect multiple supplicants, only the last unauthenticated supplicant causes the port to restart. Although the hub does not inflict harm to your network, in this situation, the previously unauthenticated supplicants do not get the benefit of the port restart configuration.

#### *Enabling Network Login Port Restart*

To enable network login port restart, use the following command:

```
configure netlogin ports [all | port_list] restart
```

#### *Disabling Network Login Port Restart*

To disable network login port restart, use the following command:

```
configure netlogin [ports port_list | all] allow egress-traffic
{all_cast | broadcast | none | unicast}

configure netlogin ports [all | port_list] no-restart
```

#### *Displaying the Port Restart Configuration*

To display the network login settings on the port, including the configuration for port restart, use the following command:

```
show netlogin port port_list
```

Output from this command includes the enable/disable state for network login port restart.

## Authentication Failure and Services Unavailable Handling

ExtremeXOS provides the following features for handling network login authentication failures, and for handling instances of services unavailable:

- [Configure Authentication Failure VLAN](#)
- [Configure Authentication Services Unavailable VLAN](#)

- **Configure Reauthentication Period** (configure netlogin mac ports [port\_list | all] timers [{reauth-period [reauth\_period]} {reauthentication [on|off]} {delay [delay\_period]}])

You can use these features to set and control the response to network login authentication failure and instances of services unavailable.

### Configuring Authentication Failure VLAN

When a network login client fails authentication, it is moved to authentication failure VLAN and given restricted access.

To configure the authentication failure VLAN, use the following commands:

```
configure netlogin authentication failure vlan
unconfigure netlogin authentication failure vlan
enable netlogin authentication failure vlan ports
disable netlogin authentication failure vlan ports
```

Use the command **enable netlogin authentication failure vlan** to configure authentication failure VLAN on network-login-enabled ports. When a supplicant fails authentication, it is moved to the authentication failure VLAN and is given limited access until it passes the authentication.

Through either a RADIUS or local server, the other database is used to authenticate the client depending on the authentication database order for that particular network login method (mac, web, or dot1x). If the final result is authentication failure and if the authentication failure VLAN is configured and enabled on that port, then the client is moved there.

For example, if the network login MAC authentication database order is local, radius and the authentication of a MAC client fails through local database, then the RADIUS server is used to authenticate. If the RADIUS server also fails authentication, the client is moved to the authentication failure VLAN. This applies for all authentication database orders (radius,local; local,radius; radius; local).

In the above example if authentication through local fails but passes through the RADIUS server, the client is moved to appropriate destination VLAN. If the local server authentication fails and the RADIUS server is not available, the client is not moved to authentication failure VLAN.

Only when Radius Access-Reject is received, the client moves to auth fail vlan in Netlogin Mac. 802.1x Authentication: Client will move to auth fail vlan for access rejection and for cases where Radius Access Challenge is received without reject from the Radius Server. After the expiration of the timeout period, client will move to auth fail vlan.

### Dependency on authentication database order

There are four different authentication orders which can be configured per authentication method. These four orders are the following:

- RADIUS
- Local
- RADIUS, Local
- Local, RADIUS

For each authentication order, the end result is considered in deciding whether to authenticate the client through the authentication failure VLAN or the authentication service unavailable VLAN (if configured).

For example, if the authentication order is radius, local, with the RADIUS server unavailable, and local authentication failed, the client is authenticated in the authentication failure VLAN (if one is configured on the port).

For local authentication, the following cases are considered as authentication failure.

- If the user is not created in the local database.
- If the user is configured, but the password does not match.

If the user is configured, but the password does not match, it is considered an authentication failure.

For RADIUS server authentication, if for some reason the user cannot be authenticated due to problems with the RADIUS configuration, the RADIUS server not running, or some other problem then it is considered as an authentication service unavailable. If the actual authentication fails then it is considered as an authentication failure.

### Configuring Authentication Service-Unavailable VLAN

When the authentication service is not available for authentication, the supplicant is moved to authentication service-unavailable VLAN and given restricted access.

Starting with ExtremeXOS 30.2, you can configure multiple (10 maximum) service-unavailable VLANs per port.

To configure the authentication services unavailable VLAN, use the following commands:

```
configure netlogin authentication service-unavailable [{add} | {delete}
| [{vlan vlan_name} {ports port_list {tagged | untagged}}}]
```

```
unconfigure netlogin authentication service-unavailable vlan vlan_name
{ports port_list}
```

```
enable netlogin authentication service-unavailable vlan ports [ports |
all]
```

```
disable netlogin authentication service-unavailable vlan ports [ports |
all]
```

If a NetLogin port has web enabled, authentication-failure VLAN and authentication service-unavailable VLAN configuration are not applicable to MAC and Dot1x clients connected to that port. For example, if port 1:2 has NetLogin MAC and web authentication enabled and the service-unavailable VLAN is configured and enabled on it, and if a MAC client connected to that port fails authentication, it is not moved to service-unavailable VLAN.

## Fallback VLANs in Policy

In version 33.2.1, the fallback VLAN functionality provided with Netlogin with Policy disabled can also be achieved with Policy enabled by using Policy admin rules. A policy profile is assigned to a port (or port/mac address combination). The profile has a default pvid specified and pvid-status enabled. Authentication mode "optional" must be enabled for both Netlogin MAC and dot1x enabled ports in order to handle first authentication failure due to service unavailability. If authentication fails or the RADIUS server is unavailable, the user will be placed in the VLAN specified as the profile's default pvid (the **show netlogin session** command will display the entries as "Auth Failed").

Windows dot1x clients must be set with "Fallback to unauthorized network access". In this case, because the authentication has failed, the session is marked as such but the traffic is handled by the admin profile as long as the authentication mode is set as "optional".

An enhancement is added to version 33.2.1 that applies to existing Netlogin sessions that fail to re-authenticate because of service unavailable. This enhancement works with both authentication modes: "optional" and "required." However, "optional" is required for the admin-profile to allow traffic to flow. The user can specify an option to retain the Netlogin session, including the original VLAN assignment in this case.

This feature only works on re-authentication, because the unavailability or failure of the first authentication is handled by the existing administration rule Policy feature.

### *Configuration Examples*

You can active this enhancement by enabling the following command options:

```
configure netlogin mac authentication database-order radius (only required
for MAC-auth and not dot1x)
```

```
configure netlogin keep-session-reauth-svc-unavail on
```

```
configure radius netlogin keep-alive interval 78
```

```
configure radius netlogin keep-alive on
```

### *Limitations*

The following are limitations for this enhancement:

- Netlogin dot1x session-timeout value sent using RADIUS must be higher than the radius keep-alive timer value.
- "Keep Session On Re-authentication Service Unavailable - On/Off" attribute doesn't apply for non-Policy Netlogin service unavailability feature.
- For dot1x, this feature depends on RADIUS keep-alive being enabled (on).
- It is recommended that **keep-session-on-reauth-svc-unavail** remain off for non-Policy mode.
- For re-authentication during service unavailable, it is possible that the dot1x client is triggered to re-authenticate due to timing of the re-authentication period and RADIUS keep-alive are synchronized. It is recommended that the dot1x client be set to use "Fallback to unauthorized network access". When this happens, the dot1x re-authentication timer does not get re-initialized but the session is still kept.

### *Supported Platforms*

All platforms.

### *Netlogin Policy Session Re-authentication*

Version 33.2.1 adds support for enabling OnePolicy to have a fallback VLAN in case the authentication service is not available when re-authentication occurs. This allows the VLAN assignment by the policy to be kept. See the previous entry on Fallback VLANs.

#### **Supported Platforms**

All platforms.

#### **New CLI Command**

The following new command supports this feature:

```
configure netlogin keep-session-reauth-svc-unavail
```

## **RADIUS Netlogin Keep Alive**

Version 33.2.1 adds support for a keep alive message on the Netlogin RADIUS server. This checks for RADIUS server reachability in order to limit unnecessary re-authentication.

### *Supported Platforms*

All platforms.

### *New CLI Commands:*

The following new commands support this feature:

```
configure radius netlogin keep-alive
```

```
configure radius netlogin keep-alive interval
```

*Modified CLI Command*

The **show radius** command is updated with Netlogin RADIUS server information (lines 20-21):

```
show radius
RADIUS Default State: disabled
RADIUS Default Timeout: 3 seconds
RADIUS Algorithm: standard
RADIUS Retries: 3
RADIUS port bounce VSA: off
RADIUS dynamic-authorization: disabled
RADIUS TLS TCP Timeout: default
RADIUS TLS OCSP: off
RADIUS TLS OCSP Attributes:
 Nonce : off
 Signer ocsf-nocheck : off
 Override Server URL : none
Switch Management RADIUS: disabled *
Switch Management RADIUS server connect time out: 3 seconds *
Switch Management RADIUS Accounting: disabled *
Switch Management RADIUS Accounting server connect time out: 3 seconds
Netlogin RADIUS: enabled
Netlogin RADIUS server connect time out: 3 seconds *
Netlogin RADIUS server keep alive: on
Netlogin RADIUS server keep alive interval: 60 seconds
Netlogin RADIUS server's last known reachability status: unreachable
Netlogin RADIUS Accounting: disabled *
Netlogin RADIUS Accounting server connect time out: 3 seconds

Primary Netlogin RADIUS server: Status is Active
 host name :
 IP address : 1.2.3.4
 Server IP Port : 1812
 Protocol : UDP
 Client address : 10.127.2.33 (VR-Mgmt)
 Retries : 3 *
 Timeout : 3 *
 shared secret : #S4/Mj804b1yid8IYgRCNF2qdlGKD+A==
Access Requests : 157 Access Accepts : 0
Access Rejects : 0 Access Challenges : 0
Access Retransmits: 117 Client timeouts : 156
Bad authenticators: 0 Unknown types : 0
Round Trip Time : 0

Legend: An asterisk (*) indicates a global value is in use.
```

[Bidirectional Forwarding Detection \(BFD\)](#) on page 1275

Operation, Administration, and Maintenance (OAM) includes functions used to detect network faults, measure network performance and distribute fault-related information, including CFM, Y.1731, EFM, and BFD.

## CFM

---

Connectivity Fault Management (CFM), discussed in the IEEE 802.1Q-2011 standard and originally specified in the IEEE 802.1ag-2007 standard, allows you to detect, verify, and isolate connectivity failures in virtual bridged LANs.

Part of this specification is a toolset to manually check connectivity, which is sometimes referred to as Layer 2 ping.

### Note

The ExtremeXOS implementation of CFM is based on the IEEE 802.1Q-2011 and Y.1731 standards.

There is no direct interaction between CFM and other Layer 2 protocols; however, blocked *STP (Spanning Tree Protocol)* ports are taken into consideration when forwarding CFM messages.

## CFM Overview

You can create hierarchical networks, or domains, and test connectivity within a domain by sending Layer 2 messages, known as *CCM (Connectivity Check Message)*.

### Note

Extreme Networks uses values defined in IEEE 802.1Q-2011 for the MAC addresses and Ethernet type for CFM.

[Figure 157](#) shows an example of hierarchical CFM domains.

**Figure 157: CFM Hierarchical Domains Example**

**Note**

The arrows in the above figure indicate the span that CCM messages take, not the direction. (See [Figure 158](#) on page 1251 for more information on spans for CCM messages.) This has been removed until the missing xref can be fixed.

To achieve this hierarchical connectivity testing, create and configure the following entities:

- Maintenance domains, or domains
- Maintenance domain (MD) level; a unique hierarchical numeric value for each domain
- Maintenance associations (MAs)
- Maintenance points (MPs) and *MEP (Maintenance End Point)*, which are one of the following types:
  - UP MEPs
  - DOWN MEPs
- Maintenance intermediate points (MIPs)

**Note**

The CFM filter function (CFF) is no longer supported from ExtremeXOS 12.1. The functionality of CFF is implicitly performed by MEPs.

An UP MEP sends CFM frames toward the frame filtering entity, which forwards the frames to all other ports of a service instance other than the port on which the UP MEP is configured. This is similar to how the frame filtering entity forwards a normal data frame, taking into account the port's *STP* state. For an UP MEP, a CFM frame exits from a port if only if the STP state of the port is in the forwarding state.

A DOWN MEP sends CFM frames directly to the physical medium without considering the port STP state. For a DOWN MEP, a CFM frame exits from a port even if the port STP state is in blocking state.

[Figure 158](#) shows the concept of UP and DOWN MEP at logical level:

**Figure 158: CFM UP and DOWN MEP at the Logical Level**

You must have at least one MP on an intermediate switch in your domain. Ensure that you map and configure all ports in your domain carefully, especially the UP MEPs and the DOWN MEPs. If these are incorrectly configured, the CCMs are sent in the wrong direction in your network, and you will not be able to test the connectivity within the domain.

You can have up to eight domains on an Extreme Networks switch. A domain is the network or part of the network for which faults are to be managed; it is that

section where you are monitoring Layer 2 connectivity. A domain is intended to be fully connected internally.

#### Note

Domains may cross VR boundaries; domains are not -aware.

You assign each domain an MD level, which functions in a hierarchy for forwarding CFM messages. The MD levels are from 0 to 7. The highest number is superior in the CFM hierarchy.

The IEEE standard 802.1Q-2011 recommends assigning different MD levels to different domains for different network users, as follows:

- 5 to 7 for end users
- 3 and 4 for Internet service providers (ISPs)
- 0 to 3 for operators (entities carrying the information for the ISPs)

All CFM messages with a superior MD level (numerically higher) pass throughout domains with an inferior MD level (numerically lower). CFM messages with an inferior MD level are not forwarded to domains with a superior MD level. Refer to the following table for an illustration of domains with hierarchical MD levels.

**Table 82: MD Levels and Recommended Use**

|             |               |                                     |   |                  |   |          |   |               |
|-------------|---------------|-------------------------------------|---|------------------|---|----------|---|---------------|
| MD level    | 0             | 1                                   | 2 | 3                | 4 | 5        | 6 | 7             |
| Use         | Operator      |                                     |   | Service provider |   | Customer |   |               |
| Superiority | Most inferior | < ----- Inferior / Superior ----- > |   |                  |   |          |   | Most superior |

Within a given domain, you create maintenance associations (MAs). Extreme Networks' implementation of CFM associates MAs with service instances (a service instance can be a VLAN (Virtual LAN), VMAN, BVLAN, or SVLAN). All of the ports in that VLAN service instance are now in that MA and its associated domain. In general, you should configure one MIP on each intermediate switch in the domain and a MEP on every edge switch.

Each MA associates with one service instance, and a service instance can be associated with more than one MA. The MA is unique within the domain. One switch can have 8 domains, 128 ports, and 256 associations (see [Supported Instances for CFM](#) on page 1254).

#### Note

You cannot associate the Management VLAN with an MA or a domain.

You assign the MPs to ports: UP MEPs, DOWN MEPs, and MIPs. These various MPs filter or forward the CFM messages to test the connectivity of your network.

Each configured MEP periodically sends out a Layer 2 multicast or unicast CCM message.

The destination MAC address in the CCM frame is from a multicast MAC address range that is reserved for CFM messages. Each MEP must have a MEP ID that is unique within the MA. The MEPs send the CCM messages differently, depending on the configuration, as follows:

- The DOWN MEPs sends out a single CCM message.
- The UP MEPs potentially sends the CCM message to all ports on the service instance (MA)—except the sending port—depending on the MPs configured on the outgoing ports.

**Note**

Ensure that you configured the UP and DOWN MEPs correctly, or the CCMs will flow in the wrong direction through the domain and not allow connectivity testing.

MIPs define intermediate points within a domain. MIPs relay the CCM messages to the next MIP or MEP in the domain.

You configure the time interval for each MEP to send a CCM. We recommend setting this interval for at least one second. Each MEP also makes a note of what port and what time it received a CCM. This information is stored in the CCM database.

Each CCM has a time-to-live (TTL) value also noted for that message. This TTL interval is 3.5 times the CCM transmission interval you configured on the switch that is originating the CCM. After the TTL expires, the connectivity is considered broken, and the system sends a message to the log. One important result of the continual transmission of CCM frames is that the MAC address of the originating MEP is known to all MPs in the association.

**Note**

All MEPs in an MA must be configured with the same CCM transmission interval.

The MD values are from 0 to 7; in the hierarchy, the MD level of 0 is lowest and 7 is highest.

Not all combinations of MPs are allowed on the same port within an MA; only the following combinations can be on the same port within an MA:

- UP MEP and MIP
- DOWN MEP with neither UP MEP nor MIP

CFM protocol imposes the following MP restrictions within an MA on a switch:

- MA can have either up MEP or down MEP and not both.
- MA can have multiple Down MEPs.
- Only one Up MEP per MA.
- MA can have both up MEP and MIP.
- MA cannot have MIP if down MEP is present.
- Down MEPs on regular ports are created in hardware for all CCM intervals for platforms that support CFM in hardware (ExtremeSwitching X460-G2).

- Up MEPs and MEPs on *LAG (Link Aggregation Group)* ports are created in software with CCM intervals 100 msec–600000 sec on all platforms.
- Dynamic Remote MEP learning is not supported for the MEPs created in hardware. You must explicitly create static Remote MEPs.
- Sender-Id-IP Address cannot be configured for the MEPs created in hardware.
- Unicast CCM transmission is not supported by the MEPs created in hardware.
- Domain name format should be of string type to create any MEPs in hardware in that domain.
- The CCM transmission state is disabled by default for the MEPs created in hardware by the CFM user interface.
- The CCM transmission state is enabled by default for the MEPs created in hardware by CFM clients like *ERPS (Ethernet Ring Protection Switching)*.
- The hardware Remote MEP status appears in `show cfm detail`. It is also forwarded to the client if created by a client like ERPS.
- CFM objects like domain, association, MEP, Remote MEP created by a client are not saved by `dotlag`.

#### Note

An MA can have an UP MEP in one switch and a DOWN MEP on another switch for the same MA.

## Ping and Traceroute

When operators see a connectivity fault message from CCM in the system log, they can send a loopback message (LBM) or a link trace message (LTM).

These are also referred to as a Layer 2 ping or a traceroute message. You can send with an LBM or an LTM only from an MEP (either UP or DOWN).

You can only send a ping from a MEP, and you ping to the unique system MAC address on the switch you are testing connectivity to. The operator sends out a unicast LBM, and the first MIP or MEP on the switch with the destination MAC address matching the embedded MAC address replies with an LBR (loopback reply).

You can only send a traceroute (LTM) from a MEP. You send the traceroute to the unique system MAC address on the switch to which you are testing connectivity. The system sends out an LTM to the special multicast address. If the destination address is not present in the *FDB (forwarding database)*, the LTM is flooded on all the ports in the MIP node. Each MIP in the path passes the frame only in the direction of the path and sends a link trace reply (LTR) message back to the originating with information that the LTM passed. The traceroute command displays every MIP along the path (see [traceroute mac port](#)).

## Supported Instances for CFM

[Table 83](#) displays the CFM support in ExtremeXOS.

**Table 83: ExtremeXOS CFM Support**

| Item                        | Limit                          | Notes                                                                                                                                           |
|-----------------------------|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| Domains                     | 8                              | Per switch; one for each MD level                                                                                                               |
| Associations (MAs)          | 256                            | Per switch                                                                                                                                      |
| UP MEPs                     | 32                             | Per switch                                                                                                                                      |
| DOWN MEPs                   | 256 hardware-placed MEPs<br>32 | Per switch                                                                                                                                      |
| MIPs                        | 32                             | Per switch                                                                                                                                      |
| Total CFM ports             | 128                            | Per switch; total number of all ports for all service instances assigned to an MA (see commands for ports configured for CFM)                   |
| Entries in the CCM database | 2000                           | Number of remote end points stored in a CCM database on each MEP; 64 end points per MEP (additional CCMs discarded after this limit is reached) |
| CFM Segments                | 1000                           | Maximum number of CFM segments for Y.1731.                                                                                                      |
| CFM Groups                  | 1000                           | Maximum number of CFM groups.                                                                                                                   |

**Note**

The total number of CFM ports is a guideline, not a limit enforced by the system.

*CFM Groups*

Loop detection protocols like EAPS (Extreme Automatic Protection Switching)/ERPS want to depend upon CFM to detect link status for faster failover recovery.

They register with LMEP and RMEP objects created by CFM in order to receive the link status event notifications to take the necessary action.

Currently LMEP is identified with domain, association, port, MEPIId quadruples. And RMEP is identified with domain, association, LMEP, RMEPIId quadruples. Each LMEP can be tied up to multiple RMEPs. So applications need to configure domain, association, LMEP and RMEPs through a client/server interface.

To simplify this, CFM provides a simple API to client applications to register/deregister CFM with a specified string name. The string name can be identified as a CFM group that binds an LMEP to multiple RMEPs. The group name is unique across the switch. Each application can create its own group for a required LMEP/RMEP combination.

You can associate a group to each LMEP created on a port. There exists a one-to-one relationship between LMEP-port-group. Whenever CFM stops receiving CCMs on this port, it informs a group DOWN event to registered clients like ERPS/EAPS. Whenever CFM starts receiving the CCMs again on this port, a group UP event is sent to registered clients.

## Configuring CFM

To configure CFM, create a maintenance domain and assign it a unique MD level. Next, associate MAs with the specified domain and assign MPs within that MA. Optionally, you can configure the transmission interval for the CCMs, destination MAC type for an MA and remote MEPs statically in an MA.

If a MEP fails to receive a CCM before the last advertised TTL value expires, the system logs a message. After the network administrator sees the system log message, he can send a Layer 2 ping and/or a traceroute message to isolate the fault.

### Note

CFM does not use ACL (Access Control List); there are no additional ACL entries present for CFM in the `show access-list dynamic` command output.

ExtremeXOS 15.5 provides support for transmitting and receiving ITU-T Y.1731 CCMs. The main difference between IEEE 802.1ag and ITU-T Y.1731 CCMs is between the MAID and MEG ID formats in CCMs:

- MAID ---- MA (format + length + name) with/without MD (format + length + name) details.
- MEG ID ---- MEG (format + length + name) without MD details.
- MA is referred to as MEG in Y.1731 and both are same.
- MA assumes four formats (string/integer/vpn-id/vlan-id) for its name.
- MEG assumes ICC format which is a combination of ICC (6 bytes) + organization specific UMC (6 bytes).
- To support Y.1731 CCMs, an additional name format for MEG name is added for association.

### Creating Maintenance Domains

You can create maintenance domains (MDs), or domains, and assign a unique MD level at that time. Available MD levels are numbered from 0 to 7. Higher numerical values are superior MD levels in the CFM hierarchy. Each switch can have a total of eight domains, each with a unique MD level.

You can name domains using any one of the following three formats:

- Simple string—Use an alphanumeric character string with a maximum of 43 characters.
- Domain name server (DNS) name—Use an alphanumeric character string with a maximum of 43 characters.
- MAC address plus 2-octet integer—Use a MAC address and a 2-octet integer. The display format is XX.XX.XX.XX.XX.XX.YYY, where X is the MAC address, and Y is the

2-octet integer. For example, a domain name in this format using 123 as the 16-bit unsigned integer appears as follows: 00:11:22:33:44:55.123.

**Note**

Whatever convention you choose, you must use that same format throughout the entire domain.

The CFM messages carry the domain name, so the name and naming format must be identical to be understood throughout the domain. You can, however, use different naming conventions on different domains on one switch (up to eight domains allowed on one switch). User-created CFM names are not case sensitive.

- To create a domain and assign an MD level using the DNS convention, use the following command:

```
create cfm domain dns name md-level level
```

- To create a domain and assign an MD level using the MAC address convention, use the following command:

```
create cfm domain mac mac-addr md-level level
```

- To create a domain and assign an MD level using the string convention, use the following command:

```
create cfm domain string str_name md-level level
```

- Although you assign an MD level to the domain when you create that domain, you can change the MD level on an existing domain by running:

```
configure cfm domain domain_name md-level level
```

- To delete a domain, use the following command:

```
delete cfm domain domain
```

### *Creating and Associating MAs*

Within a given domain, you can associate maintenance associations (MAs). Extreme Networks' implementation of CFM associates MAs with service instances. All of the ports in that service instance are now in that MA and its associated domain.

Each MA associates with one service instance, and each service instance may associate with more than one MA; you can configure more than one MAs in any one domain.

Like the domains, ExtremeXOS supports multiple formats for naming the MA. The following formats are supported for naming the MAs:

- Character string
- 2-octet integer
- RFC 2685 VPN

- VLAN ID
- Y.1731 MEG name
- To add an MA to a domain using the character string format, use the following command:  

```
configure cfm domain domain_name add association string name [vlan vlan_name|vman vman_name]
```
- To add an MA to a domain using the 2-octet integer format, use the following command:  

```
configure cfm domain domain_name add association integer int [vlan vlan_name|vman vman_name]
```
- To add an MA to a domain using the RFC 2685 VPN ID format, use the following command:  

```
configure cfm domain domain_name add association vpn-id oui oui index index [vlan vlan_name|vman vman_name]
```
- To add an MA to a domain using the VLAN ID format, use the following command:  

```
configure cfm domain domain_name add association vlan-id vlanid [vlan vlan_name|vman vman_name]
```
- To add an MA using Y.1731 compliant MEG, use the following command: `configure cfm domain domain_name add association meg [meg name] [vlan vlan_name|vman vman_name]`
- To delete an MA from a domain, use the following command:  

```
configure cfm domain domain_name delete association association_name
```

In addition to supporting multicast destination MAC address for CCM and LTM frames specified by the 802.1ag standard, ExtremeXOS CFM supports the use of a unicast destination address for CCM and LTM frames.

This allows the support of a CFM operation in a network where use of multicast address is prohibited.
- To configure the destination MAC address type for an MA, use the following command:  

```
configure cfm domain domain-name association association_name destination-mac-type [unicast | multicast]
```
- Use the following command to add a remote MEP to an MA statically:  

```
configure cfm domain domain-name association association_name add remote-mep mepid { mac-address mac_address }
```

ExtremeXOS CFM supports configuring remote MEPs statically for CFM operation where dynamic discovery of MEPs in an MA using multicast address is prohibited.
- To delete a remote MEP from an MA, use the following command:  

```
configure cfm domain domain-name association association_name delete remote-mep mepid
```
- To configure a remote MEP MAC address, use the following command:  

```
configure cfm domain domain-name association association_name remote-mep mepid mac-address mac_address
```

### Creating MPs and the CCM Transmission Interval

Within an MA, you configure the following MPs:

- Maintenance end points (MEPs), which are one of the following types:
  - UP MEPs—transmit CCMs, and maintain CCM database.
  - DOWN MEPs—transmit CCMs, and maintain CCM database.
- Maintenance intermediate points (MIPs)—pass CCMs through.

Each MEP must have an ID that is unique for that MEP throughout the MA.

- To configure UP and DOWN MEPs and its unique MEP ID, use the following command:

```
configure cfm domain domain_name association association_name ports
port_list add [end-point [up | down] mepid group { group_name }] |
[intermediate-point]]
```

- To change the MEP ID on an existing MEP, use the following command:

```
configure cfm domain domain_name association association_name ports
port_list end-point [up | down] mepid { mepid }
```

- To delete UP and DOWN MEPs, use the following command:

```
configure cfm domain domain_name association association_name ports
port_list delete [[end-point [up | down]] | intermediate-point]]
```

- To configure a MIP, use the following command:

```
configure cfm domain domain_name association association_name ports
port_list add [end-point [up | down] mepid group { group_name }]
| [intermediate-point]]
```

- To delete a MIP, use the following command:

```
configure cfm domain domain_name association association_name ports
port_list delete [[end-point [up | down]] | intermediate-point]]
```

- To configure the transmission interval for the MEP to send CCMs, use the following command:

```
configure cfm domain domain_name association association_name ports
port_list end-point [up | down] transmit-interval [3 | 10 | 100 |
1000 | 10000 | 60000 | 600000]
```

- To unconfigure the transmission interval for the MEP to send CCMs and return it to the default, use the following command:

```
unconfigure cfm domain domain_name association association_name ports
port_list end-point [up | down] transmit-interval
```

- To enable or disable a MEP, use the following command:

```
configure cfm domain domain_name association association_name ports
port_list end-point [up | down] [enable | disable]
```

### Configuring EAPS for CFM Support

- Use the following command to configure EAPS for CFM support:

For additional configuration details for CFM support, refer to [Configuring CFM](#) on page 1256.

### Assigning MEP Group Names to New MEP

To assign MEP Group name when creating a MEP, use the following command:

```
configure cfm domain domain_name association association_name ports
port_list add [[end-point [up | down] mepid group { group_name }] |
[intermediate-point]]
```

### Assign MEP Group Name to Existing MEP

To assign a MEP Group name to an existing MEP, use the following command:

```
configure cfm domain domain_name association association_name ports
port_list end-point [up|down] [add|delete] group group_name
```

### Add a RMEP to MEP Group

To add specific RMEPs for a MEP Group to monitor, use the following command:

```
configure cfm group group_name [add|delete] rmeip mepid
```

### Monitoring CFM in EAPS

#### Displaying MEP Groups

To display MEP groups, use the following command:

```
show cfm groups {group_name}
```

```
sh cfm groups
Group : eapsCfmGrp1 Status : UP
Local MEP : 11 port : 41
Remote MEPs : 10

### Executing Layer 2 Ping and Traceroute Messages

If the system logs a missed CCM message, the operator can use Layer 2 ping and traceroute messages to isolate the fault. (See [Ping and Traceroute](#) for information on how each MP handles these messages.)

#### Note

You must have all the CFM parameters configured on your network before issuing the ping and traceroute messages.

- To send a Layer 2 ping, use the following command:

```
ping mac mac port port {domain} domain_name {association}
association_name
```

- To send a Link Trace Message (LTM) and receive information on the path, use the following command:

```
traceroute mac mac {up-end-point} port port {domain} domain_name
{association} association_name {ttl ttl}
```

## Displaying CFM

To verify your CFM configuration, you can display the current CFM configuration using the `show cfm` command.

The information this command displays includes the total ports configured for CFM, the domain names and MD levels, the MAs and associated service instances, and the UP and DOWN MEPs.

To display the CCM database for each MEP, use the `show cfm detail` command.

Counters are added for missed-hellos, which mainly help to constantly monitor the health of CFM session path and hence tweaking the configured interval times to get the best reliability with the shortest fail over times for radio and wireless networks that rely on CFM to detect any failures. These counters can be displayed using `show cfm session counters missed-hellos` command. The counters can be cleared using "clear counters cfm session missed-hellos" command.

## CFM Example

As shown in [Figure 159](#) on page 1261, this example assumes a simple network and assumes that CFM is configured on the access switches, as well as the necessary VMANs configured with the ports added. This example shows a VMAN associated with two maintenance domains and two different MAs. UP MEPs are configured for an MA with MD level 6 and DOWN MEPs are configured for an MA with MD level 3.

**Figure 159: CFM Configuration Example**

- Configure switch 1 for this example.

```
create cfm domain string cust-xyz-d6 md-level 6
configure cfm domain cust-xyz-d6 add association string cust-xyz-d6-m100 vman m100
```

```
configure cfm domain cust-xyz-d6 association cust-xyz-d6-m100 port 1:1 add end-point
up 10
configure cfm domain cust-xyz-d6 association cust-xyz-d6-m100 port 2:1 add
intermediate-point
create cfm domain string core-d3 md-level 3
configure cfm domain core-d3 add association string core-d3-m100 vman m100
configure cfm domain core-d3 association core-d3-m100 port 2:1 add end-point down 10
```

- Configure switch 2 for this example.

```
create cfm domain string core-d3 md-level 3
configure cfm domain core-d3 add association string core-d3-m100 vman m100
configure cfm domain core-d3 association core-d3-m100 port 2:1 add intermediate-point
configure cfm domain core-d3 association core-d3-m100 port 2:2 add intermediate-point
```

- Configure switch 3 for this example.

```
create cfm domain string cust-xyz-d6 md-level 6
configure cfm domain cust-xyz-d6 add association string cust-xyz-d6-m100 vman m100
configure cfm domain cust-xyz-d6 association cust-xyz-d6-m100 port 1:1 add end-point
up 20
configure cfm domain cust-xyz-d6 association cust-xyz-d6-m100 port 2:1 add
intermediate-point
create cfm domain string core-d3 md-level 3
configure cfm domain core-d3 add association string core-d3-m100 vman m100
configure cfm domain core-d3 association core-d3-m100 port 2:1 add end-point down 20
```

- To display the group database, use the following command:

```
show cfm groups
```

## Y.1731—Compliant Performance Monitoring

Compliant performance monitoring is based on the ITU-T Y.1731 standard and deals with the Ethernet Delay Measurement (ETH-DM) function and Ethernet Frame-Loss Measurement (ETH-LM).

### Frame-Delay Measurement

ExtremeXOS software supports:

- Two-way delay measurement—Delay Measurement Message (DMM) and Delay Measurement Reply (DMR).
- Continuous (proactive) measurement of frame delay and frame delay variation.
- On-demand measurement of frame delay and frame delay variation.

By default, DMM is not enabled. You must explicitly enable the DMM transmission for a CFM segment, either as continuous or on-demand mode.

A network interface is considered attached to a subnetwork. The term *segment* is used to refer to such a subnetwork, whether it be an Ethernet LAN, a ring, a WAN link, or even an SDH virtual circuit.

Frame-Delay measurement is done between two specific end points within an administrative domain. Frame delay and frame delay variation measurements are performed in a maintenance association end point (MEP) by sending and receiving periodic frames with ETH-DM information to and from the peer end point during the diagnostic interval.

When a CFM segment is enabled to generate frames with ETH-DM information, it periodically sends frames with ETH-DM information to its peer in the same maintenance association (MA) and expects to receive frames with ETH-DM information from its peer in the same MA.

The following list offers specific configuration information that is required by a peer to support ETH-DM:

- Maintenance domain (MD) level—The MD level at which the peer exists.
- Priority—The priority of the frames with ETH-DM information.
- Drop eligibility—Frames with ETH-DM information that are always marked as drop ineligible.
- Transmission rate.
- Total transmit interval.

A node transmits frames with ETH-DM information with the following information element:

- TxTimeStampf: Timestamp at the transmission time of the ETH-DM frame.
- RxTimeStampb: Timestamp at which the switch receives the DMR back.

Whenever a valid DMM frame is received by the peer, a DMR frame is generated and transmitted to the requesting node.

- A DMM frame with a valid MD level and a destination MAC address equal to the receiving node's MAC address is considered to be a valid DMM frame. Every field in the DMM frame is copied to the DMR frame with the following exceptions:
  - The source and destination MAC addressed are swapped.
  - The OpCode field is changed from DMM to DMR.

The switch makes two-way frame delay variation measurements based on its ability to calculate the difference between two subsequent two-way frame delay measurements.

To allow a more precise two-way frame delay measurement, the peer replying to the frame with ETH-DM request information may include two additional timestamps in the ETH-DM reply information:

- RxTimeStampf—Timestamp at the time of receiving a frame with ETH-DM request information
- TxTimeStampb—Timestamp at the time of transmitting a frame with ETH-DM reply information

Here the frame delay is calculated by the peer that receives the DMR as follows:

- Frame Delay = (RxTimeStampb - TxTimeStampf) - (TxTimeStampb - RxTimeStampf)

Figure 160 describes the DMM and DMR message flows between two end points.

**Figure 160: Two-Way Frame Delay and Frame Delay Variance Measurement**

The PDUs used to measure frame delay and frame delay variation are the DMM and the DMR PDUs where DMM is initiated from a node as a request to its peer and DMR is the reply from the peer.

If you try to enable the transmission for a CFM segment whose configuration is not complete, the trigger is rejected and an error message similar to the following is given:

ERROR: CFM Configuration is not complete for segment "s1" to start transmission

**Note**

A CFM segment without a domain and an association is considered to be an incomplete segment.

Upon enabling the transmission from a CFM segment, the segment transmits DMM frames, one at each transmit-interval which is configured through the CLI. If the user enables on-demand transmission, the segment transmits "X" number of DMMs and moves back to the disabled state, where "X" is the number of frames specified by the user through the CLI.

For continuous transmission, the segment continues to transmit DMM frames until stopped by the user. This transmission continues even after reboot for both continuous and on-demand mode. For on-demand transmission, the segment, which was enabled to transmit "X" number of frames, and is still transmitting, starts transmitting again "X" number of frames after reboot, or failover, or process restart. The old statistics are not preserved for both continuous and on-demand mode for all the above three scenarios.

Upon transmitting a DMM, the segment is expected to get a reply from the destination within the specified time. If a reply is received after that time, that reply will be considered as a delayed one.

If a reply is not received within the transmit-interval, that is, between two subsequent DMM transmissions, then that frame is considered as lost. Once the percentage of the sum of lost and delayed frames reaches the alarm threshold, an alarm is generated and the segment is moved to the alarming state. This state is maintained until the percentage of valid replies reaches the clear threshold. These alarm and clear states are maintained for a specified window, which holds a set of recent frames and their corresponding delays.

Various times are recorded at the segment level during the transmission of DMM frames.

- Start time—Time at which the segment started the current transmission.
- Min delay time—Time at which the minimum delay occurred in the current transmission window.
- Max delay time—Time at which the maximum delay occurred in the current transmission window.
- Alarm time—The recent alarm time, if any, during the current transmission.

The mean delay and delay variance for the current window is also measured whenever the user polls the segment statistics.

## Frame-Loss Measurement

Frame-loss is measured by sending and receiving frames with frame-loss information between peer maintenance end points (MEPs).

Frame-loss ratio is defined as a percentage of the number of service frames not delivered divided by the total number of service frames during a defined time interval, where the number of service frames not delivered is the difference between the number of service frames arriving at the ingress Ethernet flow point and the number of service frames delivered at the egress Ethernet flow point in a point-to-point Ethernet connection (see [Figure 161](#)).

$$\text{Frame Loss Ratio} = \left( \frac{\text{Svc Frames at Ingress} - \text{Svc Frames at Egress}}{\text{Total \# Svc Frames for Time Interval}} \right) \times 100$$

 = Service Frames Not Delivered

### Figure 161: Frame-Loss Ratio Formula

To support frame-loss measurement, a MEP requires the following configuration information:

- Maintenance domain (MD) level—MD level at which the MEP exists.
- Frame-loss measurement transmission period—time interval when frame-loss measurement frames are sent.
- Priority—identifies the priority of the frames with frame-loss measurement information (configurable per operation).
- Drop eligibility—frames with frame-loss measurement information are always marked as drop ineligible (not necessarily configured).

A maintenance intermediate point (MIP) is transparent to frames with frame-loss measurement information. Therefore MIPs do not require any information to support frame-loss measurement functionality.

There are two frame-loss measurement methods:

- [Dual-Ended Frame-Loss Measurement](#)
- [Single-Ended Frame-Loss Measurements](#)

### Dual-Ended Frame-Loss Measurement

Dual-ended frame-loss measurement is a form of proactive OAM for performance monitoring and is useful for fault management.

#### Note

ExtremeXOS does not support dual-ended frame-loss measurement.

MEPs send periodic dual-ended frames with frame-loss measurement information to peer MEPs in a point-to-point MD. Each MEP terminates the dual-ended frames with frame-loss measurement information and makes the near-end and far-end loss measurements. Near-end frame loss refers to frame loss associated with ingress data frames, while far-end frame loss refers to frame loss associated with egress data frames. This function is used for performance monitoring at the same priority level as used for CCM.

The protocol data unit (PDU) for dual-ended frame-loss measurement information is Continuity Check Message (CCM).

### Single-Ended Frame-Loss Measurements

Single-ended frame-loss measurement facilitates on-demand OAM. MEPs carry out frame-loss measurements by sending frames to peer MEPs with frame-loss measurement request information and receiving frames with frame-loss measurement reply information. This Y\_1731 frame-loss measurement depends on VLAN statistics.

The PDU for single-ended frame-loss measurement requests is Loss Measurement Message (LMM). The PDU for single-ended frame-loss measurement reply is Loss Measurement Reply (LMR). [Figure 162](#) shows the transmission of LMM and LMR for frame-loss measurement.

**Figure 162: Two-Way Frame-Loss Measurement**

A MEP maintains two local counters for each peer MEP it is monitoring for frame-loss:

- TxFCI—in-profile data frames transmitted to the peer MEP.
- RxFCI—in-profile data frames received from the peer MEP.

For an on-demand loss measurement, a MEP periodically transmits LMM frames with TxFCf (value of the local TxFCI counter at the time of LMM frame transmission). Upon receiving a valid LMM frame, a MEP sends an LMR frame to the requesting MEP.

(Valid LMM frames have a valid MD level and a destination MAC address equal to the receiving MEP's MAC address.)

An LMR frame contains the following values:

- TxFCf—TxFCf value copied from the LMM frame.
- RxFCf—RxFCf value when the LMM frame was received.
- TxFCb—TxFCb value when the LMR frame was transmitted.

Upon receiving an LMR frame, a MEP uses the following values to make near-end and far-end loss measurements:

- Received LMR frame's TxFCf, RxFCf, and TxFCb values, and local counter RxFCf value at the time this LMR frame was received. These values are represented as TxFCf[tc], RxFCf[tc], TxFCb[tc], and RxFCf[tc]; where tc is the time the current reply frame was received.
- Previous LMR frame's TxFCf, RxFCf, and TxFCb values, and local counter RxFCf value at the time the previous LMR frame was received. These values are represented as TxFCf[tp], RxFCf[tp], TxFCb[tp], and RxFCf[tp], where tp is the time the previous reply frame was received.

Far-End Frame Loss = (TxFCf[tc] – TxFCf[tp]) – (RxFCf[tc] – RxFCf[tp])

Near-End Frame Loss = (TxFCb[tc] – TxFCb[tp]) – (RxFCf[tc] – RxFCf[tp])

#### *Availability Time and Severly Errored Seconds (SES)*

Frame loss is measured by sending and receiving frames with frame-loss information between peer MEPs.

Each MEP performs frame-loss measurements which contribute to unavailable time. Since a bidirectional service is defined as unavailable if either of the two directions is declared unavailable, frame-loss measurement must facilitate each MEP to perform near-end and far-end frame loss measurements.

Near-end frame loss refers to frame loss associated with ingress data frames, while far-end frame loss refers to frame loss associated with egress data frames. Both near-end and far-end frame loss measurements contribute to near-end severely errored seconds (near-end SES) and far-end severely errored seconds (far-end SES) respectively, which together contribute to unavailable time.

A period of unavailable time begins at the onset of x consecutive Severly Errored Seconds (SES) events. These x seconds are part of unavailable time. A new period of available time begins at the onset of x consecutive non-SES events. These x seconds are part of available time.

A SES is declared when, during one measurement period, the number of frames lost exceeds a threshold. ExtremeXOS logs the start and end time of the unavailable periods (see [Figure 163](#) from ITU-T G.7710).

**Figure 163: SES**

## Configuring a CFM Segment

Use the following commands to configure a CFM segment.

Some of these commands are optional and, if not configured, the default values are used. [Table 84](#) lists the default values for delay measurement for a CFM segment.

**Table 84: Default Values for Delay Measurement for a CFM Segment**

| Configuration     | Default Values  |
|-------------------|-----------------|
| Transmit interval | 10 seconds      |
| Window            | 60 frames       |
| Timeout           | 50 milliseconds |
| Alarm threshold   | 10%             |
| Clear threshold   | 95%             |
| Dot1p priority    | 6               |

[Table 85](#) lists the default values for loss measurement for a CFM segment.

**Table 85: Default Values for Loss Measurement for a CFM Segment**

| Configuration               | Default Values |
|-----------------------------|----------------|
| LMM Transmit interval       | 90 seconds     |
| Dot1p priority              | 6              |
| Window                      | 1200 frames    |
| SES threshold               | 0.01           |
| Consecutive available count | 4              |

### Note

The statistics for a particular transmission are preserved until the user triggers the transmission once again or if `clear counters cfm segment` is triggered from the CLI.

### Managing a CFM Segment

You can create, delete, add CFM segments.

- To create a CFM segment, use the following command:

```
create cfm segment segment_name destination mac_addr {copy
segment_name_to_copy}
```

- To delete a CFM segment, use the following command:

```
delete cfm segment [segment_name | all]
```

- To add a CFM domain to a CFM segment, use the following command:

```
configure cfm segment segment_name add domain domain_name association
association_name
```

- To delete a CFM domain from a CFM segment, use the following command:

```
configure cfm segment segment_name delete domain association
```

- To configure the transmission interval between two consecutive DMM or two consecutive LMM frames, use the following command:

```
configure cfm segment segment_name {frame-delay | frame-loss}
transmit-interval interval
```

The same transmit-interval is used for both delay and loss measurements.

- To get separate values for delay and loss measurements, use the following command:

```
configure cfm segment frame-delay/frame-loss transmit interval
interval
```

- To configure the dot1p priority of a DMM frame, use the following command:

```
configure cfm segment segment_name frame-delay dot1p dot1p_priority
```

- To configure the dot1p priority of a LMM frame, use the following command:

```
configure cfm segment segment_name frame-loss dot1p dot1p_priority
```

- To configure the dot1p priority of the CFM segment, use the following command:

```
configure cfm segment segment_name dot1p dot1p_priority
```

The same priority is used for both delay and loss measurements.

- To get separate values of priority for delay and loss measurements, use the following command:

```
configure cfm segment segment_name frame-delay dot1p dot1p_priority
```

```
configure cfm segment segment_name frame-loss dot1p dot1p_priority
```

- To configure the alarm and clear threshold value for CFM segment, use the following command:

```
configure cfm segment segment_name [alarm-threshold | clear-threshold]
value
```

- To configure the window size to be used for calculating the threshold values, use the following command:

```
configure cfm segment segment_name window size
```

The same window size is used for both delay and loss measurements.

- To get separate values of window size for delay and loss measurements, use the following:  

```
configure cfm segment segment_name frame-loss window window_size
```

```
configure cfm segment segment_name frame-delay window window_size
```
- To configure the window size of a DMM frame to be used for calculating the threshold values, use the following command:  

```
configure cfm segment segment_name frame-delay window window_size
```
- To configure the window size of a LMM frame to be used for calculating the threshold values, use the following command:  

```
configure cfm segment segment_name frame-loss window window_size
```
- To trigger DMM frames at the specified transmit interval, use the following command:  

```
enable cfm segment frame-delay measurement segment_name mep mep_id [continuous | count] value
```
- To disable the transmission of the DMM frames for a particular CFM segment, use the following command:  

```
disable cfm segment frame-delay measurement segment_name mep mep_id
```
- To show the configuration and status of a specific CFM segment, use the following command:  

```
show cfm segment {segment_name}
```
- To show the configuration and status of a specific CFM segment doing delay measurement, use the following command:  

```
show cfm segment frame-delay {segment_name}}
```
- To show the configuration and status of a specific CFM segment doing loss measurement, use the following command:  

```
show cfm segment frame-loss {segment_name}}
```
- To display the frame delay statistics for the CFM segment, use the following command:  

```
show cfm segment frame-delay statistics {segment-name}
```
- To configure the timeout value for a CFM segment, use the following command:  

```
configure cfm segment segment_name timeout msec
```
- To add or delete the local MEP for a given CFM segment, use the following command:  

```
configure cfm segment segment_name frame-loss [add|delete] mep mep_id
```
- To set the percentage of frames lost in a measurement period so that it will be marked as SES (severely errored second), use the following command:  

```
configure cfm segment segment_name frame-loss ses-threshold percent
```
- To set the number of consecutive measurements used to determine the availability status of a CFM segment, use the following command:  

```
configure cfm segment segment_name frame-loss consecutive frames
```

- To start the transmission of LMM frames for the set transmit interval, use the following command:

```
enable cfm segment frame-loss measurement segment_name mep mep_id
[continuous | count frames]
```

#### Note

For the above command, If the the segment is not completely configured, frames are not transmitted and an error occurs.

- To stop the transmission of the LMM frames for a particular CFM segment, use the following command:

```
disable cfm segment frame-loss measurement segment_name mep mep_id
```

- To display the frame loss or frame delay statistics for the CFM segment, use the following command:

```
show cfm segment {{segment_name} | {frame-delay {segment_name}} |
{frame-loss {segment_name {mep mep_id}}}}
```

#### Note

Frame-loss measurements are not supported on platforms where the VLAN packet statistics are not retrieved, and on up-meps.

## Clearing CFM Information

- To clear cfm segment counters, use the following commands:

```
clear counters cfm segment segment_name
clear counters cfm segment all
```

- To clear cfm segment counters specific to DMM, use the following command:

```
clear counters cfm segment segment_name frame-delay
```

- To clear cfm segment counters specific to LMM, use the following commands:

```
clear counters cfm segment segment_name frame-loss
clear counters cfm segment segment_name frame-loss mep mep_id
```

## Y.1731 MIB Support

ExtremeXOS 15.5 supports Y.1731 performance measurement MIB defined by MEF - 36. The performance monitoring process is made up of a number of performance monitoring instances, known as performance monitoring (PM) sessions. A PM session can be initiated between two MEPs in a MEG and be defined as either a loss measurement (LM) session or delay measurement (DM) session. The LM session can be used to determine the performance metrics frame loss ratio, availability, and resiliency. The DM session can be used to determine the performance metrics Frame Delay.

The MIB is divided into a number of different object groupings: the PM MIB MEP objects, PM MIB loss measurement objects, PM MIB delay measurement objects, and SOAM PM notifications. The initial implementation of MIB supports GET operations for Frame Loss& Frame Delay.

## MIB Specific Data

- A measurement interval of 15 min to be supported
- Default message period/transmit-interval of LMMs is 1 sec (Min = 1sec in current CLI) \*  
Default message period/transmit-interval of DMMs is 100msec (Min = 1 sec in current CLI)
- Repetition Time can be set to 0 which means that there is no gap between measurement intervals
- Number of History measurement intervals can be 2-1000, though it expects at least 32 measurement intervals to be stored and 96 are recommended.
- Both DM and LM sessions are MEP to MEP sessions. The index of all the DM/LM tables includes MD, MA, MEP table indices as well as the particular DM/LM session.
- Currently DM sessions are not MEP-to MEP based but only segment based sessions. To support DM tables in the MIB, changes are required in the current CLI & backend delay implementation.

## Limitations

- Currently we are storing a maximum of 1800 frames data for each LMM/DMM session. But to support at least 2 history and 1 current measurement intervals, we need to store 2700 frames (if message period is 1 sec, Repetition time is 0, measurement interval is 15 min) for each delay/loss session.
- Each frame's data is about 60 bytes for LMM and which takes about 44 MB of memory for 288 sessions

## EFM OAM—Unidirectional Link Fault Management

---

### Unidirectional Link Fault Management

With EFM OAM, certain physical layers can support a limited unidirectional capability.

The ability to operate a link in a unidirectional mode for diagnostic purposes supports the maintenance objective of failure detection and notification. Unidirectional OAM operation is not supported on some legacy links but is supported on newer links such as 100BASE-X PCS, 1000BASE-X PCS, and 10GbE RS. On technologies that support the feature, OAM PDUs can be transmitted across unidirectional links to indicate fault information. To the higher layers, the link is still failed in both directions, but to the OAM layer, some communication capabilities exist. The distinction between a unidirectional link and a normal link is shown in [Figure 164](#).

**Figure 164: Normal Link and Unidirectional Operation**

You can enable unidirectional link fault detection and notification on individual ports with CLI commands. This allows appropriate register settings to transmit OAM PDUs even on a link that has a slowly deteriorating quality receive path or no receive path at all. Then, when a link is not receiving a signal from its peer at the physical layer (for example, if the peer's laser is malfunctioning), the local entity can set a flag in an OAM PDU to let the peer know that its transmit path is inoperable.

The operation of OAM on an Ethernet interface does not adversely affect data traffic because OAM is a slow protocol with very limited bandwidth potential, and it is not required for normal link operation. By utilizing the slow protocol MAC address, OAM frames are intercepted by the MAC sub layer and cannot propagate across multiple hops in an Ethernet network. This implementation assures that OAM PDUs affect only the operation of the OAM protocol itself and not user data traffic.

The IEEE 802.3ah standard defines fault notifications based on one-second timers. But by sending triggered OAM PDUs on detecting link down/local fault rather than waiting to send on periodic PDUs, failure detection is less than one second can be achieved, thereby accelerating fault recovery and network restoration.

EFM OAM uses standard length Ethernet frames within the normal frame length of 64 to 1518 bytes as PDUs for their operation. [Table 86](#) describes the fields of OAM PDUs.

**Table 86: OAM PDU Fields**

| Field               | Octets | Description                       | Value             |
|---------------------|--------|-----------------------------------|-------------------|
| Destination Address | 6      | Slow protocol multicast address   | 01:80:C2:00:00:02 |
| Source Address      | 6      | Port's individual MAC address     | Switch MAC        |
| Length/Type         | 2      | Slow protocol type                | 0x8809            |
| Subtype             | 1      | Identifies specific slow protocol | 0x03              |

**Table 86: OAM PDU Fields (continued)**

| Field    | Octets  | Description             | Value                    |
|----------|---------|-------------------------|--------------------------|
| Flags    | 2       | Contains status bits    | see the following figure |
| Code     | 1       | Identifies OAM PDU type | 0x00 (Information TLV)   |
| Data/Pad | 42-1496 | OAM PDU data            | 0x00 (END of TLV)        |
| FCS      | 4       | Frame check sequence    |                          |

## Configuring Unidirectional Link Fault Management

To configure unidirectional link fault management on a port or ports, use the following command:

```
enable ethernet oam ports [port_list | all] link-fault-management
```

To clear the counters on a configured port, use the following command:

```
clear ethernet oam {ports [port_list]} counters
```

To unconfigure unidirectional link fault management, use the following command:

```
disable ethernet oam ports [port_list | all] link-fault-management
```

To display the Ethernet OAM settings, use the following command:

```
show ethernet oam {ports [port_list]} {detail}
```

When configured, the following behavior on the port is observed:

- A log indicates that traffic on the port is blocked.
- All received traffic on that port is blocked except for Ethernet OAM PDUs.
- To higher layers, a failure is reported as a link down but OAM can use the link to send OAM traffic.

## Two-Way Active Measurement Protocol

The Two-Way Active Measurement Protocol, defined in RFC 5357, specifies an industry standard for measuring round-trip performance between two devices that support the TWAMP protocols. TWAMP defines two protocols; the TWAMP-Control protocol and the TWAMP-Test protocol. The TWAMP-Control protocol is used to setup test sessions. The test sessions use the TWAMP-Test protocol to transmit and reflect performance measurement packets. The TWAMP-Control protocol utilizes TCP for communication, while the TWAMP-Test protocol utilizes UDP.

### Note

Only the TWAMP-Test protocol is supported.

The test sessions are setup via the 'Request-Session' command message, sent from the Control-Client to the Server. The Server replies with an 'Accept Session' message, which indicates if the Server is capable of accommodating the request or not. The Control-Client may send several 'Request-Session' command messages to setup multiple test sessions. To begin the tests, the Control-Client transmits a 'Start-Session' command message. The Server replies with a 'Start-Ack' message. The Control-Client does not begin its test until it receives the 'Start-Ack' message. This allows the Server ample time to configure the test sessions. The Control-Client will stop the test sessions with a 'Stop-Sessions' message. The Server does not respond to this message.

The ExtremeXOS 16.1 implementation of TWAMP consists of the development of the TWAMP logical role of the Session-Reflector. The user is required to configure endpoints, which define the destination of TWAMP-Test packets generated by the client. An endpoint receiving a new TWAMP-test packet creates a test session consisting of the following four-part tuple; client IP address, client UDP port, endpoint IP address, and endpoint UDP port. The tuple does not include the VR because it requires the default VR for the first phase. A session timeout value, configured globally, determines the amount of time test sessions exist after the last reception of a TWAMP-Test packet. Test sessions are used to keep track of the session data, such as the sequence number. The Session-Reflector will still respond to TWAMP-Test packets that do not match an existing test session or if a new test session cannot be created due to lack of resources.

## TWAMP-Test Protocol

The TWAMP logical roles of the Session-Sender and Session-Reflector use the TWAMP-Test protocol. The Session-Sender, controlled by the Client, transmits TWAMP-Test packets to the Session-Reflector. The Session-Reflector processes the packet, copies the fields from that packet into the reply, and then transmits a reply packet back to the Session-Sender. The reply packet is larger than the request packet unless the Clients adds padding.

The implementation of the Session-Reflector relies on the user to create endpoints, which open up available ports for reflecting TWAMP-Test packets. The endpoint configuration acts as a control list to limit the number of locally opened sockets. The user may choose to use authentication or encryption to protect the transmitted data from nefarious entities. The shared keys used for the TWAMP-Test derive from the TWAMP 3-way handshake that establishes the control session. Both devices must configure matching shared keys.

## Bidirectional Forwarding Detection (BFD)

### BFD Overview

Bidirectional Forwarding Detection (BFD) is a hello protocol that provides the rapid detection of failures in the path and informs the clients (routing protocols) to initiate the route convergence.

It is independent of media, routing protocols, and data protocols. BFD helps in the separation of forwarding plane connectivity and control plane connectivity.

Different routing protocol hello mechanisms operate in variable rates of detection, but BFD detects the forwarding path failures at a uniform rate, thus allowing for easier network profiling and planning, and consistent and predictable re-convergence time.

Figure 165 shows a BFD topology.

1. Routing protocol (BFD client) discovers neighbor.
2. Routing protocol informs BFD to create session with neighbor.
3. BFD establishes session with neighbor.

#### Figure 165: BFD Topology

The routing protocols first learn the neighbor and make entries in the forwarding table. Then protocols can register the neighbor address with BFD and ask to monitor the status of the path. BFD establishes the session with a remote BFD and monitors the path status.

You can configure detection multipliers and TX and RX intervals on a directly connected interface (VLAN).

- The detection multiplier signifies the number of BFD packets the BFD server waits for after which a timeout is declared.
- The receive interval is the interval at which the BFD server is ready to receive packets.
- The transmit interval is the interval at which the BFD server is ready to transmit packets.

For example, when two nodes, A and B, initiate a BFD session between them, a negotiation about the receive and transmit intervals occurs.

The receive interval of node A is calculated as the maximum of the configured receive interval of node A and the configured transmit interval of node B. The same applies to node B.

If multiple clients ask for the same neighbor on the same interface, then a single BFD session is established between the peers.

Figure 166 shows the behavior when a failure occurs.

**Figure 166: BFD Failure Detection**

BFD detects the failure first, and then informs the registered clients about the neighbors.

BFD operates in an asynchronous mode in which systems periodically send BFD control packets to one another. If a number of those packets in a row are not received by the other system, the session is declared to be down.

Simple password authentication can be included in the control packet to avoid spoofing.

BFD for OTM, BGP, and hitless failover are supported.

This feature is available on all platforms.

**Note**

BFD can be used to protect IPv4 & IPv6 static routes, OSPFv2 & *OSPFv3 (Open Shortest Path First version 3)* interfaces and *BGP (Border Gateway Protocol)* and *MPLS (Multiprotocol Label Switching)* interfaces. For more information, see [Configuring Static Routes](#) on page 890, [BFD for OSPF](#) on page 1353, or refer to [Managing the MPLS BFD Client](#) on page 1094.

## Limitations

The following limitations apply to BFD in this release:

- BGP, OSPF (Open Shortest Path First), MPLS, OTM, and static routes act as BFD clients.
- The echo function is not supported.
- Hardware assist BFD is supported only on standalone X460-G2, X465, X590, and X695 series switches.
- Hardware assist BFD is not supported Universal platforms.
- The number of sessions handled by BFD at minimal timers (less than 100ms) varies depending on the platform type, the implementation type (H/w or S/w), and the processing load (which is influenced by other protocols being enabled or other system conditions such as software forwarding).
- The following scaling limits apply to BFD hardware assist:
  - Maximum 900 sessions if PTP feature not enabled.

- Maximum 425 sessions with PTP enabled.
- Maximum of 256 sessions with 3 ms transmit interval.

## Configuring BFD

You can enable, disable, configure, and unconfigure BFD.

- To enable or disable BFD, use the following command:

```
[enable | disable] bfd vlan vlan_name
```

- To configure the detection multipliers and TX and RX intervals, use the following command:

```
configure bfd vlan vlan_name [{detection-multiplier multiplier}
{receive-interval rx_interval} {transmit-interval tx_interval}]
```

- To specify either authentication using a simple password or no authentication, use the following command:

```
configure bfd vlan vlan_name authentication [none | simple-password
{encrypted} password]]
```

- To unconfigure BFD, use the following command:

```
unconfigure bfd vlan vlan_name
```

### Configuring BFD Intervals

In case of BFD implemented in software, the ability to run low-range sub-second intervals depends on the CPU load, which in turn depends on other protocol configurations and system conditions, such as software forwarding. It also depends on switch model.

To find a suitable low-range interval for the chosen configuration and network load, statistics of missed hello packets can help. These hello packets are exchanged between BFD peers, and if  $n$  number of packets are missed in a row, path failure will be declared, where  $n$  is detection-multiplier. However, missed hellos less than  $n$  number will not declare failure, but if statistics are steadily increasing, it can indicate that the currently chosen BFD interval is not appropriate.

In that case, a next longer interval/ higher detection multiplier can be chosen for the BFD session, and statistics can be monitored again. In addition, when statistics are observed periodically, missed hellos can give an indication of whether health of the path is deteriorating. These statistics are collected continuously for each BFD session. The commands to display the statistics of missed hellos are provided in [Displaying BFD Information](#) on page 1279.

### Setting Strict BFD Session Protection

If the BFD session is down, but BFD protected static route is still in the routing table after reboot, the BFD session is never established, because during reboot, the BFD session is in the INIT state, and the static route is brought up without considering BFD session state. This situation can cause traffic loss because the link to the gateway actually is down. This command turns down the static route during reboot if BFD session is in the INIT state. This behavior is different from other BFD clients (such as *OSPF (Open Shortest Path First)*) in the same INIT situation.

To enable strict BFD session protection, use the following command:

```
enable iproute {protection} bfd strict
```

#### Note

Enabling strict BFD generates a warning message to reboot the switch so as to update the route table: **WARNING: Please reboot the switch for the strict BFD to take effect.**

To disable strict BFD session protection, use the following command:

```
disable iproute {protection} bfd strict
```

To show strict BFD session protection status, use the following command:

```
show iproute bfd
```

## Displaying BFD Information

The following commands display information regarding BFD configuration and process.

- To display information on BFD sessions, use the following command:  
`show bfd`
- To display information on BFD global counters, use the following command:  
`show bfd counters`
- To display information on BFD session counters, use the following command:  
`show bfd session {ipv4 | ipv6} {ipaddress} counters {vr [vrname | all]}`
- To display the configuration of a specific interface or those specific counters, use the following command:  
`show bfd vlan {vlan_name}`
- To display the counters of a specific interface, use the following command:  
`show bfd vlan {vlan_name} counters`
- To display the session status of a particular client, use the following command:  
`show bfd session client [ bgp {ipv4 | ipv6} | mpls | | static {ipv4 | ipv6}] {vr [vrname | all]}`
- To display the session status information for all VRs, use the following command:  
`show bfd session {ipv4 | ipv6} {ipaddress} { vr [vrname | all] }`
- To display session status information in detail for all VRs, use the following command:  
`show bfd session {ipv4 | ipv6} {ipaddress} detail {vr [vrname | all]}`
- To display counters of missed hello packets for all available sessions, use the following command:  
`show bfd session counters missed-hellos {session-id first {- last} | neighbor ipaddress {vr [vrname | all]} | vr [vrname | all]} {detail | no-refresh | refresh}`

- To display counters of missed hello packets for a session using neighbor IP address, use the following command:  

```
show bfd session counters missed-hellos neighbor ipaddress {vr [vrname | all]}
```
- To display counters of missed hello packets for a particular range of session ID, use the following command:  

```
show bfd session counters missed-hellos session-id first {- last}
```
- To show strict BFD session protection status, use the following command:  

```
show iproute bfd
```

## Clearing BFD Information

To clear global, session, or interface counters, use the following command:

```
clear counters bfd {session | interface | missed-hellos}
```

To clear missed hellos counters for a session using neighbor IP address:

```
clear counters bfd missed-hellos neighbor ipaddress {vr [vrname | all]}
```

To clear missed hellos counters for a particular range of session ID:

```
clear counters bfd missed-hellos {session-id first {- last}
```

## BFD Hardware Assist

Bidirectional Forwarding Detection (BFD) hardware assist support provides the functionality to run a BFD session in hardware. Effective failure detection requires BFD to run at high frequencies (using aggressive timers as low as 3 ms), which was not possible in the Software Mode because of CPU and ExtremeXOS restrictions.

Starting with ExtremeXOS 30.5, BFD hardware assist supports multi-hop.

To make BFD sessions run in the hardware, the following configuration is required:

- Hardware BFD is enabled by configuring one of the unused front panel port as a loopback port, which should not be available for switching user data traffic. This port is used internally by the BFD hardware to send control packets.
- Ensure IP forwarding is enabled on the BFD interfaces.
- The next hop MAC address of the neighbor should be known for the session creation. The BFD process triggers ARP to resolve the next hop MAC address, if this is not configured statically.

L2 topology convergence time might affect the BFD sessions running at the shortest interval.

Unconfiguring loopback for BFD disables the hardware assist support. The supported shortest interval is 3 ms in hardware mode.

Sample configuration:

Configure the port 1 as loopback port dedicated for BFD:

```
#configure bfd hardware-assist primary loopback-port 1
```

To check the number of BFD sessions supported in the hardware and configured loopback port:

```
#show bfd
..
..
Hardware Assist Operational State : Enabled(Loopback
port not configured)
Hardware Assist Primary Loopback Port : 1
Hardware Assist Secondary Loopback Port : None
Maximum # of Hardware Assist Sessions : 900
```

To find the session running the hardware:

```
#show bfd session detail
Neighbor : 10.10.10.2 Local : 10.10.10.1
VR-Name : VR-Default Interface : v1
Session Type : Single Hop State : Down
..
Hardware Assist : Yes
```

To see the hardware counters:

```
#show bfd counters
#show bfd session 10.10.10.2 counters
```

## BFD MIB Table Support

ExtremeXOS 15.5 supports read-only for all BFD MIB tables, global objects, and supports BFD notifications as well. BFD-MIB implementation is based on draft-ietf-bfd-mib-14, and draft-ietf-bfd-tc-mib-02. Currently, the BFD MIB is kept under the enterprise MIB in ExtremeXOS implementation.

The SET operation is supported only for MIB object 'bfdSessNotificationsEnable' (to control up/down traps). The default value for this object is disabled state. No notification is sent in disabled state. Thus, the SET operation is also supported for this MIB object in order to control the emission of traps.

### *BFD Session Up/Down Traps*

BFD has two traps, one for notifying that the session moved to the UP state, and the other trap for notifying that the session moved to DOWN state. To reduce the number of traps sent to NMS, a single trap is generated to combine the status changes of multiple sessions if the sessions have contiguous session IDs and multiple sessions move to either the UP or DOWN state in the same window of time. However, status changes of different types (UP & DOWN), will not be mixed in single trap. The window of time to combine the traps can be configured using the CLI command `configure snmp traps batch-delay bfd`.

For example, if sessions with session IDs 1, 2, 3, 4, and 5 are moving to the UP state in the same window of time, then a single trap is sent with low range index 1 and high

range index 5. As a second example, after all sessions moved to the UP state, session ID 2 goes DOWN and comes back UP before generating the first trap. In this case also, the first trap which is the UP trap, is set to include all sessions. Then, the second trap would be the DOWN trap for session ID 2, and finally the third trap would be the UP trap again for session ID 2. Thus, events are not missed or reordered.

NMS relates traps to sessions using only the session index which is provided in traps. It is necessary that the session index does not change until NMS retrieves session details via GET requests. To achieve this, the session will be retained for fifteen minutes after deletion is initiated by the BFD client (control protocol). During this period transmission and reception of BFD control packets will be stopped. If BFD protection is requested for the same destination again within this period, the same session index is reused. With this change, NMS can also have good history of the session to a particular destination.

### Configuring SNMP Traps for BFD

To enable snmp traps for bfd:

```
enable snmp traps bfd {session-down | session-up}
```

To disable snmp traps for bfd:

```
disable snmp traps bfd {session-down | session-up}
```

To configure batch delay for sending the traps:

```
configure snmp traps batch-delay bfd {none | delay}
```

To display the configuration:

```
show snmp traps bfd
```

#### Note

*SNMP (Simple Network Management Protocol)* traps for BFD are disabled by default for both session-down and session-up.

### Configuration Example

**Figure 167: BFD Configuration Example**

Consider the network segment like above, wherein two routers R1 and R2 are connected via an L2 switch. Following is the list of commands to configure BFD protection for static routes.

Router R1:

1. Create vlan and configure IP address.

```
create vlan v1 tag 100
```

```
configure vlan v1 add port 2 tagged
```

```
configure vlan v1 ipaddress 10.0.0.1/24 2
```

2. Create BFD session to the next-hop which is being monitored.

```
enable iproute bfd 10.0.0.2 vr VR-Default
```

3. Configure iproute add *<destination network>* *<gateway>* bfd

# ONEPolicy

---

[ONEPolicy Overview](#) on page 1284  
[Policy Roles](#) on page 1302  
[Classification Rules](#) on page 1305  
[Authentication and ONEPolicy](#) on page 1322  
[Configuring Policy](#) on page 1327  
[ONEPolicy Configuration Examples](#) on page 1340

ONEPolicy provides for the configuration of role-based profiles for securing and provisioning network resources based upon the role the user or device plays within the enterprise. By first defining the user or device role, network resources can be granularly tailored to a specific user, system, service, or port-based context by configuring and assigning rules to the policy role. A policy role can be configured for any combination of Class of Service, VLAN (Virtual LAN) assignment, or default behavior based upon L2, L3, and L4 packet fields. Hybrid authentication allows either policy or dynamic VLAN assignment, or both, to be applied through RADIUS (Remote Authentication Dial In User Service) authorization.

## Note

The software only allows policy to be enabled if all the devices in the stack support policy. At the time of configuration the device will provision the lowest common denominator of functionality. If a device attempts to join the stack after policy is enabled, it must be able to support the existing level of functionality or it will not be allowed to participate in policy. For more detailed information about lowest common denominator, see [Policy and Lowest Common Denominator Stacking](#) on page 1298.

## ONEPolicy Overview

---

The three primary benefits of using policy in your network are provisioning and control of network resources, security, and centralized operational efficiency. Policy provides for the provisioning and control of network resources by creating policy roles that allow you to determine network provisioning and control at the appropriate network layer, for a given user or device. With a role defined, rules can be created based upon up to 15 traffic classification types for traffic drop or forwarding. A CoS (Class of Service) can be associated with each role for purposes of setting priority, forwarding queue, rate limiting, and rate shaping.

Security can be enhanced by allowing only intended users and devices access to network protocols and capabilities. Some examples are:

- Ensuring that only approved stations can use *SNMP (Simple Network Management Protocol)*, preventing unauthorized stations from viewing, reading, and writing network management information
- Preventing edge clients from attaching network services that are appropriately restricted to data centers and managed by the enterprise IT organization such as *DHCP (Dynamic Host Configuration Protocol)* and DNS services
- Identifying and restricting routing to legitimate routing IP addresses to prevent DoS, spoofing, data integrity and other routing related security issues
- Ensuring that FTP/TFTP file transfers and firmware upgrades only originate from authorized file and configuration management servers
- Preventing clients from using legacy protocols

**Note**

Any configurations which require the use of the first stage ACL/VLAN processor, do not operate when OnePolicy is enabled. This includes, but is not limited to, certain MPLS, PStag, VXLAN, and OAM/CFM configurations.

**Note**

Configuration changes on existing policy mux entries (changing the policy profile for a convergence endpoint to 0 or a different value, disabling *LLDP (Link Layer Discovery Protocol)* or CDP, etc.) do not take effect until re-authorization. As a result, existing CEP connections remain active and *FDB (forwarding database)* is still learned on policy profile even though CDP/LLDP neighbor times out and `show cdp neighbor {detail}` and `show lldp neighbors` is empty. You can force re-authorization by clearing a CEP connection: `configure policy convergence-endpoint clear ports [port_list | all]`.

**Note**

IDM and ONEPolicy are not supported together and it is not recommended to enable both, since handling rule/role-based actions is not supported, except to support Kerberos Authentication with NAC as a RADIUS server and can be used in conjunction with IDM XML event triggers.

**Note**

In ONEPolicy mode, when enabling NetLogin web-based, the following warning message appears when the port is not part of any default VLAN:  
WARNING: The following netlogin enabled ports 1 are not part of any VLAN. The port has to be part of some VLAN for Web-Based netlogin to work.  
For NetLogin web to work, the port must be part of a default VLAN.

**Note**

Restarting the NetLogin process is not supported when policy is enabled. Doing so results in indeterminate behavior.

### Note

If Convergence End Point (CEP) (see [Convergence End Point \(CEP\) Detection](#) on page 1287) is configured and you have multiple authentication types configured, failure of a higher priority authentication results in the lower priority authentication being used.

```

## Implementing Policy

To implement policy:

1. Identify the roles of users and devices in your organization that access the network.
2. Create a policy role for each identified user role (see [Policy Roles](#) on page 1302 and [Table 98](#) on page 1327).
3. Associate classification rules and administrative profiles with each policy role (see [Classification Rules](#) on page 1305 and [Table 99](#) on page 1329).
4. Optionally, configure a class of service and associate it directly with the policy role or through a classification rule (see [Assigning a Class of Service to Policy Role](#) on page 1304, [Classification Rules](#) on page 1305, and [Table 98](#) on page 1327).
5. Optionally, enable hybrid authentication, which allows *RADIUS* filter-ID and tunnel attributes to be used to dynamically assign policy roles and VLANs to authenticating users (see [Applying Policy Using Hybrid Authentication Mode](#) on page 1325).

6. Optionally, set device response to invalid policy (see [Device Response to Invalid Policy](#) on page 1291).
7. Optionally, set captive portal to use HTTP redirection to force a client's web browser to be redirected to a particular administrative web page for authentication purposes (user login and password), payment (for example, at an airport hotspot), or use-policy enforcement (installing necessary software, agreeing to terms of service (TOS), etc.) (see [Captive Portal Redirection](#) and [Table 102](#) on page 1333).

## ONEPolicy Features

### *Convergence End Point (CEP) Detection*

Convergence End Point (CEP) is a mechanism to detect remote IP telephony or video devices on a port and dynamically apply a policy based on the type of CEP device discovered. CEP is only active when ONEPolicy is enabled and configured on the switch. When a CEP device is detected on a port, the configured policy for that device is applied to the user on that port. The switch detects a CEP by inspecting devices on CDP- and LLDP-configured ports. CEP interacts with LLDP, CDP, and ONEPolicy through callbacks and/or inter-process messaging to initiate detection and apply policy.

#### LLDP and CDP

LLDP and CDP are required to call into CEP to add detected IP telephony devices with the following data:

- MAC—MAC address of detected device
- Port—port origin of detection
- Type—the type of detected device (Cisco, LLDP)
- inetAddr—IP address of end point device
- inetType—IP address type of end point device (IPv4, IPv6)
- inetLen—length of inetAddr

#### ONEPolicy

- CEP initializes with, and exists in, the ONEPolicy process and calls directly to modify policy muxRule entries.
- CEP leverages ONEPolicy port add/del/mod callback integration, satisfying CEP platform port requirements.

For information about configuring CEP detection, see [Table 101](#) on page 1332.

#### Note

When both CEP and NetLogin are enabled on the same port, the policy profile name is "active" for both CEP and NetLogin sessions with session applied as "false" for CEP and "true" for NetLogin. If NetLogin authentication is successful, the session applied is false for CEP and true for NetLogin. NetLogin takes higher precedence than the CEP profile.

Learning of CEP entries depends on the LLDP/CDP update on active ports and on disabling and enabling CEP. New entries are learned only after receiving new LLDP/CDP information, and not from existing LLDP neighbors and CDP neighbors table.

For example:

```
configure policy convergence-endpoint disable

### Note

After CEP devices are mapped to a profile, changing the index value to "0" or to some other policy profile name, the existing CEP connections are still be mapped to the old profile that was configured initially when the CEP devices were detected. To force a refresh of existing detected devices, disable, and then enable, CEP (see `configure policy convergence-endpoint [enable | disable]` ) or disable, and then enable, the port(s) (see `disable port [port_list | all]` and `enable port [port_list | all]`).

## Captive Portal Redirection

Captive Portal Redirection uses HTTP redirection to force a client's web browser to be redirected to a particular administrative web page. You can use this feature for such web-based purposes as:

- Authentication—request a user login and password
- Payment—for example, at an airport hotspot
- Use-policy enforcement—require installing necessary software, agreeing to terms of service (TOS), etc.

Captive Portal Redirection is an extension of the ONEPolicy feature. You can configure policy roles that can force redirection of HTTP traffic by specifying a web redirection class index that associates it with up to two redirection servers. The HTTP traffic to potentially redirect is identified based on a destination captive portal server absolute URL address containing an IPv4 address, TCP port, and path. For traffic that is placed into one of these policy roles (through authentication or policy admin-profile rules) actions are taken based upon the contents of the policy profile.

If the incoming traffic is on the configured L4 port and is not destined for the configured captive portal server IP, the switch causes an HTTP redirect message (code 307) to be sent back to the client. If the incoming traffic is destined for the configured captive portal server IP, or it is not on one of the configured listening L4 ports, the traffic is handled according to the rest of the policy role configuration.

Configuring this feature occurs through the `etsysPolicyProfileMIB` and the ONEPolicy command set. There are two tables in the MIB, one that allows configuration of the listening ports and one that allows configuration of the captive portal servers. You can configure up to three ports on which ONEPolicy listens for client traffic that is (potentially) subject to HTTP redirection. A URL that explicitly identifies the server by an IPv4 address, TCP port, and path is configured along with the ports on which the Captive Portal feature listens for client traffic (for example: `configure policy captive-portal listening 80,8080`).

You can configure up to ten web-redirect groups of two captive portal servers. They can be used to redirect traffic in different roles to different servers. These web-redirect groups are identified by associating a web redirection class index with the server ID. The policy roles used for captive portal redirection each have a non-zero web redirection class index configured (for example, `configure policy profile 1 web-redirect 5`). The default captive portal web redirection class index for any given role (profile) is 0, or unset. To enable captive portal, there must be a role defined that has a valid captive portal web redirection class index with a value between 1–10.

In addition to the captive portal configuration, this policy role should also have rules to handle the traffic that is not handled by the captive portal web redirection.

**Note**

When there are two servers configured in a web-redirect, the switch uses the following algorithm to pick which server to use for redirection:

$((\text{Last byte of the client's source MAC address}) \% (\text{numServers})) + 1$

For example, (mac = 00:00:00:00:00:03) and where numServers is 2.  $(0x03 \% 2) + 1 = 2$  (This MAC uses server 2.)

**Note**

Captive portal does not work with tagged frames.

**Note**

HTTPS redirection is not supported in Captive Portal redirection.

Redirection to the portal does not happen if the user (guest-user or unauthenticated user) tries to connect to an HTTPS website. This feature only handles HTTP traffic. However, you can configure redirection to a captive portal URL based on HTTPS.

If not specified to do otherwise, ONEPolicy programs its captive portal-related rules outside of the reserved ACL rule space for ONEPolicy. This results in additional ACL slice usage. Starting with ExtremeXOS 30.4, you can specify that these rules are programmed within the already reserved ACL rule space at the expense of IPv4 rule capacity (see [Table 98](#) on page 1327).

For information about configuring Captive Portal Redirection, see [Table 102](#) on page 1333.

For an example Captive Portal Redirection configuration, see [Captive Portal Redirection Example](#) on page 1350.

### *VLAN/VXLAN to Policy Mapping*

VLAN-to-Policy mapping manually configures VLAN-to-policy associations that create a policy mappable entry between the specified VLAN and the specified policy role. When an incoming tagged VLAN packet is seen by the switch, a lookup of the policy mappable determines whether a VLAN-to-policy mapping exists. This feature can be used at the distribution layer in environments where non-policy-capable edge switches are deployed and you cannot apply Extreme policy at the edge. Tagged

frames received at the distribution layer interface for a VLAN with an entry in the policy mactable have the associated policy applied to the frame.

To create a policy mactable entry associating a policy to a VLAN, use the following command specifying a single VLAN ID or range of IDs and the policy profile-index:

```
configure policy mactable [response [tunnel | policy | both] | vlan_list
profile_index]
```

Starting with ExtremeXOS 22.5, you can map *VXLAN (Virtual Extensible LAN)s* by applying the VXLAN identifier (VNI) to a profile using the command, where NSI = VNI:

```
configure policy profile profile_index {name name} {pvid pvid}
{pvid-status pvid_status} {cos cos} {cos-status cos_status} {egress-
vlangs egress_vlan_list}{forbidden-vlangs forbidden_vlangs} {untagged-vlangs
untagged_vlangs} {append | clear} {tci-overwrite tci_overwrite}
{precedence [precedence | default]} {auth-override auth_override} {nsi
[nsi | none]} {web-redirect web_redir_index} {access-list [unassigned |
list_name | list_name_placeholder]}
```

You can then create the mactable entry, using the previous mactable command.

#### *Device Response to Invalid Policy*

The action that the device should take when asked to apply an invalid or unknown policy can be specified. The available actions are:

- Ignore the result and search for the next policy assignment rule. If all rules are missed, the default policy is applied.
- Block traffic.
- Forward traffic as if no policy has been assigned using 802.1D/Q rules.

Use the `configure policy invalid action` command to specify a default action to take when asked to apply an invalid or unknown policy.

#### *Policy-Based Mirrors*

You can apply mirrors to policy profile rules by using a "control group" mirror referenced by a unique control index number. These control group mirrors are `etsysMirrorDestinationControlEntry` entries in the `ENTERASYS-MIRROR-CONFIG-MIB` (Mirror MIB) (see [ENTERASYS-MIRROR-CONFIG-MIB](#) on page 1826). A Mirror MIB instance (designated by a control index) can be associated with up to four "physical" mirrors, each being one destination port (or tunnel).

For information about configuring policy-based mirrors, see [Table 103](#) on page 1334.

#### **Limitations**

- Mirrors with multiple destination ports are not supported.
- A maximum of four concurrently enabled mirrors is supported.
- A maximum of four control group (Mirror MIB) instances can be created using the CLI.
- Mirrors on admin profile rules is not supported.

- Mirroring cannot be enabled on LAG and MLAG ports.
- Mirroring index cannot be assigned for default mirrors.

### *Rule Trap and Syslog for ONEPolicy*

You can be notified when a policy rule is used by enabling “Syslog” or “trap” actions:

- The Syslog action sends an entry in the log after first rule use with the EMS tag “Policy.LogRuleHit”.
- The trap action sends an etsysPolicyRulePortHitNotification SNMP trap to the configured trap receiver.

By default, the Syslog and trap actions only occur when the rule is first used. However, for the Syslog action, you can configure the system to send messages every time the rule is used at a maximum rate of once every five seconds.

Additionally, a rule counter tracks the number of times a packet triggers a rule. By default, the counter is enabled for all rules. You can set an interval for how often this counter is cleared, or manually clear it at any time.

For information about configuring rule trap/Syslog, and the rule counter, see [Table 104](#) on page 1335.

### **Limitations**

Not supported on admin profile rules.

### *VCAP Partitioning*

ExtremeXOS allows multiple applications (Layer 7 policy, user-based dynamic ACLs) to share a pool of VCAP slices. This area is called the “shared pool.” The TCI overwrite-enabled case is configurable to use its own pool of VCAP slices and the “shared pool” is allocated for the other applications. VCAP slices not allocated for policy usage are available for general system use.

TCI overwrite-enabled profiles use their own resource pool of slices (0–4) for VLAN assignment (translation). Allocating less TCI overwrite-enabled VCAP space means fewer rules available for users to have their VLAN tags overwritten.

### **Supported Platforms**

All ExtremeSwitching Universal platforms.

### *Layer 7 Policy/Application Signature*

Policy rules are used to assign incoming traffic to a specific policy profile. Layer 7 policy/application signature provides an additional traffic classification capability. This layer 7 classification is accomplished by the snooping of DNS packets for pre-defined traffic application signatures. The snooping feature is activated automatically when policy is enabled and an application signature (AS) rule is created. It is deactivated if all AS rules are removed or if policy is disabled. Layer 7 policy uses shared look-up stage TCAM resources that must be configured first (see [VCAP Partitioning](#) on page 1292). The number of signature rules is dependent upon the availability of this shared space.

Dynamic policy rules are created in hardware using DNS-discovered destination IP addresses for the host name. The IP addresses ultimately map the traffic to a particular application traffic signature pattern. IP addresses and their associated dynamic rules are timed out per the TTL of the snooped IP address. The application traffic signatures are defined in groups of one or more signature names, where each signature name consists of one or more signature patterns.

Layer 7 policy is based on the use of the enterasys-application-signature-mib (see [ENTERASYS-APPLICATION-SIGNATURE-MIB](#) on page 1804).

### Supported Platforms

All ExtremeSwitching Universal platforms.

### Limitations

- V6 is not supported.
- Rule creation and deletion are controlled by a time-to-live (TTL) 5 second timer.
- TTL value is configurable in terms of 1 min., 5 mins., and 10 mins.
- When VCAP space runs out, any IP rule not already installed in hardware is not created. New attempts to install previously uninstalled rules occur after the 5 second TTL timer interval and are dependent upon the space made available by other rules that have timed out.

### Signatures

Starting with ExtremeXOS 30.4, policy rules have an additional traffic classification of application signature group and name. There is a fixed, defined set of signature groups available. Each group has a subset of pre-defined/built-in signature names; these can be enhanced with additional ones that can be created by commands or MIB. Additionally, each application signature name is defined by one or more signature patterns.

The signatures are arranged into two hierarchical levels, group and name.

Group examples: Advertising, Storage, Education

Names examples: Etrade, Skype, AOL, Facebook, Twitter, Google

### Example Signature Groups

Built-in signatures:

- Social Networking
  - Facebook
    - facebook.com
    - facebook.net
- Search Engines
  - Google
    - google.co
    - google.ca

- google.it
- google.fr

User-defined signatures:

- News and Information
  - Flipboard
    - flipboard.com
- E-commerce
  - Warehouse
    - bjs.com
    - costco.com

Pattern examples:

- wireshark.org
- mysql.com

### *ACL Style Policy*

Traditional ONEPolicy architecture uses a hierarchical approach to rule precedence where rule type dictates precedence. In addition, rule look-ups occur per role, per action type. This means, for example, that triggering a forward/drop rule without an explicit Class of Service (CoS) action results in applying the forward/drop action, and then continuing searching until a rule with CoS action matches. This hierarchical approach is implemented in hardware by maintaining one list for forward/drop actions, and one list for CoS actions. This implementation often results in underused resources, because not every rule has both forward/drop and CoS actions.

With ACL Style Policy, a mode of operation with a single ordered list per role is maintained. Rule look-ups occur in the provided ACL order per role. A match applies all actions specified, and the search stops. This approach can potentially double the advertised scale of classification rules as compared to the traditional model. It also provides a more standard approach to policy classification rules.

Default policy rule-model is hierarchical, unless you are upgrading from ExtremeXOS 30.5 with a saved configuration that is set to access list.

For information about configuring ACL Style Policy, see [Table 106](#) on page 1338.

#### **Limitations**

SNMP for configuration of ACL Style Policy classification rules is not supported.

### Traditional Versus ACL Style Policy Classification Rule Scaling

The following table compares the overall classification rule scale between "traditional" and ACL Style policy:

**Table 87: Traditional versus ACL Style policy classification rule scaling**

| Switch Model(s)     | Traditional                              | ACL Style**                             |
|---------------------|------------------------------------------|-----------------------------------------|
| 4120                | Default: 184<br>Less System ACL: 184     | Default: 440<br>Less System ACL: N/A    |
| 4220                | Default: 440<br>Less System ACL: 440     | Default: 952<br>Less System ACL: N/A    |
| 5120                | Default: 184<br>Less System ACL: 184     | Default: 440<br>Less System ACL: N/A    |
| 5320-48T            | Default: 1,976<br>Less System ACL: 1,976 | Default: 4,024<br>Less System ACL: N/A  |
| 5320-24T-4X-XT      | Default: 440<br>Less System ACL: 440     | Default: 952<br>Less System ACL: N/A    |
| 5320-24T-24S-4XE-XT | Default: 1,976<br>Less System ACL: 1,976 | Default: 4,024<br>Less System ACL: N/A  |
| 5320-16P*           | Default: 1,976<br>Less System ACL: 1,976 | Default: 4,024<br>Less System ACL: N/A  |
| 5420M               | Default: 4,024<br>Less System ACL: 4,024 | Default: 8,120<br>Less System ACL: N/A  |
| 5420F               | Default: 1,976<br>Less System ACL: 1,976 | Default: 4,024<br>Less System ACL: N/A  |
| 5520                | Default: 4,024<br>Less System ACL: 4,024 | Default: 8,120<br>Less System ACL: N/A  |
| 5720-MW             | Default: 6,072<br>Less System ACL: 6,072 | Default: 12,216<br>Less System ACL: N/A |
| 5720-MXW            | Default: 8,120<br>Less System ACL: 8,120 | Default: 16,312<br>Less System ACL: N/A |
| 7520-48Y-8C         | Default: 1,976<br>Less System ACL: 1,976 | Default: 3,512<br>Less System ACL: N/A  |
| 7520-48XT-6C        | Default: 1,976<br>Less System ACL: 1,976 | Default: 3,512<br>Less System ACL: N/A  |
| 7720-32C            | Default: 1,976<br>Less System ACL: 1,976 | Default: 3,512<br>Less System ACL: N/A  |

\* - 5320-16P models do not support MAC and IPv6 rules.

\*\* - Applies to role-based DACLS as well as static ACLs created via the Policy CLI, which are also associated with a profile. User-based DACLS may achieve lower ACL Style numbers.

### ACL Style Classification Rule Architecture

- Single ordered list per role.
- Rule look-ups done in provided ACL order.
- Rule look-up match applies all actions, and then the search stops.
- 5-tuple rule match support.
- Layer 4 port range.
- Rule types: application, ipsourcesocket, ipdestsocket, ipfrag, udpsourceportIP, udpdestportIP, tcpsourceportIP, tcpdestportIP, icmp6type, icmp6type, ipttl, iptos, ipproto, ether.
- Rule actions: permit/deny, CoS (prio, tos, rate-limit, shape, etc), mirror, Syslog, and count.

### RESTful API Support

ACL Style Policy implements a new RESTful API for configuration of classification rules.

#### Note

RESTful API is not supported for Dynamically-created ACLs via RADIUS and COA.

### Dynamic ACLs

Dynamic *ACL (Access Control List)s* are created using the CLI. They use a similar syntax and can accomplish the same actions as single rule entries used in ACL policy files. More than one dynamic ACL can be applied to an interface, and the precedence among the dynamic ACLs can be configured. By default, the priority among dynamic ACLs is established by the order in which they are configured.

#### Note

Dynamic ACLs have a higher precedence than ACLs applied using a policy file.

The steps involved in using a dynamic ACL on an interface are:

- [Creating the Dynamic ACL Rule](#)
- [Configuring the ACL Rule on the Interface.](#)
- [Configuring ACL Priority](#)
- [Network-Zone Support in ACLs](#)

### Role-based ACLs

Beginning with Release 32.1, the dynamic ACL rule(s) can be user-based or role-based. User-based rules are treated as higher priority than any other statically provisioned rules. Policy roles and the DACLs associated with them are dynamically created as needed based on the incoming RADIUS Filter-Id attribute. This attribute is automatically deleted when the last authenticated user associated with the role is removed.

When a set of role-based rules is installed for a given role or profile, they cannot be changed until that role is no longer in use. Role-based rules are shared by any other user who authenticates to the same role or profile. While both user based and role-

based DACLs can be used on the device at the same time, a mix of user based and role-based DACLs are not permitted for a given user.

A role-based operation has a type 'r' and requires a preceding add operation (a,r). Each role requires a profile pre-configured with a unique name and access-list configuration.

A role-based with create operation has a type 'c' and also requires a preceding add operation (a,rc). The role or profile is dynamically created if it does not already exist. If created dynamically, the role or profile will be deleted when no longer in use.

A delete-all operation has a type of 'da' and no match, action, or index fields are permitted. When used, the delete-all must be the first entry in the list. When present, this operation removes all existing rules associated with the user or role. Neither the action field nor the index field is permitted and will be ignored if present.

The following match conditions can be used with role-based ACLs:

- `ipv4src ipv4source/mask-length`
- `ipv4dst ipv4dest/mask-length`
- `ipproto ipproto` (TCP, UDP, ICMP, or protocol number)(ICMP and protocol number as of Release 32.1)
- `l4srcport l4sourceport-l4sourceportend/mask-length` (requires ipproto; range is role-based only and no mask)
- `l4dstport l4destport-l4destportend/mask-length` (requires ipproto; range is role-based only and no mask)
- `ether` (role-based only)
- `any` (as of Release 32.1)

### Supported Platforms

All Universal platforms.

### Limitations

- DNS is not supported on Extended Edge switches with Controlling Bridges on 5420 and 5520 Series switches.
- ACL style policy must be selected.
- Only a subset of the existing policy rules is allowed.
- SNMP is not supported.
- Not all rule types can be configured at the same time. For example, L4 port range rules with ether and other IP and masked L4 ports rules may not install correctly. This is the same limitation that applies to ACL Style Policy.

## **NEW!** Access List Mode Enhancements for Double Wide Slices

Version 33.3.1 adds support for specifying double-wide slices for IPv4 rules. The default setting (ipv4-single-only) is equivalent to the existing behavior where only single-wide slices are used. In addition, there is an IPv4 double-wide option which allows the user to specify double-wide slices for IPv4 rules. ( L4 and Ether type rules). This enhancement includes both statically configured and role-based downloadable ACLs.

The following command is added in support of this feature:

```
configure policy slices ingress [ipv4-single-only | ipv4-double-only]
```

Double-wide mode effectively decreases the ACL mode limit in half.

### Limitations

This feature has the following limitations:

- Policy must be disabled to change the ingress slice mode.
- The precedence of policy slices can't be changed.
- The setting only applies to access-list mode.

### Supported Platforms

IPv4 double-only mode is supported on 5320 (except 5320-16P-2MXT-2X), 5420, 4220, 5520, 5720, 7520, 7720 Series switches.

## Policy and Lowest Common Denominator Stacking

When devices are stacked that have different capacities, we sink to the lowest common level of capacities and functionality when possible. If the stack already has an existing configuration that exceeds the new lower capacity policy will disallow the ports on the new unit to become policy enabled.

### Note

In some cases policy capacities of a device have been determined to be so low that they are deemed non-useful for any practical policy deployment. In these cases the ports on the device are never allowed to become policy enabled.

The following algorithm is used to determine the lowest common denominator when stacking:

```
(A) More Capable device(s)
(B) Less Capable device(s)

- (A) is running and (B) is added

 If (A) is currently using less or equal resources to the maximum
 capacity (B) provides.
 - Policy will reduce the system maximum capacity
 to match (B).
 If (A) is currently using more resources than the maximum capacity (B)
 provides.
 - Policy will not be enabled on the ports of (B).
 - A message will be printed that indicates the condition to the
 customer. If the resources being used by (A) are reduced to less or equal the
 maximum capacity of (B)
 the ports on (B) will become policy enabled. A message will be printed that
 indicates the condition to the customer and thereafter every
 5 minutes as the condition exists. If the resources being used by (A) are reduced
 to less or equal the maximum capacity of (B)
 a message will be printed that indicates this slot can fully function with policy
 pending a
 reboot of (B). This message will repeat every 5 minutes until (B) is
```

```

rebooted. - (B) is running and
(A) is added o The
system maximum capacity will continue to match (B)
- If (B) is removed (A) will revert to its higher capacity. -
(A) and (B) brought
up at the same time. o The
system maximum capacity will be the lower capacity of (B)- If (B) is removed
(A) will revert to its higher maximum capacity.

```

## Standard and Enhanced Policy Considerations

This section itemizes additional policy considerations for the stackable and standalone platforms, and provides a table cross-referencing standard and enhanced policy capability and policy capability to traffic classification rules.

Not all stackable fixed switch platforms support policy. On some stackable and standalone fixed switch platforms policy support requires a purchased license. See the software release notes that come with your device for policy support.

[Table 88](#) provides a listing of policy capabilities by standard and enhanced support level. Standard policy capabilities are further granulated based upon traffic classification support. See [Table 89](#) on page 1300 for a cross-reference of traffic classification to policy capability support.

**Table 88: Standard and Enhanced Policy Capability Cross-Reference**

| Policy Support Level | Policy Capability                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Loop Prevention with Spanning Tree Protocol

See [STP](#) and [ONEPolicy](#) on page 1774.

## Terms and Definitions

[Table 90](#) lists terms and definitions used in this policy configuration discussion.

**Table 90: Policy Configuration Terms and Definitions**

| Term                   | Definition                                                                                                                                                                                                                                                                                        |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Administrative Profile | A logical container that assigns a traffic classification to a policy role.                                                                                                                                                                                                                       |
| <i>CoS</i>             | A logical container for packet priority, queue, and forwarding treatment that determines how the firmware treats a packet as it transits the link.                                                                                                                                                |
| Filter-ID              | A string that is formatted in the <i>RADIUS</i> access-accept packet sent back from the authentication server to the switch during the authentication process. In the Extreme policy context, the string contains the name of the policy role to be applied to the authenticating user or device. |

**Table 90: Policy Configuration Terms and Definitions (continued)**

| Term                     | Definition                                                                                                                                                                                                                                                                                                   |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hybrid Authentication    | An authentication feature that allows the switch to use both the filter-ID and tunnel attributes in the RADIUS response message to determine how to treat the authenticating user.                                                                                                                           |
| Policy                   | A component of Secure Networks that provides for the configuration of a role based profile for the securing and provisioning of network resources based upon the function the user or device plays within the enterprise network.                                                                            |
| Policy Mappable          | A logical entity that can be configured to provide <a href="#">VLAN</a> to policy role mappings.                                                                                                                                                                                                             |
| Policy Profile/Role      | A logical container for the rules that define a particular policy role.                                                                                                                                                                                                                                      |
| Policy Rule              | A logical container providing for the specification of policy behaviors associated with a policy role.                                                                                                                                                                                                       |
| Role                     | The grouping of individual users or devices into a logical behavioral profile for the purpose of applying policy.                                                                                                                                                                                            |
| Rule Precedence          | <p>A numeric traffic classification value, associated with the policy role, the ordering of which on a precedence list determines the sequence in which classification rules are applied to a packet.</p> <p><b>Note:</b> Rule precedence is fixed (not configurable) until ExtremeXOS 33.3.1 and later.</p> |
| TCI Overwrite            | A policy feature, when enabled in a policy role-based tci-overwrite only, allows for the overwrite of the current user priority and other classification information in the VLAN tag's TCI field.                                                                                                            |
| Traffic Classification   | A network element such as MAC or IP address, packet type, port, or VLAN used as the basis for identifying the traffic to which the policy will be applied.                                                                                                                                                   |
| Untagged and Tagged VLAN | Untagged VLAN frames are classified to the VLAN associated with the port it enters. Tagged VLAN frames are classified to the VLAN specified in the VLAN tag; the PVID is ignored.                                                                                                                            |
| VLAN Authorization       | An aspect of RFC3580 that provides for the inclusion of the VLAN tunnel attribute in the RADIUS Access-Accept packet defining the base VLAN-ID to be applied to the authenticating user or device.                                                                                                           |
| VLAN Egress List         | A configured list of ports that a frame for this VLAN can exit.                                                                                                                                                                                                                                              |

## Policy Roles

The following sections provide information about policy roles.

## The Policy Role

A role, such as sales, admin, or engineering, is first identified and defined in the abstract as the basis for configuring a policy role. Once a role is defined, a policy role is configured and applied to the appropriate context using a set of rules that can control and prioritize various types of network traffic. The rules that make up a policy role contain both classification definitions and actions to be enforced when a classification is matched. Classifications include Layer 2, Layer 3, and Layer 4 packet fields. Policy actions that can be enforced include VLAN assignment, filtering, inbound rate limiting, outbound rate shaping, priority class mapping.

## Defining a Policy Role

The policy role is a container that holds all aspects of policy configuration for a specific role. Policy roles are identified by a numeric profile-index value between 1 and the maximum number of roles supported on the platform. Policy roles are configured using the `configure policy profile` command. Policy configuration is either directly specified with the `configure policy profile` command or is associated with the role by specifying the `profile-index` value within the command syntax where the given policy option is configured. For example, when configuring a policy mactable entry using the `configure policy mactable` command (see [VLAN/VXLAN to Policy Mapping](#) on page 1290), the command syntax requires that you identify the policy role the mactable entry will be associated with, by specifying the profile-index value.

When modifying an existing policy role the default behavior is to replace the existing role with the new policy role configuration. Use the append option to limit the change to the existing policy role to the options specified in the entered command.

A policy role can also be identified by a text name of between 1 and 64 characters. This name value is used by the RADIUS filter-ID attribute to identify the policy role to be applied by the switch with a successful authentication.

## Roles in a Secure Network

The capacity to define roles is directly derived from the ability of supported devices to isolate packet flows by inspecting Layer 2, Layer 3, and Layer 4 packet fields while maintaining line rate. This capability allows for the granular application of a policy to a:

- Specific user (MAC, IP address or interface)
- Group of users (masked MAC or IP address)
- System (IP address)
- Service (such as TCP or UDP)
- Port (physical or application)

Because users, devices, and applications are all identifiable within a flow, a network administrator has the capacity to define and control network access and usage by the actual role the user or device plays in the network. The nature of the security challenge, application access, or amount of network resource required by a given attached user or device, is very much dependent upon the “role” that user or device plays in the enterprise. Defining and applying each role assures that network access and resource

usage align with the security requirements, network capabilities, and legitimate user needs as defined by the network administrator.

## Setting Default VLAN for Policy Role

A default VLAN can be configured for a policy role. A default VLAN will only be used when either a VLAN is not specifically assigned by a classification rule or all policy role classification rules are missed. To configure a default VLAN, enable pvid-status and specify the port VLAN to be used. pvid-status is disabled by default.

### Note

ExtremeXOS supports the assignment of port VLAN IDs 1–4,094. Use of VLAN ID 4094 is supported by stackable and standalone devices. VLAN IDs 0 and 4095 cannot be assigned as port VLAN IDs, but 0 has a special meaning within a policy context and can be assigned to the PVID parameter. Within a policy context 0 specifies an explicit deny of all VLANs.

If policy profiles with PVID 0 and PVID 4095 are configured and for MAC authentication profile with PVID 0 is sent using Filter ID attribute and for Dot1x profile with PVID 4095 is sent from RADIUS with VLAN tunnel ID as 11. Then if both MAC and Dot1x are enabled on the same port, on successful MAC authentication when profile with PVID 0 is applied based on the configurations "Explicit Deny all rule" is installed and Dot1x authentication is succeeded with PVID 4095 (no action) applied, but then traffic does not egress using Tunnel VLAN tag 11 or any default VLAN or admin profile VLAN where the port is bounded since the deny all rule is installed.

## Assigning a Class of Service to Policy Role

How a packet is treated as it transits the link can be configured in the CoS. It is through a CoS that QoS (Quality of Service) is implemented. A CoS can be configured for the following values:

- 802.1p priority
- IP Type of Service (ToS) rewrite value
- Priority Transmit Queue (TxQ) along with a forwarding behavior
- Inbound rate limiter per transmit queue
- Outbound rate shaper per transmit queue

CoS configurations are identified by a numeric value between 0 - 255. 0 - 7 are fixed 802.1p CoS configurations. CoS configurations 8 - 255 are user configurable. Policy uses the cos option followed by the CoS configuration ID value to associate a CoS with a policy role.

## Adding Tagged, Untagged, and Forbidden Ports to the VLAN Egress Lists

The VLAN egress list contains a list of ports that a frame for this VLAN can exit. Specified ports are automatically assigned to the VLAN egress list for this policy role as tagged, untagged, or forbidden. Ports are added to the VLAN egress list using the

egress-vlans, untagged-vlans, and forbidden-vlans options of the `configure policy profile` command.

**Note**

Egress policy is not supported.

## Overwriting VLAN Tags Priority and Classification Settings

TCI overwrite supports the application of rules to a policy role that overwrite the current user priority and other classification information in the VLAN tag's TCI field. TCI overwrite must be enabled for both the policy role and the port the role is applied to.

Use the `configure policy profile profile_index tci-overwrite` command to enable TCI overwrite on a policy role.

### *Supported Platforms*

All ExtremeSwitching Universal platforms.

## Classification Rules

Classification rules associate specific traffic classifications or policy behaviors with the policy role. There are two aspects of classification rule configuration:

- The association of a traffic classification with a policy role by assigning the traffic classification to an administrative profile.
- The assignment of policy rules that define desired policy behaviors for the specified traffic classification type.

Both the administrative profile and policy rules are associated with the policy role by specifying the **admin-pid** option, in the case of an administrative profile, or a **profile-index** value, in the case of the policy rule. Administrative profiles and policy rules are configured using the `configure policy rule` command.

The administrative profile assigns a traffic classification to a policy role by using the **admin-profile** option of the `configure policy rule` command.

**Note**

Standard policy supports the VLAN tag traffic classification for administrative profiles. All other traffic classifications are enhanced policy in an administrative profile context.

**Note**

When both admin-profile port and macsource rule are configured on the same port, macsource rule takes precedence and the VLAN classification and rules applicable to macsource are applied to the port.

**Note**

When specifying an action without an explicit "forward" or "deny" option, this is interpreted as an implicit permit, since the rule conditions are met. This type of action configuration does not appear in the output of the `show policy access-list` { [list\_dot\_rule **profile-index** *profile\_index* ] | [ {**matches** [ **app-signature** | **ether** | **icmp6type** | **icmptype** | **ipdestsocket** | **ipfrag** | **ipproto** | **ipsourcesocket** | **iptos** | **ipttl** | **tcpdestportIP** | **tcpsourceportIP** | **udpdestportIP** | **udpsourceportIP** ] {**mask** *mask*} {**data** *data*} } {**actions** [ {**drop** | **forward** } {**cos** *cos*} {-1} {**mirror-destination** *control\_index*} {**syslog** ] } ] } {**detail**} command.

When admin-profile macsource rule is configured and the port is not added to a VLAN, then the traffic arriving on this port is mapped to the admin-pid configured profile based on the port string. To map it to macsource, add the port to a VLAN.

Policy rules are based on traffic classifications. [Table 91](#) provides the supported policy rule traffic classification command options and definitions. All other traffic classifications are supported by standard policy.

**Table 91: Administrative Policy and Policy Rule Traffic Classifications**

| Traffic Classification | Description                                                                | Attribute ID | Enhanced Rule |
|------------------------|----------------------------------------------------------------------------|--------------|---------------|
| macsource              | Classifies based on MAC source address.                                    | 1            |               |
| macdest                | Classifies based on MAC destination address.                               | 2            |               |
| ip6dest                | Classifies based on destination IPv6 address.                              | 10           |               |
| ipsourcesocket         | Classifies based on source IP address.                                     | 12           |               |
| ipdestsocket           | Classifies based on destination IP address.                                | 13           |               |
| ip frag                | Classifies based on IP fragmentation value.                                | 14           |               |
| udpsourceportip        | Classifies based on UDP source port and optional post-fix IP address.      | 15           |               |
| udpdestportip          | Classifies based on UDP destination port and optional post-fix IP address. | 16           |               |
| tcpsourceportip        | Classifies based on TCP source port and optional post-fix IP address.      | 17           |               |
| tcpdestportip          | Classifies based on TCP destination port and optional post-fix IP address. | 18           |               |
| icmp                   | Classifies based on ICMP type code.                                        | 19           |               |
| ipttl                  | Classifies based on TTL.                                                   | 20           |               |

**Table 91: Administrative Policy and Policy Rule Traffic Classifications (continued)**

| Traffic Classification | Description                                                                         | Attribute ID | Enhanced Rule |
|------------------------|-------------------------------------------------------------------------------------|--------------|---------------|
| iptos                  | Classifies based on Type of Service field in IP packet.                             | 21           |               |
| ipproto                | Classifies based on protocol field in IP packet.                                    | 22           |               |
| icmp6                  | Classifies based on ICMPv6 type code.                                               | 23           |               |
| ether                  | Classifies based on type field in Ethernet II packet.                               | 25           |               |
| application            | Classifies based on Layer 7 DNS snooping.                                           | 29           |               |
| port                   | Classifies based on port-string.                                                    | 31           |               |
| IPSourceL4Range        | Classifies based on source IP address with post-fixed port-range.                   | 32           |               |
| IPDestL4Range          | Classifies based on destination IP address with post-fixed port-range.              | 33           |               |
| UDPSrcPortRange        | Classifies based on UDP source port-range with optional post-fix IPv4 address.      | 34           |               |
| UDPDestPortRange       | Classifies based on UDP destination port-range with optional post-fix IPv4 address. | 35           |               |
| TCPSrcPortRange        | Classifies based on TCP source port-range with optional post-fix IPv4 address.      | 36           |               |
| TCPDestPortRange       | Classifies based on TCP destination port-range with optional post-fix IPv4 address. | 37           |               |

A data value is associated with most traffic classifications to identify the specific network element for that classification. For data value and associated mask details, see the “Syntax Description” table in the `configure policy rule profile_index` [{**app-signature group group name name**} | **ether ether** | **icmp6type icmp6type** | **icmptype icmptype** | **ip6dest ip6dest** | **ipdestsocket ipdestsocket** | **ipfrag** | **ipproto ipproto** | **ipsourcesocket ipsourcesocket** | **iptos iptos** | **ipttl ipttl** | **macdest macdest** | **macsource macsource** | **port port** | **tcpdestportIP tcpdestportIP** | **tcpsourceportIP tcpsourceportIP** | **udpdestportIP udpdestportIP** | **udpsourceportIP udpsourceportIP**] {**mask mask**} {**port-string** [ *port\_string* | **all**]} {**storage-type** [**non-volatile** | **volatile**]} {**drop** | **forward**} {**syslog syslog**} {**trap trap**} {**cos cos**} {**mirror-destination control\_index**} {**clear-mirror**} command in the [Switch Engine v33.3.1 Command References](#).

## Specifying Storage Type

ONEPolicy provides for specifying the storage type for this rule entry. Storage types are volatile and non-volatile. Volatile storage does not persist after a reset of the device. Non-volatile storage does persist after a reset of the device. Use the **storage-type** option to specify the desired storage type for this policy rule entry in an enhanced policy context.

## Forward and Drop

Packets for this entry can be either forwarded or dropped for this traffic classification using the **forward** and **drop** policy rule options.

## Allowed Traffic Rule-Type on a Port

Use the `show policy allowed-type` command to display a table of the current allowed and disallowed traffic rule-types for the specified port(s).

See [Table 91](#) on page 1306 for a listing of supported allowed traffic classification rule-types.

## Rule Precedence

### Note

When upgrading to ExtremeXOS 30.5 or later, any previously configured (before 30.5) policy profile precedence will be reset to the default rule precedence.

Static rules (MAC + port) have higher precedence than dynamic rules (Dot1x/Mac/Web VLAN authorization rules).

### Example

```
configure policy rule admin-profile macsource 00-00-00-00-00-01 mask 48 port-string 27
admin-pid 2

configure policy profile 2 name "filter" pvid-status "enable" pvid 400 egress-vlans 200
untagged-vlans 400 tci-overwrite "enable"

configure policy mactable response both
configure policy vlanauthorization enable
enable policy
```

In the above configuration, if a dot1x user is authenticated with Tunnel Private Group Id as "3000" and filter id as "filter" via Radius, the static macsource rule takes higher precedence and the client FDB learned on VLAN SYS\_VLAN\_0400 mentioned in the static rule rather than the tunnel ID sent by Radius.

```
show fdb
Mac Vlan Age Flags Port / Virtual Port List

00:00:00:00:00:01 SYS_VLAN_0400(0400) 0010 nd m v 27
```

### Modifying Rule Precedence Order

Starting with ExtremeXOS 30.2, you can modify the default precedence of ONEPolicy profile rules. You can configure the precedence for the rule types within each rule group. The rule groups currently supported are MAC, IPv6, IPv4, and Layer2.

The default precedence order is 1–2, 10, 29, 12, 32, 13, 33, 14–15, 34, 16, 35, 17, 36, 18, 37, 19, 23, 20–22, 25, 31.

MACSource (1), MACDest (2), IPv6Dest (10), Application (29), IPSource (12), IPSourceL4Range (32), IPDest (13), IPDestL4Range (33), IPFrag (14), UDPSrcPort (15), UDPSrcPortRange (34), UDPDestPort (16), UDPDestPortRange (35), TCPSrcPort (17), TCPSrcPortRange (36), TCPDestPort (18), TCPDestPortRange (37), ICMPType (19), ICMP6Type (23), TTL (20), IPTOS (21), IPProto (22), Ether (25), Port (31).

Rule types 1–2 come under MAC group.

Rule type 10 comes under IPv6 group.

Rule types 29, 12, 32, 13, 33, 14–15, 34, 16, 35, 17, 36, 18, 37, 19, 23, 20–22 come under IPv4 group.

Rule types 25 and 31 come under L2 group.

To modify the rule precedence order, use the following command with the precedence option:

```
configure policy profile profile_index {name name} {pvid pvid}
{pvid-status pvid_status} {cos cos} {cos-status cos_status} {egress-
vlangs egress_vlan_list} {forbidden-vlangs forbidden_vlangs} {untagged-vlangs
untagged_vlangs} {append | clear} {tcip-overwrite tcip_overwrite}
{precedence [precedence | default]} {auth-override auth_override} {nsi
[nsi | none]} {web-redirect web_redir_index} {access-list [unassigned |
list_name | list_name_placeholder]}
```

## Quality of Service in a Policy Rules Context

QoS can be specified directly in a policy role as stated in [Assigning a Class of Service to Policy Role](#) on page 1304. A CoS can also be applied to a policy rule. The CoS specified at the policy role level is the default and is only used if no rule is triggered. Therefore, if a CoS is applied to both the policy role and a policy rule, the CoS specified in the policy rule takes precedence over the CoS in the policy role for the traffic classification context specified in the policy rule. As stated in the policy role discussion, CoS configuration details are beyond the scope of this document.

## Blocking Non-Edge Protocols at the Edge Network Layer

Edge clients should be prevented from acting as servers for a number of IP services. If non-edge IP services accidentally or maliciously attach to the edge of the network, they are capable of disrupting network operation. IP services should only be allowed where and when your network design requires. This section identifies ten IP Services

you should consider blocking at the edge unless allowing them is part of your network architecture.

**Table 92: Non-Edge Protocols**

| Protocol                                       | Policy Effect                                                                                                                                                                                                                                                              |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>DHCP</i> Server Protocol                    | Every network needs DHCP. Automatically mitigate the accidental or malicious connection of a DHCP server to the edge of your network to prevent DoS or data integrity issues, by blocking DHCP on the source port for this device.                                         |
| DNS Server Protocol                            | DNS is critical to network operations. Automatically protect your name servers from malicious attack or unauthorized spoofing and redirection, by blocking DNS on the source port for this device.                                                                         |
| Routing Topology Protocols                     | <i>RIP (Routing Information Protocol)</i> , <i>OSPF (Open Shortest Path First)</i> , and <i>BGP (Border Gateway Protocol)</i> topology protocols should only originate from authorized router connection points to ensure reliable network operations.                     |
| Router Source MAC and Router Source IP Address | Routers and default gateways should not be moving around your network without approved change processes being authorized. Prevent DoS, spoofing, data integrity and other router security issues by blocking router source MAC and router source IP addresses at the edge. |
| SMTP/POP Server Protocols                      | Prevent data theft and worm propagation by blocking SMTP at the edge.                                                                                                                                                                                                      |
| <i>SNMP</i> Protocol                           | Only approved management stations or management data collection points need to be speaking SNMP. Prevent unauthorized users from using SNMP to view, read, or write management information.                                                                                |
| FTP and TFTP Server Protocols                  | Ensure file transfers and firmware upgrades are only originating from authorized file and configuration management servers.                                                                                                                                                |
| Web Server Protocol                            | Stop malicious proxies and application-layer attacks by ensuring only the right Web servers can connect from the right location at the right time, by blocking HTTP on the source port for this device.                                                                    |
| Legacy Protocols                               | If IPX, AppleTalk, DECnet or other protocols should no longer be running on your network, prevent clients from using them. Some organizations even take the approach that unless a protocol is specifically allowed, all others are denied.                                |

## Platform Rule Allocation

**Table 93: Platform Rule Allocation - 4120, 4220, 5120**

| Table Profile Name                | Table Name      | 4120             | 4220             | 5120             |
|-----------------------------------|-----------------|------------------|------------------|------------------|
| Default                           | MAC Rules       | 0                | 0                | 0                |
|                                   | IPv6 Rules      | 0                | 0                | 0                |
|                                   | IPv4 Rules      | 128              | 256              | 128              |
|                                   | L2 Rules        | 56               | 184              | 56               |
|                                   | ExtremeXOS App/ | 1,024 (4 slices) | 1,024 (4 slices) | 1,024 (4 slices) |
|                                   | System Rules    | 1,024            | 1,024            | 1,024            |
| more-ipv4-less-acl                | MAC Rules       | 0                | 0                | 0                |
|                                   | IPv6 Rules      | 0                | 0                | 0                |
|                                   | IPv4 Rules      | 128              | 256              | 128              |
|                                   | L2 Rules        | 56               | 184              | 56               |
|                                   | ExtremeXOS App/ | 1,024 (4 slices) | 1,024 (4 slices) | 1,024 (4 slices) |

| <p>* The L2 rule group normally includes ether-type and port qualifiers. When no-l2 is used, all the ether rules are accounted for in the IPv4 group. If you remove both L2 and IPv4 (no-l2 and no-ipv4), then ether rules are accounted for in the IPv6 group. If you remove L2, IPv4, and IPv6, (no-l2, no-ipv4, no-ipv6), then ether rules are accounted for in the MAC group.</p> <p><b>Note:</b> The best possible ExtremeXOS system application/system rules are driven by removing the default system ACL rules (<code>disable dot1p replacement ports all</code>), while keeping these system default ACL rules.</p> <p><b>Note:</b> Free ACL-slices are required (excluding the policy utilized slices) for MLAG to function properly. <b>configure policy resource-profile</b> is required.</p> |                             |                  |                  |                  |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | ExtremeXOS App/System Rules | 20,480 (10 slices) / 2,048 rules | 6,144 (4 slices) / 1,536 rules | 2,048 (4 slices) | 2,048 (4 slices) | 2,048 (4 slices) |
| <p>* The L2 rule group normally includes ether-type and port qualifiers. When no-l2 is used, all the ether rules are accounted for in the IPv4 group. If you remove both L2 and IPv4 (no-l2 and no-ipv4), then ether rules are accounted for in the IPv6 group. If you remove L2, IPv4, and IPv6, (no-l2, no-ipv4, no-ipv6), then ether rules are accounted for in the MAC group.</p> <p><b>Note:</b> The best possible ExtremeXOS system application/system rules are driven by removing the default system ACL rules (<code>disable dot1p replacement ports all</code>), while keeping these system default ACL rules.</p> <p><b>Note:</b> Free ACL-slices are required (excluding the policy utilized slices) for MLAG to function properly. <b>configure policy resource-profile</b> is required.</p> |                             |                                  |                                |                  |                  |                  |

For information about the maximum authenticated users per switch, see the Limits table of the [ExtremeXOS Release Notes](#).

In ExtremeXOS 22.4, you can use the profile modifier feature to return resources back to ACL from the specified profile. Use the profile-modifier option in the following command:

```
configure policy resource-profile [default | less-acl [more-ipv4 | more-
ipv4-no-ipv6 | more-ipv4-no-l2 | more-ipv4-no-mac-no-ipv6] | more-ipv4-
no-mac-no-ipv6-no-l2 | more-ipv4-no-ipv6 | more-ipv4-no-mac-no-ipv6 |
more-mac-no-ipv6] {profile-modifier [{no-mac no_mac} {no-ipv4 no_ipv4}
{no-ipv6 no_ipv6} {no-l2 no_l2}]}
```

To see what profile modifier settings you have configured, use the following command:

```
show policy resource-profile {[default | less-acl [more-ipv4 | more-ipv4-
no-ipv6 | more-ipv4-no-l2 | more-ipv4-no-mac-no-ipv6 | more-ipv4-no-mac-
no-ipv6-no-l2] | more-ipv4-no-ipv6 | more-ipv4-no-mac-no-ipv6 | more-mac-
no-ipv6] {profile-modifier [{no-mac} {no-ipv4} {no-ipv6} {no-l2}]}}
```

The following tables show the maximum number of slices available with the resource profile modifier enabled.

Table 96: Slices Available with Resource Profile Modifier for ExtremeSwitching Universal Switches

| Profile Name                      | Max Slices Available | No Profile Modifier | No-mac | No-ipv4 | No-ipv6 | No-I2 | No-mac-ipv4 | No-mac-ipv6 | No-ipv4, no-ipv6 | no-ipv4-no-I2 | no-ipv6-no-I2 | no-mac-ipv4-no-I2 | no-mac-ipv6-no-I2 | no-ipv4-no-ipv6-no-I2 |
|-----------------------------------|----------------------|---------------------|--------|---------|---------|-------|-------------|-------------|------------------|---------------|---------------|-------------------|-------------------|-----------------------|
| Default                           | 4                    | 4                   | 3      | 3       | 3       | 3     | 2           | 2           | 2                | 2             | 2             | 1                 | 1                 | 1                     |

## Authentication and ONEPolicy

### Applying Policy Using the RADIUS Response Attributes

If an authentication method that requires communication with an authentication server is configured for a user, the `RADIUS` filter-ID attribute can be used to dynamically assign a policy role to the authenticating user. Supported RADIUS attributes are sent to the switch in the RADIUS access-accept message. The RADIUS filter-ID can also be applied in hybrid authentication mode. Hybrid authentication mode determines how the RADIUS filter-ID and the three RFC 3580 `VLAN` tunnel attributes (VLAN Authorization), when either or all are included in the RADIUS access-accept message, will be handled by the switch. The three VLAN tunnel attributes define the base VLAN-ID to be applied to the user. In either case, conflict resolution between RADIUS attributes is provided by the mappable response feature.

#### Note

The mappable response feature is only applicable if VLAN Authorization is enabled (`configure policy vlanauthorization enable`).

#### Note

VLAN-to-policy mapping to mappable response configuration behavior is as follows:

- If the RADIUS response is set to policy, any VLAN-to-policy mappable configuration is ignored for all platforms.
- If the RADIUS response is set to both and both the filter-ID and tunnel attributes are present, VLAN-to-policy mapping configuration is ignored. See the “When Policy Mappable Response is Both” section of the Configuring User Authentication feature guide for exceptions to this behavior.

Use the policy option of the `configure policy mappable response` command to configure the switch to dynamically assign a policy using the RADIUS filter-ID in the RADIUS response message.

[Table 97](#) shows the RADIUS access-accept attributes for ONEPolicy that ExtremeXOS supports.

**Table 97: Supported Access-Accept Attributes for ONEPolicy**

| Access-Accept Attribute | Description         | Notes                                               |
|-------------------------|---------------------|-----------------------------------------------------|
| Filter-Id               | Policy Profile Name |                                                     |
| Tunnel-Medium-Type      | IEEE-802            | Must be present when using Tunnel-Private-Group-Id. |
| Tunnel-Type             | VLAN                | Must be present when using Tunnel-Private-Group-Id. |

**Table 97: Supported Access-Accept Attributes for ONEPolicy (continued)**

| Access-Accept Attribute | Description                          | Notes                                                              |
|-------------------------|--------------------------------------|--------------------------------------------------------------------|
| Tunnel-Private-Group-Id | Tunnel-ID                            | Can be a VLAN tag or the pre-configured tagged VLAN name (string). |
| Session-Timeout         | Numbers in seconds                   | '0' if it is not present.                                          |
| Idle-Timeout            | Numbers in seconds                   | '0' if it is not present.                                          |
| Termination-action      | Default/Radius   0/1                 | Default if it is not present.                                      |
| Fabric-Attach-VLAN-ISID | Tunnel-ID:4digitNSID+4digitTunnel-ID | Example: 10:12010010.                                              |

## NetLogin Authentication

*NetLogin* provides the dynamic authentication of users as a frontend to policy. Supported authentication type for ExtremeXOS includes 802.1X, MAC Authentication, and Web Authentication.

Unknown unicast/multicast/broadcast traffic is allowed to egress NetLogin-enabled ports, even if the ports are not authenticated. Configuring the port authentication mode as optional/required does not affect egress traffic (`configure netlogin ports [all | port_list] [allowed-users allowed_users | authentication mode [optional | required] | trap [all-traps | no-traps | [{success} {failed} {terminated} {max-reached}]]]`).

### Note

When enabling policy, all VLAN-level commands supported in non-policy mode are lost, including:

- `configure netlogin vlan`
- `configure netlogin authentication failure vlan`
- `configure netlogin authentication service-unavailable vlan`
- `configure netlogin dot1x guest-vlan`
- `configure netlogin dynamic-vlan`
- `configure netlogin ports [all | port_list] mode [mac-based-vlans | port-based-vlans]`
- `configure netlogin ports [all | port_list] no-restart`
- `configure netlogin ports [all | port_list] restart`
- `configure netlogin ports [port_list | all] allow egress-traffic [none | unicast | broadcast | all_cast]`

### NetLogin Session Timeout and Idle Timeout

Use the following commands to configure session timeout and idle timeout locally. These commands take effect if RADIUS access-accept has not returned any session timeout/idle timeout:

```
configure netlogin session-timeout {dot1x | mac | web-based |
convergence-endpoint} timeout
```

#### Note

If you want to scale to 65,000 authenticated users, use a session timeout value of at least 300 minutes.

```
configure netlogin idle-timeout {convergence-endpoint | dot1x | mac |
web-based} timeout
```

These commands appear in `show configuration {module-name} {detail}` for "policy" rather than "netlogin," since they are specific to ONEPolicy mode.

The command `show netlogin session {all | summary} {mac-address mac_address} {ports ports} {agent [convergence-endpointdot1x | mac | web-based]}` shows the session timeout and idle timeout, and `show netlogin mac` does not show any reauth/session timeout values.

```
show netlogin session
Multiple authentication session entries

Port : 1:1 Station address : 00:00:03:00:00:00
Auth status : success Last attempt : Tue May 23 08:24:17 2017
Agent type : mac Session applied : true
Server type : radius VLAN-Tunnel-Attr : None
Policy index : 1 Policy name : Extreme (active)
Session timeout : 40 Session duration : 0:00:02
Idle timeout : 20 Idle time : 0:00:00
Auth-Override : enabled Termination time: Not Terminated

show netlogin port 1:1
Port : 1:1
Authentication : mac-based
Port State : Enabled
Authentication Mode : Required (Policy Enabled only)
Max Supported Users : 1024 (Policy Enabled only)
Allowed Users : 1024 (Policy Enabled only)
Current Users : 2 (Policy Enabled only)

MAC Mode Port Configuration

Re-authentication period : 3600
Re-authentication : Off
Authentication Delay : 0 seconds (Default)

Netlogin Clients

MAC IP address Authenticated Type ReAuth-Timer User
00:00:03:00:00:00 0.0.0.0 Yes, Radius MAC 0 000003000000
00:00:03:00:00:01 0.0.0.0 Yes, Radius MAC 0 000003000001

(B) - Client entry Blackholed in FDB
```

```
Number of Clients Authenticated : 2
```

When idle timeout is configured and if the FDB is removed, the `show netlogin session` and `show netlogin port / mac/dot1x/web-based` commands show the NetLogin authenticated entries until the idle timer expires. NetLogin session and NetLogin MAC/dot1x/web table is cleared only after the idle timer expires.

## Applying Policy Using Hybrid Authentication Mode

Hybrid authentication is an authentication capability that allows the switch to use both the filter-ID and tunnel attributes in the RADIUS response message to determine how to treat the authenticating user. Hybrid authentication is configured by specifying the **both** option in the `configure policy mactable response` command. The **both** option:

- Applies the VLAN tunnel attributes if they exist and the filter-ID attribute does not exist
- Applies the filter-ID attribute if it exists and the VLAN tunnel attributes do not exist
- Applies both the filter-ID and the VLAN tunnel attributes if all attributes exist

If all attributes exist, the following rules apply:

- The policy role will be enforced, with the exception that any port PVID specified in the role will be replaced with the VLAN tunnel attributes
- The policy map is ignored because the policy role is explicitly assigned
- VLAN classification rules are assigned as defined by the policy role

vlanauthorization must be enabled or the VLAN tunnel attributes are ignored and the default VLAN is used.

When policy mactable response is set to **both** and only Tunnel ID is returned from RADIUS server, tunnel ID takes precedence and FDB is learned on Tunnel ID if policy mactable is not configured on the switch. If policy mactable is configured, then the policy profile assigned to that VLAN ID takes precedence and FDB is learned on policy profile PVID and not VLAN tunnel ID if invalid action is set to default-policy/drop.

For example:

```
configure policy profile 60 name test pvid 2 pvid-status enable
configure policy mactable 1234 60
```

From RADIUS VLAN tunnel ID 1234 exclusively is sent. Now FDB after successful authentication is learned on PVID 2 and not on 1234.

Hybrid Mode support eliminates the dependency of VLAN assignment based on roles. As a result, VLANs can be assigned via the tunnel-private-group-ID, as defined per RFC3580, while assigning roles via the filter-ID. This separation gives administrators more flexibility to segment their networks for efficiency beyond the role limits.

## Authentication Override

Authentication override allows you to override port authentication using a profile-based attribute. If a port has an active policy and the authentication override is enabled, all frames arriving on that port have that policy applied, and no further authentication occurs. In addition, any pre-existing authenticated sessions on that port are removed. However, the action is reverted once the authentication override is disabled. Authentication override is disabled by default.

The ENTERASYS-POLICY-PROFILE-MIB is changed to support the policy profile-based port authentication override feature:

```
etsysPolicyProfilePortAuthOverride OBJECT-TYPE
 SYNTAX EnabledStatus
 MAX-ACCESS read-create
 STATUS current
 DESCRIPTION
 "If a port has an active policy and that policy's
 etsysPolicyProfilePortAuthOverride is set to enabled(1),
 all frames arriving on the port will have that policy applied. In addition,
 any pre-existing entries with matching
 port values in the etsysMultiAuthSessionStationTable tables will change their
 authorization status to
 authTerminated(5). No further authentication will occur on this port.
 If disabled(2), the actions described above will not occur."
 DEFVAL { disabled }
 ::= { etsysPolicyProfileEntry 21 }

etsysPolicyClassification group
 supportsProfilePortAuthOverride(24)
 -- supports per profile port authentication
 -- override via etsysPolicyProfilePortAuthOverride
```

To configure authentication override, use the following command:

```
configure policy profile profile_index {name name} {pvid pvid}
{pvid-status pvid_status} {cos cos} {cos-status cos_status} {egress-
vlans egress_vlan_list} {forbidden-vlans forbidden_vlans} {untagged-vlans
untagged_vlans} {append | clear} {tci-overwrite tci_overwrite}
{precedence [precedence | default]} {auth-override auth_override} {nsi
[nsi | none]} {web-redirect web_redir_index} {access-list [unassigned |
list_name | list_name_placeholder]}
```

### Note

If authentication override is enabled, then static VLAN has to be configured rather than using the dynamic VLAN for the PVID.

## Configuring Policy

This section presents configuration procedures and tables including command description and syntax in the following policy areas: profile, classification, and display.

**Table 98: Configuring Policy Roles and Related Functionality**

| Step | Task                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Commands                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Step | Task                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Command(s)                                                                                                                                                                                                   |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | Create a "control group" (Mirror MIB) instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | <code>create mirror control_index</code>                                                                                                                                                                     |
| 2    | Create one or more "physical" mirrors.<br><br><b>Note:</b><br>MIB support (not CLI configured) adds a port to a mirror by the ports' Interface Index. In this case, the "physical" mirror is automatically created if there are resources and a matching "physical" mirror does not already exist. To assign a mirror with a remote-ip destination, the mirror must be configured before it can be added to a mirror control index. An interface index for the tunnel mirror is created at the time the tunnel mirror is created. This Interface Index can then be added to the mirror control_index. | <code>create mirror mirror_name {to [port port   port-list port_list loopback-port port] { remote-tag rtag }   {{ } } { [   ] } { [   ] } <b>priority</b> priority_value }} {description mirror-desc}</code> |
| 3    | Apply the physical mirrors to the control group instance using the add option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | <code>configure mirror control_index [ <b>add</b>   <b>delete</b> ] mirror_name</code>                                                                                                                       |

| 1    | Enable ACL Style Policy. Select the rule model as access-list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | <pre>configure policy <b>rule-model</b> [<b>access-list</b>   <b>hierarchical</b>]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 2    | <p>Create a policy access list and match criteria. Access list names are case sensitive. The <i>list_dot_rule</i> variable cannot match an existing one (using CLI namespace). At least 1, and no more than 5, match criteria can be selected, and at least 1 action must be selected.</p> <p>You cannot edit existing rules. You must delete and re-create rules if you need to make changes and want to use the same <i>list_dot_rule</i> name.</p> <p>Match conditions must be unique within an ACL and use them as a rule identifier in some cases, such as counters. For example create policy access-list ACL.ace produces an error when an ace entry that duplicates an existing "ace" exists in that ACL. Rules with the same match type with different data (IP/Port, etc.) within that the rule are accepted.</p> <p>ACL Style Policy supports the following rule match types:</p> <ul style="list-style-type: none"> <li>• Application—Layer 7, DNS-based</li> <li>• IP source and/or destination socket—IPv4 address mask</li> <li>• IP fragmentation—indicates packet is fragmented</li> <li>• IP protocol type—UDP/TCP/ICMP</li> </ul> | <pre>create policy <b>access-list</b> <i>list_dot_rule</i> {<b>matches</b> [ {<b>app-signature</b> <b>group</b> <i>group</i> <b>name</b> <i>name</i>} {<b>ether</b> <i>ether</i> {<b>mask</b> <i>ether_mask</i>}} {<b>icmp6type</b> <i>icmp6type</i> {<b>mask</b> <i>icmp6_mask</i>}} {<b>icmptype</b> <i>icmptype</i> {<b>mask</b> <i>icmp_mask</i>}} {<b>ipdestsocket</b> <i>ipdestsocket</i> {<b>mask</b> <i>ipdest_mask</i>}} {<b>ipfrag</b>} {<b>ipproto</b> <i>ipproto</i> {<b>mask</b> <i>ipproto_mask</i>}} {<b>ipsourcesocket</b> <i>ipsourcesocket</i> {<b>mask</b> <i>ipsrc_mask</i>}} {<b>iptos</b> <i>iptos</i> {<b>mask</b> <i>iptos_mask</i>}} {<b>ipttl</b> <i>ipttl</i> {<b>mask</b> <i>ipttl_mask</i>}} {<b>tcpdestportIP</b> <i>tcpdestportIP</i> {<b>mask</b> <i>tcpdest_mask</i>}} {<b>tcpsourceportIP</b> <i>tcpsourceportIP</i> {<b>mask</b> <i>tcpsrc_mask</i>}} {<b>udpdestportIP</b> <i>udpdestportIP</i> {<b>mask</b> <i>udpdest_mask</i>}} {<b>udpsourceportIP</b></pre> |

**Table 106: Configuring ACL Style Policy (continued)**

| Step | Task                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Command(s)                                                                                                                                |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
|      | <ul style="list-style-type: none"> <li>Source/destination UDP or TCP port—L4 port</li> <li>ICMPv4 or ICMPv6 Type—ICMP packet types</li> <li>IP TOS</li> <li>IP TTL</li> <li>Ether type</li> </ul> <p>ACL rules can combine up to 5 match types in a single rule. However, there are a few limitations for specified combinations:</p> <ul style="list-style-type: none"> <li>The match type ipfrag cannot be combined with ICMP, TCP, or UDP rules, since the header is only in the first packet.</li> <li>The match types tcp and udp cannot be in a single rule since you can never have both.</li> <li>The match types icmp6type and icmp type cannot be combined together.</li> <li>The match type icmp6type cannot be combined with IPv4 rules.</li> <li>The match type icmp cannot be combined with tcp or udp rules.</li> <li>The ether type is limited with compatible types. For example: IPv4 (0x0800) with IPv4 rules (such as icmp type/ipsrc/ipdest), IPV6 (0x86DD) with IPv6 capable rules (such as icmp6Type). However, iptos and ipttl work for both, as do udp and tcp, if they only specify ports, and not IP addresses.</li> <li>The type ipproto is limited to compatible types. For example: ipproto 1 icmp, 4 ipv4, 6 tcp, 7 udp, 58 icmp6.</li> </ul> <p><b>Actions:</b> When forward/deny is not specified in the rule, the rule action is interpreted as "forward" by default. This is an implicit permit, since the rule is triggered.</p> | <pre> udpsourceportIP {mask udpsrc_mask}} ] } {actions [ {cos cos} {drop   forward} {mirror-destination control_index} {syslog}]]} </pre> |
| 3    | Add rules and configure the rule precedence list for an access list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | <pre> configure policy access-list [rule-precedence [list_dot_rule [after member_rule   before member_rule   first   last ] ] ] </pre>    |

**Table 106: Configuring ACL Style Policy (continued)**

| Step | Task                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Command(s)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4    | <p>Assign access list to a profile using the access-list option.</p> <p><b>Note:</b> Use the unassigned option to remove an access list.</p> <p>You can configure the access list name when configuring the policy profile index and create access list rules for the access list later (step 2). An access list must contain at least one rule and is not active until it is assigned to a profile. Assigning a different access list to the same policy profile index overwrites any previous assignment. An access list cannot be assigned to more than one policy profile index. You must unassigned the access list from the current policy profile index before it can be associated with another policy profile index.</p> | <pre>configure policy profile <i>profile_index</i> {<b>name</b> <i>name</i>} {<b>pvid</b> <i>pvid</i>} {<b>pvid-status</b> <i>pvid_status</i>} {<b>cos</b> <i>cos</i>} {<b>cos-status</b> <i>cos_status</i>} {<b>egress- vlangs</b> <i>egress_vlan_list</i>} {<b>forbidden-vlangs</b> <i>forbidden_vlangs</i>} {<b>untagged-vlangs</b> <i>untagged_vlangs</i>} {<b>append</b>   <b>clear</b>} {<b>tci-overwrite</b> <i>tci_overwrite</i>} {<b>precedence</b> [<i>precedence</i>   <b>default</b>]} {<b>auth- override</b> <i>auth_override</i>} {<b>nsi</b> [<i>nsi</i>   <b>none</b>]} {<b>web-redirect</b> <i>web_redir_index</i>} {<b>access-list</b> [<b>unassigned</b>   <i>list_name</i>   <i>list_name_placeholder</i>]}</pre> |
| 5    | <p>(Optional) Delete policy access lists and/or rules.</p> <p>You can remove a specific rule or remove all the rules from an access list, or remove all access lists and their rules.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <pre>delete policy <b>access- list</b> [<b>all-rules</b>   <i>list_dot_rule</i>]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## ONEPolicy Configuration Examples

The following examples demonstrate how to configure various features of ONEPolicy.

### Policy Configuration Example

This section presents a college-based policy configuration example. [Figure 168](#) displays an overview of the policy configuration. This overview display is followed by a complete discussion of the configuration example.

**Figure 168: College-Based Policy Configuration**

### Roles

The example defines the following roles:

- **guest** – Used as the default policy for all unauthenticated ports. Connects a PC to the network providing internet only access to the network. Provides guest access to a limited number of the edge switch ports to be used specifically for internet only access. Policy is applied using the port level default configuration, or by authentication, in the case of the Services Edge Switch port internet only access PCs.
- **student** – Connects a dorm room PC to the network through a “Student” Fixed Switch port. A configured *CoS* rate limits the PC. Configured rules deny access to administrative and faculty servers. The PC authenticates using *RADIUS*. Hybrid

authentication is enabled. The student policy role is applied using the filter-ID attribute. The base VLAN is applied using the tunnel attributes returned in the RADIUS response message. If all rules are missed, the settings configured in the student policy profile are applied.

- phoneFS – Connects a dorm room or faculty office VoIP phone to the network using a stackable fixed switch port. A configured CoS rate limits the phone and applies a high priority. The phone authenticates using RADIUS. Hybrid authentication is enabled. Policy is applied using the filter-ID returned in the RADIUS response message. The base VLAN is applied using the tunnel attributes returned in the RADIUS response message. If all rules are missed, the settings configured in the phoneFS policy profile are applied.
- faculty – Connects a faculty office PC to the network through a “Faculty” Fixed Switch port. A configured CoS rate limits the PC. A configured rule denies access to the administrative servers. The PC authenticates using RADIUS. Hybrid authentication is enabled. The faculty policy role is applied using the filter-ID attribute. The base VLAN is applied using the tunnel attributes returned in the RADIUS response message for the authenticating user. If all rules are missed, the settings configured in the faculty policy profile are applied.
- phoneES – Connects a services VoIP phone to the network using a Services Edge Switch port. A configured CoS rate limits the phone for both setup and payload, and applies a high priority. The phone authenticates using RADIUS. Tunnel authentication is enabled. The base VLAN is applied using the tunnel attributes returned in the RADIUS response message. Policy is applied using a mappable configuration. If all rules are missed, the settings configured in the phoneES policy profile are applied.
- services – Connects a services PC to the network through the Services Edge Switch port. A configured CoS rate limits the PC. Services are denied access to both the student and faculty servers. The PC authenticates using RADIUS. The base VLAN is applied using the tunnel attributes returned in the RADIUS response message for the authenticating user. The services policy role is applied using a policy mappable setting. The policy invalid action and TCI overwrite are enabled for this role. If all rules are missed, the settings configured in the services policy profile are applied.
- distribution – The Distribution policy role is applied at the Distribution Switch providing rate limiting.

### Policy Domains

It is useful to break up policy implementation into logical domains for ease of understanding and configuration. For this example, it is useful to consider four domains: basic edge, standard edge on the Fixed Switch, premium edge on the Services Edge Switch, and premium distribution on the Distribution Switch.

#### Basic Edge

Protocols not appropriate to the edge should be blocked. For this example we will block DHCP, DNS, SNMP, SSH, Telnet and FTP at the edge on the data VLAN. We will forward destination port DHCP and DNS and source port for IP address request to facilitate auto configuration and IP address assignment. See [Blocking Non-Edge Protocols at the Edge Network Layer](#) on page 1309 for a listing of protocols you should consider blocking at the edge.

### Standard Edge

Edge Switch platforms will be rate-limited using a configured *CoS* that will be applied to the student and faculty, and phoneFS policy roles. Fixed Switch support for hybrid authentication depends upon the platform and firmware release. The Fixed Switch in this example supports the hybrid authentication capability. Hybrid authentication will be enabled.

### Premium Edge

The Edge Switch will be rate-limited using a configured CoS that is applied to the services and phoneES policy role. This premium edge platform will be enabled for the following capabilities:

- Invalid policy action set to drop
- TCI overwrite enabled

### Premium Distribution

The Distribution Switch Router will be rate-limited using a configured CoS. Premium distribution will be enabled for the following policy capabilities:

- Invalid policy action set to drop
- TCI overwrite enabled

## Platform Configuration

This section provides the CLI based policy configuration on the following platforms:

- Student Fixed Switch
- Faculty Fixed Switch
- Services Edge Switch
- Distribution Switch

In CLI mode, configuration takes place on each platform. For this configuration example, *CoS* related configuration will be specified as a final CoS. See the *QoS* Configuration feature guide located at <http://documentation.extremenetworks.com> for a complete discussion of QoS configuration.

### Note

CLI command prompts used in this configuration example have the following meaning:

- `System->`—Input on all platforms used in this example.
- `Fixed Switch->`—Input on all Fixed Switches.
- `StudentFS->`—Input on the student Fixed Switch.
- `FacultyFS->`—Input on the faculty Fixed Switch.
- `Services->`—Input on the services S-Series device.
- `Distribution->`—Input on the distribution S-Series device.

### Configuring Guest Policy on Edge Platforms

All edge ports will be set with a default guest policy using the `configure policy port` command. This guest policy provides for an internet only access to the network. Users on all ports will attempt to authenticate. If the authentication succeeds, the policy returned by authentication or, in the case of the Services Edge Switch configuration, the mactable setting, overrides the default port policy setting. If authentication fails, the guest policy is used. On the Services Edge Switch, five ports are used by PCs at locations throughout the campus, such as the library, to provide access to the internet. The PCs attached to these five ports will authenticate with the guest policy role. Public facing services would also be configured for guest status in a school or enterprise scenario. Public facing services are not part of this example.

#### Configuring the Policy Role

The guest role is configured with:

- A profile-index value of 1
- A name of guest
- A PVID set to 0
- A *CoS* set to 4

Create the guest policy profile on all platforms:

```
System ->configure policy profile 1 name guest pvid-status enable pvid 0 cos-status enable cos 4
```

#### Assigning Traffic Classification Rules

For cases where discovery must take place to assign an IP address, DNS and *DHCP* traffic must be allowed. Forwarding of traffic is allowed on UDP source port 68 (IP address request) and UDP destination ports 53 (DNS) and 67 (DHCP).

```
System ->configure policy rule 1 udpsourceport 68 mask 16 forward
System->configure policy rule 1 udpdestportIP 53 mask 16 forward
System ->configure policy rule 1 udpdestportIP 67 mask 16 forward
```

Guest policy allows internet traffic. TCP destination Ports 80, 8080, and 443 will be allowed traffic forwarding.

```
System->configure policy rule 1 tcpdestportIP 80 mask 16 forward
System->configure policy rule 1 tcpdestportIP 443 mask 16 forward
System->configure policy rule 1 tcpdestport 8080 mask 16 forward
```

ARP forwarding is required on ether port 0x806.

```
System->configure policy rule 1 ether 0x806 mask 16 forward
```

#### Assigning the Guest Policy Profile to All Edge Ports

Assign the guest policy profile to all Fixed Switch and Services Edge Switch ports.

```
System->configure policy port 1-47 1
```

## Configuring Policy for the Edge Student Fixed Switch

### Configuring the Policy Role

The student role is configured with:

- A profile-index value of 2
- A name of student
- A port VLAN of 10
- A CoS of 8

Create a policy role that applies a CoS 8 to data VLAN 10 and configures it to rate-limit traffic to 1M with a moderate priority of 5.

```
StudentFS->configure policy profile 2 name student pvid-status
enable pvid 10 cos-status enable cos 8
```

### Assigning Hybrid Authentication

Configure the RADIUS server user accounts with the appropriate tunnel information using VLAN authorization and policy filter-ID for student role members and devices. Enable hybrid authentication, allowing the switch to use both the filter-ID and tunnel attributes in the RADIUS response message. Set a VLAN-to-policy mapping as backup incase the response does not include the RADIUS filter-ID attribute. This mapping is ignored in case RADIUS filter-ID attribute is present in the RADIUS response message.

```
StudentFS->configure policy mactable response both
StudentFS->configure policy mactable 10 2
```

### Assigning Traffic Classification Rules

Forward traffic on UDP source port for IP address request (68), and UDP destination ports for protocols DHCP (67) and DNS (53). Drop traffic on UDP source ports for protocols DHCP (67) and DNS (53). Drop traffic for protocols SNMP (161), SSH (22), Telnet (23) and FTP (20 and 21) on both the data and phone VLANs.

```
StudentFS->configure policy rule 2 udpsourceport 68 mask 16 forward
StudentFS->configure policy rule 2 udpdestport 67 mask 16 forward
StudentFS->configure policy rule 2 udpdestport 53 mask 16 forward
StudentFS->configure policy rule 2 udpsourceportIP 67 mask 16 drop
StudentFS->configure policy rule 2 udpsourceportIP 53 mask 16 drop
StudentFS->configure policy rule 2 udpdestportIP 16 mask 16 drop
StudentFS->configure policy rule 2 tcpdestportIP 22 mask 16 drop
StudentFS->configure policy rule 2 tcpdestportIP 23 mask 16 drop
StudentFS->configure policy rule 2 tcpdestportIP 20 mask 16 drop
StudentFS->configure policy rule 2 tcpdestportIP 21 mask 16 drop
```

Students should only be allowed access to the services server (subnet 10.10.50.0/24) and should be denied access to both the administrative (subnet 10.10.60.0/24) and faculty servers (subnet 10.10.70.0/24).

```
StudentFS->configure policy rule 2 ipdestsocket 10.10.60.0 mask 24 drop
StudentFS->configure policy rule 2 ipdestsocket 10.10.70.0 mask 24 drop
```

## Configuring PhoneFS Policy for the Edge Fixed Switch

### Configuring the Policy Role

The phoneFS role is configured on both the dorm room and faculty office Fixed Switches with:

- A profile-index of 3
- A name of phoneFS
- A port VLAN of 11
- A CoS of 10

Because we can not apply separate rate limits to the phone setup and payload ports on the Fixed Switch using policy rules, apply CoS 10 with the higher payload appropriate rate limit of 100k bps and a high priority of 6 to the phoneFS role.

```
Fixed Switch->configure policy profile 3 name phoneFS pvid-status enable pvid 11
cos-status enable cos 10
```

### Assigning Traffic Classification Rules

Drop traffic for protocols SNMP (161), SSH (22), Telnet (23) and FTP (20 and 21) on the phone VLAN. Forward traffic on UDP source port for IP address request (68) and forward traffic on UDP destination ports for protocols DHCP (67) and DNS (53) on the phone VLAN, to facilitate phone auto configuration and IP address assignment.

```
Fixed Switch->configure policy rule 3 udpdestportIP 161 mask 16 drop
Fixed Switch->configure policy rule 3 tcpdestportIP 22 mask 16 drop
Fixed Switch->configure policy rule 3 tcpdestportIP 23 mask 16 drop
Fixed Switch->configure policy rule 3 tcpdestportIP 20 mask 16 drop
Fixed Switch->configure policy rule 3 tcpdestportIP 21 mask 16 drop
Fixed Switch->configure policy rule 3 udpsourceport 68 mask 16 forward
Fixed Switch->configure policy rule 3 udpdestportIP 67 mask 16 forward
Fixed Switch->configure policy rule 3 udpdestportIP 53 mask 16 forward
```

### Assigning Hybrid Authentication

Configure the RADIUS server user accounts with the appropriate tunnel information using VLAN authorization and policy filter-ID for phoneFS role members and devices. Enable hybrid authentication, allowing the switch to use both the filter-ID and tunnel attributes in the RADIUS response message. Set a VLAN-to-policy mapping as backup incase the response does not include the RADIUS filter-ID attribute. This mapping is ignored if RADIUS filter-ID attribute is present in the RADIUS response message.

```
Fixed Switch->configure policy mactable response both
Fixed Switch->configure policy mactable 11 3
```

## Configuring Policy for the Edge Faculty Fixed Switch

### Configuring the Policy Role

The faculty role is configured with:

- A profile-index value of 4
- A name of faculty
- A port VLAN of 10
- A CoS of 8

Create a policy role that applies a CoS 8 to data VLAN 10 and configures it to rate-limit traffic to 1M with a moderate priority of 5.

```
FacultyFS->configure policy profile 4 name faculty pvid-status enable pvid 10
cos-status enable cos 8
```

### Assigning Hybrid Authentication

Configure the RADIUS server user accounts with the appropriate tunnel information using VLAN authorization and policy filter-ID for faculty role members and devices. Enable hybrid authentication. Set a VLAN-to-policy mapping. This mapping is ignored if the RADIUS filter-ID attribute is present in the RADIUS response message.

```
FacultyFS->configure policy mactable response both
FacultyFS->configure policy mactable 10 4
```

### Assigning Traffic Classification Rules

Forward traffic on UDP source port for IP address request (68), and UDP destination ports for protocols DHCP (67) and DNS (53). Drop traffic on UDP source ports for protocols DHCP (67) and DNS (53). Drop traffic for protocols SNMP (161), SSH (22), Telnet (23) and FTP (20 and 21) on both the data and phone VLANs

```
FacultyFS->configure policy rule 4 udpsourceport 68 mask 16 forward
FacultyFS->configure policy rule 4 udpdestport 67 mask 16 forward
FacultyFS->configure policy rule 4 udpdestport 53 mask 16 forward
FacultyFS->configure policy rule 4 udpsourceportIP 67 mask 16 drop
FacultyFS->configure policy rule 4 udpsourceportIP 53 mask 16 drop
FacultyFS->configure policy rule 4 udpdestportIP 16 mask 16 drop
FacultyFS->configure policy rule 4 tcpdestportIP 22 mask 16 drop
FacultyFS->configure policy rule 4 tcpdestportIP 23 mask 16 drop
FacultyFS->configure policy rule 4 tcpdestportIP 20 mask 16 drop
FacultyFS->configure policy rule 4 tcpdestportIP 21 mask 16 drop
```

Faculty should only be allowed access to the services (subnet 10.10.50.0/24) and the faculty servers (subnet 10.10.70.0/24) and should be denied access to the administrative server (subnet 10.10.60.0/24).

```
FacultyFS->configure policy rule 4 ipdestsocket 10.10.60.0 mask 24 drop
```

## Configuring PhoneES Policy for the Services Edge Switch

### Configuring the Policy Role

The phoneES role is configured on the Services Edge Switch with:

- A profile-index of 5 Policy
- A name of phoneES
- A default port VLAN of 0
- A default CoS of 4

Because VLANs can be applied to Services Edge Switch ports using the appropriate traffic classification, the explicit deny all PVID 0 will be applied at policy creation. Separate rate limits can be applied to the phone setup and payload ports on the

Services Edge Switch using policy rules. A default CoS of 4 will be applied at policy role creation.

```
ServicesES->configure policy profile 5 name phoneES pvid-status enable pvid 0
cos-status enable cos 4
```

### Assigning Traffic Classification Rules

Forward traffic on UDP source port for IP address request (68) and forward traffic on UDP destination ports for protocols *DHCP* (67) and DNS (53) on the phone VLAN, to facilitate phone auto configuration and IP address assignment. Drop traffic for protocols *SNMP* (161), SSH (22), Telnet (23) and FTP (20 and 21) on the phone VLAN.

```
ServicesES->configure policy rule 5 udpsourceport 68 mask 16 forward
ServicesES->configure policy rule 5 udpdestportIP 67 mask 16 forward
ServicesES->configure policy rule 5 udpdestportIP 53 mask 16 forward
ServicesES->configure policy rule 5 udpdestportIP 161 mask 16 drop
ServicesES->configure policy rule 5 tcpdestportIP 22 mask 16 drop
ServicesES->configure policy rule 5 tcpdestportIP 23 mask 16 drop
ServicesES->configure policy rule 5 tcpdestportIP 20 mask 16 drop
ServicesES->configure policy rule 5 tcpdestportIP 21 mask 16 drop
```

Apply a CoS 9 to phone setup data on VLAN 11, rate limiting the data to 5 pps with a high priority of 7 on port 2427.

Apply a CoS 10 to phone payload data on VLAN 11, rate limiting the data to 100k bps with a high priority of 7 for both source and destination on port 5004.

```
ServicesES->configure policy rule 5 udpdestIP 2427 mask 16 vlan 11 cos 9
ServicesES->configure policy rule 5 udpsourceIP 5004 mask 16 vlan 11 cos 10
ServicesES->configure policy rule 5 udpdestIP 5004 mask 16 vlan 11 cos 10
```

### Assigning the VLAN-to-Policy Association

The nature of services related devices that might connect to a switch port is not as static as with the student or faculty roles. Services related network needs can run the gamut from temporary multimedia events to standard office users. There may be multiple VLAN and policy role associations that take care of services related needs, depending upon the connected user. This may include the requirement for multiple services related roles.

For services, the network administrator desires greater resource usage flexibility in assigning the policy to VLAN association. Authentication in this case will return only the tunnel attributes in the response message based upon the requirements of the authenticating user. Setting the VLAN-to-policy association will be handled by the mactable configuration, allowing for ease in changing the policy associated with a VLAN on the fly using Policy Manager. Specify that the tunnel attributes returned in the *RADIUS* response message will be used by the authenticating user. Associate VLAN 11 with policy role 5 using the `configure policy mactable` command.

```
ServicesES->configure policy mactable response tunnel
ServicesES->configure policy mactable 11 5
```

## Configuring Policy for the Services Edge Switch

### Configuring the Policy Role

The services role is configured with:

- A profile-index value of 6
- A name of services
- A default port VLAN of 0
- A default CoS when no rule overrides CoS
- TCI overwrite enabled

```
ServicesES->configure policy profile 6 name services pvid-status enable pvid 0
cos-status enable cos 4 tci-overwrite enable
```

### Assigning the VLAN-to-Policy Association

Setting the VLAN-to-policy association will be handled by the policy mactable setting, allowing for ease in changing the policy associated with a VLAN on the fly using Policy Manager. Specify that the tunnel attributes returned in the RADIUS response message will be used by the authenticating user. Associate VLAN 10 with policy role 6 using the set policy mactable command.

```
ServicesES->configure policy mactable response tunnel
ServicesES->configure policy mactable 10 6
```

### Assigning Traffic Classification Rules

Forward traffic on UDP source port for IP address request (68) and forward traffic on UDP destination ports for protocols DHCP (67) and DNS (53) on the data VLAN, to facilitate PC auto configuration and IP address assignment. Drop traffic for protocols SNMP (161), SSH (22), Telnet (23) and FTP (20 and 21) on the phone VLAN.

```
ServicesES->configure policy rule 6 udpsourceportIP 68 mask 16 vlan 10 forward
ServicesES->configure policy rule 6 udpdestportIP 67 mask 16 vlan 10 forward
ServicesES->configure policy rule 6 udpdestportIP 53 mask 16 vlan 10 forward
ServicesES->configure policy rule 6 udpdestportIP 67 mask 16 vlan 10 drop
ServicesES->configure policy rule 6 udpdestportIP 53 mask 16 vlan 10 drop
ServicesES->configure policy rule 6 udpdestportIP 161 mask 16 drop
ServicesES->configure policy rule 6 tcpdestportIP 22 mask 16 drop
ServicesES->configure policy rule 6 tcpdestportIP 23 mask 16 drop
ServicesES->configure policy rule 6 tcpdestportIP 20 mask 16 drop
ServicesES->configure policy rule 6 tcpdestportIP 21 mask 16 drop
```

Apply a CoS 8 to data VLAN 10 and configure it to rate-limit traffic to 1M and moderate priority of 5 for services IP subnet 10.10.30.0 mask 28.

```
ServicesES->configure policy rule 6 ipsourcesocket 10.10.30.0 mask 28 vlan 10 cos 8
```

Services should only be allowed access to the services server (subnet 10.10.50.0/24) and should be denied access to the faculty servers (subnet 10.10.70.0/24) and administrative servers (subnet 10.10.60.0/24).

```
ServicesES->configure policy rule 6 ipdestsocket 10.10.60.0 mask 24 drop
ServicesES->configure policy rule 6 ipdestsocket 10.10.70.0 mask 24 drop
```

### Enable Enhanced Edge Switch Capabilities on the Services Edge Switch Platform

The Services Edge Switch platform supports invalid action set to default policy should an invalid policy occur.

```
ServicesES->configure policy invalid action default-policy
```

### Configuring the Distribution Layer Role

#### Configuring the Policy Role

The distribution role is configured with:

- A profile-index value of 7
- A name of distribution
- A default CoS when no rule overrides CoS
- TCI overwrite enabled

```
Distribution->configure policy profile 7 name distribution cos-status enable cos 4
tci-overwrite enable
```

#### Assigning Traffic Classification Rules

Assign a CoS to distribution up and down stream link ports, rate-limiting the traffic to 25M.

```
Distribution->configure policy rule 7 port 1-26 cos 11
Distribution->configure policy rule 7 port 1-26 cos 11
```

#### Enable Enhanced Policy Capability

The following enhanced policy capability is enabled: invalid action set to default policy should an invalid policy occur.

```
ServicesES->configure policy invalid action default-policy
```

This completes the policy configuration for this school example.

## Captive Portal Redirection Example

In the following example:

- Switch is configured to listen for web traffic on ports 80 and 8080.
- Web-redirect index 1 enables server 1 with a redirection URL <http://10.52.3.101:80/static/index.jsp>.
- Web-redirect index 1 enables server 2 with a redirection URL <http://10.52.3.102:80/static/index.jsp>.
- Web-redirect index 1 is associated with policy profile 1.

```
#configure policy captive-portal listening 80,8080
#configure policy captive-portal web-redirect 1 server 1 url http:// 10.52.3.101:80/
static/index.jsp enable
#configure policy captive-portal web-redirect 1 server 2 url http:// 10.52.3.102:80/
static/index.jsp enable
#configure policy profile 1 web-redirect 1

#show policy captive-portal listening
```

```
Captive Portal Listening Ports: 80 8080

#show policy captive-portal web-redirect 1
Web-redirect Index: 1
Server Index: 1
Server Status: Enabled
Server URL: http://10.52.3.101:80/static/index.jsp
Server Index: 2
Server Status: Enabled
Server URL: http://10.52.3.102:80/static/index.jsp
```

## Sending a Change of Authentication (CoA) from FreeRADIUS Example

To add a DACL:

```
Example: echo "Calling-Station-ID = <SESSION-MAC-HYPONATED>, NAS-IP-Address = <switch ip-
address>, Tunnel-Medium-Type = IEEE-802, Tunnel-Type = VLAN, Tunnel-Private-Group-ID =
<VLAN-ID/STRING>, Filter-Id = <Profile-Name>, Extreme-Policy-ACL = \"v:1 t:a
m:ipv4src=10.10.10.1/32,ipv4dst=192.168.10.25/32,ipproto=tcp,l4srcport=69/8,l4dstport=69/8
a:fwd,sys,cos=2 \" \" | radclient -x -r 1 <Switch-IP>:3799 coa secret
```

To delete the DACL:

```
echo "Calling-Station-ID = <SESSION-MAC-HYPONATED>, NAS-IP-Address = <switch ip-address>,
Tunnel-Medium-Type = IEEE-802, Tunnel-Type = VLAN, Tunnel-Private-Group-ID = <VLAN-ID/
STRING>, Filter-Id = <Profile-Name>, Extreme-Policy-ACL = \"v:1 t:d
m:ipv4src=10.10.10.1/32,ipv4dst=192.168.10.25/32,ipproto=tcp,l4srcport=69/8,l4dstport=69/8
a:fwd,sys,cos=2 \" \" | radclient -x -r 1 <Switch-IP>:3799 coa secret
```

## Example Dynamic ACL VSA String

This example shows adding two rules as part of Access-Accept operation.

```
Extreme-Policy-ACL = "v:1 t:a
m:ipv4src=1.2.3.4/32,ipv4dst=2.4.6.8/32,ipproto=tcp,l4srcport=4321/16,l4dstport=9876/16
a:fwd,sys,cos=4,mir=2"
```

```
Extreme-Policy-ACL += "v:1 t:a
m:ipv4src=1.2.3.6/32,ipv4dst=2.4.6.8/32,ipproto=tcp,l4srcport=4321/16,l4dstport=9876/16
a:fwd,sys,cos=4,mir=2"
```

```
Extreme-Policy-ACL += "v:1 t:a,r
m:ipv4src=1.2.3.6/32,ipv4dst=2.4.6.8/32,ipproto=tcp,l4srcport=101-200,l4dstport=201-300
a:fwd,sys,cos=4,mir=2"
```

This example shows the application of dacl in multiauth, if the dot1x session needs coa, echo:

```
Calling-Station-ID = <session-mac-hyponated>, NAS-IP-Address = <switch-ip>, Tunnel-Medium-
Type = IEEE-802, Tunnel-Type = VLAN, Tunnel-Private-Group-ID = 101, Enterasys-Auth-Client-
Type = 802.1X, Filter-Id = Default" | radclient -x -r 1 <switch-ip>:3799 coa secret
```

# OSPF

---

- [OSPF Overview](#) on page 1352
- [Route Redistribution](#) on page 1362
- [Configuring OSPF](#) on page 1366
- [OSPF Configuration Example](#) on page 1367
- [Displaying OSPF Settings](#) on page 1370

This chapter discusses the OSPF (Open Shortest Path First) protocol for distributing routing information between routers belonging to an autonomous system. This chapter provides an overview of the protocol's features and example configuration commands.

This chapter assumes that you are already familiar with IP unicast routing. If not, refer to the following publications for additional information:

- RFC 2328—OSPF Version 2
- RFC 1765—OSPF Database Overflow
- RFC 2370—The OSPF Opaque LSA Option
- RFC 3101—The OSPF Not-So-Stubby Area (NSSA) Option
- RFC 3623—Graceful OSPF Restart
- *Interconnections: Bridges and Routers* by Radia Perlman. Published by Addison-Wesley Publishing Company (ISBN 0-201-56332-0).

## Note

OSPF is available on platforms with an Advanced Edge (or higher) or Base (or higher) license. For specific information regarding OSPF licensing, see the licensing guide.

## OSPF Overview

---

OSPF (Open Shortest Path First) is a link state protocol that distributes routing information between routers belonging to a single IP domain; the IP domain is also known as an autonomous system (AS).

In a link-state routing protocol, each router maintains a database describing the topology of the AS. Each participating router has an identical database maintained from the perspective of that router.

From the LSDB (link state database), each router constructs a tree of shortest paths, using itself as the root. The shortest path tree provides the route to each destination in

the AS. When several equal-cost routes to a destination exist, traffic can be distributed among them. The cost of a route is described by a single metric.

OSPF is an IGP (interior gateway protocol), as is [RIP \(Routing Information Protocol\)](#), the other common IGP. OSPF and RIP are compared in [RIP](#).

**Note**

Two types of OSPF functionality are available and each has a different licensing requirement. One is the complete OSPF functionality and the other is OSPF Edge Mode, a subset of OSPF that is described below. For specific information regarding OSPF licensing, see the [Switch Engine v33.3.1 Licensing Guide](#) document.

## OSPF Edge Mode

[OSPF](#) Edge Mode is a subset of OSPF available on platforms with an Advanced Edge license.

There are two restrictions on OSPF Edge Mode:

- At most, four Active OSPF [VLAN \(Virtual LAN\)](#) interfaces are permitted. There is no restriction on the number of Passive interfaces.
- The OSPF Priority on VLANs is 0, and is not configurable. This prevents the system from acting as a DR or BDR.

## BFD for OSPF

The BFD for [OSPF](#) feature gives OSPF routing protocol the ability to utilize BFD's fast failure detection to monitor OSPF neighbor adjacencies. CLI commands are provided to configure BFD protection for OSPF, so that as a registered BFD client, OSPF can request BFD protection for interested OSPF neighbors, and receive notifications about BFD session setup status and BFD session status updates (after establishing) from the BFD server. When BFD detects a communication failure between neighbors, it informs OSPF, which causes the OSPF neighbor state be marked as "down." This allows OSPF protocol to quickly begin network convergence and use alternate paths to the affected neighbor.

**Figure 169: Basic Operational Flow of OSPF BFD**

*Establishing a BFD Session for OSPF Neighbor*

1. OSPF discovers a neighbor.
2. If BFD for OSPF is configured, OSPF on both routers sends a request to the local BFD server to initiate a BFD neighbor session with the OSPF neighbor router.
3. The BFD neighbor session with the OSPF neighbor router is established on both sides if BFD session limit is not reached.

If the BFD session limit is reached, the OSPF neighbor will be marked as BFD session failed if synchronous request is used, or pending if asynchronous request is used, and the BFD server will send an asynchronous notification when the session registration passes later. (The asynchronous request is not available until the BFD client session create API is enhanced.)

*Eliminating the OSPF Neighbor Relationship by BFD Fault Detection*

1. A failure occurs in the network.
2. The BFD neighbor session with the OSPF neighbor router is removed because the BFD timer expired.
3. On both Router A and Router B, BFD notifies the local OSPF process that the BFD neighbor is DOWN.
4. The local OSPF process tears down the OSPF neighbor relationship by marking neighbor state DOWN. (If an alternative path is available, the routers will immediately start converging on it.)

**Figure 170: OSPF Neighbor Relationship Eliminated by BFD Fault Detection**

OSPF will request the BFD server to delete the BFD session for OSPF neighbor moved to DOWN state. When the link failure is later resolved, OSPF needs to register the re-discovered neighbor to BFD again to initiate BFD session creation.

#### *Removing BFD Protection for OSPF*

1. BFD protection is removed from OSPF interface on Router A, OSPF process requests BFD server to delete all BFD sessions for neighbors learned on that interface.
2. BFD server will stop sending session status update to local OSPF process on Router A.
3. Before actually deleting any sessions, BFD server on Router A will first notify Router B to mark those session status as "Admin Down," which will cause Router B to stop using BFD protection for those OSPF neighbors.
4. When BFD protection is removed from OSPF interface on Router B, BFD sessions can be deleted immediately since they are already in "Admin Down" state.

When BFD for OSPF is configured on broadcast interface, the default behavior is to register only OSPF neighbors in FULL state with the BFD server. Separate BFD sessions are created for each neighbor learned on the same interface. If multiple clients ask for the same neighbor on the same interface, then single BFD sessions are established between the peers.

#### *OSPF Neighbor State Determination*

With active BFD protection, OSPF combines the BFD session state with the associated interface admin and operational states to determine the OSPF neighbor adjacency discovered on that OSPF interface. Regarding OSPF neighbor relationships, OSPF reacts directly to BFD session state changes only in the following circumstances:

- If BFD is enabled on the interface, and
  - If BFD for OSPF is configured on the OSPF interface, and
  - If a BFD session has been established to the neighbor, and
  - If the BFD session has passed the INIT\_COMPLETE state then:
1. The OSPF neighbor relationship will remain as FULL if the operational state of the BFD session is "UP" and the operational state of the associated VLAN interface is UP.

2. The OSPF neighbor relationship will be considered as DOWN if the operational state of the BFD session is DOWN or the operational state of the associated VLAN interface is DOWN.

In all other cases, the BFD session state is not considered as part of the reported OSPF neighbor state, and the OSPF neighbor state reverts to the operational state of the OSPF interface only. When the BFD session is in ADMIN\_DOWN state, OSPF ignores BFD events and OSPF neighbor adjacency is not be affected by the BFD session state change.

## Link State Database

Upon initialization, each router transmits a link state advertisement (LSA) on each of its interfaces. LSAs are collected by each router and entered into the LSDB of each router. After all LSAs are received, the router uses the link state database (LSDB) to calculate the best routes for use in the IP routing table. *OSPF* uses flooding to distribute LSAs between routers. Any change in routing information is sent to all of the routers in the network. All routers within an area have the exact same LSDB.

Table 107 describes LSA type numbers.

**Table 107: LSA Type Numbers**

| Type Number | Description         |
|-------------|---------------------|
| 1           | Router LSA          |
| 2           | Network LSA         |
| 3           | Summary LSA         |
| 4           | AS summary LSA      |
| 5           | AS external LSA     |
| 7           | NSSA external LSA   |
| 9           | Link local—Opaque   |
| 10          | Area scoping—Opaque |
| 11          | AS scoping—Opaque   |

### Database Overflow

The *OSPF* database overflow feature allows you to limit the size of the LSDB and to maintain a consistent LSDB across all the routers in the domain, which ensures that all routers have a consistent view of the network.

Consistency is achieved by:

- Limiting the number of external LSAs in the database of each router.
- Ensuring that all routers have identical LSAs.
- To configure OSPF database overflow, use the following command:

```
configure ospf ase-limit number {timeout seconds}
```

Where:

- *number*—Specifies the number of external LSAs that the system supports before it goes into overflow state. A limit value of 0 disables the functionality. When the LSDB size limit is reached, OSPF database overflow flushes LSAs from the LSDB. OSPF database overflow flushes the same LSAs from all the routers, which maintains consistency.
- *timeout*—Specifies the timeout, in seconds, after which the system ceases to be in overflow state. A timeout value of 0 leaves the system in overflow state until OSPF is disabled and re-enabled.

### *Opaque LSAs*

Opaque LSAs are a generic *OSPF* mechanism used to carry auxiliary information in the OSPF database. Opaque LSAs are most commonly used to support OSPF traffic engineering.

Normally, support for opaque LSAs is autonegotiated between OSPF neighbors.

- In the event that you experience interoperability problems, you can disable opaque LSAs across the entire system using the following command:  
`disable ospf capability opaque-lsa`
- Re-enable opaque LSAs across the entire system:  
`enable ospf capability opaque-lsa`

If your network uses opaque LSAs, we recommend that all routers on your OSPF network support opaque LSAs. Routers that do not support opaque LSAs do not store or flood them. At minimum a well interconnected subsection of your OSPF network must support opaque LSAs to maintain reliability of their transmission.

### *Graceful OSPF Restart*

RFC 3623 describes a way for *OSPF* control functions to restart without disrupting traffic forwarding.

Without graceful restart, adjacent routers will assume that information previously received from the restarting router is stale and will not be used to forward traffic to that router. However, in many cases, two conditions exist that allow the router restarting OSPF to continue to forward traffic correctly. The first condition is that forwarding can continue while the control function is restarted. Most modern router system designs separate the forwarding function from the control function so that traffic can still be forwarded independent of the state of the OSPF function. Routes learned through OSPF remain in the routing table and packets continue to be forwarded. The second condition required for graceful restart is that the network remain stable during the restart period. If the network topology is not changing, the current routing table remains correct. Often, networks can remain stable during the time for restarting OSPF.

### **Restarting and Helper Mode**

Routers involved with graceful restart fill one of two roles: the restarting router or the helper router.

With graceful restart, the router that is restarting sends out Grace-LSAs informing its neighbors that it is in graceful restart mode, how long the helper router should assist

with the restart (the grace period), and why the restart occurred. If the neighboring routers are configured to help with the graceful restart (helper-mode), they will continue to advertise the restarting router as if it was fully adjacent. Traffic continues to be routed as though the restarting router is fully functional. If the network topology changes, the helper routers will stop advertising the restarting router. The helper router will continue in helper mode until the restarting router indicates successful termination of graceful restart, the Grace-LSAs expire, or the network topology changes. A router can be configured for graceful restart, and for helper-mode separately. A router can be a helper when its neighbor restarts, and can in turn be helped by a neighbor if it restarts.

### Planned and Unplanned Restarts

Two types of graceful restarts are defined: planned and unplanned.

A planned restart would occur if the software module for *OSPFv3 (Open Shortest Path First version 3)* was upgraded, or if the router operator decided to restart the OSPFv3 control function for some reason. The router has advance warning, and is able to inform its neighbors in advance that OSPFv3 is restarting.

An unplanned restart would occur if there was some kind of system failure that caused a remote reboot or a crash of OSPFv3, or a failover occurs. As OSPFv3 restarts, it informs its neighbors that it is in the midst of an unplanned restart.

You can decide to configure a router to enter graceful restart for only planned restarts, for only unplanned restarts, or for both. Also, you can separately decide to configure a router to be a helper for only planned, only unplanned, or for both kinds of restarts.

### Configuring Graceful OSPF Restart

- Configure a router to perform graceful *OSPF* restart:

```
configure ospf restart [none | planned | unplanned | both]
```

Since a router can act as a restart helper router to multiple neighbors, you will specify which neighbors to help.

- Configure a router to act as a graceful OSPF restart helper:

```
configure ospf [vlan [all | vlan-name] | area area-identifier |
virtual-link router-identifier area-identifier] restart-helper [none |
planned | unplanned | both]
```

- The graceful restart period sent out to helper routers can be configured with the following command:

```
configure ospf restart grace-period seconds
```

By default, a helper router will terminate graceful restart if received LSAs would affect the restarting router.

This will occur when the restart-helper receives an LSA that will be flooded to the restarting router or when there is a changed LSA on the restarting router's retransmission list when graceful restart is initiated.

- Disable this behavior:

```
disable ospf [vlan [all {vr vrf_name} | vlan-name] | area area-identifier | virtual-link router-identifier area-identifier] restart-helper-lsa-check
```

## Areas

OSPFv3 allows parts of a network to be grouped together into areas.

The topology within an area is hidden from the rest of the AS. Hiding this information enables a significant reduction in LSA traffic and reduces the computations needed to maintain the LSDB. Routing within the area is determined only by the topology of the area.

The three types of routers defined by OSPFv3 are as follows:

- **Internal router (IR)**—An internal router has all of its interfaces within the same area.
- **Area border router (ABR)**—An ABR has interfaces in multiple areas. It is responsible for exchanging summary advertisements with other ABRs.
- **Autonomous system border router (ASBR)**—An ASBR acts as a gateway between OSPFv3 and other routing protocols, or other autonomous systems.

### Note

Configuring inter-area and external filters causes all of the neighbors in the area to be reset.

### Backbone Area (Area 0.0.0.0)

Any OSPFv3 network that contains more than one area is required to have an area configured as area 0.0.0.0, also called the backbone.

All areas in an AS must be connected to the backbone. When designing networks, you should start with area 0.0.0.0 and then expand into other areas.

### Note

Area 0.0.0.0 exists by default and cannot be deleted or changed.

The backbone allows summary information to be exchanged between area border routers (ABRs). Every ABR hears the area summaries from all other ABRs. The ABR then forms a picture of the distance to all networks outside of its area by examining the collected advertisements and adding in the backbone distance to each advertising router.

When a VLAN is configured to run OSPFv3, you must configure the area for the VLAN.

If you want to configure the VLAN to be part of a different OSPFv3 area, use the following command:

```
configure ospfv3 vlan vlan-name area area-identifier
```

If this is the first instance of the OSPFv3 area being used, you must create the area first using the following command:

```
create ospfv3 area area_identifier
```

### Stub Areas

*OSPF* allows certain areas to be configured as stub areas. A stub area is connected to only one other area. The area that connects to a stub area can be the backbone area. External route information is not distributed into stub areas. Stub areas are used to reduce memory consumption and computational requirements on OSPF routers.

Use the following command to configure an OSPF area as a stub area:

```
configure ospf area area-identifier stub [summary | nosummary] stub-
default-cost cost
```

### Not-So-Stubby-Areas

Not-so-stubby-areas (NSSAs) are similar to the existing *OSPF* stub area configuration option but have the following two additional capabilities:

- External routes originating from an ASBR connected to the NSSA can be advertised within the NSSA.
- External routes originating from the NSSA can be propagated to other areas, including the backbone area.

The CLI command to control the NSSA function is similar to the command used for configuring a stub area, as follows:

```
configure ospf area area-identifier nssa [summary | nosummary] stub-
default-cost cost {translate}
```

The translate option determines whether type 7 LSAs are translated into type 5 LSAs. When configuring an OSPF area as an NSSA, translate should only be used on NSSA border routers, where translation is to be enforced. If translate is not used on any NSSA border router in a NSSA, one of the ABRs for that NSSA is elected to perform translation (as indicated in the NSSA specification). The option should not be used on NSSA internal routers. Doing so inhibits correct operation of the election algorithm.

### Normal Area

A normal area is an area that is not:

- Area 0
- Stub area
- NSSA

Virtual links can be configured through normal areas. External routes can be distributed into normal areas.

## Virtual Links

In the situation when a new area is introduced that does not have a direct physical attachment to the backbone, a virtual link is used.

A virtual link provides a logical path between the ABR of the disconnected area and the ABR of the normal area that connects to the backbone. A virtual link must be established between two ABRs that have a common area, with one ABR connected to the backbone. [Figure 171](#) illustrates a virtual link.

**Figure 171: Virtual Link Using Area 1 as a Transit Area**

### Note

Virtual links cannot be configured through a stub or NSSA area.

Virtual links are also used to repair a discontinuous backbone area. For example, in [Figure 172](#), if the connection between ABR 1 and the backbone fails, the connection using ABR 2 provides redundancy so that the discontinuous area can continue to communicate with the backbone using the virtual link.

**Figure 172: Virtual Link Providing Redundancy**

## Point-to-Point Support

You can manually configure the *OSPF* link type for a *VLAN*. [Table 108](#) describes the link types.

**Table 108: OSPF Link Types**

| Link Type      | Number of Routers | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Auto           | Varies            | ExtremeXOS automatically determines the OSPF link type based on the interface type. This is the default setting.                                                                                                                                                                                                                                                                                                                                                                                       |
| Broadcast      | Any               | Routers must elect a designated router (DR) and a backup designated router (BDR) during synchronization. Ethernet is an example of a broadcast link.                                                                                                                                                                                                                                                                                                                                                   |
| Point-to-point | Up to 2           | This type synchronizes faster than a broadcast link because routers do not elect a DR or BDR. It does not operate with more than two routers on the same VLAN. The Point-to-Point Protocol (PPP) is an example of a point-to-point link. An OSPF point-to-point link supports only zero to two OSPF routers and does not elect a designated router (DR) or backup designated router (BDR). If you have three or more routers on the VLAN, OSPF fails to synchronize if the neighbor is not configured. |
| Passive        |                   | A passive link does not send or receive OSPF packets.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### Note

The number of routers in an OSPF point-to-point link is determined per VLAN, not per link.

All routers in the VLAN must have the same OSPF link type. If there is a mismatch, OSPF attempts to operate, but it may not be reliable.

## Route Redistribution

More than one routing protocol can be enabled simultaneously on the switch.

Route redistribution allows the switch to exchange routes, including static routes, between the routing protocols. [Figure 173](#) is an example of route redistribution between an OSPF AS and a RIP AS.

**Figure 173: OSPF Route Redistribution**

## Import Policy

Prior to ExtremeXOS 15.7, routing protocol OSPFv2 applied routing policies with keyword “import-policy”, which can only be used to change the attributes of routes installed into the switch routing table. ExtremeXOS 15.7 provides the flexibility of using import policy to determine the routes to be added to or removed from the routing table.

To prevent a route being added to the routing table, the policy file must contain a matching rule with action “deny”. If there is no matching rule for a particular route, or the keyword “deny” is missing in the rule, the default action is “permit”, which means that route will be installed into the routing table. Refer to the following policy file example:

```
entry entry-one {
 if {
 nlri 11.22.0.0/16;
 }
 then {
 cost 100;
 }
}
entry entry-two {
 if {
 nlri 22.33.0.0/16;
 }
 then {
 deny;
 }
}
```

In the above policy example, entry-one is used to change the cost of any matching routes, and entry-two is used to remove those matching routes from the routing table.

#### Note

Only “Network Layer Reachability Information” (NLRI) and “route origin” can be used as matching criteria in policy rules; using “next\_hop” as a matching criteria is not supported. Any other policy attribute is not recognized and is ignored.

## Configuring Route Redistribution

Exporting routes from one protocol to another and in the reverse direction are discrete configuration functions. For example, to run IS-IS and *RIP* simultaneously, you must first configure both protocols and then verify the independent operation of each. Then you can configure the routes to export from IS-IS to RIP and the routes to export from RIP to IS-IS. Likewise, for any other combinations of protocols, you must separately configure each to export routes to the other.

This section describes how to inject routing information learned from other IP routing protocols into an IS-IS domain, thereby advertising their reachability in the IS-IS domain. These routes are included in the locally originated LSPs. For information on exporting routes learned in IS-IS to another routing protocol, see the chapter that describes the destination routing protocol.

When you export routes from another protocol to IS-IS, the metric and the type of metric are configured. You can also configure a policy to filter out unwanted external routes.

- To enable or disable the exporting of *BGP (Border Gateway Protocol)*, *OSPF*, RIP, static, and direct (interface) IPv4 routes to IS-IS, use the following commands:

```
enable isis area area_name export {ipv4} route-type [policy | metric
mvalue {metric-type [internal | external]}} {level[1| 2 | both-1-
and-2]}
disable isis area area_name export {ipv4} route-type
```

- To enable or disable the exporting of *OSPFv3*, *RIPng (Routing Information Protocol Next Generation)*, static, and direct (interface) IPv6 routes to IS-IS, use the following commands:

```
enable isis area area_name export ipv6 route-type [policy | metric
mvalue] {level[1| 2 | both-1-and-2]}
disable isis area area_name export ipv6 route-type
```

The cost metric is inserted for all *OSPF*, RIP, static, and direct routes injected into IS-IS.

The same cost and type values can be inserted for all the export routes, or policies can be used for selective insertion. When a policy is associated with the export command, the policy is applied on every exported route. The exported routes can also be filtered using policies.

- Verify the configuration using the command:

```
show isis area [area_name | all]
```

### Redistribute Routes into OSPF

To enable or disable the exporting of *BGP*, *RIP*, static, and direct (interface) routes to *OSPF*, use the following commands:

```
enable ospf export [bgp | direct | direct-inter-vr | e-bgp | i-bgp | rip
| static | isis | isis-level-1 | isis-level-1-external | isis-level-2
| isis-level-2-external | host-mobility] [cost cost type [ase-type-1 |
ase-type-2] {tag number} | policy-map]
```

```
disable ospf export [bgp | direct | direct-inter-vr | host-mobility | e-
bgp | i-bgp | rip | static | isis | isis-level-1 | isis-level-1-external
| isis-level-2 | isis-level-2-external]
```

These commands enable or disable the exporting of RIP, static, and direct routes by way of LSA to other OSPF routers as AS-external type 1 or type 2 routes. The default setting is disabled.

The cost metric is inserted for all Border Gateway Protocol (BGP), RIP, static, and direct routes injected into OSPF. If the cost metric is set to 0, the cost is inserted from the route. For example, in the case of BGP export, the cost equals the multiple exit discriminator (MED) or the path length. The tag value is used only by special routing applications. Use 0 if you do not have specific requirements for using a tag. (The tag value in this instance has no relationship with IEEE 802.1Q *VLAN* tagging.)

The same cost, type, and tag values can be inserted for all the export routes, or policies can be used for selective insertion. When a policy is associated with the export command, the policy is applied on every exported route.

The exported routes can also be filtered using policies.

#### Note

For routes exported to OSPF via a policy file, any refresh applied on that policy may result in temporary withdrawal and then immediate readvertising of those routes.

Verify the configuration using the command `show ospf`.

## OSPF Timers and Authentication

Configuring *OSPF* timers and authentication on a per-area basis is a shortcut to applying the timers and authentication to each *VLAN* in the area at the time of configuration. If you add more VLANs to the area, you must configure the timers and authentication for the new VLANs explicitly.

Use the command:

```
configure ospf vlan [vlan-name | all] timer retransmit-interval transit-
delay hello-interval dead-interval {wait-timer-interval}
```

## OSPF Inter-VR Route Redistribution

Beginning with version 32.3, the OSPF Inter-VR route redistribution feature adds support for the redistribution of routes between multiple OSPF instances at the same time in different VRs. When inter-VR redistribution is enabled in the VR route table, OSPF uses Route Manager to install the routes.

### *Supported Platforms*

All platforms.

### *CLI Commands*

The following commands support this feature:

To configure an OSPF instance identifier, use `configure ospf instanceid instance-identifier`.

To disable an OSPF export, use `disable ospf export {vr} vr-name route-type`.

To enable an OSPF export, use `enable ospf export {vr} vr-name route-type [policy-map | cost cost type ase-type-1 | ase-type-2] {tag number}] {exclude-private}`.

To display OSPF Inter-VR export information, use `show ospf inter-vr-export .`

To display detailed OSPF Inter-VR export information, use `show ospf inter-vr-export {detail}`.

## Configuring OSPF

Each switch that is configured to run *OSPF* must have a unique router ID.

We recommend that you manually set the router ID of the switches participating in OSPF, instead of having the switch automatically choose its router ID based on the highest interface IP address. Not performing this configuration in larger, dynamic environments could result in an older LSDB remaining in use.

## Configuring OSPF Wait Interval

ExtremeXOS allows you to configure the *OSPF* wait interval, rather than using the router dead interval.

### **Caution**

Do not configure OSPF timers unless you are comfortable exceeding OSPF specifications. Non-standard settings may not be reliable under all circumstances.

To specify the timer intervals, enter the following commands:

```
configure ospf area area-identifier timer retransmit-interval transit-
delay hello-interval dead-interval {wait-timer-interval}
```

```
configure ospf virtual-link router-identifier area-identifier timer
retransmit-interval transit-delay hello-interval dead-interval
```

```
configure ospf vlan [vlan-name | all] timer retransmit-interval transit-
delay hello-interval dead-interval {wait-timer-interval}
```

## OSPF Wait Interval Parameters

You can configure the following parameters:

- **Retransmit interval**—The length of time that the router waits before retransmitting an LSA that is not acknowledged. If you set an interval that is too short, unnecessary retransmissions result. The default value is 5 seconds.
- **Transit delay**—The length of time it takes to transmit an LSA packet over the interface. The transit delay must be greater than 0.
- **Hello interval**—The interval at which routers send hello packets. Shorter times allow routers to discover each other more quickly but also increase network traffic. The default value is 10 seconds.
- **Dead router wait interval (Dead Interval)**—The interval after which a neighboring router is declared down because hello packets are no longer received from the neighbor. This interval should be a multiple of the hello interval. The default value is 40 seconds.
- **Router wait interval (Wait Timer Interval)**—The interval between the interface coming up and the election of the DR and BDR. This interval should be greater than the hello interval. If this time is close to the hello interval, the network synchronizes very quickly but might not elect the correct DR or BDR. The default value is equal to the dead router wait interval.

### Note

The *OSPF* standard specifies that wait times are equal to the dead router wait interval.

## OSPF Configuration Example

Figure 174 is an example of an autonomous system using *OSPF* routers. The details of this network follow.

**Figure 174: OSPF Configuration Example**

Area 0 is the backbone area. It is located at the headquarters and has the following characteristics:

- Two internal routers (IR1 and IR2)
- Two area border routers (ABR 1 and ABR 2)
- Network number 10.0.x.x
- Two identified VLANs (HQ\_10\_0\_2 and HQ\_10\_0\_3)

Area 5 is connected to the backbone area by way of ABR 1 and ABR 2. It is located in Chicago and has the following characteristics:

- Network number 160.26.x.x
- One identified VLAN (Chi\_160\_26\_26)
- Two internal routers

Area 6 is a stub area connected to the backbone by way of ABR 1. It is located in Los Angeles and has the following characteristics:

- Network number 161.48.x.x
- One identified VLAN (LA\_161\_48\_2)
- Three internal routers
- Uses default routes for inter-area routing

[Configuration for ABR 1](#) on page 1369 and [Configuration for IR 1](#) on page 1369 provide two router configurations for the example in [Figure 174](#) on page 1368.

## Configuration for ABR 1

The router labeled ABR 1 has the following configuration:

```
create vlan HQ_10_0_2
create vlan HQ_10_0_3
create vlan LA_161_48_2
create vlan Chi_160_26_26
configure vlan HQ_10_0_2 ipaddress 10.0.2.1 255.255.255.0
configure vlan HQ_10_0_3 ipaddress 10.0.3.1 255.255.255.0
configure vlan LA_161_48_2 ipaddress 161.48.2.2 255.255.255.0
configure vlan Chi_160_26_26 ipaddress 160.26.26.1 255.255.255.0
create ospf area 0.0.0.5
create ospf area 0.0.0.6
enable ipforwarding
configure ospf area 0.0.0.6 stub nosummary stub-default-cost 10
configure ospf add vlan LA_161_48_2 area 0.0.0.6
configure ospf add vlan Chi_160_26_26 area 0.0.0.5
configure ospf add vlan HQ_10_0_2 area 0.0.0.0
configure ospf add vlan HQ_10_0_3 area 0.0.0.0
configure ospf vlan LA_161_48_2 priority 10
configure ospf vlan Chi_160_26_26 priority 10
configure ospf vlan HQ_10_0_2 priority 5
configure ospf vlan HQ_10_0_3 priority 5
enable ospf
```

## Configuration for IR 1

The router labeled IR 1 has the following configuration:

```
configure vlan HQ_10_0_1 ipaddress 10.0.1.2 255.255.255.0
configure vlan HQ_10_0_2 ipaddress 10.0.2.2 255.255.255.0
enable ipforwarding
configure ospf add vlan all area 0.0.0.0
configure ospf area 0.0.0.0 priority 10
enable ospf
```

### Note

In *OSPF* edge mode, the *VLAN* priority is "0" and cannot be set. (Refer to [OSPF Edge Mode](#) on page 1353.) When the license is upgraded to a Premier or Extreme Platform ONE license, the VLAN priority of "0" needs to be reset in order to participate in DR/BDR election.

## Displaying OSPF Settings

You can use a number of commands to display settings for *OSPF*.

- To show global OSPF information, use the `show ospf` command with no options.
- To display information about one or all OSPF areas, enter:

```
show ospf area {detail | area-identifier}
```

The detail option displays information about all OSPF areas in a detail format.

- To display information about OSPF interfaces for an area, a *VLAN*, or for all interfaces enter:

```
show ospf interfaces {vlan vlan-name | area area-identifier | enabled}
```

The detail option displays information about all OSPF interfaces in a detail format.

ExtremeXOS provides several filtering criteria for the `show ospf lsdb` command.

You can specify multiple search criteria, and only those results matching all of the criteria are displayed. This allows you to control the displayed entries in large routing tables.

- To display the current link-state database, enter:

```
show ospf lsdb {detail | stats} {area [area-identifier | all] }
{lstype} [lstype | all] } {lsid lsid-address{lsid-mask} } {routerid
routerid-address {routerid-mask} } {interface[[ip-address{ip-mask} |
ipNetmask] | vlan vlan-name] }
```

The detail option displays all fields of matching LSAs in a multiline format. The summary option displays several important fields of matching LSAs, one line per LSA. The stats option displays the number of matching LSAs but not any of their contents. If not specified, the default is to display in the summary format.

A common use of this command is to omit all optional parameters, resulting in the following shortened form:

```
show ospf lsdb
```

The shortened form displays LSAs from all areas and all types in a summary format.

# OSPFv2 Auto-peering

---

[OSPFv2 Auto-peering Introduction](#) on page 1371  
[OSPFv2 Auto-peering Feature Description](#) on page 1371  
[OSPFv2 Auto-peering Limitations](#) on page 1372  
[OSPFv2 Auto-peering Supported Platforms](#) on page 1372  
[Configuring OSPFv2 Auto-peering](#) on page 1373

## OSPFv2 Auto-peering Introduction

---

ExtremeXOS *OSPF (Open Shortest Path First)v2* auto-peering is a network of cooperating interconnected devices that automatically create an OSPFv2 network for any topology, providing fully redundant, multipath routing. Node participation grows dynamically and is not bound to any well-known topology such as Clos or Leaf/Spine. OSPF is a link-state routing protocol that provides fast convergence and scalability. It is an interior gateway protocol (IGP) commonly used in large enterprise networks.

Auto-peering nodes build a secure network by running the OSPFv2 protocol over unnumbered point-to-point links to exchange database information that describes the topology of the autonomous system.

Any device connecting to an auto-peering device is an attachment point to the network. This network provides the underlay for services such as *VXLAN (Virtual Extensible LAN)*, policy, VRF, and Fabric Attach.

## OSPFv2 Auto-peering Feature Description

---

After running the command `create auto-peering ospf routerid ipaddress`, the default OSPF configuration that is needed for auto-peering is created, and the AutoOSPFv2 capability is advertised out all ports using *LLDP (Link Layer Discovery Protocol)*. The default configuration includes the routerid, and vxlan-extensions and export of host-mobility routes. The following series of events occurs, setting up auto-peering:

1. When an OSPFv2 Auto-peering-capable neighbor is detected out a port, LLDP messages are sent.
2. LLDP-learned port is assigned to a new dynamically created VLAN, as an unnumbered interface.
3. LLDP learns of the OSPFv2 router ID.

4. LLDP sends the AutoOSPFv2 information to the remote neighbor and learns the remote neighbor's information.
5. An Auto-peering route is created to the learned remote router ID.
6. When OSPF learns of the auto-peering dynamic VLAN, it automatically enables a point-to-point link on that VLAN and places it in the backbone area.
7. The OSPF Auto-peering network is formed. OSPFv2 routes are propagated. The nexthop of the routes is the neighbor's router ID. The routes have the loose next hop flag set so the gateway can be resolved by the auto-peering route.
8. When OSPF Auto-peering is enabled, the OSPFv2 capability to carry VXLAN information is automatically enabled on each OSPFv2 peer.
9. VNI/LTEP pairs are passed to the OSPFv2 client which generates OSPFv2-opaque advertisements to any peers.
10. When an OSPFv2-opaque LSA is received containing a VNI/LTEP pair, the OSPFv2 client passes this to the client interface.

## OSPFv2 Auto-peering Limitations

---

### Note

BGP and OSPFv2 Auto-peering are mutually exclusive. Only one form of Auto-peering can exist at a time.

The following capabilities are not supported on OSPFv2 Auto-peering:

- Stacking
- Automatic LAG configuration with MLAG
- Automatic LAG configuration with Extended Edge Switching
- Static Lag attachments to AutoOSPF
- AutoOSPF links on Extended Edge Switching ports
- MPLS, VPLS, L2VPN, L3VPN
- PIM snooping, PIM-SM, PIM-DM, SSM mode
- OSPFv2, OSPFv3, ISIS, RIP, RIPNG per VRF
- Automatic MLAG configuration
- Multiple links between two OSPFv2 auto-peering enabled switches (instead LAG can be configured to avoid connectivity problem due to link failure).

Other limitations:

- One MLAG peer per node.
- Static router must be an external router per VRF.
- VLANs spanning multiple bridges, where each bridge has automatically configured LAG connections, must be VXLAN-based or replaced with MLAG.

## OSPFv2 Auto-peering Supported Platforms

---

All ExtremeSwitching Universal platforms.

## Configuring OSPFv2 Auto-peering

---

To create and enable OSPFv2 Auto-peering, use the following command:

```
create auto-peering ospf routerid ipaddress
```

To delete OSPFv2 Auto-peering, use the following command:

```
delete auto-peering
```

To view OSPFv2 and BGP auto-peering status, use the following command:

```
show auto-peering {bgp | ospf}.
```

# OSPFv3

---

[OSPFv3 Overview](#) on page 1374

This chapter discusses the OSPFv3 (Open Shortest Path First version 3) protocol for distributing routing information between routers belonging to an autonomous system. This chapter provides an overview of the protocol's features and example configuration commands.

## Note

OSPFv3 is available on platforms with an Advanced Edge (or higher) or Base (or higher) license. For information about OSPFv3 licensing, see the licensing guide.

## OSPFv3 Overview

---

*OSPF (Open Shortest Path First)* is a link state protocol that distributes routing information between routers belonging to a single IP domain; the IP domain is also known as an *Autonomous System (AS)*.

In a link-state routing protocol, each router maintains a database describing the topology of the AS. Each participating router has an identical database for an area maintained from the perspective of that router.

From the *LSDB (Link State Database)*, each router constructs a tree of shortest paths, using itself as the root. The shortest path tree provides the route to each destination in the AS. When several equal-cost routes to a destination exist, traffic can be distributed among them. The cost of a route is described by a single metric.

OSPFv3 supports IPv6, and uses commands only slightly modified from that used to support IPv4. OSPFv3 has retained the use of the 4-byte, dotted decimal numbers for router IDs, LSA IDs, and area IDs.

OSPFv3 is an *IGP (Interior Gateway Protocol)*, as is the other common IGP for IPv6, *RIPng (Routing Information Protocol Next Generation)*. OSPFv3 and RIPng are compared in [RIPng](#).

#### Note

Two types of OSPFv3 functionality are available and each has a different licensing requirement. One is the complete OSPFv3 functionality and the other is OSPFv3 Edge Mode, a subset of OSPFv3 that is described below. For specific information regarding OSPFv3 licensing, see the [Switch Engine v33.3.1 Licensing Guide](#) document.

## OSPFv3 Edge Mode

*OSPFv3 (Open Shortest Path First version 3)* Edge Mode is a subset of OSPFv3 available on platforms with an Advanced Edge or Base license.

There are two restrictions on OSPFv3 Edge Mode:

- At most, four Active OSPFv3 *VLAN (Virtual LAN)* interfaces are permitted. There is no restriction on the number of Passive interfaces.
- The OSPFv3 Priority on VLANs is 0, and is not configurable. This prevents the system from acting as a DR or BDR.

## BFD for OSPFv3

The BFD for *OSPFv3* feature gives OSPFv3 routing protocol the ability to utilize BFD's fast failure detection to monitor OSPFv3 neighbor adjacencies. CLI commands are provided to configure BFD protection for OSPFv3, so that as a registered BFD client, OSPFv3 can request BFD protection for interested OSPFv3 neighbors, and receive notifications about BFD session setup status and BFD session status updates (after establishing) from the BFD server. When BFD detects a communication failure between neighbors, it informs OSPFv3, which causes the OSPFv3 neighbor state be marked as "down." This allows OSPFv3 protocol to quickly begin network convergence and use alternate paths to the affected neighbor.

**Figure 175: Basic Operational Flow of OSPFv3 BFD**

### *Establishing a BFD Session for OSPFv3 Neighbor*

1. OSPFv3 discovers a neighbor.
2. If BFD for OSPFv3 is configured, OSPFv3 on both routers sends a request to the local BFD server to initiate a BFD neighbor session with the OSPFv3 neighbor router.
3. The BFD neighbor session with the OSPFv3 neighbor router is established on both sides if BFD session limit is not reached.

If the BFD session limit is reached, the OSPFv3 neighbor will be marked as BFD session failed if synchronous request is used, or pending if asynchronous request is used, and the BFD server will send an asynchronous notification when the session registration passes later. (The asynchronous request is not available until the BFD client session create API is enhanced.)

### *Eliminating the OSPFv3 Neighbor Relationship by BFD Fault Detection*

1. A failure occurs in the network.
2. The BFD neighbor session with the OSPFv3 neighbor router is removed because the BFD timer expired.
3. On both Router A and Router B, BFD notifies the local OSPFv3 process that the BFD neighbor is DOWN.
4. The local OSPFv3 process tears down the OSPFv3 neighbor relationship by marking neighbor state DOWN. (If an alternative path is available, the routers will immediately start converging on it.)

**Figure 176: OSPFv3 Neighbor Relationship Eliminated by BFD Fault Detection**

OSPFv3 will request the BFD server to delete the BFD session for OSPFv3 neighbor moved to DOWN state. When the link failure is later resolved, OSPFv3 needs to register the re-discovered neighbor to BFD again to initiate BFD session creation.

### *Removing BFD Protection for OSPFv3*

1. BFD protection is removed from OSPFv3 interface on Router A, OSPFv3 process requests BFD server to delete all BFD sessions for neighbors learned on that interface.
2. BFD server will stop sending session status update to local OSPFv3 process on Router A.

3. Before actually deleting any sessions, BFD server on Router A will first notify Router B to mark those session status as "Admin Down," which will cause Router B to stop using BFD protection for those OSPFv3 neighbors.
4. When BFD protection is removed from OSPFv3 interface on Router B, BFD sessions can be deleted immediately since they are already in "Admin Down" state.

When BFD for OSPFv3 is configured on broadcast interface, the default behavior is to register only OSPFv3 neighbors in FULL state with the BFD server. Separate BFD sessions are created for each neighbor learned on the same interface. If multiple clients ask for the same neighbor on the same interface, then single BFD sessions are established between the peers.

#### *OSPFv3 Neighbor State Determination*

With active BFD protection, OSPFv3 combines the BFD session state with the associated interface admin and operational states to determine the OSPFv3 neighbor adjacency discovered on that OSPFv3 interface. Regarding OSPFv3 neighbor relationships, OSPFv3 reacts directly to BFD session state changes only in the following circumstances:

- If BFD is enabled on the interface, and
- If BFD for OSPFv3 is configured on the OSPFv3 interface, and
- If a BFD session has been established to the neighbor, and
- If the BFD session has passed the INIT\_COMPLETE state then:
  1. The OSPFv3 neighbor relationship will remain as FULL if the operational state of the BFD session is "UP" and the operational state of the associated VLAN interface is UP.
  2. The OSPFv3 neighbor relationship will be considered as DOWN if the operational state of the BFD session is DOWN or the operational state of the associated VLAN interface is DOWN.

In all other cases, the BFD session state is not considered as part of the reported OSPFv3 neighbor state, and the OSPFv3 neighbor state reverts to the operational state of the OSPFv3 interface only. When the BFD session is in ADMIN\_DOWN state, OSPFv3 ignores BFD events and OSPFv3 neighbor adjacency is not be affected by the BFD session state change.

## Link State Database

Upon initialization, each router transmits a link state advertisement (LSA) on each of its interfaces. LSAs are collected by each router and entered into the LSDB of each router. After all LSAs are received, the router uses the link state database (LSDB) to calculate the best routes for use in the IP routing table. OSPF uses flooding to distribute LSAs between routers. Any change in routing information is sent to all of the routers in the network. All routers within an area have the exact same LSDB.

Table 109 describes LSA type numbers.

**Table 109: LSA Type Numbers**

| Type Number | Description         |
|-------------|---------------------|
| 1           | Router LSA          |
| 2           | Network LSA         |
| 3           | Summary LSA         |
| 4           | AS summary LSA      |
| 5           | AS external LSA     |
| 7           | NSSA external LSA   |
| 9           | Link local—Opaque   |
| 10          | Area scoping—Opaque |
| 11          | AS scoping—Opaque   |

## Graceful OSPFv3 Restart

RFC 3623 describes a way for *OSPF* control functions to restart without disrupting traffic forwarding.

Without graceful restart, adjacent routers will assume that information previously received from the restarting router is stale and will not be used to forward traffic to that router. However, in many cases, two conditions exist that allow the router restarting *OSPFv3* to continue to forward traffic correctly. The first condition is that forwarding can continue while the control function is restarted. Most modern router system designs separate the forwarding function from the control function so that traffic can still be forwarded independent of the state of the OSPFv3 function. Routes learned through OSPFv3 remain in the routing table and packets continue to be forwarded. The second condition required for graceful restart is that the network remain stable during the restart period. If the network topology is not changing, the current routing table remains correct. Often, networks can remain stable during the time for restarting OSPFv3.

### *Restarting and Helper Mode*

Routers involved with graceful restart fill one of two roles: the restarting router or the helper router.

With graceful restart, the router that is restarting sends out Grace-LSAs informing its neighbors that it is in graceful restart mode, how long the helper router should assist with the restart (the grace period), and why the restart occurred. If the neighboring routers are configured to help with the graceful restart (helper-mode), they will continue to advertise the restarting router as if it was fully adjacent. Traffic continues to be routed as though the restarting router is fully functional. If the network topology changes, the helper routers will stop advertising the restarting router. The helper router will continue in helper mode until the restarting router indicates successful termination of graceful restart, the Grace-LSAs expire, or the network topology changes. A router

can be configured for graceful restart, and for helper-mode separately. A router can be a helper when its neighbor restarts, and can in turn be helped by a neighbor if it restarts.

### *Planned and Unplanned Restarts*

Two types of graceful restarts are defined: planned and unplanned.

A planned restart would occur if the software module for *OSPFv3* was upgraded, or if the router operator decided to restart the OSPFv3 control function for some reason. The router has advance warning, and is able to inform its neighbors in advance that OSPFv3 is restarting.

An unplanned restart would occur if there was some kind of system failure that caused a remote reboot or a crash of OSPFv3, or a failover occurs. As OSPFv3 restarts, it informs its neighbors that it is in the midst of an unplanned restart.

You can decide to configure a router to enter graceful restart for only planned restarts, for only unplanned restarts, or for both. Also, you can separately decide to configure a router to be a helper for only planned, only unplanned, or for both kinds of restarts.

### *Configuring Graceful OSPFv3 Restart*

- Configure a router to perform graceful *OSPFv3* restart:

```
configure ospfv3 restart [none | planned | unplanned | both]
```

Since a router can act as a restart helper router to multiple neighbors, you will specify which neighbors to help.

- Configure a router interface to act as a graceful OSPFv3 restart helper:

```
configure ospfv3 [[vlan | tunnel] all | {vlan} vlan-name | {tunnel}
tunnel-name | area area-identifier] restart-helper [none | planned |
unplanned | both]
```

```
configure ospfv3 virtual-link {routerid} router_identifier {area}
area_identifier timer {retransmit-interval} retransmit_interval
{transit-delay} transit_delay {hello-interval} hello_interval {dead-
interval} dead_interval
```

- The graceful restart period sent out to helper routers can be configured with the following command:

```
configure ospfv3 restart grace-period seconds
```

By default, a helper router will terminate graceful restart if received LSAs would affect the restarting router.

This will occur when the restart-helper receives an LSA that will be flooded to the restarting router or when there is a changed LSA on the restarting router's retransmission list when graceful restart is initiated.

- Disable or enable helper router LSA check:

```
disable ospfv3 [[vlan | tunnel] all | vlan vlan-name | {tunnel} tunnel-
name | area area-identifier] restart-helper-lsa-check
enable ospfv3 [[vlan | tunnel] all | {vlan} vlan-name | {tunnel}
tunnel-name | area area-identifier] restart-helper-lsa-check
```

## Areas

OSPFv3 allows parts of a network to be grouped together into areas.

The topology within an area is hidden from the rest of the AS. Hiding this information enables a significant reduction in LSA traffic and reduces the computations needed to maintain the LSDB. Routing within the area is determined only by the topology of the area.

The three types of routers defined by OSPFv3 are as follows:

- **Internal router (IR)**—An internal router has all of its interfaces within the same area.
- **Area border router (ABR)**—An ABR has interfaces in multiple areas. It is responsible for exchanging summary advertisements with other ABRs.
- **Autonomous system border router (ASBR)**—An ASBR acts as a gateway between OSPFv3 and other routing protocols, or other autonomous systems.

### Note

Configuring inter-area and external filters causes all of the neighbors in the area to be reset.

### Backbone Area (Area 0.0.0.0)

Any OSPFv3 network that contains more than one area is required to have an area configured as area 0.0.0.0, also called the backbone.

All areas in an AS must be connected to the backbone. When designing networks, you should start with area 0.0.0.0 and then expand into other areas.

### Note

Area 0.0.0.0 exists by default and cannot be deleted or changed.

The backbone allows summary information to be exchanged between area border routers (ABRs). Every ABR hears the area summaries from all other ABRs. The ABR then forms a picture of the distance to all networks outside of its area by examining the collected advertisements and adding in the backbone distance to each advertising router.

When a VLAN is configured to run OSPFv3, you must configure the area for the VLAN.

If you want to configure the VLAN to be part of a different OSPFv3 area, use the following command:

```
configure ospfv3 vlan vlan-name area area-identifier
```

If this is the first instance of the OSPFv3 area being used, you must create the area first using the following command:

```
create ospfv3 area area_identifier
```

### Stub Areas

*OSPF* allows certain areas to be configured as stub areas. A stub area is connected to only one other area. The area that connects to a stub area can be the backbone area. External route information is not distributed into stub areas. Stub areas are used to reduce memory consumption and computational requirements on OSPF routers.

Use the following command to configure an OSPF area as a stub area:

```
configure ospf area area-identifier stub [summary | nosummary] stub-
default-cost cost
```

### Not-So-Stubby-Areas

Not-so-stubby-areas (NSSAs) are similar to the existing *OSPF* stub area configuration option but have the following two additional capabilities:

- External routes originating from an ASBR connected to the NSSA can be advertised within the NSSA.
- External routes originating from the NSSA can be propagated to other areas, including the backbone area.

The CLI command to control the NSSA function is similar to the command used for configuring a stub area, as follows:

```
configure ospf area area-identifier nssa [summary | nosummary] stub-
default-cost cost {translate}
```

The translate option determines whether type 7 LSAs are translated into type 5 LSAs. When configuring an OSPF area as an NSSA, translate should only be used on NSSA border routers, where translation is to be enforced. If translate is not used on any NSSA border router in a NSSA, one of the ABRs for that NSSA is elected to perform translation (as indicated in the NSSA specification). The option should not be used on NSSA internal routers. Doing so inhibits correct operation of the election algorithm.

### Normal Area

A normal area is an area that is not:

- Area 0
- Stub area
- NSSA

Virtual links can be configured through normal areas. External routes can be distributed into normal areas.

### Virtual Links

In the situation when a new area is introduced that does not have a direct physical attachment to the backbone, a virtual link is used.

A virtual link provides a logical path between the ABR of the disconnected area and the ABR of the normal area that connects to the backbone. A virtual link must be

established between two ABRs that have a common area, with one ABR connected to the backbone. [Figure 177](#) illustrates a virtual link.

**Figure 177: Virtual Link Using Area 1 as a Transit Area**

**Note**

Virtual links cannot be configured through a stub or NSSA area.

Virtual links are also used to repair a discontinuous backbone area. For example, in [Figure 178](#), if the connection between ABR 1 and the backbone fails, the connection using ABR 2 provides redundancy so that the discontinuous area can continue to communicate with the backbone using the virtual link.

**Figure 178: Virtual Link Providing Redundancy**

## Link-Type Support

You can manually configure the *OSPFv3* link type for a *VLAN*. The following table describes the link types.

**Table 110: OSPFv3 Link Types**

| Link Type      | Number of Routers | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Auto           | Varies            | ExtremeXOS automatically determines the OSPFv3 link type based on the interface type. This is the default setting.                                                                                                                                                                                                                                                                                                                                                                                         |
| Broadcast      | Any               | Routers must elect a designated router (DR) and a backup designated router (BDR) during synchronization. Ethernet is an example of a broadcast link.                                                                                                                                                                                                                                                                                                                                                       |
| Point-to-point | Up to 2           | This type synchronizes faster than a broadcast link because routers do not elect a DR or BDR. It does not operate with more than two routers on the same VLAN. The Point-to-Point Protocol (PPP) is an example of a point-to-point link. An OSPFv3 point-to-point link supports only zero to two OSPFv3 routers and does not elect a designated router (DR) or backup designated router (BDR). If you have three or more routers on the VLAN, OSPF fails to synchronize if the neighbor is not configured. |
| Passive        |                   | A passive link does not send or receive OSPFv3 packets.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### Note

The number of routers in an OSPFv3 point-to-point link is determined per VLAN, not per link.

All routers in the VLAN must have the same OSPFv3 link type. If there is a mismatch, OSPFv3 attempts to operate, but it may not be reliable.

## Import Policy

Prior to ExtremeXOS 15.7, routing protocol OSPFv2 applied routing policies with keyword “import-policy”, which can only be used to change the attributes of routes installed into the switch routing table. ExtremeXOS 15.7 provides the flexibility of using import policy to determine the routes to be added to or removed from the routing table.

To prevent a route being added to the routing table, the policy file must contain a matching rule with action “deny”. If there is no matching rule for a particular route, or the keyword “deny” is missing in the rule, the default action is “permit”, which means that route will be installed into the routing table. Refer to the following policy file example:

```
entry entry-one {
 if {
 nlri 11.22.0.0/16;
 }
 then {
```

```
cost 100;
}
}
entry entry-two {
if {
nlri 22.33.0.0/16;
}
then {
deny;
}
}
```

In the above policy example, entry-one is used to change the cost of any matching routes, and entry-two is used to remove those matching routes from the routing table.

#### Note

Only "Network Layer Reachability Information" (NLRI) and "route origin" can be used as matching criteria in policy rules; using "next\_hop" as a matching criteria is not supported. Any other policy attribute is not recognized and is ignored.

## Route Redistribution

More than one routing protocol can be enabled simultaneously on the switch.

Route redistribution allows the switch to exchange routes, including static routes, between the routing protocols. [Figure 179](#) is an example of route redistribution between an OSPF AS and a RIP AS.

**Figure 179: OSPF Route Redistribution**

### Configuring Route Redistribution

Exporting routes from one protocol to another and in the reverse direction are discrete configuration functions. For example, to run IS-IS and [RIP \(Routing Information Protocol\)](#) simultaneously, you must first configure both protocols and then verify the

independent operation of each. Then you can configure the routes to export from IS-IS to RIP and the routes to export from RIP to IS-IS. Likewise, for any other combinations of protocols, you must separately configure each to export routes to the other.

This section describes how to inject routing information learned from other IP routing protocols into an IS-IS domain, thereby advertising their reachability in the IS-IS domain. These routes are included in the locally originated LSPs. For information on exporting routes learned in IS-IS to another routing protocol, see the chapter that describes the destination routing protocol.

When you export routes from another protocol to IS-IS, the metric and the type of metric are configured. You can also configure a policy to filter out unwanted external routes.

- To enable or disable the exporting of *BGP (Border Gateway Protocol)*, *OSPF*, RIP, static, and direct (interface) IPv4 routes to IS-IS, use the following commands:

```
enable isis area area_name export {ipv4} route-type [policy | metric
mvalue {metric-type [internal | external]}} {level[1 | 2 | both-1-
and-2]}
```

```
disable isis area area_name export {ipv4} route-type
```

- To enable or disable the exporting of *OSPFv3*, *RIPng*, static, and direct (interface) IPv6 routes to IS-IS, use the following commands:

```
enable isis area area_name export ipv6 route-type [policy | metric
mvalue] {level[1 | 2 | both-1-and-2]}
```

```
disable isis area area_name export ipv6 route-type
```

The cost metric is inserted for all *OSPF*, RIP, static, and direct routes injected into IS-IS.

The same cost and type values can be inserted for all the export routes, or policies can be used for selective insertion. When a policy is associated with the export command, the policy is applied on every exported route. The exported routes can also be filtered using policies.

- Verify the configuration using the command:

```
show isis area [area_name | all]
```

## Redistributing Routes into OSPFv3

To enable or disable the exporting of *RIPng*, static, and direct (interface) routes to *OSPFv3*, use the following command:

```
enable ospfv3 export [direct | ripng | static | isis | isis-level-1
| isis-level-1-external | isis-level-2 | isis-level-2-external | bgp | e-
bgp | i-bgp | host-mobility] [cost cost type [ase-type-1 | ase-type-2] |
policy_map]
```

These commands enable or disable the exporting of RIPng, static, and direct routes by way of LSA to other OSPFv3 routers as AS-external type 1 or type 2 routes. The default setting is disabled.

The cost metric is inserted for all RIPng, static, and direct routes injected into OSPFv3. If the cost metric is set to 0, the cost is inserted from the route. The tag value is used

only by special routing applications. Use 0 if you do not have specific requirements for using a tag. (The tag value in this instance has no relationship with IEEE 802.1Q [VLAN](#) tagging.)

The same cost, type, and tag values can be inserted for all the export routes, or policies can be used for selective insertion. When a policy is associated with the export command, the policy is applied on every exported route. The exported routes can also be filtered using policies.

#### Note

For routes exported to OSPFv3 via a policy file, any refresh applied on that policy may result in temporary withdrawal and then immediate readvertising of those routes.

Verify the configuration using the command:

```
show ospfv3
```

## OSPFv3 Timers

Configuring [OSPFv3](#) timers on a per area basis is a shortcut to applying the timers to each [VLAN](#) in the area at the time of configuration.

If you add more VLANs to the area, you must configure the timers for the new VLANs explicitly. Use the command:

```
configure ospfv3 [vlan vlan-name | tunnel tunnel-name | [vlan |
tunnel] all] timer {retransmit-interval} retransmit-interval {transit-
delay} transit-delay {hello-interval} hello-interval {dead-interval}
dead-interval
```

## Virtual Routing and Forwarding (VRF) for OSPFv3

ExtremeXOS supports multiple Virtual Routing and Forwarding (VRFs) in the same . Each VRF can have a separate instance of a routing protocol with its own routing table. [OSPFv3](#) can run in a Non-VPN VRF and support multiple instances of the protocol in different VRFs at the same time. This allows more scalable deployments of OSPFv3 as ExtremeXOS can have more VRFs than VRs, and OSPFv3 VRF instances belonging to the same VR run in a single ExtremeXOS process. Each VR still has its own process, so different VRs have very low impact on one another.

#### Limitations

- Only non-VPN VRFs are supported. OSPFv3 is blocked on VPN VRFs.
- [BGP](#) does not support VPN-IPv6 routes, so PE-CE support is not available.

## OSPFv3 Authentication

There are two ways to perform authentication for OSPFv3: using IPsec and using Authentication Trailer. See the following for more information:

- [IPsec Authentication](#) on page 1387
- [Authentication Trailer](#) on page 1388

### *IPsec Authentication*

IPsec is a framework for ensuring secure private communication over IP networks and is based on standards developed by the International Engineering Task Force (IETF). IPsec provides security services at the network layer of the Open Systems Interconnection (OSI) model by enabling a system to select required security protocols, determine the algorithms to use for the security services, and implement any cryptographic keys required to provide the requested services. IPsec can be used to protect one or more paths between a pair of hosts, between a pair of security gateways (such as switches), or between a security gateway and a host.

ExtremeXOS supports IPv6 Encapsulating Security Payload (ESP) in transport mode to provide authentication to OSPFv3 packets, and encryption is not supported. The transport mode Security Association (SA) is generally used between two hosts or routers/gateways when they are acting as hosts, and in OSPFv3 the routers assume the role of hosts as protocol packets are locally delivered. With ESP in transport mode, it will only provide authentication to OSPFv3 protocol packets excluding the IPv6 header, extension headers and options.

OSPFv3 exchanges both multicast and unicast packets. While running OSPFv3 over a broadcast interface, the authentication required is "one to many." Since IKE is based on the Diffie-Hellman key agreement protocol and works only for two communicating parties, it is not possible to use IKE for providing the required "one to many" authentication. *RFC4552* mandates the usage of Manual Keying with current IPsec implementation. In manual keying, SAs are statically installed on the routers and these static SAs are used to authenticate packets. It is not scalable and is practically infeasible to use different security associations for inbound and outbound traffic to provide the required "one to many" security. Therefore, *RFC4552* requires the implementations to use manually configured keys with the same SA parameters (for example, Security Parameter Index (SPI), keys, and so forth) for both inbound and outbound SAs.

### Configuring OSPFv3 IPsec Authentication

To configure IPsec with a manual key to provide authentication for OSPFv3 interfaces, run the following command:

```
configure ospfv3 [{vlan} vlan-name | {tunnel} tunnel-name]
authentication [none | ipsec spi spi esp-auth-algorithm algorithm key
[key-string | encrypted encrypted-key-string]
```

To configure IPsec with a manual key to provide authentication on OSPFv3 virtual-links, run the following command:

```
configure ospfv3 virtual-link {routerid} router-identifier {area} area-identifier authentication [none | ipsec spi spi esp-auth-algorithm
algorithm key [key-string | encrypted encrypted-key-string]
```

### Authentication Trailer

Authentication Trailer for OSPFv3 (as described in RFC 7166) provides an alternative way to authenticate packets, as IPsec may not be suitable in some environments.

Authentication Trailer uses Keychain Manager to manage keys (see [Keychain Manager Overview](#) on page 992). Keychain Manager provides OSPFv3 the key string and algorithm to use for authentication when a key becomes active, and it will notify OSPFv3 when a key expires. The authentication configuration is per interface or virtual interface, and the corresponding peers need to be configured with the same authentication keys. The maximum length of a key string that OSPFv3 can accommodate is 127 characters, which is the same as the maximum length of a key string currently allowed by Keychain Manager.

The cryptographic algorithms supported are HMAC-SHA-1, HMAC-SHA-256, HMAC-SHA-384, and HMAC-SHA-512.

#### Note

OSPFv3 Authentication Trailer does not support the accept tolerance feature of Keychain Manager.

### Configuring OSPFv3 Authentication Trailer

To configure Authentication Trailer to provide authentication for OSPFv3 interfaces see [Configuring and Using Keychain Manager](#) on page 994, or run the following commands:

```
configure ospfv3 [{vlan} vlan-name | {tunnel} tunnel-name]
authentication [keychain keychain-name | none]
```

To configure Authentication trailer to provide authentication on OSPFv3 virtual-links, run the following command:

```
configure ospfv3 virtual-link {routerid} router-identifier {area} area-identifier authentication [keychain keychain_name | none]
```

# PoE

---

[Extreme Networks PoE Devices](#) on page 1389

[Power Delivery](#) on page 1391  
[Configuring PoE](#) on page 1398  
[Displaying PoE Settings and Statistics](#) on page 1403

Power over Ethernet (PoE) is an effective method of supplying 48 VDC power to certain types of powered devices (PDs) through Category 5 and above twisted pair Ethernet cables.

PDs include wireless access points, IP telephones, laptop computers, web cameras, and other devices. With PoE, a single Ethernet cable supplies power and the data connection, reducing costs associated with separate power cabling and supply.

In a SummitStack, power is maintained across a failover on all PoE ports of non-primary nodes but is lost on all PoE ports of the failed primary node. Each ExtremeSwitching switch has its own PSU and the power budget for each ExtremeSwitching switch is determined by the internal/external PSUs connected to that ExtremeSwitching switch.

PoE+ supports higher power levels as defined by the IEEE 802.3at standard.

PoE++ supports higher power levels as defined by the IEEE 802.3bt standard.

## Extreme Networks PoE Devices

---

Following is a list of the Extreme Networks devices that support PoE+ and PoE++ and the minimum required software:

### PoE+

- ExtremeSwitching 5420F-8W-16P-4XE—ExtremeXOS 31.3 and later.
- ExtremeSwitching 5420F-24P-4XE—ExtremeXOS 31.3 and later.
- ExtremeSwitching 5420F-16MW-32P-4XE—ExtremeXOS 31.3 and later.
- ExtremeSwitching 5420F-16W-32P-4XE—ExtremeXOS 31.3 and later.
- ExtremeSwitching 5420F-48P-4XE—ExtremeXOS 31.3 and later.
- ExtremeSwitching 5420F-48P-4XL—ExtremeXOS 31.3 and later.
- ExtremeSwitching 5420M-16MW-32P-4YE—ExtremeXOS 31.3 and later.
- ExtremeSwitching 5320-48P-8XE—Switch Engine 31.6 and later.

- ExtremeSwitching 5320-24P-8XE—Switch Engine 31.6 and later.
- ExtremeSwitching 5320-16P-4XE—Switch Engine 31.7 and later.
- ExtremeSwitching 5320-16P-4XE-DC—Switch Engine 31.7 and later.
- 4220-12P-4X—Switch Engine 32.7.1 and later.
- 4220-24P-4X—Switch Engine 32.7.1 and later.
- 4220-48P-4X—Switch Engine 32.7.1 and later.
- 4220-4MW-8P-4X—Switch Engine 32.7.1 and later.
- 4220-4MW-20P-4X—Switch Engine 32.7.1 and later.
- 4220-8MW-40P-4X—Switch Engine 32.7.1 and later.

## PoE++

- ExtremeSwitching 5520-24W—ExtremeXOS 31.1 and later.
- ExtremeSwitching 5520-48W—ExtremeXOS 31.1 and later.
- ExtremeSwitching 5520-12MW-36W—ExtremeXOS 31.1 and later.
- ExtremeSwitching 5420F-8W-16P-4XE—ExtremeXOS 31.3 and later.
- ExtremeSwitching 5420F-16MW-32P-4XE—ExtremeXOS 31.3 and later.
- ExtremeSwitching 5420F-16W-32P-4XE—ExtremeXOS 31.3 and later.
- ExtremeSwitching 5420M-24W-4YE—ExtremeXOS 31.3 and later.
- ExtremeSwitching 5420M-16MW-32P-4YE—ExtremeXOS 31.3 and later.
- ExtremeSwitching 5420M-48W-4YE—ExtremeXOS 31.3 and later.
- ExtremeSwitching 5720-24MW—Switch Engine 32.1 and later.
- ExtremeSwitching 5720-24MXW—Switch Engine 32.1 and later.
- ExtremeSwitching 5720-48MW—Switch Engine 32.1 and later.
- ExtremeSwitching 5720-48MXW—Switch Engine 32.1 and later.
- 4120-24MW-4Y—Switch Engine 32.7.1 and later.
- 4120-48MW-4Y—Switch Engine 32.7.1 and later.
- 4220-4MW-8P-4X—Switch Engine 32.7.1 and later.
- 4220-4MW-20P-4X—Switch Engine 32.7.1 and later.
- 4220-8MW-40P-4X—Switch Engine 32.7.1 and later.

## Summary of PoE Features

The ExtremeXOS implementation of PoE (Power over Ethernet) supports the following features:

- Configuration and control of the power distribution for PoE at the system, slot, and port levels
- Real-time discovery and classification of IEEE 802.3af-compliant PDs and many legacy devices
- Support for IEEE 802.3at-compliant PDs on PoE+ devices
- Support for IEEE 802.3bt compliant PDs on PoE++ devices

- Monitor and control of port PoE fault conditions including exceeding configured class limits and power limits and short-circuit detection
- Support for configuring and monitoring PoE status at the system, slot, and port levels
- Management of an over-subscribed power budget
- Port LED control for indicating the link state
- Support for hitless failover in a SummitStack with a master and backup node.
- (Fast PoE) Ability to provide PoE power when the switch is powered on without waiting for boot up based on last saved PoE state on all Universal (per port) platforms).
- (Perpetual PoE) Preserve PoE power delivery to devices during reboot on all Universal platforms.

## Power Delivery

This section describes how the system provides power to the PDs. ExtremeXOS always configures the PoE controller to use Dynamic Power Management mode.

### Enabling PoE to the Switch

*PoE* is enabled by default. For details about changing the configuration, see [Configuring PoE](#) on page 1398.

### Power Reserve Budget

Power supply equipment (PSEs) can be categorized as either Type 1, Type 2, Type 3, or Type 4 PSEs . Type 3 PSEs support powered devices (PDs) up to class 6. Type 4 PSEs support PDs up to class 8.

#### *4120 Series Switches*

| Switch Model              | With Internal Fixed PSU | With Internal Fixed PSU + 920W PSU | With Internal Fixed PSU + 1200W PSU | With Internal Fixed PSU + 2000W PSU |
|---------------------------|-------------------------|------------------------------------|-------------------------------------|-------------------------------------|
| 4120-24MW-4Y (100-120VAC) | 680W                    | 1440W                              | 1380W                               | Not Supported                       |
| 4120-48MW-4Y (100-120VAC) | 640W                    | Not Supported                      | 1340W                               | 1230W                               |
| 4120-24MW-4Y (200-240VAC) | 680W                    | 1440W                              | 1540W                               | Not Supported                       |
| 4120-48MW-4Y (200-240VAC) | 980W                    | Not Supported                      | 1780W                               | 2180W                               |

*4220 Series Switches*

| Switch Model    | PoE Budget |
|-----------------|------------|
| 4220-12P-4X     | 124W       |
| 4220-24P-4X     | 195W       |
| 4220-48P-4X     | 370W       |
| 4220-4MW-8P-4X  | 240W       |

### ExtremeSwitching 5720 Series Switches

ExtremeSwitching series switches have the following power reserve budgets:

**Table 125: ExtremeSwitching 5720 PoE Power Budget**

| Switch Model | 1 x 715W | 2 x 715W | 1 x 1100W | 2 x 1100W | 1 x 2000W @110-132 VAC | 2 x 2000W @110-132 VAC | 1 x 2000W @220-264VAC | 2 x 2000W @220-264VAC |
|--------------|----------|----------|-----------|-----------|------------------------|------------------------|-----------------------|-----------------------|
| 5720-24M W   | 450W     | 1093W    | 835W      | 1825W     | 835W                   | 1825W                  | 1735W                 | 2160W                 |
| 5720-24M XW  | 450W     | 1093W    | 835W      | 1825W     | 835W                   | 1825W                  | 1735W                 | 2160W                 |
| 5720-48M W   | 450W     | 1093W    | 835W      | 1825W     | 835W                   | 1825W                  | 1735W                 | 3535W                 |
| 5720-48M XW  | 450W     | 1093W    | 835W      | 1825W     | 835W                   | 1825W                  | 1735W                 | 3535W                 |

#### Note

It's recommended that primary and secondary PSUs be of the same type to support optimal PoE operation.

### Guard Band

To reduce the chances of ports fluctuating between powered and non-powered states, newly inserted PDs are not powered when the actual delivered power for the switch is within a preset value below the configured inline power budget for that slot or switch.

This band is called the guard band and the value used is 20 W for all ExtremeSwitching series switches. However, actual aggregate power can be delivered up to the configured inline power budget for the slot or switch (for example, when delivered power from ports increases or when the configured inline power budget for the slot is reduced).

If total consumed power is within the guard band, new ports are not powered up.

## PD Disconnect Precedence

After a PD is discovered and powered on an ExtremeSwitching switch, the actual power drain is continuously measured.

If the usage for power by PDs is within the guard band, the system begins denying power to PDs.

You can configure the switch to handle a request for power that exceeds the power budget situation in one of two ways, called the disconnect precedence:

- Disconnect PDs according to the configured *PoE* port priority for each PD.
- Deny power to the next PD requesting power, regardless of that port's PoE priority. The default value is deny-port.

#### *Port Priority Enabled*

- When a PD is detected on a specific port, the PoE controller allows power on the port if available power from the power source is greater than the maximum power threshold configured on the port and the total allocated power is below the guard band.
- When available power is less than the maximum power threshold configured on the port and port priority is less than the port priority set on all powered ports, the PoE controller does not allow power on the port.
- When available power is less than the maximum power threshold configured on the port and the port priority is greater than the priority of currently powered ports, the PoE controller disconnects the two priority ports(s) and allows the port to power up.
- When the total consumed power exceeds the configured power limit of the power source, the PoE controller disconnects the low priority ports(s) and allows the port to power up.

#### *Port Priority Disabled*

- When a PD is detected on a specific port, the PoE controller allows power on the port if available power from the power source is greater than the maximum power threshold configured on the port and the total allocated power is below the guard band. Note that "maximum power threshold" is the same as "operator-limit".
- When available power is less than the maximum power threshold configured on the port, the PoE controller does not allow power on this port.
- When the total consumed power exceeds the configured power limit of the power source, the PoE controller starts powering down ports beginning with the highest port number.

## Port Disconnect or Fault

On all PoE devices, when a port enters a fault state if you set the operator limit lower than the amount requested by the PD, the system removes power from that port. The power removed is, again, available only to other ports on the same slot or stand-alone switch. The port stays in the fault state until you disable that port, disconnect the attached PD, or reconfigure the operator limit to be high enough to satisfy the PD requirements.

When a port is disconnected or otherwise moves into a fault state, SNMP (Simple Network Management Protocol) generates an event (after you configure SNMP and a log message is created).

## PoE Usage Threshold

The system generates an SNMP event when any slot or stand-alone switch has consumed a specified percentage of that slot's reserved power budget or of the entire power for the stand-alone switch.

The default value is 70%; you can configure this threshold to generate events from 1% to 99% consumption of the reserved power budget. You can also configure the system

to log an EMS message when the usage threshold is crossed (for more information on EMS, see [Using the Event Management System/Logging](#) on page 1685).

## Legacy Devices

ExtremeXOS software allows the use of non-standard PDs with the switch. These are PDs that do not comply with the IEEE 802.3af standard.

The system detects non-standard PDs using a capacitance measurement. You must enable the switch to detect legacy devices; the default value is disabled.

Detecting a PD through capacitance is used only if the following two conditions are both met:

- Legacy PD detection is enabled.
- The system unsuccessfully attempted to discover the PD using the standard resistance measurement method.

## PoE Operator Limits

You can set the power limit that a PD can draw on the specified ports. For PoE, the range is 3,000 to 16800mW and the default value is 15,400 mW. For PoE+, the range is 3,000 to 32,000 mW and the default value is 30,000 mW. For PoE++ Type 3, the range is 3,000 mW to 64,000 mW and the default value is 60,000 mW. For PoE++ Type 4, the range is 3,000 mW to 98,000 mW and the default value is 90,000 mW.

If the measured power for a specified port exceeds the port's operator limit, the power is withdrawn from that port and the port moves into a fault state.

If you attempt to set an operator limit outside the accepted range, the system returns an error message.

With a class-based operator-limit type, if a class4 PD is attached, then the operator-limit set will be ignored and the switch will not deliver more than 30W to the PD.

When class-based operator-limit is configured on a port, "Max Allowed Power" will show the maximum power for the class of the attached PD. Without the class-based option, "Max Allowed Power" will show the configured or default value of operator-limit.

## Configuring PoE

PoE supports a full set of configuration and monitoring commands that allows you to configure, manage, and display PoE settings at the system, slot, and port level. To enable inline power, or PoE, you must have a powered switch.

To configure inline power, or PoE, you must accomplish the following tasks:

1. Enable inline power to the system, slot, and/or port.
2. On ExtremeSwitching all Universal switches, configure the disconnect precedence for the PDs in the case of excessive power demands.
3. Configure the threshold for initiating system alarms on power usage.

Additionally, you can configure the switch to use legacy PDs, apply specified PoE limits to ports, apply labels to PoE ports, and configure the switch to allow you to reset a PD without losing its power allocation.

For complete information on using the CLI commands, see the [Switch Engine v33.3.1 Command References](#).

## enable inline-power

```
enable inline-power [{fast {ports [port_list | all]}} | perpetual]
```

### Description

Enables *PoE*, and perpetual PoE to all ports; or fast PoE to all ports, or selected ports, for some platforms.

### Syntax Description

|                  |                                                                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| fast             | Deliver PoE power to devices at the time of switch power on without waiting for boot up based on last saved PoE state. The default is disabled. |
| ports            | For fast PoE, specifies selecting ports. 4120, 4220, ExtremeSwitching 5320, 5420, 5520 and 5720 series switches only.                           |
| <i>port_list</i> | For fast PoE, specifies the port list separated by a comma or -. 4120, 4220, ExtremeSwitching 5320, 5420, 5520 and 5720 series switches only.   |
| all              | For fast PoE, specifies selecting all ports. 4120, 4220, ExtremeSwitching 5320, 5420, 5520 and 5720 series switches only.                       |
| perpetual        | Preserves PoE power delivery to devices during reboot. Perpetual PoE is a switch-wide setting. The default is disabled.                         |

### Default

By default:

- PoE is enabled.
- Fast PoE is disabled.
- Perpetual PoE is disabled.

### Usage Guidelines

You can control whether inline power is provided to the system by using the [disable inline-power](#) command and the [enable inline-power](#) command. By default, inline power provided to all ports is enabled. Additionally, you can opt to deliver PoE power to devices at the time of switch power on without waiting for boot up (fast PoE) based on last saved PoE state. Per-port fast PoE is available on certain platforms. You can also elect to preserve PoE power delivery to devices during reboot (perpetual PoE). The default for both PoE options is disabled.

Enabling inline power starts the PoE detection process used to discover, classify, and power remote PDs.

Disabling inline power using the `disable inline-power` command does not affect the data traffic traversing the port. And, disabling the port using the `disable port` command does not affect the inline power supplied to the port.

**Note**

Inline power cannot be delivered to connected PDs unless the switch is powered on.

*Example*

The following command enables inline power currently provided to all ports:

```
enable inline-power
```

The following example turns on perpetual PoE for the switch:

```
enable inline-power perpetual
```

The following example turns on fast PoE for ports 1,2, and 5:

```
enable inline-power fast ports 1,2,5
```

*History*

This command was first available in ExtremeXOS 11.1.

The fast and perpetual PoE options were added in ExtremeXOS 30.3.

Per-port fast PoE was added for ExtremeXOS 31.1.

*Platform Availability*

This command is available on the PoE devices listed in [Extreme Networks PoE Devices](#).

The fast and perpetual options are only available on the 4120, 4220, ExtremeSwitching 5320, 5420, 5520 and 5720 (per port) series switches.

## Setting the Disconnect Precedence

All ExtremeSwitching Universal *PoE* switches.

**Note**

The switch generates an *SNMP* event if a PD goes offline, and the port's state moves from Power to Searching. You must configure SNMP to generate this event.

When the actual power used by the PDs on a switch or slot exceeds the power budgeted for that switch or slot, the switch refuses power to PDs. There are two methods used by the switch to refuse power to PDs, and whichever method is in place applies to all PoE slots in the switch. This is called the disconnect precedence method, and you configure one method for the entire switch.

The available disconnect precedence methods are:

- Deny port
- Lowest priority

The default value is deny port. Using this method, the switch simply denies power to the next PD requesting power from the slot, regardless of that port's PoE priority or port number.

Using the lowest priority method of disconnect precedence, the switch disconnects the PDs connected to ports configured with lower PoE priorities.

When several ports have the same PoE priority, the lower port numbers have higher PoE priorities. That is, the switch withdraws power (or disconnects) those ports with the highest port number(s).

The system keeps dropping ports, using the algorithm you selected with the disconnect ports command, until the measured inline power for the slot is lower than the reserved inline power.

- To Configure the disconnect precedence for the switch, use the following command:  
`configure inline-power disconnect-precedence [deny-port | lowest-priority]`
- To return the disconnect precedence to the default value of deny port, use the following command:  
`unconfigure inline-power disconnect-precedence`
- To display the currently configured disconnect precedence, use the following command:  
`show inline-power`

## Configuring the Usage Threshold

The system generates an SNMP event after a preset percentage of the reserved power for any slot or total power for a stand-alone switch is actually used by a connected PD. This preset percentage is called the usage threshold and is the percentage of the measured power to the budgeted power for each slot or total power for a stand-alone switch.

The default value for this usage threshold is 70%. You can configure the usage threshold to be any integer between 1% and 99%.

- To configure the threshold percentage of budgeted power used on a slot or the total power on a stand-alone switch that causes the system to generate an SNMP event and EMS message, use the following command:  
`configure inline-power usage-threshold threshold`
- To reset the threshold that causes the system to generate an SNMP event and EMS message per slot to 70% for measured power compared to budgeted power, use the following command:  
`unconfigure inline-power usage-threshold`

- To display the currently configured usage threshold, use the following command:  
`show inline-power`

## Configuring the Switch to Detect Legacy PDs

The *PoE* device can detect non-standard, legacy PDs, which do not conform to the IEEE 802.3af standard, using a capacitance measurement. However, you must specifically enable the switch to detect these non-standard PDs; the default value for this detection method is disabled.

This configuration applies to the entire switch; you cannot configure the detection method per slot.

The switch detects PDs through capacitance only if both of the following conditions are met:

- The legacy detection method is enabled.
- The switch unsuccessfully attempted to discover the PD using the standard resistance measurement method.
- To configure a switch to detect legacy, non-standard PDs for a specified slot, use the following command:

```
configure inline-power detection [802.3af-only | legacy-and-802.3af
[4-point | 2-point] | bypass] ports port_list
```

- To configure the switch to detect legacy PDs on a switch, use the following command:

```
configure inline-power detection [802.3af-only | legacy-and-802.3af
[4-point | 2-point] | bypass] ports port_list
```

## Configuring the Operator Limit

You can configure the maximum amount of power that the specified port can deliver to the connected PD, in milliwatts (mW). For *PoE*, the default value is 15400 mW, and the range is 3000 to 16800 mW. For PoE+, the range is 3,000 to 32,000 mW and the default value is 30,000 mW. For PoE++ Type 3, the range is 3,000 mW to 64,000 mW and the default value is 60,000 mW. For PoE++ Type 4, the range is 3,000 mW to 98,000 mW and the default value is 90,000 mW.

If the operator limit for a specified port is less than the power drawn by the legacy PD, the legacy PD is denied power.

- To set the operator limit on specified ports, which limits how much power a PD can draw from that port, use the following command:  

```
configure inline-power operator-limit milliwatts ports [all | port_list]
```
- To reset the operator limit to the default value of 15.4 W for PoE, 30 W for PoE+, or 60 W for PoE++, use the following command:  

```
unconfigure inline-power operator-limit ports [all | port_list]
```

- To display the current operator limit on each port, use the following command:

```
show inline-power configuration ports {port_list}
```

**Note**

With a class-based operator-limit type, if a class4 PD is attached, then the operator-limit set will be ignored and the switch will not deliver more than 30W to the PD.

When class-based operator-limit is configured on a port, "Max Allowed Power" will show the maximum power for the class of the attached PD. Without the class-based option, "Max Allowed Power" will show the configured or default value of operator-limit.

## Configuring PoE Port Labels

You can assign labels to a single or group of *PoE* ports using a string of up to 15 characters.

- To assign a label to PoE ports, use the following command:

```
configure inline-power label [string | none] ports port_list
```

To rename a port or to return it to a blank label, reissue the command.

- To display the PoE port labels, use the following command:

```
show inline-power configuration ports {port_list}
```

## Power Cycling Connected Powered Devices

You can power cycle a connected PD without losing the power allocated to its port using the following command:

```
reset inline-power ports port_list
```

## Displaying PoE Settings and Statistics

You can display the *PoE* status, configuration, and statistics for the system, slot, and port levels.

### Clearing Statistics

You can clear the *PoE* statistics for specified ports or for all ports.

To clear the statistics and reset the counters to 0, enter the following command:

```
clear inline-power stats ports [all | port_list]
```

## Displaying System Power Information

You can display the status of the inline power for the system and, for additional information, display the power budget of the switch.

### Display System PoE Status

- Display the PoE status for the switch.

```
show inline-power [fast | perpetual]
```

The command provides status for the following areas:

- Configured inline power status—The status of the inline power for the switch: enabled or disabled.
- System power surplus—The surplus amount of power on the system, in watts, available for budgeting.
- Redundant power surplus—The amount of power on the system, in watts, available for budgeting if one power supply is lost.
- System power usage threshold—The configured power usage threshold for each slot, shown as a percentage of budgeted power. After this threshold has been passed on any slot, the system sends an SNMP event and logs a message.
- Disconnect precedence—The method of denying power to PDs if the budgeted power on any slot is exceeded.
- Legacy mode—The status of the legacy mode, which allows detection of non-standard PDs.

The output indicates the following inline power status information for each slot:

- Inline power status—The status of inline power. The status conditions are:
  - Enabled
  - Disabled
- Firmware status—The operational status of the slot. The status conditions are:
  - Operational
  - Not operational
  - Disabled
  - Subsystem failure
  - Card not present
  - Slot disabled
- Budgeted power—The amount of inline power, in watts, that is reserved and available to the slot.
- Measured power—The amount of power, in watts, that is currently being used by the slot.

PoE optimization options:

- Fast—Specifies showing fast PoE power status, which is the ability to provide power to devices at the time of switch power on without waiting for boot up based on last saved PoE state.
- Perpetual—Specifies showing perpetual PoE power status, which is the ability to preserve PoE power delivery to devices during reboot. Perpetual PoE is a switch-wide setting.

## Displaying PoE Status and Statistics on Stand-alone Switches

To display the *PoE* statistics for the switch, run the `show inline-power stats` command.

The command provides the following information:

- Firmware status—Displays the firmware state:
  - Operational
  - Not operational
  - Disabled
  - Subsystem failure
- Firmware revision—Displays the revision number of the PoE firmware.
- Total ports powered—Displays the number of ports powered on specified slot.
- Total ports awaiting power—Displays the number of remaining ports in the slot that are not powered.
- Total ports faulted—Displays the number of ports in a fault state.
- Total ports disabled—Displays the number of ports in a disabled state.

## Displaying Port PoE Information

You can display the *PoE* configuration, status, and statistics per port.

### *Displaying Port PoE Configuration*

To display *PoE* configuration for each port, use the following command:

```
show inline-power configuration ports {port_list}
```

This command provides the following information:

- Config—Indicates whether the port is enabled to provide inline power:
  - Enabled: The port can provide inline power.
  - Disabled: The port cannot provide inline power.
- Operator Limit—Displays the configured limit, in milliwatts, for inline power on the port.
- Label—Displays a text string, if any, associated with the port (15 characters maximum).
- Priority – Displays the configured PoE priority of the port.
- Detection – Displays the configured detection of the PoE Port
- Classification – Displays the configured classification of the PoE Port
- Fast – Displays the configured status of fast PoE of the PoE Port

*Display Port PoE Status*

To display the *PoE* status per port, run the `show inline-power info {detail} ports {port_list}` command. This command provides the following information:

- State—Displays the port power state:
  - Disabled
  - Searching
  - Delivering
  - Faulted
  - Disconnected
  - Other
  - Denied
- PD's power class—Displays the class type of the connected PD:
  - "-----": disabled or searching
  - "class0": class 0 device
  - "class1": class 1 device
  - "class2": class 2 device
  - "class3": class 3 device
  - "class4": class 4 device
  - "class5": class 5 device
  - "class6": class 6 device
  - "class7": class 7 device
  - "class8": class 8 device
- Volts—Displays the measured voltage. A value from 0 to 2 is valid for ports that are in a searching or discovered state.
- Curr—Displays the measured current, in milliamperes, drawn by the PD.
- Power—Displays the measured power, in watts, supplied to the PD.
- Fault—Displays the fault value:
  - None
  - UV/OV fault
  - UV/OV spike
  - Over current
  - Overload
  - Undefined
  - Underload
  - HW fault
  - Discovery resistance fail
  - Operator limit violation
  - Disconnect
  - Discovery resistance, A2D failure
  - Classify, A2D failure

- Sample, A2D failure
- Device fault, A2D failure
- Force on error

The detail command option lists all inline power information for the selected ports. Detail output displays the following information:

- Configured admin state
- Inline power state
- MIB detect status
- Label
- Operator limit
- PD class
- Max allowed power
- Measured power
- Line voltage
- Current
- Fault status
- Detailed status
- Priority

```
* (CIT_32.1.1.6) 5720-24MW-SwitchEngine.1 # show inline-power perpetual
Perpetual PoE

Disabled
```

To display PoE fast information by port, run the `show inline-power fast ports {port_list}` command. This command displays the following information:

- Port status (enabled/disabled)
- Operator limits
- Priority
- Detection method

```
* (CIT_32.1.0.383) 5720-24MW-SwitchEngine.2 # sh inline-power fast
State Enable Disconnect Last Fast Boot Status

HW Disabled Deny-port Succeeded
Cfg Disabled Deny-port

State: (HW) Hardware state per-slot, (Cfg) Configured state per-slot.
Fast Boot Status:
 Succeeded - Fast PoE boot succeeded and configuration matches.
 Disabled - Fast PoE was disabled in hardware at boot time.
 Mismatch - Fast PoE booted but the configuration in hardware
 did not match the configuration file.
 Failed - Fast PoE boot failed and PoE was reset.
* (CIT_32.1.0.383) 5720-24MW-SwitchEngine.3
```

*Displaying Port PoE Statistics*

To display the *PoE* statistics for each port, run the `show inline-power stats ports {port_list}` command. The command provides the following information:

- State—Displays the port power state:
  - Disabled
  - Searching
  - Delivering
  - Faulted
  - Disconnected
  - Other
  - Denied
- PD's power class—Displays the class type of the connected PD:
  - "----": disabled or searching
  - "class0": class 0 device
  - "class1": class 1 device
  - "class2": class 2 device
  - "class3": class 3 device
  - "class4": class 4 device
  - "class5": class 5 device
  - "class6": class 6 device
  - "class7": class 7 device
  - "class8": class 8 device
- Absent—Displays the number of times the port was disconnected.
- InvSig—Displays the number of times the port had an invalid signature.
- Denied—Displays the number of times the port was denied.
- Over-current—Displays the number of times the port entered an overcurrent state.
- Short—Displays the number of times the port entered undercurrent state.

# Policy Manager

---

[Policy Manager and Policies Overview](#) on page 1409

[Creating and Editing Policies](#) on page 1409

[Applying Policies](#) on page 1412

This chapter provides information about how ExtremeXOS implements policy statements. It includes an overview of the Policy Manager, as well as specific information about how to create, edit, check, and apply policies.

## Policy Manager and Policies Overview

---

One of the processes that make up the ExtremeXOS system is the policy manager. The policy manager is responsible for maintaining a set of policy statements in a policy database and communicating these policy statements to the applications that request them.

Policies are used by the routing protocol applications to control the advertisement, reception, and use of routing information by the switch. Using policies, a set of routes can be selectively permitted (or denied) based on their attributes, for advertisements in the routing domain. The routing protocol application can also modify the attributes of the routing information, based on the policy statements.

Policies are also used by the *ACL (Access Control List)* application to perform packet filtering and forwarding decisions on packets. The ACL application will program these policies into the packet filtering hardware on the switch. Packets can be dropped, forwarded, moved to a different *QoS (Quality of Service)* profile, or counted, based on the policy statements provided by the policy manager.

## Creating and Editing Policies

---

A policy is created by writing a text file that contains a series of rule entries describing match conditions and actions to take.

Policies are created by writing a text file on a separate machine and then downloading it to the switch. Once on the switch, the file is then loaded into a policy database to

be used by applications on the switch. Policy text files can also be created and edited directly on the switch.

**Note**

Although ExtremeXOS does not prohibit mixing ACL and routing type entries in a policy file, it is best to use separate policy files for ACL and routing policies instead of mixing the entries.

When you create a policy file, name the file with the policy name that you will use when applying the policy, and use “.pol” as the filename extension. For example, the policy name “boundary” refers to the text file “boundary.pol”.

## Using the Edit Command

A VI-like editor is available on the switch to edit policies. There are many commands available with the editor. For information about the editor commands, use any tutorial or documentation about VI. The following is only a short introduction to the editor.

The editor operates in one of two modes: command and input.

1. To edit a policy file on the switch by launching the editor, enter the command:

```
edit policy filename.pol
```

When a file first opens, you are in the command mode.

2. To write in the file, use the keyboard arrow keys to position your cursor within the file, then press one of the following keys to enter input mode:
  - a. **[i]**—Inserts text ahead of the initial cursor position.
  - b. **[a]**—Appends text after the initial cursor position.
3. To escape the input mode and return to the command mode, press the **[Esc]** key.

Several commands can be used from the command mode. The following commands are the most commonly used:

- **[dd]**—Deletes the current line.
- **[yy]**—Copies the current line.
- **[p]**—Pastes the line copied.
- **[:w]**—Writes (saves) the file.
- **[:q]**—Quits the file if no changes were made.
- **[:q!]**—Forcefully quits the file without saving changes.
- **[:wq]**—Writes and quits the file.

## Using a Separate Machine to Edit Policies

You can also edit policies on a separate machine. Any common text editor can be used to create a policy file. The file is then transferred to the switch using TFTP and then applied.

To transfer policy files to the switch, enter the command:

```
tftp [ip-address | host-name] { -v vr_name } { -b block_size } [-g | -p] [-l local-file { -r remote-file } | -r remote-file { -l localfile }]
```

## Checking Policies

A policy file can be checked to see if it is syntactically correct. This command can only determine if the syntax of the policy file is correct and can be loaded into the policy manager database. Since a policy can be used by multiple applications, a particular application may have additional constraints on allowable policies.

To check the policy syntax, enter the command:

```
check policy policy_name
```

## Refreshing Policies

When a policy file is changed (such as adding, deleting an entry, adding/deleting/modifying a statement), the information in the policy database does not change until the policy is refreshed. The user must refresh the policy so that the latest copy of policy is used. When the policy is refreshed, the new policy file is read, processed, and stored in the server database.

Any clients that use the policy are updated.

- To refresh the policy, enter the command:

```
refresh policy policy_name
```

For ACL policies only, during the time that an ACL policy is refreshed, packets on the interface are blackholed, by default. This is to protect the switch during the short time that the policy is being applied to the hardware. It is conceivable that an unwanted packet could be forwarded by the switch as the new ACL is being set up in the hardware. You can disable this behavior.

### Note

Performing a refresh on multiple ports requires the original and modified policy to coexist at the same time in the intermittent state. If this is not possible due to slice limitations, the refresh will fail with "ACL slice full" error.

- To control the behavior of the switch during an ACL refresh, enter the commands:

```
enable access-list refresh blackhole
```

```
disable access-list refresh blackhole
```

In releases previous to ExtremeXOS 11.4, when ACLs were refreshed, all the ACL entries were removed, and new ACL entries were created to implement the newly applied policy.

Beginning in release 11.4, the policy manager uses Smart Refresh to update the ACLs. When a change is detected, only the ACL changes needed to modify the ACLs are sent to the hardware, and the unchanged entries remain. This behavior avoids having to blackhole packets because the ACLs have been momentarily cleared. Smart Refresh works well up for up to 200 changes. If the number of changes

exceeds 200, you will see this message: Policy file has more than 200 new rules. Smart refresh can not be carried out. Following this message, you will see a prompt based on the current blackhole configuration. If blackhole is disabled you will see the following prompt:

Note, the current setting for Access-list Refresh Blackhole is Disabled. WARNING: If a full refresh is performed, it is possible packets that should be denied may be forwarded through the switch during the time the access list is being installed. Would you like to perform a full refresh?

If blackhole is enabled, you will see the following prompt:

Note, the current setting for Access-list Refresh Blackhole is Enabled. Would you like to perform a full refresh?

#### Note

ACL refresh may take additional time if the ACL is applied on multiple VLANs with several ACL slices already in the filled state. Additionally, in SummitStack, ACL refresh happens sequentially, such that after successful installation on one node, it will be applied to other nodes one-by-one, causing a slight delay in refresh operation.

To take advantage of Smart Refresh, disable access-list refresh blackholing.

## Applying Policies

ACL policies and routing policies are applied using different commands.

### Applying ACL Policies

A policy intended to be used as an ACL is applied to an interface, and the CLI command option is named *aclname*.

Supply the policy name in place of the *aclname* option.

- To apply an ACL policy, enter the command:

```
configure access-list aclname [any | ports port_list] {ingress | egress}
```

When you use the any keyword, the ACL is applied to all the interfaces and is referred to as the wildcard ACL. This ACL is evaluated for any ports without specific ACLs, and it is also applied to any packets that do not match the specific ACLs applied to the interfaces.

When an ACL is already configured on an interface, the command is rejected and an error message is displayed.

- To remove an ACL from an interface, enter the command:

```
unconfigure access-list policy_name {any | ports port_list} {ingress | egress}
```

- To display the interfaces that have ACLs configured and the ACL that is configured on each. enter the command:

```
show access-list {any | ports port_list} {ingress | egress}
```

## Applying Routing Policies

To apply a routing policy, use the command appropriate to the client. Different protocols support different ways to apply policies, but there are some generalities.

Commands that use the keyword `import-policy` are used to change the attributes of routes installed into the switch routing table by the protocol. These commands cannot be used to determine the routes to be added to the routing table. The following are examples for the *BGP (Border Gateway Protocol)* and *RIP (Routing Information Protocol)* protocols:

```
configure bgp import-policy [policy-name | none]
```

```
configure rip import-policy [policy-name | none]
```

Commands that use the keyword `route-policy` control the routes advertised or received by the protocol. For BGP and RIP, here are some examples:

```
configure bgp neighbor [remoteaddr | all] {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} route-policy [in | out] [none | policy]
```

```
configure bgp peer-group peer-group-name {address-family [ipv4-unicast | ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} route-policy [in | out] [none | policy]
```

```
configure rip vlan [vlan_name | all] route-policy [in | out] [policy-name | none]
```

Other examples of commands that use routing policies include:

```
configure ospf area area-identifier external-filter [policy-map | none]
```

```
configure ospf add vlan [vlan-name | all] area area-identifier {passive} {vr vrf_name}
```

```
configure rip vlan [vlan_name | all] trusted-gateway [policy-name | none]
```

To remove a routing policy, use the **none** option in the command.

### Note

When exporting a route into BGP with an export policy, the AS-Path is limited to a maximum of 15 AS numbers.

# Quality of Service

---

[QoS Overview](#) on page 1415

[Applications and Types of QoS](#) on page 1416

[Traffic Groups](#) on page 1418

[Introduction to Rate Limiting, Rate Shaping, and Scheduling](#) on page 1423

[Introduction to WRED](#) on page 1426

[Meters](#) on page 1430

[QoS Profiles](#) on page 1430

[Class of Service \(CoS\)](#) on page 1433

[Configuring QoS](#) on page 1435

[Displaying QoS Configuration and Performance](#) on page 1448

VXLAN gateway uses a DSCP value of 0 when the tenant packet is not IP. Otherwise, it copies the tenant DSCP value to the outer IP header. In order to overwrite this, user must configure an [ACL \(Access Control List\)](#) rule. This ACL is general and applied to all virtual networks. The following is an example of this ACL rule:

```
entry map {
 if {
 protocol udp;
 destination-port 4789;
 }
 then {
 qosprofile qp3;
 replace-dscp;
 replace-dotlp;
 }
}
```

Then, the following command is used to put the outer DSCP value to a fixed value of 32:

```
configure diffserv replacement qp3 code-point 32
```

As indicated in the example above, the dotlp value can also be replaced. In the absence of the ACL, VXLAN gateway copies the tenant dotlp value to the network. The replacement happens on the outer headers as the example above illustrates. [QoS \(Quality of Service\)](#) examination (dotlp or diffserv) happens on the first header. On the tenant port, it is examining the ethernet and IP header of tenant frames. On the network port, it is examining the outer Ethernet and IP header. There is no change to the existing support for treatment of packets, such as rate-limiting and queuing.

## QoS Overview

Quality of Service (QoS) is a feature that allows you to configure a switch to provide different levels of service to different groups of traffic. For example, QoS allows you to do the following:

- Give some traffic groups higher priority access to network resources.
- Reserve bandwidth for special traffic groups.
- Restrict some traffic groups to bandwidth or data rates defined in a Service Level Agreement (SLA).
- Count frames and packets that exceed specified limits and optionally discard them (rate limiting).
- Queue or buffer frames and packets that exceed specified limits and forward them later (rate shaping).
- Modify QoS related fields in forwarded frames and packets (remarking).

Figure 180 shows the QoS components that provide these features on Extreme Networks switches.

**Figure 180: QoS on Extreme Networks Switches**

Data enters the ingress port and is sorted into traffic groups, which can be classified as either ACL-based or non-ACL-based.

The ACL-based traffic groups provide the most control of QoS features and can be used to apply ingress and egress rate limiting and rate shaping as follows:

- Subject ingress traffic to rate limit meters
- Specify ingress hardware queues (QoS profiles) for rate limiting and rate shaping
- Specify ingress software traffic queues for rate limiting and rate shaping (these can be associated with egress traffic queues for additional QoS control)

- Specify egress software traffic queues for rate limiting and rate shaping
- Specify egress QoS profiles for rate limiting and rate shaping
- Change the dot1p or Differential Services (DiffServ) values in egress frames or packets

Non-ACL-based traffic groups specify an ingress or egress QoS profile for rate limiting and rate shaping. These groups cannot use ingress or egress software traffic queues. However, non-ACL-based traffic groups can use the packet marking feature to change the dot1p or DiffServ values in egress frames or packets.

The ingress rate-limiting and rate-shaping features allow you to apply QoS to incoming traffic before it reaches the switch fabric. If some out-of-profile traffic needs to be dropped, it is better to drop it before it consumes resources in the switch fabric.

All ingress traffic is linked to an egress traffic queue or QoS profile before it reaches the switch fabric. This information is forwarded with the traffic to the egress interface, where it selects the appropriate egress traffic queue or QoS profile. Egress traffic from all traffic queues and QoS profiles is forwarded to the egress port rate-shaping feature, which applies QoS to the entire port. When multiple QoS profiles are contending for egress bandwidth, the scheduler determines which queues are serviced.

The following sections provide more information on QoS.

## Applications and Types of QoS

Different applications have different [QoS](#) requirements. [Table 126](#) on page 1416 summarizes the QoS guidelines for different types of network traffic.

**Table 126: Traffic Type and QoS Guidelines**

| Traffic Type | Key QoS Parameters                                                                          |
|--------------|---------------------------------------------------------------------------------------------|
| Voice        | Minimum bandwidth, priority                                                                 |
| Video        | Medium bandwidth, priority, buffering (varies)                                              |
| Database     | Minimum bandwidth                                                                           |
| Web browsing | Minimum bandwidth for critical applications, maximum bandwidth for noncritical applications |
| File server  | Minimum bandwidth                                                                           |

Consider these parameters as general guidelines and not as strict recommendations. After QoS parameters have been set, you can monitor the performance of the application to determine if the actual behavior of the applications matches your expectations. It is very important to understand the needs and behavior of the particular applications you want to protect or limit. Behavioral aspects to consider

include bandwidth needs, sensitivity to latency and jitter, and sensitivity and impact of packet loss.

**Note**

Full-duplex links should be used when deploying policy-based QoS. Half-duplex operation on links can make delivery of guaranteed minimum bandwidth impossible.

## Voice Applications

Voice applications, or voice over IP (VoIP), typically demand small amounts of bandwidth. However, the bandwidth must be constant and predictable because voice applications are typically sensitive to latency (inter-packet delay) and jitter (variation in inter-packet delay). The most important *QoS* parameter to establish for voice applications is minimum bandwidth, followed by priority.

## Video Applications

Video applications are similar in needs to voice applications, with the exception that bandwidth requirements are somewhat larger, depending on the encoding. It is important to understand the behavior of the video application being used. For example, in the playback of stored video streams, some applications can transmit large amounts of data for multiple streams in one spike, with the expectation that the end stations will buffer significant amounts of video-stream data. This can present a problem to the network infrastructure, because the network must be capable of buffering the transmitted spikes where there are speed differences (for example, going from gigabit Ethernet to Fast Ethernet). Key *QoS* parameters for video applications include minimum bandwidth and priority, and possibly buffering (depending upon the behavior of the application).

## Critical Database Applications

Database applications, such as those associated with Enterprise Resource Planning (ERP), typically do not demand significant bandwidth and are tolerant of delay. You can establish a minimum bandwidth using a priority less than that of delay-sensitive applications.

## Web Browsing Applications

*QoS* needs for web browsing applications cannot be generalized into a single category. For example, ERP applications that use a browser front-end might be more important than retrieving daily news information. Traffic groupings can typically be distinguished from each other by their server source and destinations. Most browser-based applications are distinguished by the dataflow being asymmetric (small dataflows from the browser client, large dataflows from the server to the browser client).

An exception to this might be created by some Java™-based applications. In addition, web-based applications are generally tolerant of latency, jitter, and some packet loss;

however, small packet loss might have a large impact on perceived performance because of the nature of TCP. The relevant parameter for protecting browser applications is minimum bandwidth. The relevant parameter for preventing non-critical browser applications from overwhelming the network is maximum bandwidth.

## File Server Applications

With some dependencies on the network operating system, file serving typically poses the greatest demand on bandwidth, although file server applications are very tolerant of latency, jitter, and some packet loss, depending on the network operating system and the use of TCP or UDP.

## Traffic Groups

---

A traffic group defines the ingress traffic to which you want to apply some level of *QoS*. You can use the ExtremeXOS software to define traffic groups based on the following:

- Frame or packet header information such as IP address or MAC address
- *CoS (Class of Service)* 802.1p bits in the frame header
- DiffServ information in a packet header
- Ingress port number
- *VLAN (Virtual LAN)* ID

Traffic groups that are defined based on frame or packet information are usually defined in Access Control Lists (ACLs). The exception to this rule is the CoS and DiffServ information, which you can use to define traffic groups without ACLs.

The function of the CoS and DiffServ traffic groups is sometimes referred to as explicit packet marking, and it uses information contained within a frame or packet to explicitly determine a class of service. An advantage of explicit packet marking is that the class of service information can be carried throughout the network infrastructure, without repeating what can be complex traffic group policies at each switch location. Another advantage is that end stations can perform their own packet marking on an application-specific basis. Extreme Networks switch products have the capability of observing and manipulating packet marking information with no performance penalty.

The CoS and DiffServ capabilities (on supported platforms) are not impacted by the switching or routing configuration of the switch. For example, 802.1p information can be preserved across a routed switch boundary and DiffServ code points can be observed or overwritten across a Layer 2 switch boundary.

During QoS configuration, you configure the QoS level first by configuring QoS profiles, traffic queues, and meters, and then you define a traffic group and assign the traffic group to the QoS configuration.

## ACL-Based Traffic Groups

An *ACL*-based traffic group allows you to use ACL rules in an ACL policy file to define the traffic to which you want to apply *QoS*. An ACL-based traffic group requires more effort to create, but the ACL rules give you more control over which traffic is selected for

the traffic group. For example, you can use an ACL to add traffic to a traffic group based on the following frame or packet components:

- MAC source or destination address
- Ethertype
- IP source or destination address
- IP protocol
- TCP flag
- TCP, UDP, or other Layer 4 protocol
- TCP or UDP port information
- IP fragmentation

Depending on the platform you are using, traffic in an ACL traffic group can be processed as follows:

- Assigned to an ingress meter for rate limiting
- Marked for an egress QoS profile for rate shaping
- Marked for an egress traffic queue for rate shaping
- Marked for DSCP replacement on egress
- Marked for 802.1p priority replacement on egress
- Assigned to an egress meter for rate limiting

When you are deciding whether to use an ACL-based traffic group or another type of traffic group, consider what QoS features you want to apply to the traffic group. Some QoS features can only apply to ACL-based traffic groups.

**Note**

ACLs are discussed in detail in the [ACLs](#) chapter.

## CoS 802.1p-Based Traffic Groups

CoS 802.1p-based traffic groups forward traffic to QoS features based on the three 802.1p priority bits in an Ethernet frame. The 802.1p priority bits are located between the 802.1Q type field and the 802.1Q VLAN ID as shown in [Figure 181](#).

Typically CoS will be used in conjunction with policy, however it may also work independently. In a policy-enabled system, policy may use any CoS index setting (0-255) to configure ACLs to assign a qosprofile, meter, dot1p replacement and TOS-rewrite value. By default, 802.1p priorities 0-7 are mapped to CoS indices 0-7.

**Figure 181: 802.1p Priority Bits**

The three 802.1p priority bits define up to eight traffic groups that are predefined in the ExtremeXOS software.

On SummitStack and ExtremeSwitching series switches, the traffic groups direct traffic to egress QoS profiles for egress rate shaping (see the following table).

You do not need to define 802.1p-based traffic groups. You can enable or disable the use of these traffic groups by enabling or disabling the 802.1p examination feature. You can also configure which 802.1p values map to which QoS profiles.

A related feature is the 802.1p replacement feature, which allows you to configure the software to replace the 802.1p bits in an ingress frame with a different value in the egress frame. For more information on 802.1p replacement, see [Configuring 802.1p or DSCP Replacement](#) on page 1438.

### DiffServ-Based Traffic Groups

DiffServ-based traffic groups forward traffic to egress *QoS* profiles based on the type-of-service (TOS) or traffic class (TC) information in an IP packet. In many systems, this TOS or TC information is replaced with a DiffServ field that uses six of the eight bits for a *DSCP (Differentiated Services Code Point)*, as shown in [Figure 182](#). (The other two bits are not used.)

**Figure 182: DiffServe Code Point**

Because the DSCP uses six bits, it has 64 possible values ( $2^6 = 64$ ). By default, the values are grouped and assigned to the default QoS profiles as listed in [Table 127](#).

**Table 127: Default DSCP-to-QoS-Profile Mapping**

| Traffic Group Code Point | SummitStack and ExtremeSwitching Switches QoS Profile |
|--------------------------|-------------------------------------------------------|
| 0-7                      | QP1                                                   |
| 8-15                     | QP1                                                   |
| 16-23                    | QP1                                                   |
| 24-31                    | QP1                                                   |
| 32-39                    | QP1                                                   |
| 40-47                    | QP1                                                   |
| 48-55                    | QP1                                                   |
| 56-63                    | QP8                                                   |

**Note**

The default DiffServ examination mappings apply on ports in more than one virtual router. If you attempt to configure DiffServ examination or replacement on a port that is in more than one virtual router, the system returns the following message:

Warning: Port belongs to more than one VR. Port properties related to diff serv and code replacement will not take effect.

You do not need to define these traffic groups. You can enable or disable the use of these traffic groups by enabling or disabling the DiffServ examination feature as

described in [Configuring a DiffServ-Based Traffic Group](#) on page 1444. You can also configure which DSCP values map to which queues.

**Note**

When DiffServ examination is enabled on 1 Gigabit Ethernet ports, 802.1p replacement is enabled and cannot be disabled. The ingress 802.1p value is replaced with the 802.1p value assigned to the egress QoS profile.

A related feature is the DiffServ replacement feature, which allows you to configure the software to replace the DSCP in an ingress frame with a different value in the egress frame. For more information on DiffServ replacement, see [Configuring 802.1p or DSCP Replacement](#) on page 1438.

## Port-Based Traffic Groups

Port-based traffic groups forward traffic to egress [QoS](#) profiles based on the incoming port number. There are no default port-based traffic groups; you must configure each port-based traffic group.

**Note**

Port-based traffic groups apply to all packets.

## VLAN-Based Traffic Groups

[VLAN](#)-based traffic groups forward traffic to egress [QoS](#) profiles based on the VLAN membership of the ingress port. There are no default VLAN-based traffic groups; you must configure each VLAN-based traffic group.

**Note**

VLAN-based traffic groups apply to all packets.

## Precedence of Traffic Groups

The ExtremeXOS software allows you to define multiple traffic groups, and you can configure traffic groups in such a way that multiple traffic groups apply to an ingress frame or packet. When an ingress frame or packet matches two or more traffic groups, the software chooses one traffic group based on the precedence defined for the switch platform. In general, the more specific traffic group definition takes precedence.

Table 128 on page 1423 shows the traffic group precedence for the supported switch platforms (number 1 is the highest precedence).

#### Note

Beginning in ExtremeXOS 16.1, the port, VLAN and DiffServ-based traffic groups will only work if 802.1p examination is disabled.

**Table 128: Traffic Group Precedence**

| SummitStack and ExtremeSwitching Switches                                                                                                                                                                                                                                                                                                                                                                    |

## Introduction to Rate Limiting, Rate Shaping, and Scheduling

The terms rate limiting and rate shaping are used throughout this chapter to describe QoS features. Some QoS features perform both rate limiting and rate shaping. Rate limiting is the process of restricting traffic to a peak rate (PR). Rate shaping is the process of reshaping traffic throughput to give preference to higher priority traffic or to buffer traffic until forwarding resources become available.

Both rate limiting and rate shaping allow you to take action on traffic that exceeds the configured limits. These actions include forwarding traffic, dropping traffic, and marking the excess traffic for possible drops later in the communication path. Software counters allow you to record traffic statistics such as total packets forwarded and total packets dropped.

### Single-Rate QoS

Single-rate QoS defines a single rate for traffic that is subject to QoS. Single-rate QoS is the most basic form of rate limiting and is well suited for constant rate traffic flows such as video or where more complex dual-rate QoS is not needed. The traffic that meets the rate requirement is considered in-profile. Traffic that does not meet the specified rate is considered out-of-profile. A two-color system is often used to describe or mark the single-rate QoS result. In-profile traffic is marked green, and out-of-profile traffic is marked red.

Single-rate rate-limiters pass traffic that is in-profile or marked green. Out-of-profile traffic (marked red) is subject to whatever action is configured for out-of-profile traffic. Out of profile traffic can be forwarded if bandwidth is available, dropped, or marked for a possible drop later in the communication path.

All traffic that arrives at or below the PR is considered in-profile and marked green. All traffic that arrives above the PR is considered out-of-profile and marked red. When the

traffic exceeds the capacity of the rate-limiting component, all traffic that is marked red is dropped.

Another type of single-rate QoS is used on SummitStack and ExtremeSwitching series switches. A committed information rate (CIR) establishes a reserved traffic rate, and a peak burst size (PBS) establishes a maximum size for a traffic stream. If a traffic stream is at or below the CIR and the PBS, it is considered to be within profile and marked green. If a traffic stream exceeds either the CIR or the PBS, it is considered out-of-profile and marked red. On these switches, you can configure the single-rate rate-limiting components to drop traffic marked red or set a drop precedence for that traffic. You can also specify a DSCP value to mark the out-of-profile traffic.

## Dual-rate QoS

Dual-rate QoS defines two rates for traffic that is subject to QoS. The lower of the two rates is the CIR, which establishes a reserved traffic rate. The higher of the two rates is the peak rate, which establishes an upper limit for traffic. Dual-rate QoS is well suited to bursty traffic patterns which are common with typical data traffic. Dual-rate QoS is widely used in legacy Frame Relay and ATM leased lines.

### Note

You must configure the peak rate higher than the committed rate.

A three-color system is used with dual-rate QoS. As with single-rate QoS, traffic at or below the CIR is considered in-profile, marked green, and forwarded. The traffic that is above the CIR and below the PIR is out-of-profile and marked yellow. Traffic above the PIR is also out-of-profile and marked red. When incoming traffic is already marked yellow and is out of profile, it is marked red. Different switch platforms take different actions on the traffic marked yellow or red.

## Rate Specification Options

The ExtremeXOS software allows you to specify the CIR and PR in gigabits per second (Gbps), megabits per second (Mbps), or kilobits per second (Kbps). Most commands also allow you to specify the CIR and PR as a percentage of the maximum port bandwidth using the **minbw** (CIR) and **maxbw** (PR) options. The default value on all minimum bandwidth parameters is 0%, and the default value on all maximum bandwidth parameters is 100%.

QoS can be applied at different locations in the traffic path using the following rate-limiting and rate-shaping components:

- Ingress meters
- Egress traffic queues
- Egress meters
- Egress QoS profiles
- Egress ports

The CIR or minimum bandwidth configuration for a rate-limiting or rate-shaping component is a bandwidth guarantee for that component at a particular location in the traffic path. The guarantees for all components at a specified location should add up to less than 100% and should account for the traffic needs of the other components. For example, if you configure 25% minimum bandwidth for four out of eight queues at a particular location, there will be no available bandwidth for the remaining four queues when traffic exceeds the port capacity. Bandwidth unused by a queue can be used by other queues.

The rate-shaping configuration is configured at the location to which it applies on most platforms.

## Disabling Rate Limiting and Rate Shaping

All switch platforms provide multiple [QoS](#) components in the traffic path that provide rate limiting or rate shaping. These components give you control over where and how the rate shaping is applied. However, your application might not require rate shaping at every component. The default configuration for most components provides no rate shaping. When rate shaping is disabled on a component, the CIR is set to 0 (minbw=0%) and the PR is set to the maximum bandwidth (maxbw=100%). This setting reserves no bandwidth for the component and allows the component to use 100% of the port bandwidth. If you need to remove rate shaping from a QoS component, configure these settings on that component.

## Scheduling

Scheduling is the process that determines which traffic is forwarded when multiple [QoS](#) components are competing for egress bandwidth. The ExtremeXOS software supports the following scheduling methods:

- **Strict priority:** All higher priority queues are serviced before lower priority queues. This ensures that high priority traffic receives access to available network bandwidth immediately, but can result in lower priority traffic being starved. As long as a queued packet remains in a higher-priority queue, any lower-priority queues are not serviced.
- **Weighted round robin:** All queues are given access to a relative amount of bandwidth based on the weight assigned to the queue. When you configure a QoS profile with a weight of 4, that queue is serviced four times as frequently as a queue with a weight of 1. The hardware services higher-weighted queues more frequently, but lower-weighted queues continue to be serviced at all times. Initially, the weight for all queues is set to 1, which gives them equal weight. If all queues are set to 4, for example, all queues still have equal weight, but each queue is serviced for a longer period.
- **Weighted deficit round robin:** All queues are given access based on the configured priority level and a round-robin algorithm.

Scheduling takes place on the egress interface and includes consideration for the color-marking of egress frames and packets. Green-marked traffic has the highest priority and is forwarded based on the scheduling method. When multiple queues are

competing for bandwidth, yellow-marked traffic might be dropped or remarked red. Red-marked traffic is dropped when no bandwidth is available. If yellow-marked traffic is forwarded to the egress port rate-shaping component, it can be dropped there if the egress port is congested.

## Introduction to WRED

---

The weighted random early detection (WRED) feature is supported on some platforms to avoid congestion in traffic queues or [QoS](#) profiles. WRED improves upon the TCP congestion control mechanism.

The TCP congestion control mechanism on hosts detects congestion when packets are lost and lowers the packet transmission rate in response. At the switch, packets are dropped when a queue is full. When multiple hosts forward packets that are dropped, multiple hosts reduce the transmission rate. This creates a global synchronization problem as multiple hosts overwhelm a queue and then simultaneously lower their transmission rate and under utilize the queue.

WRED is an extension to random early detection (RED), which calculates an average queue size and randomly discards packets in proportion to the queue usage. At low usage levels, no packets are discarded. As the average queue size exceeds configured thresholds, packets are discarded in proportion to the queue usage. Discarding packets early causes some (but not all) hosts to reduce their transmission rate, which reduces queue congestion. The random nature of the discard process reduces the global synchronization problem.

WRED extends RED by applying different discard rules for different types of traffic. Typically, WRED is used on core routers and takes action based on the packet contents established at edge routers. Edge routers can use the IP precedence or DSCP value to mark packets as committed (green), conforming (yellow), or exceeded (red). The marking process and these colors are described in [Introduction to Rate Limiting, Rate Shaping, and Scheduling](#) on page 1423.

The ExtremeXOS WRED implementation varies per platform and allows you to configure the following:

- Minimum threshold for dropped packets.
- Maximum threshold for dropped packets.
- Maximum drop rate.
- An average weight control that determines how WRED calculates the average queue size.

WRED does not drop packets at calculated average queue sizes below the minimum threshold (although packets would be dropped if the queue fills).

When the calculated average queue size rises above the maximum threshold, WRED drops packets at the maximum drop rate. When the calculated average falls between the minimum and maximum thresholds, packets are randomly dropped at a proportional rate between zero and the maximum drop rate. As the queue fills, more packets are dropped.

The average weight parameter provides some control over how the average queue size is calculated and the probability of packet drop. Increasing the `avg_weight` value reduces the probability that traffic is dropped. Conversely, decreasing the `avg_weight` value increases the probability that traffic is dropped.

On ExtremeSwitching Universal switches, you can configure up to four WRED profiles or configurations per QoS profile, enabling you to create custom WRED configurations for up to 32 traffic flows (4 WRED profiles x 8 QoS profiles).

Each QoS profile supports WRED profiles for the following colors of traffic:

- TCP green
- Non-TCP green
- TCP red
- Non-TCP red

Without support for non-TCP traffic management, non-TCP traffic could monopolize a QoS profile in which TCP traffic is regulated, effectively giving non-TCP traffic priority over TCP traffic. With support for both TCP and non-TCP traffic, WRED allows you to regulate different types of traffic independently, giving you greater control over which type of traffic is dropped first and most frequently.

The typical WRED configuration establishes the lowest probability for packet drop for green traffic, which conforms to established limits along the transmission path. A typical WRED configuration establishes a higher probability for packet drop for red colored traffic, because it has already exceeded established limits earlier in the transmission path. All traffic (green and red) is dropped when the queue is full, so the goal is to configure the WRED settings for each color in such a way as to prevent the queue from filling frequently.

## Explicit Congestion Notification (ECN)

Weighted Random Early Detection (WRED) drops packets based on the average length exceeding a specific threshold value to indicate congestion. Explicit Congestion Notification (ECN) is an extension to WRED that marks the drop-eligible packets, instead of dropping, using the same criteria of minimum threshold, maximum threshold, and drop probability. [Figure 183](#) shows the WRED behavior without ECN and with ECN.

**Figure 183: WRED Behavior with and without ECN**

The current WRED implementation prevents tail dropping of packets that are queued in the output queue by selectively dropping packets early. This avoids dropping of all packets at once when congestion occurs. With ECN functionality, routers are no longer limited to packet drops to indicate congestion. Routers can instead set the CE (Congestion Experienced) codepoint in the IP header of packets from ECN-capable transport entities. The transport endpoints use the ECE and CWR bits of the TCP header to mitigate congestion.

*RFC 3168* states that the two-bit ECN field comprises an ECT bit and a CE bit that are used to implement ECN. The ECT bit and the CE bit can be combined into four possible ECN field values 00 to 11. The first number is ECT bit and the second number is the CE bit. [Table 129](#) shows the possible combination.

**Table 129: ENC Field Values**

| ECT Bit Value | CE Bit Value | Combined Inference                                                                                                                                    |
|---------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0             | 0            | Not ECN capable.<br>Packet is not using ECN.                                                                                                          |
| 0             | 1            | Endpoints are ECN capable.<br>Data senders use these values to indicate that the endpoints are ECN capable. Routers treat the two values identically. |
| 1             | 0            |                                                                                                                                                       |
| 1             | 1            | Congestion experienced.                                                                                                                               |

Table 130 indicates the processing applied on incoming packets that are identified as drop-eligible in various ECN scenarios.

**Table 130: ECN Processing**

| Incoming ECN Bits | ECN Configuration | Action if Packet Is Drop-Eligible                 | Outgoing ECN bits                      |
|-------------------|-------------------|---------------------------------------------------|----------------------------------------|
| 00 (Non-ECT)      | On/Off            | Drop.                                             | N/A (packet dropped).                  |
| ECT (01 or 10)    | Off               | Drop.                                             | N/A (packet dropped).                  |
| ECT (01 or 10)    | On                | Not dropped. CE bit is marked.                    | 11 indicates "Congestion Experienced". |
| CE (11)           | Off               | Drop.                                             | N/A (packet dropped).                  |
| CE (11)           | On                | Not dropped. Packet already marked, just forward. | 11 indicates "Congestion Experienced". |

To configure ECN capability as on or off, use the following command:

```
configure qosprofile egress qp_num wred ecn [on | off] ports [port_list | all]
```

To view ECN information, use the following commands:

```
show wredprofile {ports [port_list | all]}
```

```
show ports port_list wred ecn {no-refresh | refresh}
```

To clear the ECN counters, use the following commands:

```
clear counters wred ecn
```

### *Supported Platforms*

This feature is available on all ExtremeSwitching Universal switches.

### *Limitations*

- TCP yellow traffic color is not supported.
- ECN over VXLAN is not supported. Any tunneling protocol implemented with double headers is not supported.
- The ECN counters showing the number of marked packets is not available yet, so those appear as 0.
- This implementation is limited to ECN pass-through. End points having TCP/DCTCP/RoCEv2 capabilities can use the ECN services.

## Meters

---

Meters are used to define ingress rate-limiting and rate-shaping. Some platforms also support meters for egress traffic. The following sections provide information on meters for specific platforms.

The SummitStack and standalone switches use a single-rate meter to determine if ingress traffic is in-profile or out-of-profile.

On all ExtremeSwitching switches, you can also use single-rate meters to determine if egress traffic is in-profile or out-of-profile.

When [ACL](#) meters are applied to a [VLAN](#) or to any, the rate limit is applied to each port group. To determine which ports are contained within a port group, use any of the following commands:

```
show access-list usage acl-range port port
```

```
show access-list usage acl-rule port port
```

```
show access-list usage acl-slice port port
```

The out-of-profile actions are drop, set the drop precedence, mark the dot1p, or mark the DSCP with configured value. Additionally, each meter has an associated out-of-profile counter that counts the number of packets that were above the committed-rate (and subject to the out-of-profile-action).

Prior to ExtremeXOS 21.1, when traffic exceeded the specified meter rate, the traffic could be marked with a user-specified diffserv code point. As of ExtremeXOS 21.1, this out-of-profile marking capability is enhanced to additionally include the option of marking the 802.1p value. The 802.1p value that is marked will be the outer 802.1p value in both VLAN and VMAN tagging scenarios. In the latter, the SVLAN's 802.1p value will be modified. Like the existing dscp out-of-profile meter action, this out-of-profile action will work on global and per-port meters.

On ExtremeSwitching series switches, the meters are a per-chip, per-slice resource (see [ACLs](#) for complete information.)

**Note**

If set-drop-precedence is used as a meter out-of-profile action, you should configure WRED on the egress port so that red packets marked by the meter are dropped in case of egress congestion.

## QoS Profiles

---

[QoS](#) profiles are queues that provide ingress or egress rate limiting and rate shaping. The following sections provide more information on QoS profiles.

## Egress QoS Profiles

Egress [QoS](#) profiles are supported on all ExtremeXOS switches and allow you to provide dual-rate egress rate-shaping for all traffic groups on all egress ports. Any configuration you apply to an egress QoS profile is applied to the same egress QoS profile on all other ports, unless a QoS profile parameter has been overridden for a port.

When you are configuring [ACL](#)-based traffic groups, you can use the qosprofile action modifier to select an egress QoS profile. For DiffServ-, port-, and [VLAN](#)-based traffic groups, the traffic group configuration selects the egress QoS profile. For [CoS](#) dot1p traffic groups on all platforms, the dot1p value selects the egress QoS profile.

Egress QoS profile operation depends on the switch type and is described in the following sections.

SummitStack and ExtremeSwitching series switches have two default egress QoS profiles named QP1 and QP8. You can configure up to six additional QoS profiles (QP2 through QP7) on the switch. However, on a SummitStack, you cannot create QoS profile QP7, as this profile is reserved for system control traffic. The default settings for egress QoS profiles are summarized [Table 131](#) on page 1431.

**Table 131: Default QoS Profile Parameters on all Platforms**

| Ingress 802.1p Priority Value | Egress QoS Profile Name | Queue Service Priority Value | Buffer | Weight | Notes                                                                                                |
|-------------------------------|-------------------------|------------------------------|--------|--------|------------------------------------------------------------------------------------------------------|
| 0-6                           | QP1                     | 1 (Low)                      | 100%   | 1      | This QoS profile is part of the default configuration and cannot be deleted.                         |
|                               | QP2                     | 2 (LowHi)                    | 100%   | 1      | You must create this QoS profile before using it.                                                    |
|                               | QP3                     | 3 (Normal)                   | 100%   | 1      | You must create this QoS profile before using it.                                                    |
|                               | QP4                     | 4 (NormalHi)                 | 100%   | 1      | You must create this QoS profile before using it.                                                    |
|                               | QP5                     | 5 (Medium)                   | 100%   | 1      | You must create this QoS profile before using it.                                                    |
|                               | QP6                     | 6 (MediumHi)                 | 100%   | 1      | You must create this QoS profile before using it.                                                    |
|                               | QP7                     | 7 (High)                     | 100%   | 1      | You must create this QoS profile before using it. You cannot create this QoS profile on SummitStack. |
| 7                             | QP8                     | 8 (HighHi)                   | 100%   | 1      | This QoS profile is part of the default configuration and cannot be deleted.                         |

<sup>9</sup> The QoS Profile Name cannot be changed.

<sup>10</sup> The Queue Service Priority value cannot be changed.

For CoS 802.1p traffic groups, the ingress 802.1p priority value selects a specific QoS profile as shown in [Table 131](#). This mapping can be changed as described in [Changing the 802.1p Priority to QoS Profile Mapping](#) on page 1444. For traffic groups other than 802.1p-based groups, the traffic group configuration selects a specific egress QoS profile by name.

The default dual-rate QoS configuration is 0% for minimum bandwidth and 100% for maximum bandwidth.

The QoS profile for each port receives a default buffer reservation. All unreserved buffer space is part of a buffer pool, which can be used by QoS profiles when reserved space runs out, provided that the configuration for that QoS profile and port allows it.

You can increase the size of the shared buffer pool by reducing the global buffer reservation for a QoS profile on all switch ports. You can restrict buffer usage for a QoS profile in amounts ranging from 1 to 100%, in whole integers.

You can also override the global buffer reservation to increase or decrease the buffer space allotment for a specific QoS profile on one or more ports. Using the buffer override feature, you can override the global setting to use from 1–10,000% of the configured global allotment. The system does not drop any packets as long as reserved packet buffer memory for the port and QoS profile or shared packet memory for the port (`configure port port_list shared-packet-buffer` command) remains available.

#### Note

In a SummitStack, the scheduling algorithm is automatically programmed by ExtremeXOS for the stacking links only, and might be different from the algorithm you select.

Use of all eight queues on all ports can result in insufficient buffering to sustain zero packet loss throughput during full-mesh connectivity with large packets.

When multiple QoS profiles are contending for port bandwidth and the egress traffic in each profile is within profile, the scheduler determines how the QoS profiles are serviced as described in [Scheduling](#) on page 1425. In strict-priority mode, the queues are serviced based on the queue service priority value. In weighted fair-queuing mode, the queues are serviced based on the configured weight.

When configured to do so, the priority of a QoS profile can determine the 802.1p bits used in the priority field of a forwarded frame (see [Introduction to Rate Limiting, Rate Shaping, and Scheduling](#) on page 1423). The priority of a QoS profile can determine the DiffServ code point value used in an IP packet when the packet is forwarded (see [Replacement of DSCP on Egress](#) on page 1439).

A QoS profile change does not alter the behavior of the switch until it is assigned to a traffic group.

## Egress Port Rate Limiting and Rate Shaping

Egress port rate limiting and rate shaping allow you to define limits for all egress traffic coming from the egress [QoS](#) profiles and traffic queues.

You can apply single-rate rate-limiting and control shared packet buffer space (configure port `port_list` **shared-packet-buffer** command) for each port.

You can also configure ports to pass an unlimited flow as described in [Disabling Rate Limiting and Rate Shaping](#) on page 1425.

## Configuring Overhead-Bytes in Calculating Rate-Limiting and Rate-Shaping

You can configure the size of overhead-bytes used in the calculation of rate-limiting and rate-shaping. Overhead-bytes include size of preamble and inter-frame gap. In releases earlier than 21.1, ExtremeXOS included these overhead-bytes during traffic rate-limit and shaping techniques. Now, you can configure overhead-bytes using the `configure forwarding rate-limit overhead-bytes <bytes>` command.

For example, if the frame size is 68 bytes configuring overhead-bytes of 0, the switch calculates rate-limit and shaping techniques with 68 bytes as the frame size. If 20 is the configured overhead-bytes size, the switch calculates rate-limit and shaping techniques with 88 bytes as the frame size. This configuration is applicable for ingress meters, egress [QoS](#) profile, egress port rate-limiting, and rate-shaping configurations.

## Class of Service (CoS)

[CoS](#) provides a means to configure 802.1p-based traffic grouping, [QoS](#) rate-shaping and scheduling, ingress and egress metering and flood rate-limiting via [SNMP \(Simple Network Management Protocol\)](#). The CoS MIB is fully integrated with ONEPolicy to provide a solution to management entities.

## Class of Service (CoS) Settings

Each of the 256 [CoS](#) entries, indexed 0-255, are mapped to a 802.1p priority (0-7), ToS value (0-255), virtual txq-reference (0-15) and virtual irl-reference (0-31). A virtual reference is used to abstract the hardware capabilities from the CoS row. This allows for the management entity to create user CoS profiles based on the user and not multiple user profiles for each hardware platform. The virtual references are then mapped to actual hardware resources. On ExtremeXOS, the txq-reference mappings 0-7 are fixed to [QoS](#) profiles 1-8 and txq-reference 8-15 map to QoS profile 8. The irl-reference mappings are also fixed to the per-port ingress meters. This mapping is dependent on the number of per-port ingress meters supported on the platform. CoS entries 0-7 are equivalent to the dot1p traffic groupings for priorities 0-7.

## Port Groups

Port groups allow you to define ports by similar functionality or role. You can create port groups and use them to configure QoS profiles, ingress meters and flood rate-limiters for ports that share the same role. QoS commands that use port groups are updated

automatically if the ports group is removed or if ports are added or removed from the group.

In addition, ExtremeCloud IQ Site Engine can create and manipulate port groups through the CoS MIB using SNMP. These groups are used to configure the ExtremeCloud IQ Site Engine-specified CoS resources that are mapped to QoS profiles, ingress meters, and flood rate-limiters. Since the ExtremeCloud IQ Site Engine CoS feature is port group-oriented, ExtremeXOS QoS entities (QoS profiles, ingress meter, and flood rate-limiting) that are configured on a per-port basis are not exposed through the CoS MIB using SNMP.

To create port groups, use the following command:

```
create ports group port_group
```

To delete port groups, use the following command:

```
delete ports group port_group
```

To add/delete ports from a port group, use the following command:

```
configure ports {group} port_group [[add | delete] port_list]
```

To show port group information, use the following command:

```
show ports group {port_group}
```

## CoS Port Resource

The TXQ, IRL and Flood Control port resource tables in *CoS* are configured using the *QoS* profile, ingress meter and rate-limit flood resource commands in the CLI. These port resources are mapped to CoS when the resources in the CLI are configured using a port group.

## CoS Global Enable Action

An *SNMP* set to enable *CoS* will automatically enable per-port dot1p examination and diffserv replacement controls as needed for the functionality of CoS. Diffserv replacement is enabled for a *QoS* profile on all ports if the corresponding tosValue for CoS index 0-7 is configured. Otherwise, diffserv replacement is disabled for the corresponding QoS profile on all ports. Dot1p replacement is disabled for all QoS profiles on all ports. In addition, all QoS profiles are created and the dot1p examination to QoS profile mapping are fixed to match the TXQ reference mapping for CoS indexes 0-7. The internal CoS state is used to warn the user in the CLI in the event that the controls setup by CoS are modified. A subsequent SNMP set to disable CoS disables the internal CoS state. This turns off the warning messages in the CLI; however, it does not restore the configuration to its original state before the global enable action occurred.

When the internal CoS state is enabled, the global enable action is performed on any new switch that is inserted into the stack.

## Meter and Flood Actions

ExtremeXOS 16.1 has been expanded to implement the syslog, trap, and disable-port out-actions for meters and flood rate-limiters. This requires additional counters and a polling task to periodically check the thresholds for the configured events.

## Meter and Flood Limitations

### *Port-Meter Out-of-profile Limitations*

The CoS MIB supports an out-of-profile status and counter for each per-port meter on each port. On all 16.1 supported platforms, the hardware only supports a global counter for each per-port meter. The out-of-profile status is supported for each per-port meter on each port; however, the status is only valid while the meter is out-of-profile. When the per-port meter rate is no longer exceeded, the out-of-profile status is automatically cleared in the hardware. The ability to detect an out-of-profile per-port meter on a given port is dependent on the out-of-profile status of the per-port meter at the time of the software polling interval.

Due to this limitation, the out-of-profile actions can only accurately be performed if the exceeded per-port meter rate is sustained for the duration of the software polling interval. Any change in the global out-of-profile counter for the per-port meter will be evenly distributed between the ports that indicate an out-of-profile status at the time of the software polling interval. This should give a rough approximation of the out-of-profile count of the per-port meter on each port.

### *Flood Out-of-profile Limitations*

The CoS MIB supports an out-of-profile status and counter on each port for each flood type (unknown unicast, multicast, and broadcast). On all ExtremeXOS 16.1 supported platforms, the hardware only supports a single counter and status per port for all flood types. Any out-of-profile actions configured for one flood type on a given port will be performed if any flood type is out-of-profile on that port. The out-of-profile counter will be the aggregate count of all flood types on a given port.

## Configuring QoS

---

### Configuring QoS on SummitStack and ExtremeSwitching Switches

[Figure 184](#) shows the QoS configuration components for SummitStack and ExtremeSwitching switches.

**Figure 184: QoS on SummitStack and ExtremeSwitching Switches**

The considerations below apply to QoS on SummitStack and ExtremeSwitching switches:

- The following QoS features share resources:
  - ACLs
  - dot1p
  - VLAN-based QoS
  - Port-based QoS
- You might receive an error message when configuring a QoS feature in the above list; it is possible that the shared resource is depleted. In this case, unconfigure one of the other QoS features and reconfigure the one you are working on.
- On a SummitStack, you cannot create QoS profile QP7. This QoS profile is reserved for system control traffic.
- These switches allow dynamic creation and deletion of QoS queues, with QP1 and QP8 always available.
- ACL egress rate-limit meters are supported only on all platforms.

### Configuration Summary

Use the following procedure to configure QoS:

1. Configure basic Layer 2 connectivity (prerequisite).

2. Configure QoS scheduling, if needed, as described in [Selecting the QoS Scheduling Method](#) on page 1438.
3. Configure ingress and egress rate-limiting as needed:
  - a. Create a meter as described in [Creating Meters](#) on page 1446.
  - b. Configure the meter as described in [Configuring a Meter](#) on page 1446.
  - c. Apply the meter to ingress traffic as described in [Applying a Meter to Ingress Traffic](#) on page 1447.
4. Configure non-[ACL](#)-based egress QoS profile selection as described in the following sections:
  - [Configuring a CoS 802.1p-Based Traffic Group](#) on page 1443
  - [Configuring a DiffServ-Based Traffic Group](#) on page 1444
  - [Configuring a Port-Based Traffic Group](#) on page 1445
  - [Configuring a VLAN-Based Traffic Group](#) on page 1446
5. Configure 802.1p or DiffServ packet marking as described in [Configuring 802.1p or DSCP Replacement](#) on page 1438.
6. Configure egress QoS profile rate shaping as needed:
  - a. Create egress QoS profiles as described in [Creating or Deleting an Egress QoS Profile](#) on page 1441.
  - b. Configure egress QoS profile rate shaping parameters as described in [Configuring an Egress QoS Profile](#) on page 1441.
7. Configure egress port rate shaping as described in [Configuring Egress Port Rate Limits](#) on page 1442.
8. Finalize ACL traffic-based group configuration as described in [Configuring an ACL-Based Traffic Group](#) on page 1443.
9. Verify the configuration using the commands described in [Displaying QoS Configuration and Performance](#) on page 1448.

## **NEW** Quality of Service Port Speed Calculation

Version 33.3.1 adds an enhancement to the Quality of Service (QoS) profile that lets you use the "minbw" and "maxbw" settings to calculate the bandwidth based on the actual port speed and not on the maximum port speed.

### *Supported Platforms*

All platforms.

### *Modified CLI Commands*

The `configure qosprofile` command adds the **minbw\_actual** *minbw\_actnum* and **maxbw\_actual** *maxbw\_actnum* options.

The `show configuration`, `show port information`, and `show qosprofile` commands add **minbw\_actual** and **maxbw\_actual** information.

## Selecting the QoS Scheduling Method

QoS scheduling determines the order of QoS profile service and varies between platforms. SummitStack and ExtremeSwitching series switches support three scheduling methods: strict-priority, weighted-round-robin, and weighted-deficit-round-robin. These scheduling methods are described in [Scheduling](#) on page 1425. Scheduling can be applied globally or on a per-port or per-PortGroup basis. If no port\_list or port\_group is specified in the command, the global scheduling algorithm is set and applied to ports that are not configured via a port\_list or port\_group. Specifying a port\_list or port\_group in the command configures the scheduling algorithm for specific ports.

QoS profiles can also be overridden on a global, per-port or per-port\_group basis. If no port\_list or port\_group is specified, the global qosprofile configuration is changed and applied to all ports that are not configured on a per-port or per-port\_group basis.

1. Select the QoS scheduling method for a switch.

```
configure qosscheduler [strict-priority | weighted-round-robin | weighted-deficit-round-robin] {ports [port_list | port_group | all] }
```

### Note

In a SummitStack, the scheduling algorithm is automatically programmed by ExtremeXOS for the stacking links only, and will likely be different than the algorithm you select.

2. Override the weighted-round-robin switch configuration on a specific QoS profile.

```
configure qosprofile qosprofile use-strict-priority
```

## Configuring 802.1p or DSCP Replacement

### *Replacement of 802.1p Priority Information on Egress*

By default, 802.1p priority information is not replaced or manipulated, and the information observed on ingress is preserved when forwarding the frame. This behavior is not affected by the switching or routing configuration of the switch. However, the switch is capable of inserting and/or overwriting 802.1p priority information when it transmits an 802.1Q tagged frame as described below.

### Replacement in ACL-Based Traffic Groups

If you are using ACL-based traffic groups, you can use the `replace-dot1p` action modifier to replace the ingress 802.1p priority value with the 802.1p priority value of the egress QoS profile as listed in the following table. To specify a specific 802.1p priority value on egress, use the `replace-dot1p-value` action modifier.

### Note

If you are using ACL-based traffic groups, you must use ACL action modifiers to replace the 802.1p priority. Traffic that meets any ACL match conditions is not subject to non-ACL-based 802.1p priority replacement.

### Replacement in Non-ACL-Based Traffic Groups

For non-ACL-based traffic groups, you can enable or disable 802.1p priority replacement on specific ingress ports. When 802.1p priority replacement is enabled, the default egress 802.1p priority value is set to the priority value of the egress QoS profile as listed in [Table 132](#).

**Table 132: Default Queue-to-802.1p Priority Replacement Value**

| Egress QoS Profile | 802.1p Priority Replacement Value |
|--------------------|-----------------------------------|
| QP1                | 0                                 |
| QP2                | 1                                 |
| QP3                | 2                                 |
| QP4                | 3                                 |
| QP5                | 4                                 |
| QP6                | 5                                 |
| QP7                | 6                                 |
| QP8                | 7                                 |

To enable 802.1p priority replacement on egress, use the following command:

```
enable dot1p replacement ports [port_list | all]
```

#### Note

The port in this command is the ingress port.

To disable this feature, use the following command:

```
disable dot1p replacement ports [port_list | all]
```

#### Note

If only DiffServ traffic groups are enabled, then 802.1p priority enforcement for 802.1q tagged packets continues for non-IP packets using the default 802.1p map shown in the following table.

Only QP1 and QP8 exist by default; you must create QP2 to QP7 (QP2 to QP5 in a SummitStack). If you have not created these QPs, the replacement feature will not take effect.

When DiffServ examination is enabled on 1 Gigabit Ethernet ports, 802.1p replacement is enabled and cannot be disabled. The ingress 802.1p value is replaced with the 802.1p value assigned to the egress QoS profile.

### Replacement of DSCP on Egress

The switch can be configured to change the DSCP in a packet before forwarding the packet. This is done with no impact on switch performance and can be configured as described in the following sections:

<sup>11</sup> You cannot direct traffic to this QoS profile in a SummitStack.

### Replacement in ACL-Based Traffic Groups

If you are using ACL-based traffic groups, you can use the `replace-dscp` action modifier to replace the ingress DSCP value with the DSCP value of the egress QoS profile as listed in [Table 133](#). This action modifier functions for both IPv4 and IPv6 traffic.

#### Note

If you are using ACL-based traffic groups, you must use ACL action modifiers to replace the DSCP. Traffic that meets any ACL match conditions is not subject to non-ACL-based DSCP priority replacement. For all platforms, we recommend that you use ACL-based traffic groups when configuring DSCP replacement.

### Replacement in Non-ACL-Based Traffic Groups

For non-ACL-based traffic groups, you can enable or disable DSCP replacement on specific ingress ports. When DSCP replacement is enabled, the DSCP value used on egress is determined by either the QoS profile or the 802.1p priority value. [Table 133](#) shows the default mappings of QoS profiles and 802.1p priority values to DSCPs.

**Table 133: Default QoS Profile and 802.1p Priority Value Mapping to DiffServ Code Points**

| QoS Profile | 802.1p Priority Value | DSCP |
|-------------|-----------------------|------|
| QP1         | 0                     | 0    |
|             | 1                     | 8    |
|             | 2                     | 16   |
|             | 3                     | 24   |
|             | 4                     | 32   |
|             | 5                     | 40   |
|             | 6                     | 48   |
| QP8         | 7                     | 56   |

### Replacing a DSCP on Egress

- To replace DSCPs by enabling DiffServ replacement, use the command:  

```
enable diffserv replacement ports [port_list | all]
```

#### Note

The port in this command is the ingress port.

- To disable this feature, use the command:  

```
disable diffserv replacement ports [port_list | all]
```
- To view the current DiffServ replacement configuration, use the command:  

```
show diffserv replacement
```
- To change the DSCP mapping, use the commands:  

```
configure diffserv replacement [{qosprofile} qosprofile | priority
priority] code-point code_point
unconfigure diffserv replacement
```

### DiffServ Example

In this example, we use DiffServ to signal a class of service throughput and assign any traffic coming from network 10.1.2.x with a specific DSCP. This allows all other network switches to send and observe the DSCP instead of repeating the same [QoS](#) configuration on every network switch.

To configure the switch:

1. Using ACLs, assign a traffic grouping for traffic from network 10.1.2.x to QP3:

```
configure access-list qp3sub any
```

The following is a sample policy file example:

```
#filename: qp3sub.pol
entry QP3-subnet {
 if {
 source-address 10.1.2.0/24
 } then {
 qosprofile qp3;
 replace-dscp;
 }
}
```

2. Configure the switch so that other switches can signal calls of service that this switch should observe.

```
enable diffserv examination ports all
```

#### Note

The switch only observes the DSCPs if the traffic does not match the configured access list. Otherwise, the [ACL](#) QoS setting overrides the QoS DiffServ configuration.

## Configuring Egress QoS Profile Rate Shaping

### Creating or Deleting an Egress QoS Profile

The default configuration for most platforms defines eight egress [QoS](#) profiles. The default configuration defines two egress QoS profiles.

- Use the following command to create an additional egress QoS profile:

```
create qosprofile [QP2 | QP3 | QP4 | QP5 | QP6 | QP7]
```

- Use the following command to delete an egress QoS profile:

```
delete qosprofile [QP2 | QP3 | QP4 | QP5 | QP6 | QP7]
```

### Configuring an Egress QoS Profile

- Egress [QoS](#) profile rate shaping is disabled by default on all ports. On all platforms, use the following commands to configure egress QoS profile rate shaping on one or more ports:

```
configure qosprofile egress qosprofile [{minbw minbw_number} {maxbw maxbw_number} | {peak_rate peak_bps [K | M]}] [ports [port_list | all]]
```

```
configure qosprofile qosprofile [{minbw minbw_number} {maxbw
maxbw_number} | [{committed_rate committed_bps [K | M]} {peak_rate
peak_bps [K | M]} | [ports [port_list | all]]]
configure {qosprofile} qosprofile [{maxbuffer buffer_percentage}
{use-strict-priority}] | [maxbuffer buffer_percentage ports [port_list
| all]]]
```

#### Note

You must use these commands on all platforms if you want to configure the buffer size or weight value. Otherwise, you can use the command in the following description.

You cannot configure the priority for the QoS profile.

- To remove the limit on egress bandwidth per QoS profile per port, re-issue this command using the default values.
- To display the current configuration for the QoS profile, use the following command.  
show qosprofile [ all | port\_list | port\_group]

### Configuring WRED on an Egress QoS Profile

- To configure or unconfigure WRED on an egress *QoS* profile, use the following commands:  
configure {qosprofile} {egress} qosprofile [wred [{color [tcp [green | red] | non-tcp [any|red]] [{min-threshold min\_thresh} {max-threshold } {max-drop-rate max\_drop\_rate}]] | avg-weight avg\_weight]] ports [port\_list | all]  
unconfigure qosprofile wred {ports [port\_list | all]}
- To display the WRED configuration settings, use the following command:  
show wredprofile {ports [port\_list | all]}

## Configuring Egress Port Rate Limits

### Configuring Egress Traffic

- The default behavior is to have no limit on the egress traffic per port. To configure egress rate limiting, use the following command:  
configure ports [port\_list | port\_group] rate-limit egress [no-limit | cir-rate [Kbps | Mbps | Gbps] {max-burst-size burst-size [Kb | Mb]}]
- To view the configured egress port rate-limiting behavior, use the following command.  
show port {mgmt | port\_list | tag tag} information {detail}

You must use the *detail* parameter to display the egress port rate configuration and, if configured, the maximum burst size. Refer to [Displaying Port Information](#) on page 315 for more information on the `show ports information` command.

You can also display this information using the following command:

```
show configuration vlan
```

The following is sample output from the show configuration vlan command for configured egress rate limiting:

```
Module vlan configuration.
#
configure vlan Default tag 1
config port 3:1 rate-limit egress 128 Kbps max-burst-size 200 Kb
config port 3:2 rate-limit egress 128 Kbps
config port 3:10 rate-limit egress 73 Kbps max-burst-size 128 Kb
configure vlan Default add ports 3:1-48 untagged
```

**Note**

Refer to [FDB](#) for more information on limiting broadcast, multicast, or unknown MAC traffic ingressing the port.

## Configuring Traffic Groups

### Configuring an ACL-Based Traffic Group

[ACL](#)-based traffic groups are introduced in [ACL-Based Traffic Groups](#) on page 1418. An ACL can implement multiple [QoS](#) features, so it is usually best to finalize the ACL after all other features have been configured.

To configure an ACL-based traffic group, do the following:

1. Create an ACL policy file and add rules to the file using the following guidelines:
  - a. Use ACL match conditions to identify the traffic for the traffic group.
  - b. Use ACL action modifiers to apply QoS features such as ingress meter or traffic queue selection, egress QoS profile or traffic queue selection, and 802.1p priority replacement to the traffic group.
2. Apply the ACL policy file to the ports where you want to define the traffic groups. You can apply the file to specific ports, all ports, or all ports in a [VLAN](#).

**Note**

ACLs are described in detail in the [ACLs](#) chapter.

### Configuring a CoS 802.1p-Based Traffic Group

As described in [CoS 802.1p-Based Traffic Groups](#) on page 1419, the default switch configuration defines [CoS](#) 802.1p-based traffic groups. The configuration options for these groups are described in the following sections:

- [Enabling and Disabling 802.1p Examination](#) on page 1444
- [Changing the 802.1p Priority to QoS Profile Mapping](#) on page 1444

**Note**

If you are using [ACL](#)-based traffic groups, use the `qosprofile` or `traffic-queue` action modifier to select a forwarding queue. Traffic that meets any ACL match conditions is not evaluated by other traffic groups.

## Enabling and Disabling 802.1p Examination

CoS 802.1p examination is supported on all platforms and enabled by default. However, you can only disable and enable this feature. To free ACL resources, disable this feature whenever another QoS traffic grouping is configured. (See [ACLs](#) for information on available ACL resources.)

### Note

If you disable this feature when no other QoS traffic grouping is in effect, 802.1p priority enforcement of 802.1q tagged packets continues. If only DiffServ traffic groups are enabled, then 802.1p priority enforcement for 802.1q tagged packets continues for non-IP packets using the default 802.1p map shown in the following table.

- To disable the 802.1p examination feature, use the following command.

```
disable dot1p examination ports [port_list | all]
```

### Note

802.1p examination cannot be disabled for 802.1p priority level 6 in a SummitStack. When 802.1p examination is disabled on a SummitStack, the precedence for the remaining examination becomes lower than that of all other traffic groupings.

- To re-enable the 802.1p examination feature, use the following command:
- To display whether the 802.1p examination feature is enabled or disabled, use the following command:

```
enable dot1p examination ports [port_list | all]
```

```
show ports {mgmt | port_list | tag tag} information {detail}
```

## Changing the 802.1p Priority to QoS Profile Mapping

To view the current 802.1p priority to QoS profile mapping on a switch, enter the following command:

```
show dot1p
```

To change the mapping, enter the following command:

```
configure dot1p type dot1p_priority {qosprofile} qosprofile
```

## Configuring a DiffServ-Based Traffic Group

As described in [DiffServ-Based Traffic Groups](#) on page 1420, the default switch configuration defines DiffServ-based traffic groups. The configuration options for these groups are described in the following sections:

- [Enabling and Disabling Diffserv Examination](#) on page 1445

- [Changing the DSCP to QoS Profile Mapping](#) on page 1445

**Note**

If you are using [ACL](#)-based traffic groups, use the `qosprofile` or `traffic-queue` action modifier to select a forwarding queue. Traffic that meets any ACL match conditions is not evaluated by other traffic groups.

### Enabling and Disabling Diffserv Examination

When a packet arrives at the switch on an ingress port and Diffserv examination is enabled, the switch uses the DSCP value to select the egress [QoS](#) profile that forwards the packet. The QoS profile configuration defines the forwarding characteristics for all traffic assigned to the QoS profile.

- The DiffServ examination feature is disabled by default. To enable DiffServ examination, use the following command:

```
enable diffserv examination ports [port_list | all]
```

**Note**

When DiffServ examination is enabled on 1 Gigabit Ethernet ports for ExtremeSwitching series switches, 802.1p replacement is enabled and cannot be disabled. The ingress 802.1p value is replaced with the 802.1p value assigned to the egress QoS profile.

- To disable DiffServ examination, use the following command:

```
disable diffserv examination ports [port_list | all]
```

### Changing the DSCP to QoS Profile Mapping

- You can change the egress [QoS](#) profile assignment for each of the 64 code points. To view the current DSCP to QoS profile mapping, use the following command:

```
show diffserv examination
```

- Use the following commands to change the DSCP to QoS profile mapping:

```
configure diffserv examination code-point code_point {qosprofile}
qosprofile
```

```
unconfigure diffserv examination
```

After a QoS profile is assigned, the rest of the switches in the network prioritize the packet using the characteristics specified by the QoS profile.

### Configuring a Port-Based Traffic Group

A port-based traffic group links a physical ingress port to an egress [QoS](#) profile for traffic forwarding.

To configure a port-based traffic group, use the following command:

```
configure ports port_list {qosprofile} qosprofile
```

#### Note

If you are using [ACL](#)-based traffic groups, use the `qosprofile` or `traffic-queue` action modifier to select a forwarding queue. Traffic that meets any ACL match conditions is not evaluated by other traffic groups.

Port-based traffic groups apply to all packets.

### Configuring a VLAN-Based Traffic Group

A [VLAN](#)-based traffic group links all ports in a VLAN to an egress [QoS](#) profile for traffic forwarding. All intra-VLAN switched traffic and all routed traffic sourced from the named VLAN uses the specified QoS profile.

To configure a VLAN-based traffic group, use the following command:

```
configure vlan vlan_name {qosprofile} qosprofile
```

#### Note

If you are using [ACL](#)-based traffic groups, use the `qosprofile` or `traffic-queue` action modifier to select a forwarding queue. Traffic that meets any ACL match conditions is not evaluated by other traffic groups.

VLAN-based traffic groups apply to all packets.

## Creating and Managing Meters

You can configure meters to define bandwidth requirements on SummitStack and ExtremeSwitching series switches.

### Creating Meters

- To create a meter, use the following command:  

```
create meter meter-name
```
- To display the meters already configured on the switch, use the command:  

```
show meter meter_name
```

ExtremeXOS now creates 8 to 16 default ingress meters that are used for per-port metering. These are named "ingmeter<n>" where n is 0-15.

### Configuring a Meter

After you create a meter, you can configure the meter using the command for the platform you are using. To configure a [QoS](#) meter on all platforms, use the following command:

```
configure meter metername {committed-rate cir [Gbps | Mbps | Kbps | Pps]} {max-burst-size burst-size [Kb | Mb | packets]} {out-actions [{disable-port} {drop | set-drop-precedence {dscp [none | dscp-value]}}
```

```
{dot1p [none | dot1p-value]} {log} {trap}} {ports [port_group |
port_list]}
```

**Note**

The disable-port, log, and trap options are only allowed for per-port meters (i.e. ingmeter0, ingmeter1,...).

*Applying a Meter to Ingress Traffic*

You can apply a meter to ingress traffic using an [ACL](#) on SummitStack and ExtremeXOS switches.

Use rules within the ACL to identify the ingress traffic to which you want to apply the meter. Apply the meter by specifying the meter name with the `meter metername` action modifier. For information on completing the ACL configuration, see [Configuring an ACL-Based Traffic Group](#) on page 1443.

*Deleting a Meter*

To delete a meter, use the following command:

```
delete meter meter-name
```

**Note**

The associated meters are not deleted when you delete any type of traffic queue. Those meters remain and can be associated with other traffic queues. To display the configured meters, use the `show meter meter_name` command.

## Adjusting the Byte Count Used to Calculate Traffic Rates

You can configure a per-packet byte adjustment that the system uses to calculate the ingress traffic rate, traffic utilization, and traffic statistics. You configure either the number of bytes you want subtracted from each packet ingressing the specified ports or the number of bytes you want added to the packet ingressing the specified ports.

By default, all bytes are counted for the ingressing traffic rate. After you issue this command, the default number of bytes removed is 0; you can add or subtract from one to four bytes from each ingressing packet on the specified ports for calculating the ingressing traffic rate.

- To display the number of bytes added to or subtracted from the packet to calculate the ingressing traffic rate, traffic utilization, and traffic statistics, enter the command:

```
show ports port_list information detail
```

**Note**

You must use the detail keyword to display this information.

- To unconfigure this setting, re-issue the command and enter the value 0.

## Controlling Flooding, Multicast, and Broadcast Traffic on Ingress Ports

You can control ingress flooding of broadcast and multicast traffic and traffic for unknown destination MAC addresses.

To control ingress flooding of broadcast and multicast traffic and traffic for unknown destination MAC addresses, enter the command:

```
configure ports port_list | port_group rate-limit flood [broadcast |
multicast | unknown-destmac] [no-limit | pps]
```

## Displaying QoS Configuration and Performance

### Displaying Traffic Group Configuration Data

#### *Displaying 802.1p Priority to QoS Profile Mappings*

To display the 802.1p priority to egress *QoS* profile mappings, enter the command:

```
show dot1p
```

#### *Displaying DiffServ DSCP to QoS Profile Mappings*

To display the DiffServ DSCP to egress *QoS* profile mappings, enter the command:

```
show diffserv examination
```

#### *Displaying Port and VLAN QoS Settings*

To display *QoS* settings assigned to ports or *VLANs*, enter the command:

```
show port {mgmt | port_list | tag tag} information {detail}
```

#### **Note**

To ensure that you display the QoS information, you must use the detail keyword.

This command displays which QoS profile, if any, is configured.

## Displaying Performance Statistics

#### *Displaying QoS Profile Traffic Statistics*

After you have created *QoS* policies that manage the traffic through the switch, you can use the QoS monitor to determine whether the application performance meets your expectations.

The QoS monitor allows you to display the traffic packet counts in a real-time or a snapshot display for the specified ports.

- View QoS profile traffic statistics entering the command:

```
show ports port_list qosmonitor {congestion} {no-refresh}
```

- View or clear the WRED statistics by entering the command:

```
show ports port_list wred {no-refresh}
clear counters wred
```

### *Displaying Congestion Statistics*

- To display a count of the packets dropped due to congestion on a port, use the command:
- To display a count of the packets dropped due to congestion in the *QoS* profiles for a port, use the command:

```
show ports port_list congestion {no-refresh}
```

```
show ports port_list qosmonitor {congestion} {no-refresh}
```

- To display traffic counts for each profile on the specified stacking ports, use the command:

```
show ports stack-ports stack_port_list qosmonitor {no-refresh |
refresh} {port-number}
```

- To display packet counts or dropped-traffic counts for each profile on the specified stacking ports, use the command:

```
show ports stack-ports stack_port_list qosmonitor congestion {no-
refresh | refresh} {port-number}
```

- To display the stacking port congestion statistics (dropped packets) for the specified ports on the front panel, use the command:

```
show ports stack-ports stack_port_list congestion {no-refresh |
refresh} port-number
```

# RADIUS over TLS

---

[TLS Connection Persistence](#) on page 1450

[PKI Authentication of TLS Connections](#) on page 1451

[Revocation Checking of Server Certificates via OCSP](#) on page 1451

[Limitations](#) on page 1452

[Supported Platforms](#) on page 1452

[RADIUS Over TLS CLI Commands](#) on page 1453

[Setting Up FreeRADIUS TLS](#) on page 1453

[RADIUS TLS Cipher Configuration](#) on page 1454

This chapter introduces Remote Authentication Dial In User Service (RADIUS) over Transport Layer Security (TLS), an option for transporting RADIUS packets over the secure, reliable, and connection-oriented TLS protocol as defined by RFC 6614.

Using RADIUS over TLS enables dynamic trust relationships between RADIUS servers. Up to eight (8) RADIUS servers are configurable. If all servers are configured as User Datagram Protocol (UDP), then a round-robin algorithm is used to determine which UDP server the initial transmission will be sent to. If more than one TLS servers is live, the highest priority TLS server is chosen for the first transmission.

When a RADIUS server is configured for TLS:

- The destination port is 2083/TCP (radsec).
- The RADIUS shared secret is radsec.
- The TLS connection is authenticated using X.509 certificates.

When a mixture of UDP and TLS servers are configured, TLS takes priority. The only time the UDP servers will be used is if all TLS servers are down.

## TLS Connection Persistence

---

With RADIUS over TLS, the state of the TLS connection indicates whether the server is “live” or “dead.” As soon as a RADIUS over TLS server is configured, the switch attempts to open a connection. If successful, the server is considered live. If unsuccessful, the server is considered dead and the switch will periodically attempt to reconnect.

If one or more RADIUS over TLS servers is live, then an initial request is sent to a single TLS server, based on priority. This means that the highest priority TLS server is always chosen for the first transmission. If this transaction times out, but that TLS server

status is live, there will be no retransmissions to other TLS servers (or to UDP servers, if configured) and user authentication will fail.

When a TLS connection is broken or closed, any prior request messages that have not yet received a response will be handled on timeout as follows:

- If there are no other live TLS connections, then the user session will fail. If there are UDP servers configured, they will not be tried.
- If there are other live TLS connections, then the user request will be retransmitted to one of the new TLS servers.

## PKI Authentication of TLS Connections

---

Each TLS connection is authenticated using existing, customer-provisioned SSL X.509 certificates and private keys. The RADIUS over TLS connection is established by the AAA application, passing a pointer to these credentials to the OpenSSL cryptographic library.

If there are no live RADIUS over TLS connections, then the AAA application will fall back on legacy RADIUS over UDP (if configured).

Failed RADIUS over TLS connections are retried once every minute, indefinitely. If any live server connections go down, ExtremeXOS will automatically make a reconnect attempt every five seconds for one minute. After one minute, the reconnect attempt occurs every five minutes.

## Revocation Checking of Server Certificates via OCSP

---

In addition to checking the server certificate's validity (signatures, expiration date, uses), the switch also checks the revocation status of each certificate in the chain using the Online Certificate Status Protocol (OCSP).

The following rules are enforced:

- The location of the OCSP server must be embedded in the certificate being verified. If missing, the certificate will not be trusted.
- If the OCSP server is not reachable, the certificate will not be trusted.
- If the OCSP server reports that the certificate has been revoked, the certificate will not be trusted.
- Every certificate in the chain will be revocation checked (except for the Root certificate, which is not revokable by definition).
- The OCSP response must be signed. The switch supports all three OCSP trust models:
  - Common Issuer: Certificate Authority (CA) that signs cert also signs OCSP response
  - Trusted Responder Model (TRM): OCSP response signed by a self-signed certificate that is trusted by the switch for this purpose
  - Delegated Trust Model (DTM): CA that signs cert issues the CA that signs OCSP response

Beginning with ExtremeXOS 31.6, you can configure RADIUS over TLS OCSF attributes (nonce, override, and ocsf-nocheck, respectively) using the following commands:

- `configure radius tls ocsf nonce [on | off]`
- `configure radius tls ocsf override [url | none]`
- `configure radius tls ocsf signer ocsf-nocheck [on | off]`

OCSP nonce cryptographically binds an OCSP request and an OCSP response with an `id-pkix-ocsp-nonce` extension to prevent replay attacks.

OCSP override configures one HTTP Online Certificate Status Protocol (OCSP) override URL for a RADIUS TLS server.

When OCSP-nocheck is done for a peer certificate, ExtremeXOS sends the OCSP request to the OCSP server. The OCSP response is signed by the OCSP responder/signer. The response also comes along with the certificate of the OCSP signer. When ExtremeXOS receives the response, it only checks whether the status of the peer certificate is not revoked.

## Limitations

---

The following features of Change-of-Authorization (RFC5176) are not implemented in ExtremeXOS:

- Reverse Path Forwarding Check—Typically this is used in a proxy scenario. This check is used to determine if the IP address indicated by the *RADIUS (Remote Authentication Dial In User Service)* attributes is a routable destination address for a request sent by the switch software.
- IPSEC encryption—End-to-end encryption of both the RADIUS requests and responses.
- Disconnect-Request and Change-of-Authorization packets identifying sessions with anything other than the Calling-Station-Id attribute containing a properly formatted MAC address. In addition to the Calling-Station-ID attribute, you can also use a NAS-Port attribute, which indicates the index of the specific port the session is connected to.
- Acct-Session-Id attribute—This is an alternate means of session identification. Sessions are currently uniquely identified by port and MAC address pair.
- Retransmissions of Disconnect-Request or Change-of-Authorization ACK and NAK packets—Retransmissions of packets is the responsibility of the device initiating the dynamic authorization transactions.

## Supported Platforms

---

*MSDP (Multicast Source Discovery Protocol)* is supported on all platforms running a minimum software version of ExtremeXOS 12.0 with the Premier or Extreme Platform ONE license.

Our implementation of MSDP is compliant with RFC 3618 and RFC 3446, and compatible with other devices that are compliant with these standards.

## RADIUS Over TLS CLI Commands

The following commands support RADIUS over TLS:

```
configure radius {mgmt-access | netlogin} [primary | secondary |
index] server [host_ipaddr | host_ipV6addr | hostname] {udp_port | tls
{tls_port}} client-ip [client_ipaddr | client_ipV6addr] {vr vr_name}
{shared-secret {encrypted} secret}

configure radius-accounting { mgmt-access | netlogin } [primary |
secondary | index] server [host_ipaddr | host_ipV6addr | hostname]
{udp_port | tls {tls_port}} client-ip [client_ipaddr | client_ipV6addr]
{vr vr_name} {shared-secret {encrypted} secret}

configure radius tls ocsp nonce [on | off]

configure radius tls ocsp [on | off]

configure radius tls ocsp override [url | none]

configure radius tls ocsp signer ocsp-nocheck [on | off]

configure radius tls tcp-user-timeout [seconds | default]
```

## Setting Up FreeRADIUS TLS

The following is an example setup configuration of FreeRADIUS as a RADIUS TLS server.

1. Edit the following CA config file (ca.cnf) to have key usage:

```
/etc/freeradius/3.0/certs (otherwise /etc/raddb/certs)

[v3_ca]
subjectKeyIdentifier = hash
authorityKeyIdentifier = keyid:always,issuer:always
basicConstraints = critical,CA:true
#crlDistributionPoints = URI:http://www.example.org/example_ca.crl
keyUsage = cRLSign, keyCertSign, digitalSignature
extendedKeyUsage = OCSP Signing
noCheck = yes
```

### Note

ExtremeXOS requires key usage for a CA certificate.

2. Edit the file /etc/freeradius/3.0/certs/xpextensions with the OCSP server address:

```
[xpserver_ext] extendedKeyUsage = 1.3.6.1.5.5.7.3.1
authorityKeyIdentifier = keyid,issuer
authorityInfoAccess = OCSP;URI:http://10.127.2.236:2561
```

### Note

Use the IP of the machine in which the OCSP server runs. It can be the same machine where FreeRADIUS runs. DNS can also be used instead of the IP.

3. Run the OCSP server using the following command in the same path where the certificates and `index.txt` are present:

```
openssl ocsp -port 2561 -text -index index.txt -CA ca.pem -rkey ca.key -rsigner ca.pem
```

4. Clean up by entering **make destroycerts**.
5. Create the RADIUS TLS server key and certificate by entering **make server.pem**
6. Create the ExtremeXOS switch key and certificate by entering **make client.pem**.
7. Create the DH by entering **make dh**.
8. Enable TLS in FreeRADIUS:

**File: etc/freeradius/3.0/sites-available/tls**

- a. If you do not want the RADIUS server authenticating ExtremeXOS, search for the previous command line and set **require\_client\_cert= no**.
- b. Search for 'clients radsec' and add the ExtremeXOS switch IP:

```
clients radsec {
 client 10.127.2.19 {
 ipaddr = 10.127.2.19
 proto = tls
 secret = radsec
 }
}
```

- c. Add a soft link for `etc/freeradius/3.0/sites-available/tls` at `etc/freeradius/3.0/sites-available/tls` by running **ln -s <file>**.
- d. Restart FreeRADIUS (or `radiusd`).

```
EXOS Switch Setup:

```

9. Copy the `ca.pem` to the TFTP server.
10. Copy the `client.pem` to the TFTP server.
11. Convert the private, encrypted client key to plain format:

```
openssl rsa -in client.key -out clientPlain.key
```

12. Copy the `clientPlain.key` to the TFTP server.
13. Install the following to the switch:
  - a. Download the `ca.pem` as a trusted ca in the switch by entering **download ssl <ip> certificate trusted-ca <file>**
  - b. Download the `client.pem` as an ssl-cert in the switch by entering **download ssl <ip> certificate ssl-cert <file>**
  - c. Download the `clientPlain.key` as priv-key in the switch by entering **download ssl <ip> privkey <file>**
14. Configure RADIUS or RADIUS-accounting with the TLS option.

## NEW! RADIUS TLS Cipher Configuration

Version 33.3.1 adds support for RADIUS TLS cipher configuration. Additionally, for ECDHA ciphers, the curves list is fixed as `secp256r1`, `secp384r1`, and `secp521r1`. The following ciphers are supported:

Default mode -

- TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA
- TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA256
- TLS\_RSA\_WITH\_AES\_256\_CBC\_SHA256
- TLS\_DHE\_RSA\_WITH\_AES\_256\_CBC\_SHA256
- TLS\_DHE\_RSA\_WITH\_AES\_128\_CBC\_SHA256
- TLS\_ECDHE\_RSA\_WITH\_AES\_128\_CBC\_SHA256
- TLS\_ECDHE\_RSA\_WITH\_AES\_256\_CBC\_SHA384

FIPS mode -

- TLS\_ECDHE\_RSA\_WITH\_AES\_128\_CBC\_SHA256
- TLS\_ECDHE\_RSA\_WITH\_AES\_256\_CBC\_SHA384

To configure RADIUS TLS ciphers, use the following command:

```
configure radius tls cipher [[cipher | fips_cipher | all] on |
[cipher | fips_cipher] off].
```

Use the **show radius** command to show RADIUS TLS Cipher information.

# RIP

---

[IGPs Overview](#) on page 1456  
[Overview of RIP](#) on page 1457  
[Route Redistribution](#) on page 1459  
[RIP Configuration Example](#) on page 1461

This chapter assumes that you are already familiar with IP unicast routing. If not, refer to the following publications for additional information:

- RFC 1058—Routing Information Protocol (RIP)
- RFC 1723—RIP Version 2
- *Interconnections: Bridges and Routers* by Radia Perlman. ISBN 0-201-56332-0. Published by Addison-Wesley Publishing Company.

## Note

RIP is available on platforms with an Edge (or higher) or Base (or higher) license. For specific information regarding RIP licensing, see the licensing guide.

## IGPs Overview

---

The switch supports the use of the following interior gateway protocols (IGPs):

- [\*RIP \(Routing Information Protocol\)\*](#)
- [\*OSPF \(Open Shortest Path First\)\*](#)
- Intermediate System-Intermediate System (IS-IS)

RIP is a distance-vector protocol, based on the Bellman-Ford (or distance-vector) algorithm. The distance-vector algorithm has been in use for many years and is widely deployed and understood.

OSPF and IS-IS are link-state protocols, based on the Dijkstra link-state algorithm. OSPF and IS-IS are newer IGPs and solve a number of problems associated with using RIP on today's complex networks.

## Note

RIP can be enabled on a [\*VLAN \(Virtual LAN\)\*](#) with either OSPF or IS-IS. OSPF and IS-IS cannot be enabled on the same VLAN.

RIP is described in this chapter, OSPF is described in [OSPF](#) and IS-IS is described in [IS-IS](#).

## RIP Versus OSPF and IS-IS

The distinction between *RIP* and the *OSPF* and IS-IS link-state protocols lies in the fundamental differences between distance-vector protocols and link-state protocols.

Using a distance-vector protocol, each router creates a unique routing table from summarized information obtained from neighboring routers. Using a link-state protocol, every router maintains an identical routing table created from information obtained from all routers in the autonomous system (AS). Each router builds a shortest path tree, using itself as the root. The link-state protocol ensures that updates sent to neighboring routers are acknowledged by the neighbors, verifying that all routers have a consistent network map.

## Advantages of RIP, OSPF, and IS-IS

The biggest advantage of using *RIP* is that it is relatively simple to understand and to implement, and it has been the de facto routing standard for many years.

RIP has a number of limitations that can cause problems in large networks, including the following:

- A limit of 15 hops between the source and destination networks
- A large amount of bandwidth taken up by periodic broadcasts of the entire routing table
- Slow convergence
- Routing decisions based on hop count; no concept of link costs or delay
- Flat networks; no concept of areas or boundaries

*OSPF* and IS-IS offer many advantages over RIP, including the following:

- No limitation on hop count
- Route updates multicast only when changes occur
- Faster convergence
- Support for load balancing to multiple routers based on the actual cost of the link
- Support for hierarchical topologies where the network is divided into areas

The details of RIP are explained later in this chapter.

## Overview of RIP

*RIP* is an IGP first used in computer routing in the Advanced Research Projects Agency Network (ARPAnet) as early as 1969. It is primarily intended for use in homogeneous networks of moderate size.

To determine the best path to a distant network, a router using RIP always selects the path that has the least number of hops. Each router that data must traverse is considered to be one hop.

## Routing Table

The routing table in a router using *RIPng (Routing Information Protocol Next Generation)* contains an entry for every known destination network.

Each routing table entry contains the following information:

- IP address and prefix length of the destination network
- Metric (hop count) to the destination network
- IP address of the next hop router, if the destination is not directly connected
- Interface for the next hop
- Timer that tracks the amount of time since the entry was last updated
- A flag that indicates if the entry is a new one since the last update
- The source of the route, for example, static, RIPng, *OSPFv3 (Open Shortest Path First version 3)*, etc.

The router exchanges an update message with each neighbor every 30 seconds (default value), or when there is a change to the overall routed topology (also called *triggered updates*). If a router does not receive an update message from its neighbor within the route timeout period (180 seconds by default), the router assumes the connection between it and its neighbor is no longer available.

## Split Horizon

Split horizon is a scheme for avoiding problems caused by including routes in updates sent to the router from which the route was learned.

Split horizon omits routes learned from a neighbor in updates sent to that neighbor.

## Poison Reverse

Like split horizon, poison reverse is a scheme for eliminating the possibility of loops in the routed topology.

In this case, a router advertises a route over the same interface that supplied the route, but the route uses a hop count of 16, which defines that router as unreachable.

## Triggered Updates

Triggered updates occur whenever a router changes the metric for a route.

The router is required to send an update message immediately, even if it is not yet time for a regular update message to be sent. This generally results in faster convergence, but may also result in more *RIPng*-related traffic.

## Route Advertisement of VLANs

Virtual LANs (VLANs) that are configured with an IP address but are configured to not route IP or are not configured to run *RIP*, do not have their subnets advertised by RIP.

RIP advertises only those VLANs that are configured with an IP address, are configured to route IP, and run RIP.

## RIP Version 1 Versus RIP Version 2

A new version of *RIP*, called RIP version 2, expands the functionality of RIP version 1 to include the following:

- Variable-length subnet masks (VLSMs).
- Support for next-hop addresses, which allows for optimization of routes in certain environments.
- Multicasting.

RIP version 2 packets can be multicast instead of being broadcast, reducing the load on hosts that do not support routing protocols.

### Note

If you are using RIP with supernetting/Classless Inter-Domain Routing (CIDR), you must use RIPv2 only.

## Route Redistribution

More than one routing protocol can be enabled simultaneously on the switch.

Route redistribution allows the switch to exchange routes, including static routes, between the routing protocols. [Figure 185](#) is an example of route redistribution between an OSPF AS and a RIP AS.

**Figure 185: OSPF Route Redistribution**

## Configuring Route Redistribution

Exporting routes from one protocol to another and in the reverse direction are discrete configuration functions. For example, to run IS-IS and *RIP* simultaneously, you must first configure both protocols and then verify the independent operation of each. Then you can configure the routes to export from IS-IS to RIP and the routes to export from RIP to IS-IS. Likewise, for any other combinations of protocols, you must separately configure each to export routes to the other.

This section describes how to inject routing information learned from other IP routing protocols into an IS-IS domain, thereby advertising their reachability in the IS-IS domain. These routes are included in the locally originated LSPs. For information on exporting routes learned in IS-IS to another routing protocol, see the chapter that describes the destination routing protocol.

When you export routes from another protocol to IS-IS, the metric and the type of metric are configured. You can also configure a policy to filter out unwanted external routes.

- To enable or disable the exporting of *BGP (Border Gateway Protocol)*, *OSPF*, RIP, static, and direct (interface) IPv4 routes to IS-IS, use the following commands:

```
enable isis area area_name export {ipv4} route-type [policy | metric
mvalue {metric-type [internal | external]}} {level[1 | 2 | both-1-
and-2]}
```

```
disable isis area area_name export {ipv4} route-type
```

- To enable or disable the exporting of *OSPFv3*, *RIPng*, static, and direct (interface) IPv6 routes to IS-IS, use the following commands:

```
enable isis area area_name export ipv6 route-type [policy | metric
mvalue] {level[1 | 2 | both-1-and-2]}
```

```
disable isis area area_name export ipv6 route-type
```

The cost metric is inserted for all *OSPF*, RIP, static, and direct routes injected into IS-IS.

The same cost and type values can be inserted for all the export routes, or policies can be used for selective insertion. When a policy is associated with the export command, the policy is applied on every exported route. The exported routes can also be filtered using policies.

- Verify the configuration using the command:

```
show isis area [area_name | all]
```

### Redistribute Routes into RIP

- Enable or disable the exporting of static, direct, *BGP*-learned, and *OSPF*-learned routes into the *RIP* domain.

```
enable rip export [bgp | direct | e-bgp | i-bgp | ospf | ospf-
extern1 | ospf-extern2 | ospf-inter | ospf-intra | static | isis
| isis-level-1 | isis-level-1-external | isis-level-2 | isis-level-2-
external] [cost number {tag number} | policy policy-name]
```

```
disable rip export [bgp | direct | e-bgp | i-bgp | ospf | ospf-
extern1 | ospf-extern2 | ospf-inter | ospf-intra | static | isis
```

```
| isis-level-1 | isis-level-1-external | isis-level-2 | isis-level-2-external]
```

These commands enable or disable the exporting of static, direct, and OSPF-learned routes into the RIP domain.

- You can choose which types of OSPF routes are injected, or you can simply choose `ospf`, which will inject all learned OSPF routes regardless of type. The default setting is disabled.

## RIP Configuration Example

Figure 186 on page 1461 illustrates a switch with three VLANs defined as follows:

- Finance
  - Protocol-sensitive VLAN using the IP protocol.
  - All ports on slots 1 and 3 have been assigned.
  - IP address 192.207.35.1.
- Personnel
  - Protocol-sensitive VLAN using the IP protocol.
  - All ports on slots 2 and 4 have been assigned.
  - IP address 192.207.36.1.
- MyCompany
  - Port-based VLAN.
  - All ports on slots 1 through 4 have been assigned.

This example does use protocol-sensitive VLANs that admit only IP packets. This is not a common requirement for most networks. In most cases, VLANs will admit different types of packets to be forwarded to the hosts and servers on the network.

**Figure 186: RIP Configuration Example**

The stations connected to the system generate a combination of IP traffic and NetBIOS traffic. The IP traffic is filtered by the protocol-sensitive VLANs. All other traffic is directed to the VLAN MyCompany.

In this configuration, all IP traffic from stations connected to slots 1 and 3 have access to the router by way of the VLAN Finance. Ports on slots 2 and 4 reach the router by way of the VLAN Personnel. All other traffic (NetBIOS) is part of the VLAN MyCompany.

The example in [Figure 186](#) is configured as follows:

```
create vlan Finance
create vlan Personnel
create vlan MyCompany
configure Finance protocol ip
configure Personnel protocol ip
configure Finance add port 1:*,3:*
configure Personnel add port 2:*,4:*
configure MyCompany add port all
configure Finance ipaddress 192.207.35.1
configure Personnel ipaddress 192.207.36.1
enable ipforwarding
configure rip add vlan all
enable rip
```

More commonly, NetBIOS traffic would be allowed on the Finance and Personnel VLANs, but this example shows how to exclude that traffic. To allow the NetBIOS traffic (or other type of traffic) along with the IP traffic, remove the `configure finance protocol ip` and `configure Personnel protocol ip` commands from the example.

# RIPng

---

[RIPng Overview](#) on page 1463

[RIPng Routing](#) on page 1464

[Route Redistribution](#) on page 1466

[RIPng Configuration Example](#) on page 1467

This chapter describes the *RIPng (Routing Information Protocol Next Generation)* interior gateway protocol for IPv6 networks. It provides the various protocol schemes available, commands for configuring redistribution, and an example for configuring multiple protocols on one switch. This chapter assumes that you are already familiar with IP unicast routing. If not, refer to the following publication for additional information:

- RFC 2080—RIPng for IPv6

## Note

RIPng is available on platforms with an Edge (or higher) or Base (or higher) license. For specific information regarding RIPng licensing, see the [Switch Engine v33.3.1 Licensing Guide](#) document.

## RIPng Overview

---

*RIPng* is an interior gateway protocol (IGP) developed for IPv6 networks.

The analogous protocol used in IPv4 networks is called *RIP (Routing Information Protocol)*. Like RIP, RIPng is a relatively simple protocol for the communication of routing information among routers. Many concepts and features of RIPng are directly parallel to those same features in RIP.

RIPng is a distance-vector protocol, based on the Bellman-Ford (or distance-vector) algorithm. The distance-vector algorithm has been in use for many years and is widely deployed and understood. The other common IGPs for IPv6 are *OSPFv3 (Open Shortest Path First version 3)* and Intermediate System-Intermediate System (IS-IS), which are link-state protocols.

## Note

RIPng can be enabled on a *VLAN (Virtual LAN)* with either [OSPFv3](#) or [IS-IS](#). OSPFv3 and ISIS cannot be enabled on the same VLAN.

## RIPng versus OSPFv3 and IS-IS

The distinction between *RIPng* and the link-state protocols (*OSPFv3* and IS-IS) lies in the fundamental differences between distance-vector protocols (RIPng) and link-state protocols.

Using a distance-vector protocol, each router creates a unique routing table from summarized information obtained from neighboring routers. Using a link-state protocol, every router maintains an identical routing table created from information obtained from all routers in the autonomous system. Each router builds a shortest path tree, using itself as the root. The link-state protocol ensures that updates sent to neighboring routers are acknowledged by the neighbors, verifying that all routers have a consistent network map.

## Advantages of RIPng, OSPFv3, and IS-IS

The biggest advantage of using *RIPng* is that it is relatively simple to understand and implement, and it has been the de facto routing standard for many years.

RIPng has a number of limitations that can cause problems in large networks, including the following:

- A limit of 15 hops between the source and destination networks
- A large amount of bandwidth taken up by periodic broadcasts of the entire routing table
- Slow convergence
- Routing decisions based on hop count; no concept of link costs or delay
- Flat networks; no concept of areas or boundaries

OSPFv3 and IS-IS offer many advantages over RIPng, including the following:

- No limitation on hop count
- Route updates multicast only when changes occur
- Faster convergence
- Support for load balancing to multiple routers based on the actual cost of the link
- Support for hierarchical topologies where the network is divided into areas

The details of RIPng are explained later in this chapter.

## RIPng Routing

*RIPng* is primarily intended for use in homogeneous networks of moderate size.

To determine the best path to a distant network, a router using RIPng always selects the path that has the least number of hops. Each router that data must traverse is considered to be one hop.

## Routing Table

The routing table in a router using *RIPng* contains an entry for every known destination network.

Each routing table entry contains the following information:

- IP address and prefix length of the destination network
- Metric (hop count) to the destination network
- IP address of the next hop router, if the destination is not directly connected
- Interface for the next hop
- Timer that tracks the amount of time since the entry was last updated
- A flag that indicates if the entry is a new one since the last update
- The source of the route, for example, static, RIPng, *OSPFv3*, etc.

The router exchanges an update message with each neighbor every 30 seconds (default value), or when there is a change to the overall routed topology (also called *triggered updates*). If a router does not receive an update message from its neighbor within the route timeout period (180 seconds by default), the router assumes the connection between it and its neighbor is no longer available.

## Split Horizon

Split horizon is a scheme for avoiding problems caused by including routes in updates sent to the router from which the route was learned.

Split horizon omits routes learned from a neighbor in updates sent to that neighbor.

## Poison Reverse

Like split horizon, poison reverse is a scheme for eliminating the possibility of loops in the routed topology.

In this case, a router advertises a route over the same interface that supplied the route, but the route uses a hop count of 16, which defines that router as unreachable.

## Triggered Updates

Triggered updates occur whenever a router changes the metric for a route.

The router is required to send an update message immediately, even if it is not yet time for a regular update message to be sent. This generally results in faster convergence, but may also result in more *RIPng*-related traffic.

## Route Advertisement of VLANs

Virtual LANs (VLANs) that are configured with an IP address but are configured to not route IP or are not configured to run *RIP*, do not have their subnets advertised by RIP.

RIP advertises only those VLANs that are configured with an IP address, are configured to route IP, and run RIP.

## Route Redistribution

More than one routing protocol can be enabled simultaneously on the switch.

Route redistribution allows the switch to exchange routes, including static routes, between the routing protocols. [Figure 187](#) is an example of route redistribution between an OSPF AS and a RIP AS.

**Figure 187: OSPF Route Redistribution**

## Configuring Route Redistribution

Exporting routes from one protocol to another and in the reverse direction are discrete configuration functions. For example, to run IS-IS and *RIP* simultaneously, you must first configure both protocols and then verify the independent operation of each. Then you can configure the routes to export from IS-IS to RIP and the routes to export from RIP to IS-IS. Likewise, for any other combinations of protocols, you must separately configure each to export routes to the other.

This section describes how to inject routing information learned from other IP routing protocols into an IS-IS domain, thereby advertising their reachability in the IS-IS domain. These routes are included in the locally originated LSPs. For information on exporting routes learned in IS-IS to another routing protocol, see the chapter that describes the destination routing protocol.

When you export routes from another protocol to IS-IS, the metric and the type of metric are configured. You can also configure a policy to filter out unwanted external routes.

- To enable or disable the exporting of *BGP (Border Gateway Protocol)*, *OSPF (Open Shortest Path First)*, RIP, static, and direct (interface) IPv4 routes to IS-IS, use the following commands:

```
enable isis area area_name export {ipv4} route-type [policy | metric
mvalue {metric-type [internal | external]}] {level[1 | 2 | both-1-
and-2]}
```

```
disable isis area area_name export {ipv4} route-type
```

- To enable or disable the exporting of *OSPFv3*, *RIPng*, static, and direct (interface) IPv6 routes to IS-IS, use the following commands:

```
enable isis area area_name export ipv6 route-type [policy | metric
mvalue] {level[1 | 2 | both-1-and-2]}
```

```
disable isis area area_name export ipv6 route-type
```

The cost metric is inserted for all *OSPF*, RIP, static, and direct routes injected into IS-IS.

The same cost and type values can be inserted for all the export routes, or policies can be used for selective insertion. When a policy is associated with the export command, the policy is applied on every exported route. The exported routes can also be filtered using policies.

- Verify the configuration using the command:

```
show isis area [area_name | all]
```

### Redistributing Routes into RIPng

- Enable or disable the exporting of static, direct, or other protocol-learned routes into the *RIPng* domain using the following commands:

```
enable ripng export [direct | ospfv3 | ospfv3-extern1 | ospfv3-extern2
| ospfv3-inter | ospfv3-intra | static | isis | isis-level-1 | isis-
level-1-external | isis-level-2 | isis-level-2-external | bgp | e-bgp
i-bgp] [cost number {tag number} | policy policy-name]
```

```
disable ripng originate-default
```

```
enable ripng originate-default {always} {cost value}
```

These commands enable or disable the exporting of static, direct, and OSPFv3-learned routes into the RIPng domain.

- You can choose which types of OSPFv3 routes are injected, or you can simply choose *ospf*, which will inject all learned OSPFv3 routes regardless of type. The default setting is disabled.

## RIPng Configuration Example

The following configuration is similar to the example in the *RIP* chapter, but uses IPv6 addresses. It illustrates a switch with three VLANs defined as follows:

- Finance
  - All ports on slots 1 and 3 have been assigned.

- IP address 2001:db8:35::1/48.
- Personnel
  - All ports on slots 2 and 4 have been assigned.
  - IP address 2001:db8:36::1/48.
- MyCompany
  - Port-based VLAN.
  - All ports on slots 1 through 4 have been assigned.

The stations connected to the system generate a combination of IPv6 traffic and NetBIOS traffic.

In this configuration, all traffic from stations connected to slots 1 and 3 have access to the router by way of the VLAN Finance. Ports on slots 2 and 4 reach the router by way of the VLAN Personnel. All traffic (NetBIOS and IPv6) is part of the VLAN MyCompany.

The example is configured as follows:

```
create vlan Finance
create vlan Personnel
create vlan MyCompany
configure Finance add port 1:*,3:*
configure Personnel add port 2:*,4:*
configure MyCompany add port all
configure Finance ipaddress 2001:db8:35::1/48
configure Personnel ipaddress 2001:db8:36::1/48
enable ipforwarding ipv6
configure ripng add vlan Finance
configure ripng add vlan Personnel
enable ripng
```

# Routing Policies

---

[Routing Policies Overview](#) on page 1469

[Routing Policy File Syntax](#) on page 1470

[Applying Routing Policies](#) on page 1476

[Policy Examples](#) on page 1476

This chapter provides information about Routing Policies. It includes an overview, specific information about Routing Policy File Syntax, how to apply Routing Policies, and offers some Policy examples.

## Routing Policies Overview

---

Routing policies are used to control the advertisement or recognition of routes communicated by routing protocols, such as *RIP (Routing Information Protocol)*, *OSPF (Open Shortest Path First)*, Intermediate System-Intermediate System (IS-IS) and *BGP (Border Gateway Protocol)*.

Routing policies can be used to “hide” entire networks or to trust only specific sources for routes or ranges of routes. The capabilities of routing policies are specific to the type of routing protocol involved, but these policies are sometimes more efficient and easier to implement than access lists.

Routing policies can also modify and filter routing information received and advertised by a switch.

A similar type of policy is an *ACL (Access Control List)* policy, used to control, at the hardware level, the packets accessing the switch. ACL policy files and routing policy files are both handled by the policy manager and the syntax for both types of files is checked by the policy manager.

### Note

Although ExtremeXOS does not prohibit mixing ACL and routing type entries in a policy file, it is strongly recommended that you do not mix the entries, and you use separate policy files for ACL and routing policies.

## Routing Policy File Syntax

A routing policy file contains one or more policy rule entries. Each routing policy entry consists of:

- A policy entry rule name, unique within the same policy.
- Zero or one match type. If no type is specified, the match type is all, so all match conditions must be satisfied.
- Zero or more match conditions. If no match condition is specified, then every routing entity matches.
- Zero or more actions. If no action is specified, the packet is permitted by default.

Each policy entry in the file uses the following syntax:

```
entry <routingrulename>{
 if <match-type> {
 <match-conditions>;
 } then {
 <action>;
 }
}
```

The following is an example of a policy entry:

```
entry ip_entry {
 if match any {
 nlri 10.203.134.0/24;
 nlri 10.204.134.0/24;
 } then {
 next-hop 192.168.174.92;
 origin egp;
 }
}
```

Policy entries are evaluated in order, from the beginning of the file to the end, as follows:

- If a match occurs, the action in the then statement is taken:
  - if the action contains an explicit permit or deny, the evaluation process terminates.
  - if the action does not contain an explicit permit or deny, the action is an implicit permit, and the evaluation process terminates.
- If a match does not occur, the next policy entry is evaluated.
- If no match has occurred after evaluating all policy entries, the default action is deny.

Often a policy has a rule entry at the end of the policy with no match conditions. This entry matches anything not otherwise processed, so that the user can specify an action to override the default deny action.

Policy match type, match conditions and action statements are discussed in the following sections:

- [Policy Match Type](#) on page 1471
- [Policy Match Conditions](#) on page 1471

- [Autonomous System Expressions](#) on page 1472
- [Policy Action Statements](#) on page 1474

## Policy Match Type

The two possible choices for the match type are:

- match all—All the match conditions must be true for a match to occur. This is the default.
- match any—If any match condition is true, then a match occurs.

## Policy Match Conditions

[Table 134](#) lists the possible policy entry match conditions.

**Table 134: Policy Match Conditions**

| Match Condition                                                                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| as-path [<as-number>   <as-path-regular-expression>];                                                                                    | Where <as-number> is a valid 2-byte AS number in the range of 1 to 65535 or a 4-byte AS number in the range of 65536 to 4294967294.<br><br>Where <as-path-regular-expression> is a multi-character regular expression (with 2-byte unsigned Integer being an Atom). Regular expression will consist of the AS-Numbers and various regular expression symbols. Regular expressions must be enclosed in double quotes ("").          |
| community [no-advertise   no-export   no-export-subconfed   number <community_num>   <community_regular_expression>   <as_num> : <num>]; | Where no-advertise, no-export and no-export-subconfed are the standard communities defined by RFC.<br><community_num> is a four-byte unsigned integer, <as_num> is a two-byte or four-byte AS-Number and <num> is the 2-bytes community number.<br><br>Community regular expression is a multi-character regular expression (with four byte unsigned integer being an Atom). Regular expression is enclosed in double quotes (""). |
| med <number>;                                                                                                                            | Where <number> is a 4-byte unsigned integer.                                                                                                                                                                                                                                                                                                                                                                                       |
| next-hop [<ipaddress>   <ipaddress-regular-expression>];                                                                                 | Where <ipaddress> is a valid IP address in dotted decimal format.                                                                                                                                                                                                                                                                                                                                                                  |

**Table 134: Policy Match Conditions (continued)**

| Match Condition                                                                                                                                                                                                                                                                                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>nlri [ <i>ipaddress</i>   any ] <i>mask-length</i> {exact}; nlri [ <i>ipaddress</i>   any ] mask <i>mask</i> {exact}; nlri [ <i>ipv6address</i>   any-ipv6 ] /<i>mask-length</i> {exact};</code>                                                                                                                                                | Where <i>ipaddress</i> and <i>mask</i> are IPv4 addresses and masks, <i>mask-length</i> is an integer with maximum value of 32 for IPv4 addresses. The keyword <i>any</i> matches any IPv4 address with a given (or larger) mask/mask-length.<br><br>Similarly <i>ipv6address</i> is an IPv6 address and <i>masklength</i> is an integer with a maximum value of 128 for IPv6 addresses. The keyword <i>any-ipv6</i> matches any IPv6 address with a given (or larger) mask-length. |
| <code>origin [igp   egp   incomplete];</code>                                                                                                                                                                                                                                                                                                         | Where <i>igp</i> , <i>egp</i> and <i>incomplete</i> are the <i>BGP</i> route origin values.                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>tag &lt;number&gt;;</code>                                                                                                                                                                                                                                                                                                                      | Where <number> is a 4-byte unsigned number.<br><br><b>Note:</b> The tag match condition only works with export policy.                                                                                                                                                                                                                                                                                                                                                              |
| <code>route-origin [direct   static   icmp   egp   ggp   hello   rip   isis   esis   cisco-igrp   ospf   bgp   idrp   dvmrp   mospf   pim-dm   pim-sm   ospf-intra   ospf-inter   ospf-extern1   ospf-extern2   bootp   e-bgp   i-bgp   mbgp   i-mbgp   e-mbgp   isis-level-1   isis-level-2   isis-level-1-external   isis-level-2-external];</code> | Matches the origin (different from BGP route origin) of a route.<br><br>A match statement "route-origin bgp" will match routes whose origin are "i-bgp" or "e-bgp" or "i-mbgp" or "e-mbgp". Similarly, the match statement "route-origin ospf" will match routes whose origin is "ospf-inta" or "ospf-inter" or "ospf-as-external" or "ospf-extern-1" or "ospf-extern-2"                                                                                                            |

**Note**

When entering an AS number in a policy file, you must enter a unique 2-byte or 4-byte AS number. The transition AS number, AS 23456, is not supported in policy files.

*Autonomous System Expressions*

The AS-path keyword uses a regular expression string to match against the autonomous system (AS) path. [Table 135](#) lists the regular expressions that can be used in the match conditions for BGP AS path and community. It also shows examples of regular expressions and the AS paths they match.

**Table 135: AS Regular Expression Notation**

| Character | Definition                                                      |
|-----------|-----------------------------------------------------------------|
| N         | As number                                                       |
| N1 - N2   | Range of AS numbers, where N1 and N2 are AS numbers and N1 < N2 |

**Table 135: AS Regular Expression Notation (continued)**

| Character    | Definition                                                                   |
|--------------|------------------------------------------------------------------------------|
| [Nx ... Ny]  | Group of AS numbers, where Nx and Ny are AS numbers or a range of AS numbers |
| [^Nx ... Ny] | Any AS numbers other than the ones in the group                              |
| .            | Matches any number                                                           |
| ^            | Matches the beginning of the AS path                                         |
| \$           | Matches the end of the AS path                                               |
| –            | Matches the beginning or end, or a space                                     |
| -            | Separates the beginning and end of a range of numbers                        |
| *            | Matches 0 or more instances                                                  |
| +            | Matches 1 or more instances                                                  |
| ?            | Matches 0 or 1 instance                                                      |
| {            | Start of AS SET segment in the AS path                                       |
| }            | End of AS SET segment in the AS path                                         |
| (            | Start of a confederation segment in the AS path                              |
| )            | End of a confederation segment in the AS path                                |

**Table 136: Policy Regular Expression Examples**

| Attribute                                                        | Regular Expression        | Example Matches                                                    |
|------------------------------------------------------------------|---------------------------|--------------------------------------------------------------------|
| AS path is 64496                                                 | "64496"                   | 64496                                                              |
| Zero or more occurrences of AS number 1234                       | "64496*"                  | 64496<br>64496 64496                                               |
| Start of AS path set                                             | "64496 64500 { 64505"     | 64496 64500 64505<br>{ 64511<br>64509 64496 64500<br>{ 64505 64507 |
| End of AS path set                                               | "64500 } 64505"           | 64500 } 64505 56                                                   |
| Path that starts with 99 followed by 34                          | "^64511 64505 "           | 64511 64505 45                                                     |
| Path that ends with 99                                           | "64511 \$"                | 45 66 64511                                                        |
| Path of any length that begins with AS numbers 64496 64497 64498 | "64496 64497 64498 .*"    | 64496 64497 64498<br>64499 64500 64501<br>64502 64503 64504        |
| Path of any length that ends with AS numbers 64496 64497 64498   | ".* 64496 64497 64498 \$" | 64496 64497 64498<br>64502 64503 64504<br>64496 64497 64498        |

Following are additional examples of using regular expressions in the AS-Path statement.

The following AS-Path statement matches AS paths that contain only (begin and end with) AS number 64511:

```
as-path "^64511$"
```

The following AS-Path statement matches AS paths beginning with AS number 64500, ending with AS number 64511, and containing no other AS paths:

```
as-path "^64500 64511$"
```

The following AS-Path statement matches AS paths beginning with AS number 64496, followed by any AS number from 65500 - 65505, and ending with either AS number 65507, 65509, or 65511:

```
as-path "^64496 65500-65505 [65507 65509 65511]$"
```

The following AS-Path statement matches AS paths beginning with AS number 65511 and ending with any AS number from 65500 - 65505:

```
as-path "65511 [65500-65505]$"
```

The following AS-Path statement matches AS paths beginning with AS number 65511 and ending with any additional AS number, or beginning and ending with AS number 65511:

```
as-path "65511 .?"
```

## Policy Action Statements

[Table 137](#) lists policy action statements. These are the actions taken when the policy match conditions are met in a policy entry.

**Table 137: Policy Actions**

| Action                                                                                                                                                                                                                                           | Description                                                                                                                                                |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| as-path "<as_num> {<as_num1> <as_num2> <as_num3> .... <as_numN>}";                                                                                                                                                                               | Prepends the entire list of as-numbers to the as-path of the route.                                                                                        |
| community set [no-advertise   no-export   noexport- subconfed   <community_num>   <as_num> : <community_num>];                                                                                                                                   | Replaces the existing community attribute of a route by the community specified by the action statement. Community must be enclosed in double quotes (""). |
| community [add   delete] [no-advertise   no-export   no-export-subconfed   <community_num> {<community_num1> <community_num2> .... <community_numN>}   <as_num> : <community_num> {<as_num1> <community_num1> <as_num2> <community_num2> ....}]; | Adds/deletes communities to/from a route's community attribute. Communities must be enclosed in double quotes ("").                                        |
| community remove;                                                                                                                                                                                                                                | Strips off the entire community attribute from a route. Communities must be enclosed in double quotes ("").                                                |
| cost <cost(0-4261412864)>;                                                                                                                                                                                                                       | Sets the cost/metric for a route.                                                                                                                          |

**Table 137: Policy Actions (continued)**

| Action                                                                                                                                         | Description                                                                                                                                                                               |
|------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cost-type {ase-type-1   ase-type-2   external   internal};                                                                                     | Sets the cost type for a route.                                                                                                                                                           |
| dampening half-life <minutes (1-45)><br>reuse-limit <number (1-20000)><br>suppress-limit <number (1-20000)><br>max-suppress <minutes (1-255)>; | Sets the <i>BGP</i> route flap dampening parameters.                                                                                                                                      |
| deny;                                                                                                                                          | Denies the route.                                                                                                                                                                         |
| local-preference <number>;                                                                                                                     | Sets the BGP local preference for a route.                                                                                                                                                |
| med {add   delete} <number>;                                                                                                                   | Performs MED arithmetic. Add means the value of the MED in the route will be incremented by <number>, and delete means the value of the MED in the route will be decremented by <number>. |
| med {internal   remove};                                                                                                                       | Internal means that the Interior Gateway Protocol (IGP) distance to the next hop will be taken as the MED for a route. Remove means take out the MED attribute from the route.            |
| med set <number>;                                                                                                                              | Sets the MED attribute for a route.                                                                                                                                                       |
| next-hop <ipv4 address   ipv6 address>;                                                                                                        | Sets the next hop attribute for a route.                                                                                                                                                  |
| nlri [<ipaddress>   any]/<mask-length> {exact};nlri [<ipaddress>   any] mask <mask> {exact};                                                   | These set statements are used for building a list of IP addresses. This is used by PIM to set up the RP list.                                                                             |
| origin {igp   egp   incomplete};                                                                                                               | Sets the BGP route origin values.                                                                                                                                                         |
| permit;                                                                                                                                        | Permits the route.                                                                                                                                                                        |
| tag <number>;                                                                                                                                  | Sets the tag number for a route.                                                                                                                                                          |
| weight <number>                                                                                                                                | Sets the weight for a BGP route.                                                                                                                                                          |

**Note**

Multiple communities couldn't be used in "community set" attribute in the BGP policy file. The way to set multiple communities in BGP policy file could be accomplished by two set of attributes as given in below example:

```
entry permit-anything-else {
 if {
 } then {
 community set "2342:6788";
 community add "2342:6789 2342:6790";
 }
 }
}
```

## Applying Routing Policies

To apply a routing policy, use the command appropriate to the client. Different protocols support different ways to apply policies, but there are some generalities.

Commands that use the keyword `import-policy` are used to change the attributes of routes installed into the switch routing table by the protocol. These commands cannot be used to determine the routes to be added to the routing table. The following are examples for the *BGP* and *RIP* protocols:

```
configure bgp import-policy [policy-name | none]
```

```
configure rip import-policy [policy-name | none]
```

Commands that use the keyword `route-policy` control the routes advertised or received by the protocol. For BGP and RIP, here are some examples:

```
configure bgp neighbor [remoteaddr | all] {address-family [ipv4-unicast |
| ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} route-policy
[in | out] [none | policy]
```

```
configure bgp peer-group peer-group-name {address-family [ipv4-unicast |
| ipv4-multicast | ipv6-unicast | ipv6-multicast | vpnv4]} route-policy [in
| out] [none | policy]
```

```
configure rip vlan [vlan_name | all] route-policy [in | out] [policy-
name | none]
```

Other examples of commands that use routing policies include:

```
configure ospf area area-identifier external-filter [policy-map | none]
```

```
configure ospf add vlan [vlan-name | all] area area-identifier {passive}
{vr vrf_name}
```

```
configure rip vlan [vlan_name | all] trusted-gateway [policy-name |
none]
```

To remove a routing policy, use the `none` option in the command.

### Note

When exporting a route into BGP with an export policy, the AS-Path is limited to a maximum of 15 AS numbers.

## Policy Examples

### Translating an Access Profile to a Policy

```
entry entry-5 {
```

```

 If {
 nlri 22.16.0.0/14;
 }
 then {
 permit;
 }
}
entry entry-10 {
 if {
 nlri 192.168.0.0/18 exact;
 }
 then {
 permit;
 }
}
entry entry-15 {
 if {
 nlri any/8;
 }
 then {
 deny;
 }
}
entry entry-20 {
 if {
 nlri 10.10.0.0/18;
 }
 Then {
 permit;
 }
}
entry entry-25 {
 if {
 nlri 22.44.66.0/23 exact;
 }
 then {
 deny;
 }
}
}

```

The policy above can be optimized by combining some of the if statements into a single expression.

The compact form of the policy looks like this:

```

entry permit_entry {
 If match any {
 nlri 22.16.0.0/14;
 nlri 192.168.0.0/18 exact ;
 nlri 10.10.0.0/18;
 }
 then {
 permit;
 }
}
entry deny_entry {
 if match any {
 nlri any/8;
 nlri 22.44.66.0/23 exact;
 }
 then {
 deny;
 }
}

```

```
 }
}
```

## Translating a Route Map to a Policy

```
entry entry-10 {
 If {
 origin incomplete;
 }
 then {
 permit;
 }
}
entry entry-20 {
 if {
 community 6553800;
 }
 then {
 deny;
 }
}
entry entry-30 {
 if {
 med 30;
 }
 then {
 next-hop 10.201.23.10;
 as-path 64502;
 as-path 64503;
 as-path 64504;
 as-path 64504;
 permit;
 }
}
entry entry-40 {
 if {
 }
 then {
 local-preference 120;
 weight 2;
 permit;
 }
}
entry entry-50 match any {
 if {
 origin incomplete;
 community 19661200;
 }
 then {
 dampening half-life 20 reuse-limit 1000 suppress-limit 3000 max-suppress 40
 permit;
 }
}
entry entry-60 {
 if {
 next-hop 192.168.1.5;
 }
 then {
 community add 949616660;
 permit;
 }
}
```

```
 }
 }
 entry deny_rest {
 if {
 }
 then {
 deny;
 }
 }
}
```

## General

---

Security is a term that covers several different aspects of network use and operation.

One general type of security is control of the devices or users that can access the network. Ways of doing this include authenticating the user at the point of logging in, controlling access by defining limits on certain types of traffic, or protecting the operation of the switch itself. Security measures in this last category include routing policies that can limit the visibility of parts of the network or denial of service protection that prevents the CPU from being overloaded. Another general type of security is data integrity and confidentiality, which is provided by the MACsec protocol. Finally,

management functions for the switch can be protected from unauthorized use. This type of protection uses various types of user authentication.

## Security Modes

---

For information on ExtremeXOS security modes, see [Security Mode Overview](#) on page 1482.

## Security Features

---

ExtremeXOS has enhanced security features designed to protect, rapidly detect, and correct anomalies in your network. Extreme Networks products incorporate a number of features designed to enhance the security of your network while resolving issues with minimal network disruption. No one feature can ensure security, but by using a number of features in concert, you can substantially improve the security of your network.

The following list provides a brief overview of some of the available security features:

- [\*ACL \(Access Control List\)s\*](#)—ACLs are policy files used by the ACL application to perform packet filtering and forwarding decisions on incoming traffic and packets. Each packet arriving on an ingress port is compared to the ACL applied to that port and is either permitted or denied.

For more information about using ACLs to control and limit network access, see [ACLs](#) on page 325.

- **CLEAR-Flow**—CLEAR-Flow inspects Layer 2 and Layer 3 packets, isolates suspicious traffic, and enforces policy-based mitigation actions. Policy-based mitigation actions include the switch taking an immediate, predetermined action or sending a copy of the traffic off-switch for analysis.

For more information about CLEAR-Flow, see [CLEAR-Flow](#).

- **Denial of Service Protection**—DoS protection is a dynamic response mechanism used by the switch to prevent critical network or computing resources from being overwhelmed and rendered inoperative. In essence, DoS protection protects the switch, CPU, and memory from attacks and attempts to characterize the attack (or problem) and filter out the offending traffic so that other functions can continue. If the switch determines it is under attack, the switch reviews the packets in the input buffer and assembles ACLs that automatically stop the offending packets from reaching the CPU. For increased security, you can enable DoS protection and establish CLEAR-Flow rules at the same time.

For more information about DoS attacks and DoS protection, see [Denial of Service Protection](#) on page 1535.

- **Network Login**—Controls the admission of user packets and access rights thereby preventing unauthorized access to the network. Network login is controlled on a per port basis. When network login is enabled on a port in a [\*VLAN \(Virtual LAN\)\*](#), that port does not forward any packets until authentication takes place. Network login is capable of three types of authentication: web-based, MAC-based, and 802.1X.

For more information about network login, see [Network Login](#) on page 1191.

- Policy Files—Text files that contain a series of rule entries describing match conditions and actions to take. Policy files are used by both routing protocol applications (routing policies) and the ACL application (ACLs).

For more information about policy files, see [Routing Policies](#) on page 1469.

- Routing Policies—Policy files used by routing protocol applications to control the advertisement, reception, and use of routing information by the switch. By using policies, a set of routes can be selectively permitted or denied based on their attributes for advertisements in the routing domain. Routing policies can be used to “hide” entire networks or to trust only specific sources for routes or ranges of routes.

For more information about using routing policies to control and limit network access, see .

- sFlow—A technology designed to monitor network traffic by using a statistical sampling of packets received on each port. sFlow also uses IP headers to gather information about the network. By gathering statistics about the network, sFlow becomes an early warning system, notifying you when there is a spike in traffic activity. Upon analysis, common response mechanisms include applying an ACL, changing *QoS (Quality of Service)* parameters, or modifying VLAN settings.

For more information, see [Using sFlow](#) on page 1705.

- MAC Security (MACsec)—A protocol designed to provide data integrity (ensure data has not been altered in an unauthorized manner) and data confidentiality (ensure data cannot be read by an unauthorized party). This feature provides line rate data encryption/decryption by the use of specialized cryptographic hardware.

For more information about MACsec, see [MAC Security with Pre-shared Key Authentication](#) on page 1506.

## Security Mode Overview

---

ExtremeXOS has multiple security modes used in multiple applications such as AAA, SSH, *SNMP (Simple Network Management Protocol)*, etc.:

- Secure mode (see [Secure Mode](#) on page 1482).
- FIPS mode (see [Federal Information Processing Standards \(FIPS\) Mode](#) on page 1483).
- Default normal mode.

### Secure Mode

Secure mode only works in SSH. As per this mode, only strong ciphers and Message Authentication Codes (MACs) are allowed in SSH server and SSH client connections. After enabling secure-mode:

- For communication, SSH server uses a new secure-mode list made each for ciphers and MACs.
- For the SSH client, EPM is notified to change the bit dedicated to SSH secure-mode, which hides the weak ciphers and MACs from SSH client CLI commands.

### *Applications*

Only SSH is uses this mode.

## Federal Information Processing Standards (FIPS) Mode

Federal Information Processing Standards (FIPS) is a collection of standards defined by the United States Federal Government for document process, encryption algorithms, personal identification and verification, as well as many other areas. These standards are used within the United States federal government (civilian agencies, Department of Defense, and intelligence agencies).

FIPS, in the context of ExtremeXOS, refers to the specific standard 140-2, *System Requirements for Cryptographic Modules*. The publication series was issued to coordinate the requirements and standards for cryptographic modules that include both hardware and software components. Protection of a cryptographic module within a security system is necessary to maintain the confidentiality and integrity of the information protected by the module. This standard specifies the security requirements that are satisfied by a cryptographic module. The standard provides four increasing, qualitative levels of security intended to cover a wide range of potential applications and environments. The security requirements cover areas related to the secure design and implementation of a cryptographic module.

These areas include:

- Cryptographic module specification
- Cryptographic module ports and interfaces
- Roles, services, and authentication
- Finite state model; physical security
- Operational environment
- Cryptographic key management
- Electromagnetic interference/electromagnetic compatibility (EMI/EMC)
- Self-tests
- Design assurance
- Mitigation of other attacks

The US Government requirements break down FIPS 140-2 into two distinct categories: FIPS 140-2 Certified and FIPS 140-2 Compliant. Compliant is needed when only network management data is encrypted or decrypted, which typically includes SSH, SNMPv3, etc. When the product encrypts and decrypts user data this changes the requirement to FIPS 140-2 Certified. An example of a product that would require FIPS 140-2 certification is wireless, since user data is encrypted and decrypted as it flows across the radio waves.

In ExtremeXOS for all cryptographic functions, applications generally use OpenSSL library. OpenSSL module itself is not validated, so a new carefully defined software component called the OpenSSL FIPS Object Module has been created. It is designed for compatibility with the OpenSSL library so products using the OpenSSL library and API can be converted to use FIPS 140-2 validated cryptography with minimal effort. The

most recent open source-based validation is the OpenSSL FIPS Object Module v2.0, FIPS 140-2 certificate #1747.

ExtremeXOS uses both OpenSSL libraries:

- openssl-1.0.2l—When FIPS Mode is off.
- openssl-fips-2.0.16—When FIPS Mode is on.

**Note**

Digital Signature Algorithm (DSA) is not supported in FIPS mode. After turning on FIPS mode, you need to generate a new SSH host key.

*Applications*

SSH, SNMP, AAA, NTP, and EMS use this mode.

## Ciphers and Message Authentication Codes (MACs) Supported by Security Modes

| Cryptographic Functions                                           | Full Name (Default Mode)                | FIPS Mode | Secure Mode (SSH Only) |
|-------------------------------------------------------------------|-----------------------------------------|-----------|------------------------|
| <b>Hash Function (used for authentication)</b>                    |                                         |           |                        |
| In SNMPv3                                                         | <u>MD5 (Message-Digest algorithm 5)</u> |           |                        |
|                                                                   | SHA                                     | Yes       |                        |
|                                                                   | HMAC-MD5                                |           |                        |
|                                                                   | HMAC-SHA-1                              | Yes       |                        |
| In SSH                                                            | hmac-md5-96                             |           |                        |
|                                                                   | hmac-md5-etm@openssh.com                |           |                        |
|                                                                   | hmac-md5-96-etm@openssh.com             |           |                        |
|                                                                   | hmac-sha1                               | Yes       | Yes                    |
|                                                                   | hmac-sha1-96                            |           |                        |
|                                                                   | hmac-sha1-etm@openssh.com               |           |                        |
|                                                                   | hmac-sha1-96-etm@openssh.com            |           |                        |
|                                                                   | hmac-sha2-256                           | Yes       | Yes                    |
|                                                                   | hmac-sha2-512                           | Yes       | Yes                    |
|                                                                   | hmac-sha2-256-etm@openssh.com           |           |                        |
|                                                                   | hmac-sha2-512-etm@openssh.com           |           |                        |
| In AAA                                                            | SHA-256                                 | Yes       | Yes                    |
| In NTP                                                            | SHA-256                                 | Yes       |                        |
| <b>Symmetric Algorithms (used for encryption of file or text)</b> |                                         |           |                        |

| Cryptographic Functions                                  | Full Name (Default Mode)                                 | FIPS Mode                                               | Secure Mode (SSH Only) |
|----------------------------------------------------------|----------------------------------------------------------|---------------------------------------------------------|------------------------|
| In SSH, SNMPv3                                           | DES                                                      |                                                         |                        |
|                                                          | AES128                                                   | Yes                                                     |                        |
|                                                          | AES192                                                   | Yes                                                     |                        |
|                                                          | AES256                                                   | Yes                                                     |                        |
| In SSH                                                   | AES128-CTR                                               | Yes                                                     | Yes                    |
|                                                          | AES192-CTR                                               | Yes                                                     | Yes                    |
|                                                          | AES256-CTR                                               | Yes                                                     | Yes                    |
|                                                          | rijndael-cbc@lysator.liu.se                              | Yes                                                     |                        |
|                                                          | chacha20-poly1305@openssh.com                            |                                                         |                        |
| <b>Asymmetric Algorithms (Factorization of integers)</b> |                                                          |                                                         |                        |
| In SSH                                                   | DSA (Authentication and Digital Signature)               | Yes                                                     |                        |
|                                                          | RSA (Authentication and Encryption)                      | Non-approved, but allowed for Key Encryption Decryption |                        |
|                                                          | diffie-hellman-group1-sha1 exchange key (authentication) | Non-approved, but allowed for key exchange              |                        |

## Priority with Multiple Security Modes

Multiple modes can be in effect at the same time for certain applications (for example, all modes are applicable for SSH).

The precedence from highest priority to the lowest:

1. Secure mode
2. FIPS mode
3. Default mode

Example: If for SSH, FIPS mode and Secure Mode are both enabled, Secure mode takes precedence over FIPS mode.

## Using Safe Defaults Mode

When you take your switch from the box and set it up for the first time, you set the safe defaults mode. You should use the safe defaults mode, which lets you configure IP management connectivity if you choose not to use Auto Provisioning. It also lets you choose whether to enable or disable Telnet, *STP* (*Spanning Tree Protocol*), and *SNMP*. All ports are enabled in the factory default setting; you can choose to have all unconfigured ports disabled on reboot using the interactive questions. Also, *STPD*

*(Spanning Tree Domain)* s0 is enabled on the default *VLAN*; you have the option to disable STPD in safe defaults mode.

After you connect to the console port of the switch, or after you run `unconfigure switch {all}` or run `provisioning`, you can change management access to your device to enhance security.

1. Connect the console and log in to the switch.

```
This switch currently has some management methods enabled for convenience reasons.
Please answer these questions about the security settings you would like to use.
You may quit and accept the default settings by entering 'q' at any time.
```

```
Would you like to change the switch OS to Fabric Engine? [y/N/q]
```

2. You are prompted to select your network operating system: Switch Engine (default) or Fabric Engine:

- For Switch Engine, type `N`.
- For Fabric Engine, type `y`.

3. Type `y` (to disable) or `n` (to enable ) auto-provisioning.

```
By default, Auto-Provisioning uses DHCP on all Ethernet ports as this switch
attempts to connect to an Extreme Networks management product.
Instead of using DHCP, do you want to 'disable auto-provision' and
configure a static IP address, default gateway and DNS server now? [y/N/q]: y
```

Select `y` to be prompted for a port to use for management, an IP address and subnet mask length, an optional default gateway IP address, a DNS name server and DNS domain suffix.

4. Type `y` (to disable) or `n` (to enable ) *MSTP (Multiple Spanning Tree Protocol)*.

```
The switch offers an enhanced security mode. Would you like to read more,
and have the choice to enable this enhanced security mode? [y/N/q]:
```

If you select "no," go to [6](#) on page 1486.

5. If you select "yes," the following appears:

```
Enhanced security mode configures the following defaults:
```

- \* Disable Telnet server.
- \* Disable HTTP server.
- \* Disable SNMP server.
- \* Remove all factory default login accounts.
- \* Force creation of a new admin (read-write) account.
- \* Lockout accounts for 5 minutes after 3 consecutive login failures.
- \* Plaintext password entry will not be allowed.
- \* Generate an event when the logging memory buffer exceeds 90% of capacity.
- \* Only admin privilege accounts are permitted to run "show log".
- \* Only admin privilege accounts are permitted to run "show diagnostics".

```
Would you like to use this enhanced security mode? [Y/n/q]:
```

If you select "yes," enhanced security mode is enabled. Go to step [10](#) on page 1487.

6. If you select "no," you are prompted to disable Telnet:

```
Telnet is enabled by default. Telnet is unencrypted and has been the target of
security exploits in the past.
```

```
Would you like to disable Telnet? [y/N/q]:
```

7. You are prompted to enable SNMPv2c:

```
SNMP access is disabled by default.
SNMPv2c uses no encryption, SNMPv3 can be configured to eliminate this problem.
Would you like to enable SNMPv2c? [y/N/q]: Yes
```

8. You are prompted to set up the community string:

```
SNMP community string is a text string that is used to authenticate SNMPv2c messages.
It is required for managing the switch using SNMPv2c.
Would you like to configure a read-only and read-write community string? [Y/n/q]: Yes

Read-only community string:
Re-enter read-only community string:
Read-write community string:
Re-enter read-write community string:
```

9. You are prompted to enable SNMPv3:

```
Would you like to enable SNMPv3? [y/N/q]: Yes

SNMPv3 uses usernames/passwords to authenticate and encrypt SNMP messages.
Would you like to create an SNMPv3 user? [Y/n/q]: Yes

User name: admin
Authentication password:
Reenter authentication password:
Privacy password:
Reenter privacy password:

SNMPv3 user 'admin' was created with authentication protocol SHA and privacy protocol
AES-128.
```

10. Reboot the switch.

## MAC Security

The switch maintains a database of all media access control (MAC) addresses received on all of its ports.

The switch uses the information in this database to decide whether a frame should be forwarded or filtered. MAC security (formerly known as MAC address security) allows you to control the way the *FDB (forwarding database)* is learned and populated. For more information, see [FDB](#).

MAC security includes several types of control. You can:

- Limit the number of dynamically learned MAC addresses allowed per virtual port. For more information, see [Limiting Dynamic MAC Addresses](#) on page 1497.
- “Lock” the FDB entries for a virtual port, so that the current entries will not change, and no additional addresses can be learned on the port. For information, see [MAC Address Lockdown](#) on page 1500.

**Note**

You can either limit dynamic MAC FDB entries or lockdown the current MAC FDB entries, but not both.

- Set a timer on the learned addresses that limits the length of time the learned addresses will be maintained if the devices are disconnected or become inactive. For more information, see [MAC Address Lockdown with Timeout](#) on page 1501.

**Note**

When limit-learning is configured in the port which is also associated with some other vlan where learning is disabled, then few packets with new MAC address beyond learning limit will get flooded. This flooding will take place for fraction of second until new black-hole entry is created in hardware.

- Use ACLS to prioritize or stop packet flows based on the source MAC address of the ingress virtual LAN ([VLAN](#)) or the destination MAC address of the egress VLAN. For more information about [ACL](#) policies, see [Security](#) on page 1573.
- Enhance security, depending on your network configuration, by disabling Layer 2 flooding. For more information about enabling and disabling Layer 2 flooding, see [Managing Egress Flooding](#) on page 815.

## MAC Locking

MAC locking helps prevent unauthorized access to the network by limiting access based on a device's MAC address. MAC locking enables the binding of specific MAC addresses to specific ports on a switch. MAC locking locks a port to one or more MAC addresses, preventing connection of unauthorized devices via a port. With MAC locking enabled, the only frames forwarded on a MAC locked port are those with the configured or dynamically selected MAC addresses for that port.

Frames received on a port with a Source MAC address not bound to the port are discarded or optionally allowed to dynamically bind to the port, up to a user-controlled maximum number of MAC addresses per port.

There are two different types of MAC locking:

- Static MAC locking - Locking one or more specified MAC addresses to a port.
- First Arrival MAC locking - Locking one or more MAC addresses to a port based on first arrival of received frames after First Arrival MAC locking is enabled. The configuration specifies the maximum number of end users that will be allowed. As each new end user is identified, it is MAC locked up to the maximum number of users. Once the maximum number of users has been MAC locked, all other users will be denied access to the port until a MAC locked address is either aged, if aging is configured, or the session for that user ends.

The MAC locking feature is disabled in the device, by default. MAC locking must be enabled both globally and on port level. Once enabled, ports can be configured for static and First Arrival MAC locking.

Existing limit learning and lock learning features are supported on a port-[VLAN](#) combination. The MAC locking feature implemented in ExtremeXOS 15.7 supports MAC locking functionality on a port basis.

### MAC Locking Limitations

The following limitations exist for the MAC locking feature:

- MAC locking cannot be enabled along with existing limit learning and lock learning features.
- MAC locking is supported on ports in the VPLS service VLAN.

### MAC Locking Functionality

This feature provides a global enable/disable control and controls per port. Additional controls are provided to create, destroy, enable and disable static MAC to Interface bindings. The MAC and port, together are required to be unique (the same MAC may be bound to multiple ports).

The configuration of a maximum number of static and dynamic entries (each individually) is provided per port. First Arrival bindings (also known as first arrival MAC locking stations) are not persistent through a device reset. Static bindings (also known as static MAC locking stations) are maintained through a device reset. First Arrival bindings are removed in the event of link loss, or after the FDB entry with the MAC locked MAC ages out. A port, may have both the static and dynamic entries, at any instance.

Dynamic locking may be disabled by setting the maximum number of First Arrival MAC addresses to zero.

Controls are provided per port to convert all current first arrival entries to static entries. This converts only the first arrival MAC bindings to static bindings. This is not to be confused with MAC locking where all dynamic FDB entries are converted to static permanent locked FDB entries and further learning is disabled. Controls are provided to clear current (both static and dynamic) bindings. Each port is configurable to support the aging of dynamically locked bindings.

The device keeps a record of the number of MAC locked stations and when the configured threshold is reached, a threshold SNMP trap/notification and/or a log message is issued based on the per-port configuration. The Source MAC Address of the frame causing the last invalid attempt is also recorded. In the event that the device is so configured, a violation SNMP Trap/ Notification and/or a violation log message is issued – these controls will be exercised per port.

### Configuring MAC Locking

The following content describes the MAC locking commands:

#### Enabling and Disabling MAC Locking Globally

To enable or disable the MAC locking feature, use the following commands:

- `enable mac-locking`
- `disable mac-locking`

### Enabling and Disabling MAC Locking on Ports

To enable MAC locking on specific ports, use the following command:

- `enable mac-locking ports [all| port_list]`

To Disable MAC locking on specific ports, use the following command:

- `disable mac-locking ports [all| port_list]`

### Configuring First-arrival/Dynamic MAC Locking Limit

To configure first arrival MAC locking on a port, use the following command:

- `configure mac-locking ports port_list first-arrival limit-learning learn_limit`

When the configured limit is reached, no further entries are learnt. However, if the learnt entries are aged out, new MAC addresses can be learned.

By default, Aging is disabled for first arrival MAC locking entries on a configured port. When the *FDB* entries are aged out, they are removed from the FDB, but they are retained in the MAC locking table. So when the first arrival limit is reached, only those entries in the MAC locking table can be learned again if these devices start sending out traffic. Any new MAC addresses cannot be learned.

The maximum number of dynamic MAC addresses that can be locked on a port is 600.

#### Note

There is no command to unconfigure first arrival or static MAC locking limit. The value can be reset giving the default learn limit specified in the help text. When First arrival MAC locking is configured to a value that is lower than the number of MACs that are locked, all the MAC locking bindings on the port are cleared.

### Configuring Static MAC Locking Limit

To configure static MAC locking on a port, use the following command:

- `configure mac-locking ports port_list static limit-learning learn_limit`

When the configured limit is reached, no further entries are learned (either black holed or not further learned depending on the configured action). However, if the learned entries are cleared or deleted, new MAC addresses can be created and learned. The maximum number of MAC addresses that will be locked on a port configured for static MAC locking is 64. Aging is not applicable for the static MAC locking entries.

#### Note

There is no command to unconfigure first arrival or static MAC locking limit. The value can be reset giving the default learn limit specified in the help text. CLI doesn't allow changing the static MAC locking limit value to a value lower than the number of MACs locked in the MAC lock station table. Some or all of the created MAC locking stations should be removed to change the limit to a lower value.

**Note**

Assume that port 2:22 is enabled for MAC Locking. The maximum static entry limit value is configured to 5 on port 2:22. If the user wants to configure the maximum static entry limit value to 3,

1. The device will display an error, as maximum number of static stations already locked on the port and the value cannot be reduced.
2. In the same example, the port 2:22 has only 1 static station locked. If the maximum static entry limit value is reduced to 3, the device will allow to reduce the value.

**Scenario A:**

```
* Slot-1 DUT1.94 # show mac-locking ports 2:22
```

MAC locking is globally enabled.

| Port | MAC Lock Stat | Trap Thr | Log Viol Thr | FA Aging | Limit Action Cfg | Link Down Action | Max Stc | Max FA | Last Violating MAC Address |   |    |                   |

### Create/Enable/Disable static MAC Locking Entries

To create a static MAC locking entry (also known as MAC locking station) and enable or disable MAC locking for the specific MAC address and port, use the following command:

```
configure mac-locking ports port_list static [add | enable | disable]
station station_mac_address
```

#### Note

A static MAC locking station is enabled by default.

To disable the static MAC locking station, use the following command.

```
configure mac-locking ports port_list static disable station
station_mac_address
```

When created and enabled, a static MAC lock configuration allows only the end station designated by the MAC address to participate in forwarding of traffic.

The disabled entries are also counted when calculating the total number of locked stations. Static MAC locking stations that are disabled are only shown in “show mac-locking stations static” command. When “static” keyword is not given in “show mac-locking stations”, the disabled entries are not shown.

### Enable/Disable Aging of First-arrival MAC Addresses

To enable or disable first arrival MAC address aging, use the following command.

```
configure mac-locking ports port_list first-arrival aging [enable |
disable]
```

Dynamic MAC locking mode MAC address aging is disabled by default.

This is applicable only to MAC addresses locked by first-arrival locking and not to MAC addresses locked by static locking.

When First arrival aging is disabled, MAC locking stations are retained even when the corresponding FDB entry ages out.

When First arrival aging is enabled, MAC locking station starts aging when all the FDB entries corresponding to the station MAC are removed. MAC lock stations do not start aging when FDB entries are present.

When “first arrival aging” is configured to be enabled in first-arrival locking, when an FDB entry ages out, the entry is no more locked and so new MAC addresses can be learned till the configured first-arrival limit is reached.

**Note**

First arrival Aging – Age out time for First Arrival MAC locking station is same as FDB aging time that is configured using `configure fdb agingtime`.

**Move First-arrival MACs to Static Entries**

To move all current first-arrival MACs to static entries on a port, use the following command:

```
configure mac-locking ports port_list first-arrival move-to-static
```

This command converts dynamic MAC locked stations to static MAC locked stations. There is no change to FDB entries.

The static MAC locked station entries are saved in configuration and so are preserved across reboots.

**Note**

Ensure the static limit can accommodate the entries before moving them from to static. Otherwise, the device may throw the following error: `Error: Some dynamic stations could not be converted to static stations for port <port_list>.`

**Note**

An FDB entry created from the CLI will not be removed when a static MAC lock station is created and disabled for the corresponding MAC address. It is necessary to delete the FDB entry from the CLI. MAC-Locking does not remove user created FDB entries.

## Managing MAC Locking

### Enable/Disable Clearing First-arrival MACs on Link Change

To manage the behavior of first arrival MAC locking on link state change, use the following command.

```
configure mac-locking ports port_list first-arrival link-down-action
[clear-macs | retain-macs]
```

Clear MAC on link change is enabled by default.

When the link goes down, by default, all the first arrival MAC locking addresses will be removed. When link-down-action is configured to “retain-macs”, the first arrival MAC locking addresses will be retained even when the link goes down.

### Disable/Enable port when MAC threshold is reached

This command is used to configure the disabling of ports when the configured MAC threshold is met. This is used for both “first arrival” and “static” MAC locking methods.

```
configure mac-locking ports port_list learn-limit-action [disable-port |
remain-enabled]
```

The port is disabled when the configured MAC threshold is met. All the *FDB* entries learned on this port are flushed as the port is disabled. This configuration can be reset using the `clear mac-locking disabled-state ports port_list` command. When MAC locking is disabled on the port, the port comes back up.

### Clearing the Disabled-state of a Port

This command is used to return the behavior of first arrival MAC locking with link state change to its default value of enabled.

```
clear mac-locking disabled-state ports port_list
```

### Delete Static MAC Locking Entries

To delete MAC locking for all static MAC address or the specified static MAC address on the given port, use the following command:

```
configure mac-locking ports port_list static delete station
[station_mac_address | all]
```

### Clearing MAC Locking entries

The following command is used to clear MAC locking station entries for the given parameters:

```
clear mac-locking station [all | {mac station_mac_address} {first-
arrival | static} {ports port_list}]
```

This command clears MAC locking configuration by port/mac/first arrival/static etc.

#### Note

Clearing static MAC locking stations will remove them from the configuration. The cleared static MAC locking stations will not be saved across reboots.

### Displaying MAC Locking Information

This command is used to display the status of MAC locking on one or more ports.

```
show mac-locking {ports port_list}
```

#### Note

In MLAG, the mac-locking entries shown in this command's output are only natively learned FDB entries on the switch.

If port is not specified, MAC locking status will be displayed for all ports.

Sample output:

```
Slot-1 Stack.2 # show mac-locking

MAC locking is globally enabled.
```

| Port | MAC Lock Stat | Trap Thr Viol | Log Thr Viol | FA Aging Cfg | Limit Action Stat | Link Down | Max Stc | Max FA | Last Violating MAC Address |

```

Legend:
Stat - Status
Max Stc - Max Static Count
dis - Disabled
retain - Retain MACs
Limit Action Cfg - If port should be disabled when learnt limit is exceeded
 dis - Port to be disabled when learn limit is exceeded
 ena - Port to remain enabled when learn limit is exceeded
Limit Action Stat - Port status on exceeding learn limit

```

The following command displays MAC locking stations for different parameters:

```
show mac-locking stations {first-arrival | static} {ports port_list}
```

### MAC Locking Configuration Example

The following command enables MAC locking both globally for the device (stack) and at the port level for ports 2:1 through 2:5:

```
Slot-1 Stack.1 # enable mac-locking
```

```
Slot-1 Stack.2 # enable mac-locking ports 2:1-2:5
```

The following command lines enable port 2:1 for a maximum of 3 static MAC address entries. This is followed by four static MAC address creation entries. The fourth entry fails because the maximum allowed has been set to 3.

```
* Slot-1 Stack.3 # configure mac-locking ports 2:1 static limit-learning 3
* Slot-1 Stack.4 # configure mac-locking ports 2:1 static add station 00:22:33:44:55:66
* Slot-1 Stack.5 # configure mac-locking ports 2:1 static add station 00:22:33:44:55:77
* Slot-1 Stack.6 # configure mac-locking ports 2:1 static add station 00:22:33:44:55:88
* Slot-1 Stack.7 # configure mac-locking ports 2:1 static add station 00:22:33:44:55:99
Error: Station 00:22:33:44:55:99 cannot be added as maximum static limit of 3 is already
reached on port 2:1.

* Slot-1 Stack.10 # show mac-locking stations static ports 2:1
Port MAC Address Status State Aging

2:1 00:22:33:44:55:66 active static false
2:1 00:22:33:44:55:77 active static false
2:1 00:22:33:44:55:88 active static false

Total for specified ports: 3 Static: 3 First-Arrival: 0
* Slot-1 Stack.11 #
```

The following commands configure ports 2:2 through 2:5 for dynamic MAC locking with a maximum of 15 users on each port. This is followed by a line enabling MAC locking trap messaging on ports 2:1 through 5:

```
* Slot-1 Stack.12 # configure mac-locking ports 2:2-2:5 first-arrival limit-learning 15
* Slot-1 Stack.13 # configure mac-locking ports 2:2-2:5 trap on
* Slot-1 Stack.14 # show mac-locking ports 2:1-2:5

MAC locking is globally enabled.
```

## Limiting Dynamic MAC Addresses

You can set a predefined limit on the number of dynamic MAC addresses that can participate in the network.

After the *FDB* reaches the MAC limit, all new source MAC addresses are blackholed at both the ingress and egress points. These dynamic blackhole entries prevent the MAC addresses from learning and responding to *ICMP* (*Internet Control Message Protocol*) and address resolution protocol (ARP) packets.

#### Note

Blackhole FDB entries added due to MAC security violations are removed after each FDB aging period regardless of whether the MAC addresses in question are still sending traffic. If the MAC addresses are still sending traffic, the blackhole entries will be re-added after they have been deleted.

### Configuring Limit Learning

- To limit the number of dynamic MAC addresses that can participate in the network, use the limit-learning option in following command:

```
configure ports port_list {tagged tag} vlan vlan_name | vlan_list
[limit-learning number {action [blackhole | stop-learning]} | lock-
learning | unlimited-learning | unlock-learning]
```

This command specifies the number of dynamically learned MAC entries allowed for these ports in this *VLAN*. The range is 0 to 500,000 addresses.

When the learned limit is reached, all new source MAC addresses are blackholed at the ingress and egress points. This prevents these MAC addresses from learning and responding to *ICMP* and ARP packets.

Dynamically learned entries still get aged and can be cleared. If entries are cleared or aged out after the learning limit has been reached, new entries will then be able to be learned until the limit is reached again.

Permanent static and permanent dynamic entries can still be added and deleted using the `create fdb` and `disable flooding ports` commands. These override any dynamically learned entries.

For ports that have a learning limit in place, the following traffic still flows to the port:

- Packets destined for permanent MAC addresses and other non-blackholed MAC addresses
- Broadcast traffic
- *EDP* (*Extreme Discovery Protocol*) traffic

Traffic from the permanent MAC and any other non-blackholed MAC addresses still flows from the virtual port.

- To remove the learning limit, use the **unlimited-learning** option.

```
configure ports port_list {tagged tag} vlan vlan_name | vlan_list
[limit-learning number {action [blackhole | stop-learning]} | lock-
learning | unlimited-learning | unlock-learning]
```

The MAC limit-learning feature includes a stop-learning argument that protects the switch from exhausting *FDB* resources with blackhole entries. When limit-learning is configured with stop-learning, the switch is protected from exhausting FDB

resources by not creating blackhole entries. Any additional learning and forwarding is prevented, but packet forwarding is not impacted for existing FDB entries.

#### Display Limit Learning Information

- To verify the configuration, enter the commands:

```
show vlan vlan name security
```

This command displays the MAC security information for the specified VLAN.

```
show ports {mgmt | portlist} info {detail}
```

This command displays detailed information, including MAC security information, for the specified port.

#### Example of Limit Learning

In [Figure 188](#), three devices are connected through a hub to a single port on the Extreme Networks device.

If a learning limit of three is set for that port, and you connect a fourth device to the same port, the switch does not learn the MAC address of the new device; rather, the switch blackholes the address.

**Figure 188: Switch Configured for Limit Learning**

#### Limiting MAC Addresses with ESRP Enabled

If you configure a MAC address limit on VLANs that participate in an ESRP (Extreme Standby Router Protocol) domain, you should add an additional back-to-back link (that has no MAC address limit on these ports) between the ESRP-enabled switches.

Doing so prevents ESRP protocol data units (PDUs) from being dropped due to MAC address limit settings.

[Figure 189](#) is an example of configuring a MAC address limit on a VLAN participating in an ESRP domain.

**Figure 189: MAC Address Limits and VLANs Participating in ESRP**

S2 and S3 are ESRP-enabled switches, while S1 is an ESRP-aware (regular Layer 2) switch. Configuring a MAC address limit on all S1 ports might prevent ESRP communication between S2 and S3. To resolve this, you should add a back-to-back link between S2 and S3. This link is not needed if MAC address limiting is configured only on S2 and S3, but not on S1.

## MAC Address Lockdown

- In contrast to limiting learning on virtual ports, you can lockdown the existing dynamic *FDB* entries and prevent any additional learning using the lock-learning option from the following command:

```
configure ports port_list {tagged tag} vlan vlan_name | vlan_list
[limit-learning number {action [blackhole | stop-learning]} | lock-
learning | unlimited-learning | unlock-learning]
```

This command causes all dynamic FDB entries associated with the specified *VLAN* and ports to be converted to locked static entries. It also sets the learning limit to 0, so that no new entries can be learned. All new source MAC addresses are blackholed.

### Note

Blackhole FDB entries added due to MAC security violations are removed after each FDB aging period regardless of whether the MAC addresses in question are still sending traffic. If the MAC addresses are still sending traffic, the blackhole entries will be re-added after they have been deleted.

Locked entries do not get aged, but can be deleted like a regular permanent entry.

For ports that have lock-down in effect, the following traffic still flows to the port:

- Packets destined for the permanent MAC and other non-blackholed MAC addresses
- Broadcast traffic

- EDP traffic
- Traffic from the permanent MAC still flows from the virtual port.
- Remove MAC address lockdown, use the unlock-learning option.

```
configure ports port_list {tagged tag} vlan vlan_name | vlan_list
[limit-learning number {action [blackhole | stop-learning]}] | lock-
learning | unlimited-learning | unlock-learning]
```

When you remove the lockdown using the unlock-learning option, the learning-limit is reset to unlimited, and all associated entries in the FDB are flushed.

- Display the locked entries on the switch.

```
show fdb
```

Locked MAC address entries have the "I" flag.

## MAC Address Lockdown with Timeout

The MAC address lockdown with timeout feature provides a timer for aging out MAC addresses on a per port basis and overrides the FDB aging time. That is, when this feature is enabled on a port and the port goes down/restarted, MAC addresses learned on that port age out based on the MAC lockdown timeout corresponding to the port, not based on the FDB aging time. By default, the MAC address lockdown timer is disabled.

### Note

MAC address lockdown is not supported on NetLogin Dot1x non-policy mode.

When this feature is enabled on a port, MAC addresses learned on that port remain locked for the MAC lockdown timeout duration corresponding to the port, even when the port goes down. As a result, when a device is directly connected to the switch and then disconnected, the MAC address corresponding to the device will be locked up for the MAC lockdown timeout duration corresponding to that port. If the same device reconnects to the port before the MAC lockdown timer expires and sends traffic, the stored MAC address becomes active and the MAC lockdown timer is restarted. If the device is not reconnected for the MAC lockdown timeout duration, the MAC entry is removed.

MAC lockdown timeout entries are dynamically learned by the switch, which means these entries are not saved or restored during a switch reboot. If the switch reboots, the local MAC entry table is empty, and the switch needs to relearn the MAC addresses.

MAC address lockdown with timeout is configured by individual ports. The lockdown timer and address learning limits are configured separately for a port.

### Note

You cannot enable the lockdown timeout feature on a port that already has MAC address lockdown enabled. For more information about MAC address lockdown, see [MAC Address Lockdown](#) on page 1500.

MAC address learning limits and the lockdown timer work together in the following ways:

- When the learning limit has been reached on a port, a new device attempting to connect to the port has its MAC address blackholed.
- As long as the timer is still running for a MAC entry, a new device cannot connect in place of the device that entry represents. That is, if a device has disconnected from a port, a new device cannot replace it until the lockdown timer for the first device has expired. This condition is true if the limit on the port is set to 1 or if the limit (greater than 1) on the port has been reached.
- If a learning limit is already configured on a port when you enable the lockdown timeout feature, the configured limit will continue to apply. Existing blackholed entries are therefore not affected. If you enable this feature on a port with no configured learning limit, the default maximum learning limit (unlimited learning) is used.

#### *Understanding the Lockdown Timer*

The lockdown timer works in the following ways:

- When you enable this feature on a port, existing MAC entries for the port begin aging out based on the configured MAC lockdown timer value.
- If you move a device from one port to another, its MAC address entry is updated with the new port information, including the lockdown timer value configured for that port.
- If this feature is enabled on a port and you decrease the lockdown timer value for that port, all of the MAC *FDB* entries for that port will time out and be removed at the next polling interval.
- When you disable the lockdown timer on a port, existing MAC address entries for the port will time out based on the FDB aging period.
- The MAC lockdown timer takes effect when the port goes down/restarted.

#### *Examples of Active and Inactive Devices*

[Figure 190](#) shows three devices (A, B, and C) connected through a hub to an Extreme Networks device with MAC lockdown timeout configured on the ports.

When each device starts sending traffic, the source MAC address of the device is learned and *FDB* entries are created. The MAC lockdown timer is set at 100 seconds.

**Figure 190: Devices Using MAC Address Lockdown**

#### Device Inactivity for Less than the MAC Lockdown Timer

As long as a device continues to send traffic, the MAC entry for that device is refreshed, and the MAC lockdown timer corresponding to the MAC entry is refreshed.

Therefore, as long as the device is active, the timer does not expire. The traffic can be continuous or can occur in bursts within the MAC lockdown timeout duration for the port.

In this example, Device A starts sending traffic. When the MAC address of Device A is learned and added to the FDB, the MAC lockdown timer is started for this entry.

Device A stops sending traffic and resumes sending traffic after 50 seconds have elapsed. At this point the MAC entry for Device A is refreshed and the MAC lockdown timer is restarted.

#### Device Inactivity for Longer than the MAC Lockdown Timer

When a device stops sending traffic and does not resume within the MAC lockdown timer interval for the port, the MAC lockdown timer expires, and the MAC entry is removed from the FDB.

In this example, Devices A, B, and C start sending traffic. As each MAC address is learned, the MAC lockdown timer is started for each entry.

Device A stops sending traffic; Devices B and C continue sending traffic. After 100 seconds, the MAC lockdown timer for the Device A entry is removed from the FDB. Because Devices B and C have continued to send traffic, their MAC entries continue to be refreshed and their MAC lockdown timers continue to be restarted.

#### *Examples of Disconnecting and Reconnecting Devices*

Figure 191 shows Device A connected to an Extreme Networks device with MAC lockdown timeout configured for the ports.

When Device A starts sending traffic, the source MAC address is learned on the port, the *FDB* entry is created, and the MAC lockdown timer is started for the entry. The MAC lockdown timer is set at 3,000 seconds.

**Figure 191: Single Device with MAC Lockdown Timeout**

#### Disconnecting a Device

In this example, Device A is disconnected from the port, triggering a port-down action.

The MAC entry for Device A is removed from the hardware FDB; however, the MAC entry for the device is maintained in the software. The MAC lockdown timer for this entry starts when the port goes down.

After 3,000 seconds, the MAC entry for Device A is removed from the software.

#### Disconnecting and Reconnecting a Device

When Device A is disconnected from the port, the resulting port-down action causes the MAC entry for Device A to be removed from the hardware FDB.

The MAC entry in software is maintained, and the MAC lockdown timer is started for the port.

After only 1,000 seconds have elapsed, Device A is reconnected to the same port and starts sending traffic. A MAC entry is created in the hardware FDB, and the MAC lockdown timer is restarted for the MAC entry in the software.

If Device A is reconnected but does not send any traffic for 3,000 seconds, no MAC entry is created in the hardware FDB, and the MAC lockdown timer will expire after reaching 3,000 seconds.

#### Disconnecting and Reconnecting Devices with MAC Limit Learning

In this example, a MAC learning limit of 1 has also been configured on the ports in addition to the MAC lockdown timer of 3000 seconds.

When Device A is disconnected, the resulting port-down action removes the MAC entry for Device A from the hardware FDB. The MAC entry for Device A is maintained in the software, and the MAC lockdown timer for this entry is restarted when the port goes down.

After 1000 seconds, a different device is connected to the same port and starts sending traffic. Because the MAC learning limit is set to 1 and the MAC lockdown timer is still running, the MAC address of the new device is not learned. Instead, the new MAC address is blackholed in the hardware.

When the MAC lockdown timer for Device A expires, its MAC entry is removed from the software. If the new device is still connected to the same port and sends traffic, the MAC address for the new device is learned and added to the FDB. The MAC lockdown

timer for the new device is started, and the blackhole entry that was created for this device is deleted.

#### Example of Port Movement

Figure 192 shows Device A connected to port X.

Port X has a MAC lockdown timer setting of 100 seconds, and port Y has a MAC lockdown timer setting of 200 seconds.

**Figure 192: Port Movement with MAC Lockdown Timeout**

Device A starts sending traffic on port X. The MAC address for Device A is learned and added to the *FDB*, and the MAC lockdown timer (100 seconds) is started for this entry.

After 50 seconds, Device A is disconnected from port X and connected to port Y where it begins sending traffic. When Device A starts sending traffic on port Y, the existing MAC entry for Device A is refreshed, and port X in the entry is replaced with port Y. At the same time, the MAC lockdown timer for the entry is restarted for a duration of 200 seconds (the configured MAC lockdown timer setting for port Y).

#### Configuring MAC Address Lockdown with Timeout

- Configure the MAC lockdown timeout value on one or more specified ports, or on all ports using the following command:

```
configure mac-lockdown-timeout ports [all | port_list] aging-time
seconds
```

#### Enabling and Disabling MAC Address Lockdown with Timeout

- Enable the MAC lockdown timeout feature on one or more specified ports, or on all ports. using the command:

```
enable mac-lockdown-timeout ports [all | port_list]
```

- Disable the MAC lockdown timeout feature on one or more specified ports, or on all ports using the command:

```
disable mac-lockdown-timeout ports [all | port_list]
```

#### Displaying MAC Address Lockdown Information

- Display configuration information about the MAC lockdown timeout feature using the command:

```
show mac-lockdown-timeout ports [all | port_list]
```

Output from this command includes the configured timeout value and whether the feature is enabled or disabled.

- Display the MAC entries learned on one or more ports, or on all ports using the command:

```
show mac-lockdown-timeout fdb ports [all | port_list]
```

Output from this command also lists the aging time of the port.

## MAC Security with Pre-shared Key Authentication

Media Access Control Security (MACsec) as defined by *IEEE Std 802.1X-2010 Port-Based Network Access Control* (control plane) and *IEEE Std 802.1AE-2006 Media Access Control (MAC) Security* (data plane) allows authorized systems that attach to, and interconnect, LANs in a network to maintain confidentiality of transmitted data and to take measures against frames transmitted or modified by unauthorized devices.

### Overview

MACsec is configured on a per-port basis to protect point-to-point links between switches. Mutual authentication is achieved by provisioning the same set of credentials (pre-shared key) on each end of a link.

Prior to authentication, all port traffic is blocked. After authentication, all port traffic is protected by the GCM-AES-128 cipher suite by default, or optionally, by GCM-AES-256. MACsec operates at Layer 2 and is therefore protocol agnostic, encrypting everything it passes. Because encryption takes place at the hardware level, line-rate traffic passes with low latency, but due to additional MACsec headers, some throughput drop occurs. MACsec operates on a hop-by-hop basis, allowing for deep packet inspection.

#### Note

The following table lists the switches/ports that support the optional GCM-AES-256 cipher.

**Table 138: Switches/Ports that Support the GCM-AES-256 Cipher**

| Platform                             | Ports                                           | LRM/<br>MACsec<br>Adap-<br>ter<br>Requir-<br>ed? |
|--------------------------------------|-------------------------------------------------|--------------------------------------------------|
| ExtremeSwitching 5320-24T-24S-4XE-XT | All ports except stacking ports.                | No                                               |
| ExtremeSwitching 5320                | All ports of all models except stacking ports.  | No                                               |
| ExtremeSwitching 5420                | All ports of all models except stacking ports.  | No                                               |
| ExtremeSwitching 5520                | All ports, except 5520-VIM-4X and 24X 10G ports | No                                               |
| ExtremeSwitching 5720                | All ports of all models except stacking ports.  | No                                               |
| Extreme 7520-48YE-8CE                | All front panel ports.                          | No                                               |

Authentication is provided by pre-shared-keys (PSK), which consist of a public secure connectivity association key name (CKN) and a private secure connectivity association key (CAK). Each PSK is configured against a connectivity-association namespace. Each connectivity-association can be applied to one or more MACsec-capable ports. Each port may belong to only one connectivity-association.

**Note**

When MACsec is enabled, every protected packet is prefixed with an 8-byte (include-sci disable) or 16-byte (include-sci enable) SecTAG and suffixed with a 16-byte Integrity Check Value (ICV). If the average packet size on a port is small, then these 24 to 32 extra bytes per packet have a non-trivial impact on throughput. This is a function of the protocol, and is not a factor of this implementation.

**Note**

MACsec-enabled port mirroring for egress traffic is not supported on 5420 switches.

### *MAC Security with Pre-shared Keys Authentication Limitations*

The following limitations apply to the MAC Security (MACsec) with Pre-shared Keys (PSK) Authentication:

- This initial release of MACsec only implements section point-to-point LANs within a secured network as described in *Clause 7.4 MACsec to support Infrastructure LANs* of the much broader standard outlined in *IEEE802.1X-2010 Port-Based Access Control*. All other sections and clauses are not supported.

**Note**

MACSec between customer edges over L2VPN is supported on untagged access ports.

- MACsec is only configurable using CLI commands. There is no SNMP access to the two MACsec MIBs defined by IEEE: IEEE8021X-PAE-MIB and IEEE8021-SECY-MIB.
- MACsec is not supported on ports with stacking enabled.
- MACsec is not supported on Extended Edge Switching ports.
- Hot swapping LRM/MACsec Adapters is not supported. MACsec must be disabled before hot swapping.
- The LRM/MACsec Adapters cannot be connected across slots on a stack.
- The 5320 and 5720 switches use their native MACsec. MACsec is not supported on an LRM/MACsec Adapter when connected to this switch.
- On the 5720 switch, corresponding 5720-VIM-6YE port groups need to be configured to 3x10G partition to support an LRM/MACsec Adapter and 10G-LRM optics.
- MACSec is not supported on MLAG ports in 5420 and 5320 stacked switches.

### *MAC Security with Pre-shared Keys Authentication Supported Platforms*

MAC Security (MACsec) with Pre-shared Keys (PSK) authentication is supported natively the following platforms.

| Platform              | Ports                                                                      |
|-----------------------|----------------------------------------------------------------------------|
| ExtremeSwitching 5320 | All ports of all models, except 5320-24T-4X-XT, and except stacking ports. |
| ExtremeSwitching 5420 | All ports of all models except stacking ports.                             |
| ExtremeSwitching 5520 | All ports, except 5520-VIM-4X and 5520-24X 10G ports                       |
| ExtremeSwitching 5720 | All ports of all models except stacking ports.                             |
| Extreme 7520-48YE-8CE | All front-panel ports.                                                     |

**Note**

5120 Series MAC Security support is available in version 33.4.x and later.

**Note**

The MACsec feature requires the installation of the MAC Security feature pack license.

**Note**

When an LRM/MACsec adapter is connected to 5320 or 5720 switch, MACsec will be provided by the native switch port rather than by the adapter.

**Note**

On 5420 and 5320 switches, when OnePolicy is enabled, the MACsec link may fail due to the unavailability of ACL resources. The only way to overcome this is to reduce the number of ACLs reserved by Policy by using the `configure policy resource-profile default profile-modifier` command.

### Configuring MAC Security with Pre-shared Keys Authentication

To configure MAC Security (MACsec) with pre-shared keys (PSKs) authentication on a switch port:

1. Install a MACsec license key (if one is not already installed) by using the following command:

```
install license file filename {slot slot}
```

**Note**

ExtremeSwitching Universal switches natively support MACsec and do not require an adapter.

2. Create a connectivity-association (CA) object that holds MACSec authentication data (secure connection association key (CAK) and secure connection association key name (CKN) pair, which makes up the PSK on each port enabled for MKA by using the following command:

```
create macsec connectivity-association ca_name pre-shared-key ckn ckn
cak [encrypted encrypted_cak | cak]
```

3. Optionally, modify MACsec replay protection packet window, which allows for dropping of out-of-order packets received on a port by using the following command:

```
configure macsec replay-protect [window_size_in_packets | disable]
ports port_list
```

The replay protection feature provides for the dropping of out-of-order packets received on a port. The window size is set to 0 by default, meaning any packet received out-of-order is dropped. Setting the window size to non-zero sets the range of sequence numbers that are tolerated, to allow receipt of packets that have been misordered by the network. If replay protection is disabled, packet sequence numbers are not checked and out-of-order packets are not dropped.

4. Optionally, configure a port's priority for becoming a key server by using the following command:

```
configure macsec mka actor-priority actor_priority ports port_list
```

5. Optionally, configure the include-SCI flag (to ensure interoperability with third-party devices that do not decode encrypted MACsec packets when the SCI is not present) using the following command:

```
configure macsec include-sci [enable | disable] ports port_list
```

6. Optionally, change the MACsec cipher suite by using the following command:

```
configure macsec cipher-suite [gcm-aes-128 | gcm-aes-256] ports
port_list
```

#### Note

Universal Switches support both GCM-AES-128 and GCM-AES-256 cipher natively on all ports except for Universal ports U1 and U2.

7. Enable MACsec authentication on the desired ports by using the following command:

```
configure macsec connectivity-association ca_name [pre-shared-key {ckn
ckn} {cak [encrypted encrypted_cak] | cak} | ports [port_list] [enable
| disable]]
```

Use the *ca\_name* set up in Step 2 on page 1508, use the enable option, and designate the port(s).

#### Important

After enabling MACsec, if you change the actor priority, replay protection window, mka life-time, or include-SCI flag, you must run the `configure macsec initialize ports port_list` afterward. Otherwise, the change is not accepted.

To **delete** a previously created CA object, use the following command:

```
delete macsec connectivity-association ca_name
```

To **clear MACsec counters**, use the following command:

```
clear macsec counters {ports [port_list]}
```

To **reset** the MACsec Key Agreement protocol state machine on one or more ports, use the following command:

```
configure macsec initialize ports port_list
```

Issuing this command resets the MKA state machine, which in turn deletes any secured channels and their secure association keys (SAKs). This command is also used to apply MACsec configuration changes (mka actor-priority, include-sci, replay-protect, mka life-time) to an already enabled port. All traffic is blocked until MKA renegotiates a new set of keys and those keys are installed. For more information, see *IEEE802.1X-2010 Clause 12.9.3 Initialization*.

### Displaying MACsec Information

To display a system-wide view of MACsec, use the following command:

```
show macsec
```

To display a global summary of MACsec capabilities and status for all or a specified CA, use the following command:

```
show macsec { connectivity-association {ca_name}
```

To display per-port MKA and MACsec data in tabular format, use the following command:

```
show macsec ports port-list usage
```

To display a table of all configurable parameters, use the following command:

```
show macsec ports port-list configuration
```

To display configuration, status, and statistics for both MKA and MACsec, use the following command:

```
show macsec ports port-list detail
```

To display the number of ports that have MACsec enabled and the maximum number of ports allowed per slot, use the following command:

```
show macsec usage
```

To display the transmitted and dropped packets for each MACsec engine, use the following command:

```
show ports macsec-engines [qosmonitor | congestion] {no-refresh | refresh}
```

### Displaying LRM/MACsec Adapter Information

To display that a LRM/MACsec adapter is connected to a port, use either of the following commands:

```
show ports {mgmt | port_list | tag tag} configuration {no-refresh | refresh}
```

show port {**mgmt** | *port\_list* | **tag tag**} **information** {**detail**} using the detail option.

### Troubleshooting MAC Security

If you find that a connection that you have set up MAC Security (MACsec) on is not secure, use the following information to troubleshoot the issue.

1. Verify that the port is enabled.

```
show ports {port_list | tag tag} {no-refresh | refresh}
```

E = Enabled.

2. Verify that the link is up before MACsec is enabled.

```
show ports {port_list | tag tag} {no-refresh | refresh}
```

A = Active.

3. Verify MACsec license is installed.

```
show licenses {[slot slot | all]} {detail}
```

```
show license
Enabled License Level:
 Advanced Edge
Enabled Feature Packs:
 MACsec
```

4. Verify that MACsec is enabled.

```
show macsec ports port-list usage
```

5. Verify that pre-shared-keys (PSKs) are identical by looking for the event:

PortCKNMismatch.

To have PortCKNMismatch logged by default, change the severity of logged MACsec events from "error" to "notice":

```
configure log filter DefaultFilter add events macsec severity notice
```

Look for the following event.

```
<Noti:MACsec.MKA.PortCKNMismatch> On port 50, Secure Connectivity Association Key Name (CKN) is not included in local Secure Connectivity Association (CA). A possible CKN mismatch.
```

```
show log {messages [memory-buffer | nvr]} {events {event-condition | event-component}} {severity severity {only}} {starting [date date time time | date date | time time]} {ending [date date time time | date date | time time]} {match regex} {chronological}
```

6. Verify MACsec Key Agreement PDUs (MKPDUs) are being transmitted and received.

```
show macsec ports port-list usage
```

Verify that local and peer message numbers are incrementing.

#### Note

If a warning message in the log indicates that LRM/MACsec adapter port firmware is out-of-date:

```
<Warn:HAL.Port.Warning> LRM/MACsec Adapter port firmware on port 2:16 is out of date, do 'install firmware lrm-macsec-adapter' to update.
```

use the following command to update the firmware:

```
install firmware {{force} {slot slot_number} | lrm-macsec-adapter
ports [port_list | all]}
```

#### Note

If MACsec link flap periodically occurs, try to increase "mka life-time". This solution works best with lower-end switches.

## Alternate MAC Address Support

Version 33.2.1 adds support for configuring an alternate MAC address using the command line. This command enables you to set a new MAC address that differs from the original one stored in the Electrically Erasable Programmable Read-Only Memory (EEPROM). The alternate MAC address is saved in a persistent "well-known info" database, which is used by the operating system for switch management tasks. When restarting, the operating system detects if an alternate MAC address has been configured. If it has, the operating system overwrites the factory MAC address.

This feature is only applicable to standalone switches and does not support switch stacks.

### *Supported Platforms*

All platforms.

### *Limitations*

The following limitations apply to this feature:

- You cannot configure a Locally Administered Address (LAA) as the alternate MAC address.
- You cannot configure multicast MAC addresses as the alternate MAC address.

### *New CLI Command*

The following new CLI command is introduced in this version:

```
configure switch mac-address
```

## DHCP Server

---

The *DHCP (Dynamic Host Configuration Protocol)* server implementation in ExtremeXOS only supports address allocation on the primary IP interface of the configured *VLAN*. That is, all DHCP clients residing on a bridging domain have IP addresses belonging to the primary subnet. To add a host on secondary subnet, you must manually configure the IP address information on that host.

### Enabling and Disabling DHCP

*DHCP* is enabled on a per port, per *VLAN* basis.

- Enable or disable DHCP on a port in a VLAN using the commands:

```
enable dhcp ports port_list vlan vlan_name
```

```
disable dhcp ports port_list vlan vlan_name
```

### Configuring the DHCP Server

The following commands allow you to configure the *DHCP* server included in the switch.

#### Note

Configuring both the DHCP server and the DHCP client on the same VLAN and the same ports is not recommended.

The parameters available to configure include the IP address range, IP address lease, and multiple DHCP options. Until ExtremeXOS 15.1, the DHCP server had a limited set of known DHCP options it could send out on request, i.e., Default Gateway, DNS, and WINS server(s). General option support has been added in ExtremeXOS 15.2. This allows you to add support for any option needed, with no ExtremeXOS code changes. The three options mentioned above can also be overwritten to support a larger number of servers, if needed. This feature allows the switch administrator to add an option based on DHCP option code value, and support various ways of setting the value.

1. Configure the range of IP addresses assigned by the DHCP server using the command:

```
configure vlan vlan_name dhcp-address-range ipaddress1 - ipaddress2
```

2. Remove the address range information using the command:

```
unconfigure vlan vlan_name dhcp-address-range
```

3. Set how long the IP address lease assigned by the server exists using the command:

```
configure vlan vlan_name dhcp-lease-timer lease-timer
```

#### Note

The ExtremeXOS DHCP server allows the configuration of a DHCP lease timer value greater than two seconds only. The timer value range is 3–4294967295. If the DHCP lease timer is not configured, the ExtremeXOS DHCP server offers an IP address with the default lease time of 7200 seconds.

#### Note

Maximum number of DHCP leases supported by the ExtremeXOS DHCP server is limited by the number of VLANs and IP address range configured on that VLAN, and there is no hardware/software limit for the DHCP leases.

#### Note

The maximum number of DHCP servers supported by ExtremeXOS is limited by the number of VLANs the ExtremeXOS switch supports.

4. To set the generic DHCP option code, default gateway, Domain Name Servers (DNS) addresses, or Windows Internet Naming Service (WINS) server, use the following command:

```
configure {vlan} vlan_name dhcp-options [code option_number [16-bit value1 {value2 {value3 {value4}}} | 32-bit value1 {value2 {value3 {value4}}} | flag [on | off] | hex string_value | ipaddress ipaddress1 {ipaddress2 {ipaddress3 {ipaddress4}}} | string string_value] | default-gateway | dns-server {primary | secondary} | wins-server] ipaddress
```

5. To remove the generic DHCP option code, default gateway, DNS server addresses, and WINS server information for a particular VLAN, use the following command:

```
unconfigure {vlan} vlan_name dhcp-options {[default-gateway | dns-server {primary | secondary} | wins-server]}
```

6. Remove all the DHCP information for a particular VLAN using the command:

```
unconfigure vlan vlan_name dhcp
```

You can clear the DHCP address allocation table selected entries, or all entries.

7. Clear entries using the command:

```
clear vlan vlan_name dhcp-address-allocation [[all {offered | assigned | declined | expired}] | ipaddress]
```

You would use this command to troubleshoot IP address allocation on the VLAN.

## Displaying DHCP Information

- Display the DHCP configuration, including the DHCP range, DHCP lease timer, network login lease timer, DHCP-enabled ports, IP address, MAC address, and time assigned to each end device using the command:

```
show dhcp-server {vlan vlan_name}
```

- View only the address allocation of the DHCP server on a VLAN using the command:  
`show {vlan} vlan_name dhcp-address-allocation`
- View only the configuration of the DHCP server on a VLAN using the command:  
`show {vlan} vlan_name dhcp-config`

## IP Security

This section describes a collection of IP security features implemented in ExtremeXOS software.

If you configure any of the features described in this section, you can enhance your network security by controlling which hosts are granted or not granted access to your network.

Figure 193 displays the dependencies of IP security. Any feature that appears directly above another feature depends on it. For example, to configure ARP validation, you must configure DHCP snooping and trusted DHCP server.

EX\_178

**Figure 193: IP Security Dependencies**

### Note

IP security features are supported on link aggregation ports with the exception of DHCP snooping with the **block-mac** option and source IP lockdown. You can enable IP security on pre-existing trunks, but you cannot make IP security-enabled ports into trunks without first disabling IP security.

## DHCP Snooping and Trusted DHCP Server

A fundamental requirement for most of the IP security features described in this section is to configure DHCP snooping and trusted DHCP server.

DHCP snooping enhances security by filtering untrusted DHCP messages and by building and maintaining a DHCP bindings database. Trusted DHCP server also enhances security by forwarding DHCP packets from only configured trusted servers within your network.

The DHCP bindings database contains the IP address, MAC Address, VLAN ID, and port number of the untrusted interface or client. If the switch receives a DHCP ACK message and the IP address does not exist in the DHCP bindings database, the switch creates an entry in the DHCP bindings database. If the switch receives a DHCP RELEASE, NAK or DECLINE message and the IP address exists in the DHCP bindings database, the switch removes the entry.

You can enable DHCP snooping on a per port, per VLAN basis and trusted DHCP server on a per-vlan basis. If configured for DHCP snooping, the switch snoops DHCP packets on the indicated ports and builds a DHCP bindings database of IP address and MAC address bindings from the received packets. If configured for trusted DHCP server, the switch forwards only DHCP packets from the trusted servers. The switch drops DHCP packets from other DHCP snooping-enabled ports.

In addition, to prevent rogue DHCP servers from farming out IP addresses, you can optionally configure a specific port or set of ports as trusted ports. Trusted ports do not block traffic; rather, the switch forwards any DHCP server packets that appear on trusted ports. When configured to do so, the switch drops packets from DHCP snooping-enabled ports and causes one of the following user-configurable actions: disables the port temporarily, disables the port permanently, blocks the violating MAC address temporarily, blocks the violating MAC address permanently, and so on.

#### Note

When IP security DHCP snooping is enabled on a VLAN, if ports are removed from the VLAN, the IP security snooping configuration is removed. If ports are added back to the VLAN, you must manually enable the IP security snooping configuration again. This is true for both plain and LAG ports.

Also, if LAG is unconfigured, the IP security configuration is removed for those ports.

Also, if a new port is added to a VLAN that has IP security snooping enabled on it already for other ports, you must manually enable IP security snooping again for the new added port. IP security commands are not automatically applied to added ports to a VLAN. They must be manually configured again.

#### Note

Beginning with version 32.5, the functionality of the option *port all* in the commands **enable ip-security dhcp-snooping dynamic vlan ports all violation-action drop-packet** or **enable ip-security dhcp-snooping vlan v2 ports all violation-action drop-packet** is enhanced to cover all the *\_future\_* member ports of a VLAN or *\_future\_* VLANs.

If the port is dynamically removed or added by any module, for example Netlogin or ONEPolicy, the *ports all* option enables IP-security snooping on the ports corresponding to the VLAN it adds.

### Configuring DHCP Snooping

DHCP snooping is disabled on the switch by default.

- To enable DHCP snooping on the switch, use the command:

```
enable ip-security dhcp-snooping [dynamic | {vlan} vlan_name] ports
[all | ports] violation-action [drop-packet {[block-mac | block-port]
[duration duration_in_seconds | permanently] | none]}] {snmp-trap}
```

#### Note

Snooping IP fragmented DHCP packets is not supported.

The violation action setting determines what action(s) the switch takes when a rogue DHCP server packet is seen on an untrusted port or the IP address of the originating server is not among those of the configured trusted DHCP servers.

The DHCP server packets are DHCP OFFER, ACK and NAK. The following list describes the violation actions:

#### **block-mac**

The switch automatically generates an ACL to block the MAC address on that port. The switch does not blackhole that MAC address in the FDB. The switch can either temporarily or permanently block the MAC address.

#### **block-port**

The switch blocks all traffic on that port by disabling the port either temporarily or permanently.

#### **none**

The switch takes no action to drop the rogue DHCP packet or block the port, and so on. In this case, DHCP snooping continues to build and manage the DHCP bindings database and DHCP forwarding will continue in hardware as before. This option can be used when the intent is only to monitor the IP addresses being assigned by the DHCP server.

#### **Note**

You must enable DHCP snooping on both the DHCP server port as well as on the client port. The latter ensures that DHCP client packets (DHCP Request, DHCP Release etc.) are processed appropriately.

#### **Note**

DHCP snooping does not work when the client and server are in different VRs and server reachability is established by inter-VR leaked routes on client VR.

#### **Note**

Enabling DHCP snooping and source IP lockdown on the same port applies ACL rules with the same match conditions, but different actions. The rule with deny action takes precedence, so packets are dropped if these ACL rules are installed on different slices. Many factors influence which slice rules are installed on. To see which slice these rules are installed on, use the command `show access-list usage acl-slice port port` or `show access-list usage acl-rule port port`.

Any violation that occurs causes the switch to generate an EMS log message. You can configure to suppress the log messages by configuring EMS log filters. For more information about EMS, see [Using the Event Management System/Logging](#) on page 1685.

- To disable DHCP snooping on the switch, use the command:

```
disable ip-security dhcp-snooping [dynamic | {vlan} vlan_name] ports
[all | ports]
```

### Configuring Trusted DHCP Server

- Configure a trusted DHCP server on the switch using the command:  

```
configure trusted-servers [dynamic vlan_id | {vlan} vlan_name] add
server ip_address trust-for dhcp-server
```

If you configure one or more trusted ports, the switch assumes that all DHCP server packets on the trusted port are valid. You can configure a maximum of eight trusted DHCP servers per VLAN on the switch.

For more information about configuring trusted ports, see [Configuring Trusted DHCP Ports](#) on page 1518.

- Delete a trusted DHCP server using the command:  

```
configure trusted-servers [dynamic vlan_id | vlan vlan_name] delete
server ip_address trust-for dhcp-server
```

### Configuring Trusted DHCP Ports

Trusted ports do not block traffic; rather, the switch forwards any DHCP server packets that appear on trusted ports. Depending on your DHCP snooping configuration, the switch drops packets and can disable the port temporarily, disable the port permanently, block the MAC address temporarily, block the MAC address permanently, and so on.

- Enable trusted ports on the switch using the command:  

```
configure trusted-ports [ports|all] trust-for dhcp-server
```
- Disable trusted ports on the switch using the command:  

```
unconfigure trusted-ports [ports |all] trust-for dhcp-server
```

### Displaying DHCP Snooping and Trusted Server Information

- Display the DHCP snooping configuration settings using the command:  

```
show ip-security dhcp-snooping {vlan} vlan_name
```

Below is sample output from this command:

```
DHCP Snooping enabled on ports: 1:2, 1:3, 1:4, 1:7, 1:9
Trusted Ports: 1:7
Trusted DHCP Servers: None

Port Violation-action

1:2 none
1:3 drop-packet
1:4 drop-packet, block-mac permanently
1:7 none
1:9 drop-packet, snmp-trap
```

- Display the DHCP bindings database using the command:  

```
show ip-security dhcp-snooping entries {vlan} vlan_name
```

Below is sample output from this command:

```

Vlan: dhcpVlan

Server Client
```

| IP Addr      | MAC Addr          | Port  | Port  |
|--------------|-------------------|-------|-------|
| -----        | -----             | ----- | ----- |
| 172.16.100.9 | 00:90:27:c6:b7:65 | 1:1   | 1:2   |

### Clearing DHCP Snooping Entries

- To clear Existing *DHCP* snooping entries, use the command:  

```
clear ip-security dhcp-snooping entries {vlan} vlan_name
```

#### Note

This will also clear out any associated source IP lockdown and DHCP secured ARP entries.

### Configuring the DHCP Relay Agent Option (Option 82) at Layer 2

This section describes how to configure the *DHCP* Relay agent option for Layer 2 forwarded DHCP packets.

The DHCP relay agent option feature inserts a piece of information, called option 82, into any DHCP request packet that is to be relayed by the switch. Similarly, if a DHCP reply received by the switch contains a valid relay agent option, the option will be stripped from the packet before it is relayed to the client. This is a Layer 2 option that functions only when the switch is not configured as a Layer 3 BOOTP relay.

The **Agent remote ID sub-option** always contains the Ethernet MAC address of the relaying switch. You can display the Ethernet MAC address of the switch by issuing the show switch command.

The contents of the inserted option 82 sub-options is as follows:

**Table 139: Contents of the Inserted Option 82 Sub-options**

| Code<br>(1 byte) | Length<br>(1 byte) | Sub-Option<br>(1 byte) | Length<br>(1 byte) | Value<br>(1-32 bytes) | Sub-Option<br>(1 byte) | Length<br>(1 byte) | Switch<br>MAC<br>address<br>(6 bytes) |
|------------------|--------------------|------------------------|--------------------|-----------------------|------------------------|--------------------|---------------------------------------|
| 82               |                    | 1 (Circuit ID)         | 1-32               | vlan_info-port_info   | 2 (Remote ID)          | 6                  |                                       |

To enable the DHCP relay agent option at Layer 2, use the following command:

```
configure ip-security dhcp-snooping information option
```

#### Note

When DHCP relay is configured in a DHCP snooping environment, the relay agent IP address should be configured as the trusted server.

When DHCP option 82 is enabled, two types of packets need to be handled:

- DHCP Request:** When the switch (relay agent) receives a DHCP request, option 82 is added at the end of the packet. If the option has already been enabled, then the action taken depends on the configured policy (drop packet, keep existing option 82 value, or replace the existing option). Unless configured otherwise using

the configure ip-security dhcp-snooping information circuit-id vlan-information *vlan\_info* [**dynamic** | {**vlan**} *vlan\_name* | **all**] , the *vlan\_info* portion of the circuit ID added will be the VLAN ID of the ingress VLAN.

- **DHCP Reply:** When the option 82 information check is enabled, the packets received from the DHCP server are checked for option 82 information. If the remote ID sub-option is the switch's MAC address, the packet is sent to the client; if not, the packet is dropped. If the check is not enabled. The packets are forwarded as-is.

To disable the DHCP relay agent option, use the following command:

```
unconfigure ip-security dhcp-snooping information option
```

In some instances, a DHCP server may not properly handle a DHCP request packet containing a relay agent option.

To prevent DHCP reply packets with invalid or missing relay agent options from being forwarded to the client, use the following command:

```
configure ip-security dhcp-snooping information check
```

To disable checking of DHCP replies, use this command:

```
unconfigure ip-security dhcp-snooping information check
```

A DHCP relay agent may receive a client DHCP packet that has been forwarded from another relay agent.

If this relayed packet already contains a relay agent option, then the switch will handle this packet according to the configured DHCP relay agent option policy. The possible actions are to replace the option information, to keep the information, or to drop packets containing option 82 information. To configure this policy, use the following command:

```
configure ip-security dhcp-snooping information policy [drop | keep | replace]
```

The default relay policy is replace.

To configure the policy to the default, use this command:

```
unconfigure ip-security dhcp-snooping information policy
```

The Layer 2 relay agent option allows you to configure the circuit ID on a VLAN or port basis., the Circuit-ID can contain a variable length (up to 32 bytes long) ASCII string with the following format:

```
<VLAN Info>-<Port Info>
```

If the configuration of either VLAN Info or Port Info causes the total string length of <VLAN Info>-<Port Info> to exceed 32 bytes, then it is truncated to 32 bytes. The string is not NULL terminated, since the total circuit ID length is being specified.

For a DHCP client packet ingressing on a VLAN with the VLAN ID equal to 200 and the ingress port at 3:5, the following are true:

- When neither VLAN Info or Port Info is specified, circuit ID value is = 200-3005
- When VLAN Info is configured to SomeInfo and Port Info is not specified, the circuit ID value is SomeInfo-3005
- When VLAN Info is not specified and Port Info is configured to User1, the circuit ID value is 200-User1
- When VLAN Info is configured to SomeInfo and Port Info to User1, the circuit ID value is SomeInfo-User1

VLAN Info is configurable per VLAN.

When not explicitly configured for a VLAN, VLAN Info defaults to the ASCII string representation of the ingress VLAN ID. To configure the circuit ID on a VLAN, use the following command:

```
configure ip-security dhcp-snooping information circuit-id vlan-
information vlan_info [dynamic | {vlan} vlan_name | all]
```

To unconfigure the circuit ID on a VLAN, use the following command:

```
unconfigure ip-security dhcp-snooping information circuit-id vlan-
information [dynamic | {vlan} vlan_name | all]
```

Port Info is configurable.

When not explicitly configured for a port, port info defaults to the ASCII representation of the ingress port's *SNMP* ifIndex. To configure the port information portion of the circuit-ID, use the following command:

```
configure ip-security dhcp-snooping information circuit-id port-
information port_info port port
```

To unconfigure the port information portion of the circuit-ID, use the following command:

```
unconfigure ip-security dhcp-snooping information circuit-id port-
information ports [port_list | all]
```

#### Note

When this feature is enabled, all DHCP traffic must be forwarded in slowpath only, which means that this feature functions only in the context of IP Security and only on interfaces where DHCP snooping is enabled in enforcement (violation-action of 'drop') mode. In other words, with DHCP snooping not configured with a violation-action of 'none' (which is pure monitoring mode).

### Configuring DHCP Binding

The *DHCP* bindings database contains the IP address, MAC address, *VLAN* ID, and port number of the client. You can add or delete the static IP to the MAC DHCP binding entries using the following commands:

```
configure ip-security dhcp-bindings add
```

```
configure ip-security dhcp-bindings delete
```

You can specify the storage details of the DHCP binding database. Use the following commands to specify the DHCP binding database location, filename, write-interval, and write threshold limits:

```
configure ip-security dhcp-bindings storage filename
```

```
configure ip-security dhcp-bindings storage location
```

```
configure ip-security dhcp-bindings storage
```

You can upload the DHCP binding database periodically by enabling the DHCP binding restoration. Binding write intervals occur in minutes, 5 to 1440 (24 hours). The default is 30 minutes.

Upload the latest DHCP binding database using the upload command:

```
enable ip-security dhcp-bindings restoration
```

You can also upload the DHCP binding database by the number of DHCP entries (the write-threshold is 25 to 200).

The periodic backup of the DHCP binding database can be disabled using the following command:

```
disable ip-security dhcp-bindings restoration
```

**Note**

There is no command to unconfigure the DHCP binding storage server details. To disable the DHCP binding storage server details, use the preceding command.

For information about configuring option 82 at Layer 3, see [Configuring the DHCP Relay Agent Option \(Option 82\) at Layer 3](#) on page 905.

**Note**

When configuring static DHCP binding entries, DHCP binding restoration needs to be configured.

**Example of Option 82 Configuration**

The following example describes Option 82 configuration for circuit ID fields.

```
create vlan v1
conf v1 add ports 21
enable ip-security dhcp-snooping v1 ports all violation-action drop-packet
configure trusted-ports 21 trust-for dhcp-server
conf ip-security dhcp-snooping information option
conf ip-security dhcp-snooping information check
conf ip-security dhcp-snooping information circuit-id vlan-information ServiceProvider-1
v1
conf ip-security dhcp-snooping information circuit-id port-information customer-1 port 1
```

```

conf ip-security dhcp-snooping information circuit-id port-information cutomer-2 port 2
CLI display output
=====

## Source IP Lockdown

Another type of IP security prevents IP address spoofing by automatically placing source IP address filters on specified ports. This feature, called *source IP lockdown*, allows only traffic from a valid *DHCP*-assigned address obtained by a DHCP snooping-enabled port to enter the network. In this way, the network is protected from attacks that use random source addresses for their traffic. With source IP lockdown enabled, end systems that have a DHCP address assigned by a trusted DHCP server can access the network, but traffic from others, including those with static IP addresses, is dropped at the switch.

Source IP lockdown is linked to the “DHCP snooping” feature. The same DHCP bindings database created when you enable DHCP snooping is also used by source IP lockdown to create ACLs that permit traffic from DHCP clients. All other traffic is dropped. In addition, the DHCP snooping violation action setting determines what action(s) the switch takes when a rogue DHCP server packet is seen on an untrusted port.

When source IP lockdown is enabled on a port, a default *ACL* is created to deny all IP traffic on that port. Then an ACL is created to permit DHCP traffic on specified ports. Each time source IP lockdown is enabled on another port, the switch creates ACLs to allow DHCP packets and to deny all IP traffic for that particular port.

Source IP lockdown is enabled on a per-port basis; it is not available at the *VLAN* level. If source IP lockdown is enabled on a port, the feature is active on the port for all VLANs to which the port belongs.

### Note

The source IP lockdown feature works only when hosts are assigned IP address using DHCP; source IP lockdown does not function for statically configured IP addresses.

### Note

Source IP lockdown cannot be enabled on Load sharing ports.

The source IP lockdown ACLs listed in table are applied per port (in order of precedence from highest to lowest).

**Table 140: Source IP Lockdowns Applied Per-port**

| ACL Name                                         | Match Condition         | Action       | When Applied       | Comments                                                                  |
|--------------------------------------------------|-------------------------|--------------|--------------------|---------------------------------------------------------------------------|
| esSrcIpLockdown_<portIfIndex>_<source IP in hex> | Source IP               | Permit       | Runtime            | Multiple ACLs of this type can be applied, one for each permitted client. |
| esSrcIpLockdown_<portIfIndex>_1                  | Proto UDP, Dest Port 67 | Permit       | Configuration time |                                                                           |
| esSrcIpLockdown_<portIfIndex>_2                  | Proto UDP, Dest Port 68 | Permit       | Configuration time |                                                                           |
| esSrcIpLockdown_<portIfIndex>_3                  | Ethertype ARP           | Permit       | Configuration time |                                                                           |
| esSrcIpLockdown_<portIfIndex>_4                  | All                     | Deny + count | Configuration time |                                                                           |

The counter has the same name as that of the rule of the catch-all ACL, so the counter is also named esSrcIpLockdown\_<portIfIndex>\_4.

### Configuring Source IP Lockdown

To configure source IP lockdown, you must enable [DHCP](#) snooping on the ports connected to the DHCP server and DHCP client before you enable source IP lockdown. You must enable source IP lockdown on the ports connected to the DHCP client, not on the ports connected to the DHCP server.

#### Note

Enabling DHCP snooping and source IP lockdown on the same port applies ACL rules with the same match conditions, but different actions. The rule with deny action takes precedence, so packets are dropped if these ACL rules are installed on different slices. Many factors influence which slice rules are installed on. To see which slice these rules are installed on, use the command `show access-list usage acl-slice port port` or `show access-list usage acl-rule port port`.

- Enable DHCP snooping using the command:  

```
enable ip-security dhcp-snooping [dynamic | {vlan} vlan_name] ports
[all | ports] violation-action [drop-packet {[block-mac | block-port]
[duration duration_in_seconds | permanently] | none]}] {snmp-trap}
```

For more information about DHCP snooping see, [Configuring DHCP Snooping](#) on page 1516.

Source IP lockdown is disabled on the switch by default.

- To enable source IP lockdown, use the command:  
`enable ip-security source-ip-lockdown ports [all | ports]`
- To disable source IP lockdown, use the command:  
`disable ip-security source-ip-lockdown ports [all | ports]`

### Displaying Source IP Lockdown Information

- Display the source IP lockdown configuration on the switch using the command:  
`show ip-security source-ip-lockdown`

Below is sample output from this command:

| Ports | Locked IP Address |
|-------|-------------------|
| 23    | 10.0.0.101        |

### Clear Source IP Lockdown Information

- Remove existing source IP lockdown entries on the switch using the command:  
`clear ip-security source-ip-lockdown entries ports [ports | all]`

## ARP Learning

The address resolution protocol (ARP) is part of the TCP/IP suite used to dynamically associate a device's physical address (MAC address) with its logical address (IP address).

The switch broadcasts an ARP request that contains the IP address, and the device with that IP address sends back its MAC address so that traffic can be transmitted across the network. The switch maintains an ARP table (also known as an ARP cache) that displays each MAC address and its corresponding IP address.

By default, the switch builds its ARP table by tracking ARP requests and replies, which is known as ARP learning. You can disable ARP learning so that the only entries in the ARP table are either manually added or those created by *DHCP* secured ARP; the switch does not add entries by tracking ARP requests and replies. By disabling ARP learning and adding a permanent entry or configuring DHCP secured ARP, you can centrally manage and allocate client IP addresses and prevent duplicate IP addresses from interrupting network operation.

### Configuring ARP Learning

As previously described, ARP learning is enabled by default. The switch builds its ARP table by tracking ARP requests and replies.

- Disable ARP learning on one or more ports in a *VLAN* using the command:  
`disable ip-security arp learning learn-from-arp [dynamic | {vlan} vlan_name] ports [all | ports]`
- Re-enable ARP learning on one or more ports in a VLAN using the command:  
`enable ip-security arp learning learn-from-arp [dynamic | {vlan} vlan_name] ports [all | ports]`

### Adding a Permanent Entry to the ARP Table

If you disable ARP learning, you must either manually add a permanent entry to the ARP table or configure [DHCP](#) secured ARP to populate the ARP table.

- Manually add a permanent entry to the ARP table using the command:

```
configure iparp add ip_addr {vr vr_name} mac
```

For more detailed information about this command and IP routing, see [IPv4 Unicast Routing](#).

### Configuring DHCP Secured ARP

Before you configure [DHCP](#) secured ARP, you must enable DHCP snooping on the switch.

Another method available to populate the ARP table is DHCP secured ARP. DHCP secured ARP requires that ARP entries be added to or deleted from the ARP table only when the DHCP server assigns or re-assigns an IP address. These entries are known as a secure ARP entry. If configured, the switch adds the MAC address and its corresponding IP address to the ARP table as a permanent ARP entry. Regardless of other ARP requests and replies seen by the switch, the switch does not update secure ARP entries. DHCP secured ARP is linked to the “DHCP snooping” feature. The same DHCP bindings database created when you enabled DHCP snooping is also used by DHCP secured ARP to create secure ARP entries. The switch only removes secure ARP entries when the corresponding DHCP entry is removed from the trusted DHCP bindings database.

#### Note

If you enable DHCP secured ARP on the switch without disabling ARP learning, ARP learning continues which allows insecure entries to be added to the ARP table.

- Enable DHCP snooping using the command:

```
enable ip-security dhcp-snooping [dynamic | {vlan} vlan_name] ports
[all | ports] violation-action [drop-packet [{block-mac | block-port}]
[duration duration_in_seconds | permanently] | none]] {snmp-trap}
```

For more information about DHCP snooping see, [Configuring DHCP Snooping](#) on page 1516.

DHCP secured ARP learning is disabled by default.

- Enable DHCP secured ARP using the command:

```
enable ip-security arp learning learn-from-dhcp [dynamic vlan | {vlan}
vlan_name] ports [all | ports]
```

DHCP Secured ARP must be enabled on the DHCP server port as well as the DHCP client ports.

- Disable DHCP secured ARP using the command:

```
disable ip-security arp learning learn-from-dhcp [dynamic vlan |
{vlan} vlan_name ports [all | ports]
```

#### Note

You must enable DHCP secured ARP on the DHCP server, as well as on the client ports. DHCP snooping must also be enabled on both the server and client ports.

### Displaying ARP Information

- Display how the switch builds an ARP table and learns MAC addresses for devices on a specific VLAN and associated member ports using the command:

```
show ip-security arp learning {vlan} vlan_name | vlan_list
```

Below is sample output from this command:

| Port  | Learn-from |
|-------|------------|
| ----- |            |
| 2:1   | ARP        |
| 2:2   | DHCP       |
| 2:3   | ARP        |
| 2:4   | None       |
| 2:5   | ARP        |
| 2:6   | ARP        |
| 2:7   | ARP        |
| 2:8   | ARP        |

- View the ARP table, including permanent and DHCP secured ARP entries using the command:

```
show iparp {ip_address | mac | vlan {vlan_name | vlan_list} |
permanent} {vr vr_name}
```

#### Note

DHCP secured ARP entries are stored as static entries in the ARP table.

## Gratuitous ARP Protection

When a host sends an ARP request to resolve its own IP address it is called gratuitous ARP. A gratuitous ARP request is sent with the following parameters:

- Destination MAC address—FF:FF:FF:FF:FF:FF (broadcast)
- Source MAC address—Host's MAC address
- Source IP address = Destination IP address—IP address to be resolved

In a network, gratuitous ARP is used to:

- Detect duplicate IP address.

In a properly configured network, there is no ARP reply for a gratuitous ARP request. However, if another host in the network is configured with the same IP address as the source host, then the source host receives an ARP reply.

- Announce that an IP address has moved or bonded to a new network interface card (NIC).

If you change a system NIC, the MAC address to its IP address mapping also changes. When you reboot the host, it sends an ARP request packet for its own IP address. All of the hosts in the network receive and process this packet. Each host updates their old mapping in the ARP table with this new mapping

- Notify a Layer 2 switch that a host has moved from one port to another port.

However, hosts can launch man-in-the-middle attacks by sending out gratuitous ARP requests for the router's IP address. This results in hosts sending their router traffic to the attacker, and the attacker forwarding that data to the router. This allows passwords, keys, and other information to be intercepted.

To protect against this type of attack, the router sends out its own gratuitous ARP request to override the attacker whenever a gratuitous ARP request broadcast packet with the router's IP address as the source is received on the network.

If you enable both *DHCP* secured ARP and gratuitous ARP protection, the switch protects its own IP address and those of the hosts that appear as secure entries in the ARP table.

### Configuring Gratuitous ARP

You enable the gratuitous ARP feature on a per *VLAN* basis, not on a per port basis. The validation is done for all gratuitous ARP packets received on a VLAN in which this feature is enabled irrespective of the port in which the packet is received.

When enabled, the switch generates gratuitous ARP packets when it receives a gratuitous ARP request where either of the following is true:

- The sender IP is the same as the switch VLAN IP address and the sender MAC address is not the switch MAC address.
- The sender IP is the same as the IP of a static entry in the ARP table and the sender MAC address is not the static entry's MAC address.

When the switch generates an ARP packet, the switch generates logs and traps.

- Enable gratuitous ARP protection using the command:

```
enable ip-security arp gratuitous-protection [dynamic | {vlan} all |
vlan_name]
```

- In addition, to protect the IP addresses of the hosts that appear as secure entries in the ARP table, use the following commands to enable *DHCP* snooping, DHCP secured ARP, and gratuitous ARP on the switch:

```
enable ip-security dhcp-snooping [dynamic | {vlan} vlan_name] ports
[all | ports] violation-action [drop-packet {[block-mac | block-port]
[duration duration_in_seconds | permanently] | none]}] {snmp-trap}
enable ip-security arp learning learn-from-dhcp {vlan} vlan_name ports
[all | ports]
enable ip-security arp gratuitous-protection {vlan} [all | vlan_name]
```

- Disable gratuitous ARP protection using the command:  

```
disable ip-security arp gratuitous-protection [dynamic | {vlan}
vlan_name | all]
```
- In ExtremeXOS 11.5 and earlier, you enable gratuitous ARP protection using the following command:  

```
enable iparp gratuitous protect vlan vlan-name
```
- In ExtremeXOS 11.5 and earlier, you disable gratuitous ARP protection with the following command:  

```
disable iparp gratuitous protect vlan vlan-name
```

### Displaying Gratuitous ARP Information

- Display information about gratuitous ARP using the command:

```
show ip-security arp gratuitous-protection
```

Below is sample output from this command:

```
Gratuitous ARP Protection enabled on following VLANs:
Default, test
```

## ARP Validation

ARP validation is also linked to the “[DHCP snooping](#)” feature. The same DHCP bindings database created when you enabled DHCP snooping is also used to validate ARP entries arriving on the specified ports.

| Validation Option | ARP Request Packet Type                                                                                                                                                                                                                     | ARP Response Packet Type                                                                                                                           |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| DHCP              |                                                                                                                                                                                                                                             | Source IP is not present in the DHCP snooping database OR is present but Source Hardware Address doesn't match the MAC in the DHCP bindings entry. |
| IP                | Source IP == Mcast OR<br>Target IP == Mcast OR<br>Source IP is not present in the DHCP snooping database OR<br>Source IP exists in the DHCP bindings database but Source Hardware Address doesn't match the MAC in the DHCP bindings entry. | Source IP == Mcast OR<br>Target IP == Mcast                                                                                                        |
| Source-MAC        | Ethernet source MAC does not match the Source Hardware Address.                                                                                                                                                                             | Ethernet source MAC does not match the Source Hardware Address.                                                                                    |
| Destination-MAC   |                                                                                                                                                                                                                                             | Ethernet destination MAC does not match the Target Hardware Address.                                                                               |

Depending on the options specified when enabling ARP validation, the following validations are done. Note that the 'DHCP' option does not have to be specified explicitly, it is always implied when ARP validation is enabled.

### Configuring ARP Validation

Before you configure ARP validation, you must enable *DHCP* snooping on the switch.

- Enable DHCP snooping using the command:

```
enable ip-security dhcp-snooping [dynamic | {vlan} vlan_name] ports
[all | ports] violation-action [drop-packet {[block-mac | block-port]
[duration duration_in_seconds | permanently] | none]}] {snmp-trap}
```

For more information about DHCP snooping see, [Configuring DHCP Snooping](#) on page 1516.

ARP validation is disabled by default.

- Enable and configure ARP validation using the command:

```
enable ip-security arp validation {destination-mac} {source-mac}
{ip} [dynamic vlan_id | {vlan} vlan_name] [all | ports] violation-
action [drop-packet {[block-port] [duration duration_in_seconds |
permanently]}] {snmp-trap}
```

The violation action setting determines what action(s) the switch takes when an invalid ARP is received. Any violation that occurs causes the switch to generate an EMS log message. You can configure to suppress the log messages by configuring EMS log filters. For more information about EMS, see the section [Using the Event Management System/Logging](#) on page 1685.

- Disable ARP validation using the command:

```
disable ip-security arp validation [dynamic | {vlan} vlan_name] [all |
ports]
```

### Displaying ARP Validation Information

- Display information about ARP validation using the command:

```
show ip-security arp validation {vlan} vlan_name
```

Below is sample output from this command:

| Port | Validation | Violation-action                                   |
|------|------------|----------------------------------------------------|
| 7    | DHCP       | drop-packet, block-port for 120 seconds, snmp-trap |
| 23   | DHCP       | drop-packet, block-port for 120 seconds, snmp-trap |

## VSA RADIUS Support for DHCP Snooping and ARP Validation

RADIUS support for *DHCP* DHCP snooping and ARP validation allows users transitioning from Ethernet Routing Switch to ExtremeXOS at Edge with Fabric Attach using RADIUS to dynamically configure port security through RADIUS VSA Attributes. ExtremeXOS can provision items via RADIUS VSA Attributes currently supported with ERS switching. Dynamic configuration can be applied to the following VLAN settings:

- The ability to enable Dynamic ARP Inspection.

- The ability to enable DHCP Snooping.

The RADIUS user configuration attributes for VLAN settings can specify a single VLAN or a range of VLANs for each setting request. The RADIUS user configuration attributes, which request the settings, include:

- Fabric-Attach-Service-Request += "DAI:<vid>[-<vid>]"
- Fabric-Attach-Service-Request += "DHCP Snooping:<vid>[-<vid>]"

This FA-Service-Request attribute contains a DHCP Snooping and ARP Validation enable status for VLAN. When a new user is authenticated by netlogin, the new attributes of the DHCP Snooping and ARP Validation enable is given to netlogin. Netlogin will process and send the attribute message to the IP Security module as "enable". If all users are unauthenticated by netlogin, a disable message for the VLAN will be sent to IP Security. RADIUS configuration is applicable for both static and dynamic VLANs.

Whenever a DHCP Snooping or ARP Validation configuration is received from RADIUS, IP Security will enable the feature on all the ports in VLAN with the violation action "Drop-packet."

#### *RADIUS Configuration Over ExtremeXOS CLI*

RADIUS configuration takes precedence over ExtremeXOS CLI. Once RADIUS configuration is applied for a VLAN, any CLI command action (for example disable DHCP snoop for a port or changing violation action) will be ignored, but the configuration will be saved. Once the RADIUS configuration is disabled, CLI configuration will be applied. The following tables summarize the various DHCP snoop configuration actions with respect to ExtremeXOS CLI and RADIUS configurations. The same configuration actions are also applicable for ARP Validation.

The following command equivalencies exist for RADIUS configurations received for a VLAN:

DHCP Snooping:<vid> is equivalent to `enable ip-security dhcp-snooping vlan default ports all violation-action drop-packet`

DAI:<vid> is equivalent to enable ip-security arp validation Default ports all violation-action drop-packet

**Table 141: EXOS CLI Configuration over RADIUS Configuration Actions**

| ExtremeXOS CLI configuration                                                        | RADIUS configuration            | Configuration action                                                                     |
|-------------------------------------------------------------------------------------|---------------------------------|------------------------------------------------------------------------------------------|
| Enable DHCP snooping for a VLAN and all VLAN ports with the violation action "None" | Enable DHCP snooping for a VLAN | DHCP snooping will be enabled for all VLAN ports with the violation action "Drop packet" |
| Enable DHCP snooping for a VLAN but not all ports                                   | Enable DHCP snooping for a VLAN | DHCP snooping will be enabled for all VLAN ports with the violation action "Drop packet" |
| Disable DHCP snooping for a VLAN and all its ports                                  | Enable DHCP snooping for a VLAN | DHCP snooping will be enabled for all VLAN ports with the violation action "Drop packet" |

**Table 142: RADIUS Configuration over EXOS CLI Configuration Actions**

| RADIUS configuration            | ExtremeXOS CLI Configuration                                            | Configuration action                                                                     |
|---------------------------------|-------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| Enable DHCP snooping for a VLAN | Disable DHCP snooping for a VLAN and all its port.                      | DHCP snooping will be enabled for all VLAN ports with violation action as "Drop packet". |
| Enable DHCP snooping for a VLAN | Modify DHCP snoop violation action for VLAN to "port-block permanently" | DHCP snooping will be enabled for all VLAN ports with violation action as "Drop packet". |

## DHCP Security Support for MLAG Controlling Bridge

DHCP Security Support for MLAG Controlling Bridge implements the checkpointing of DHCP snooping entries and DHCP and ARP violations between MLAG peers. This allows IP security to share the data or state required for its features, and to exhibit identical behavior in the MLAG topology.

### Note

DHCP security for MLAG controlling bridges is also supported in VPEX and W-MLAG topologies.

In a typical deployment, a DHCP snooping entry is captured in MLAG Peer1 when it receives a DHCP ACK packet from the DHCP server and forwards it to the DHCP client. The DHCP snoop entry is then checkpointed to MLAG Peer2 as soon as it is received by the IP security module. This ensures redundancy and identical functional behavior in MLAG Peer2 when MLAG Peer1 goes down for any reason:

**Figure 194: MLAG Topology**

In the following configuration, if a DHCP entry is snooped by Peer1 and checkpointed to Peer2, Peer2 must allow ARP requests arriving on its Port 1 with an IP address that exists in the DHCP snooping database:

#### MLAG Peer1 configuration

```

create vlan v1 tag 900
configure vlan v1 add port 10,11,12 tagged
enable ip-security dhcp-snooping vlan v1 ports 11 violation-action drop-packet block-port
duration 300
enable ip-security arp learning learn-from-dhcp vlan v1 ports 11
enable ip-security arp validation v1 ports 11 violation-action drop-packet block-port
duration 300

```

#### MLAG Peer2 configuration

```

create vlan v1 tag 900
configure vlan v1 add port 20,21,22 tagged
enable ip-security dhcp-snooping vlan v1 ports 21 violation-action drop-packet block-port
duration 300
enable ip-security arp learning learn-from-dhcp vlan v1 ports 21

```

```
enable ip-security arp validation vl ports 21 violation-action drop-packet block-port
duration 300
```

### *MLAG Checkpointing*

After Inter-Switch Connection (ISC) connectivity between the MLAG peers is established, IP security begins checkpointing DHCP snooping and DHCP or ARP violation actions. As long as MLAG peers have ISC connectivity, addition and deletion of entries/data will be checkpointed. The checkpoint is only done for MLAG ports.

### *DHCP Snoop Checkpointing*

When a DHCP snoop entry is checkpointed from Peer1 to Peer2, the receiving peer checks if it has the received DHCP snoop entry present in its DHCP bindings table. If it is a new entry, it will be added to the DHCP binding table with the server ports as ISC ports. The client port is then identified using FDB lookup on the received client MAC. If the receiving entry already exists, the lease time will be updated so that it is in sync with the peer. If the server ports are BPE ports, the checkpoint receiving peer will set to the BPE port as a server instead of an ISC port.

Using the previous configuration example, once a DHCP ACK is received, Peer1 creates a new DHCP snoop entry into its DHCP binding table, with the server port as 11, the client port as 10, and checkpoints the entry to Peer2. On receiving the checkpoint entry, Peer2 adds the entry to its DHCP binding table with the server port as 22 (ISC port) and the client port as 20 (FDB lookup port).

### *DHCP and ARP Violation Checkpoint*

DHCP and ARP Violation events - “block-port” and “block-mac” are checkpointed between MLAG peers for front panel ports. However, violation actions are not applied at the receiving peer. The receiving peer stores the block action, block duration internally, and applies the checkpointed block time (violationTime - lapsedTime) once a similar violation occurs. For example, if Peer1 receives a MAC violation on MAC “00:04:96:97:fa:a2”, then IP security will block the MAC for 300 seconds and checkpoint the information to Peer2. Once the same MAC “00:04:96:97:fa:a2” violation is seen in Peer2 after a period of time, Peer2 will block the MAC for remaining 200 seconds (instead of 300 seconds). This ensures both Peer1 and Peer2 removes or unblocks the violation action at the same time.

#### **Tip**

With BPE ports, the violation action is also checkpointed and applied in the peer.

## Denial of Service Protection

A Denial-of-Service (DoS) attack occurs when a critical network or computing resource is overwhelmed and rendered inoperative in a way that legitimate requests for service cannot succeed.

In its simplest form, a DoS attack is indistinguishable from normal heavy traffic. There are some operations in any switch or router that are more costly than others, and

although normal traffic is not a problem, exception traffic must be handled by the switch's CPU in software.

**Note**

DoS protection is not supported for IPv6.

Some packets that the switch processes in the CPU software include:

- Traffic resulting from new MAC learning.

**Note**

When certain features such as Network Login are enabled, hardware learning is disabled to let software control new MAC learning.

- Routing and control protocols including *ICMP*, *BGP (Border Gateway Protocol)*, *OSPF (Open Shortest Path First)*, *STP*, *EAPS (Extreme Automatic Protection Switching)*, *ESRP*, etc.
- Switch management traffic (switch access by Telnet, SSH, HTTP, *SNMP*, etc.)
- Other packets directed to the switch that must be discarded by the CPU

If any one of these functions is overwhelmed, the CPU may be too busy to service other functions and switch performance will suffer. Even with very fast CPUs, there will always be ways to overwhelm the CPU with packets that require costly processing.

DoS Protection is designed to help prevent this degraded performance by attempting to characterize the problem and filter out the offending traffic so that other functions can continue. When a flood of CPU bound packets reach the switch, DoS Protection will count these packets. When the packet count nears the alert threshold, packets headers are saved. If the threshold is reached, then these headers are analyzed, and a hardware *ACL* is created to limit the flow of these packets to the CPU. This ACL will remain in place to provide relief to the CPU. Periodically, the ACL will expire, and if the attack is still occurring, it will be re-enabled. With the ACL in place, the CPU will have the cycles to process legitimate traffic and continue other services.

**Note**

User-created ACLs take precedence over the automatically applied DoS protect ACLs.

DoS Protection sends a notification when the notify threshold is reached.

You can also specify some ports as trusted ports, so that DoS protection is not applied to those ports.

## Configuring Simulated Denial of Service Protection

The conservative way to deploy DoS protection is to use the simulated mode first. In simulated mode, DoS protection is enabled, but no *ACLs* are generated.

- Enable the simulated mode using the command:  
`enable dos-protect simulated`

This mode is useful to gather information about normal traffic levels on the switch. This will assist in configuring denial of service protection so that legitimate traffic is not blocked.

The following topics describe how to configure DoS protection, including alert thresholds, notify thresholds, ACL expiration time, and so on.

## Configuring Denial of Service Protection

- Enable or disable DoS protection using the command:

```
enable dos-protect
disable dos-protect
```

After enabling DoS protection, the switch will count the packets handled by the CPU and periodically evaluate whether to send a notification and/or create an [ACL](#) to block offending traffic.

You can configure a number of the values used by DoS protection if the default values are not appropriate for your situation.

The values that you can configure are:

- interval—How often, in seconds, the switch evaluates the DoS counter (default: 1 second)
- alert threshold—The number of packets received in an interval that will generate an ACL (default: 4000 packets)
- notify threshold—The number of packets received in an interval that will generate a notice (default: 3500 packets)
- ACL expiration time—The amount of time, in seconds, that the ACL will remain in place (default: 5 seconds)
- Configure the interval at which the switch checks for DoS attacks using the command:  

```
configure dos-protect interval seconds
```
- Configure the alert threshold using the command:  

```
configure dos-protect type l3-protect alert-threshold packets
```
- Configure the notification threshold using the command:  

```
configure dos-protect type l3-protect notify-threshold packets
```
- Configure the ACL expiration time using the command:  

```
configure dos-protect acl-expire seconds
```

### Configuring Trusted Ports

Traffic from trusted ports will be ignored when DoS protect counts the packets to the CPU. If we know that a machine connected to a certain port on the switch is a safe "trusted" machine, and we know that we will not get a DoS attack from that machine,

the port where this machine is connected to can be configured as a trusted port, even though a large amount of traffic is going through this port.

- Configure the trusted ports list using the command:

```
configure dos-protect trusted-ports [ports [ports | all] | add-ports
[ports-to-add | all] | delete-ports [ports-to-delete | all]]
```

### Displaying DoS Protection Settings

- Display the DoS protection settings using the command:

```
show dos-protect {detail}
```

## Protocol Anomaly Protection

The Extreme chipsets contain built-in hardware protocol checkers that support port security features for security applications, such as stateless DoS protection.

The protocol checkers allow users to drop the packets based on the following conditions, which are checked for ingress packets prior to the L2/L3 entry table:

- SIP = DIP for IPv4/IPv6 packets.
- TCP\_SYN Flag = 0 for IPv4/IPv6 packets
- TCP Packets with control flags = 0 and sequence number = 0 for IPv4/IPv6 packets
- TCP Packets with FIN, URG & PSH bits set & seq. number = 0 for IPv4/IPv6 packets
- TCP Packets with SYN & FIN bits are set for IPv4/IPv6 packets
- TCP Source Port number = TCP Destination Port number for IPv4/IPv6 packets
- First TCP fragment does not have the full TCP header (less than 20 bytes) for IPv4/IPv6 packets
- TCP header has fragment offset value as 1 for IPv4/IPv6 packets
- UDP Source Port number = UDP Destination Port number for IPv4/IPv6 packets
- ICMP ping packets payload is larger than programmed value of */ICMP*max size for IPv4/IPv6 packets
- Fragmented ICMP packets for IPv4/IPv6 packets

The protocol anomaly detection security functionality is supported by a set of anomaly-protection enable, disable, configure, clear, and show CLI commands. For further details, see the [Switch Engine v33.3.1 Command References](#).

## Flood Rate Limitation

Flood rate limitation, or storm control, is used to minimize the network impact of ingress flooding traffic. You can configure ports to accept a specified rate of packets per second. When that rate is exceeded, the port blocks traffic and drops subsequent packets until the traffic again drops below the configured rate.

- Configure the rate limit.

```
configure ports port_list rate-limit flood [broadcast | multicast |
unknown-destmac] [no-limit | pps]
```

- Display rate limiting statistics.

```
show ports {port_list} rate-limit flood {no-refresh}
```

**Note**

ExtremeXOS switches implement rate limiting granularity at millisecond intervals. The traffic bursts are monitored at millisecond intervals and the actions are performed within sub-seconds (when applicable). When the switch evaluates the traffic pattern for bursts against the configured value in pps, the value is calibrated on a per-millisecond interval. For example, using the `configure port 1 rate-limit flood broadcast 1000` command would be equivalent to 1 packet per millisecond.

## Authenticating Management Sessions Through a TACACS+ Server

You can use a Terminal Access Controller Access Control System Plus (TACACS+) server to authenticate management sessions for multiple switches.

A TACACS+ server allows you to centralize the authentication database, so that you do not have to maintain a separate local database on each switch. TACACS+ servers provide the following services:

- Username and password authentication
- Command authorization (the TACACS+ server validates whether the user is authorized to execute each command within the subset of commands, based on login privilege level)

**Note**

Command usage that should be restricted for a user account by TACACS with CLI authorization enabled may not occur when users are logged in by Chalet or when using the XML API directly.

- Accounting service (tracks authentication and authorization events)

**Note**

You can use a local database on each switch as a backup authentication service if the TACACS+ service is unavailable. When the TACACS+ service is operating, privileges defined on the TACACS+ server take precedence over privileges configured in the local database.

To use TACACS+ server features, you need the following components:

- TACACS+ client software, which is included in the ExtremeXOS software.

- A TACACS+ server, which is a third-party product.

**Note**

- TACACS+ provides many of the same features provided by *RADIUS (Remote Authentication Dial In User Service)*, but enabling both RADIUS and TACACS+ at the same time is not supported for Management User Authentication.
- RADIUS can be used for both Switch Management User Authentication as well as Network Login user/device authentication, while TACACS+ can be used only for Management User Authentication.

TACACS+ is a communications protocol that is used between client and server to implement the TACACS+ service. The TACACS+ client component of the ExtremeXOS software should be compatible with any TACACS+ compliant server product.

**Note**

The switch allows local authentication when the client IP is excluded in TACACS+ server by default. To disallow local authentication when the client IP is excluded in TACACS+ server the local authentication disallow option should be used.

**Note**

Version 32.6 adds support for configuration of TACACS+ IPv6 server.

For information on installing, configuring, and managing a TACACS+ server, see the product documentation for that server.

The following describes how to configure the ExtremeXOS TACACS+ client component in the ExtremeXOS software: [Configuring the TACACS+ Client for Authentication and Authorization](#) on page 1540.

## Configuring the TACACS+ Client for Authentication and Authorization

### Changing the TACACS+ Server

Use the following steps to change TACACS+ server configuration to avoid service interruption of authentication and authorization.

1. Unconfigure the existing primary TACACS+ server.

**Note**

The command `disable tacacs` is *not* required while changing TACACS+ servers.

If only a single TACACS+ server is configured, you must disable TACACS authorization (if enabled) before reconfiguring TACACS+ server:

```
disable tacacs-authorization
```

To unconfigure the existing primary TACACS+ server:

```
unconfigure tacacs server [primary | secondary]
```

**Note**

After this step, TACACS+ will failover to secondary server.

2. Configure the new primary TACACS+ server:

```
configure tacacs [primary | secondary] server [host_ipaddr |
host_ipV6addr | hostname] {tcp_port} client-ip [client_ipaddr |
client_ipV6addr] {vr vr_name}
```

3. Configure the shared-secret password for primary TACACS+ server:

```
configure tacacs [primary | secondary] shared-secret {encrypted}
string
```

**Note**

Only after configuring shared-secret password for primary server, TACACS+ will fallback to primary server from secondary.

4. Unconfigure existing secondary TACACS+ server:

```
unconfigure tacacs server [primary | secondary]
```

5. Configure new secondary TACACS+ server:

```
configure tacacs [primary | secondary] server [host_ipaddr |
host_ipV6addr | hostname] {tcp_port} client-ip [client_ipaddr |
client_ipV6addr] {vr vr_name}
```

6. Configure shared-secret password for secondary TACACS+ server:

```
configure tacacs [primary | secondary] shared-secret {encrypted}
string
```

### *Specifying TACACS+ Server Addresses*

Before the TACACS+ client software can communicate with a TACACS+ server, you must specify the server address in the client software. You can specify up to two TACACS+ servers, and you can use either an IP address or a host name to identify each server.

- To configure the TACACS+ servers in the client software, use the following command:

```
configure tacacs [primary | secondary] server [host_ipaddr |
host_ipV6addr | hostname] {tcp_port} client-ip ipaddress {vr vr_name}
```

To configure the primary TACACS+ server, specify **primary**. To configure the secondary TACACS+ server, specify **secondary**.

### *Configuring the TACACS+ Client Timeout Value*

- To configure the timeout if a server fails to respond, use the following command:

```
configure tacacs timeout seconds
```

To detect and recover from a TACACS+ server failure when the timeout has expired, the switch makes one authentication attempt before trying the next designated TACACS+ server or reverting to the local database for authentication. In the event that the switch still has IP connectivity to the TACACS+ server, but a TCP session

cannot be established, (such as a failed TACACS+ daemon on the server), fail over happens immediately regardless of the configured timeout value.

For example, if the timeout value is set for three seconds (the default value), it will take three seconds to fail over from the primary TACACS+ server to the secondary TACACS+ server. If both the primary and the secondary servers fail or are unavailable, it takes approximately six seconds to revert to the local database for authentication.

#### *Configuring the Shared Secret Password for TACACS+ Communications*

The shared secret is a password that is configured on each network device and TACACS+ server. The shared secret is used to verify communication between network devices and the server.

- To configure the shared secret for client communications with TACACS+ servers, use the following command:

```
configure tacacs [primary | secondary] shared-secret {encrypted}
string
```

To configure the shared secret for a primary TACACS+ server, specify **primary**. To configure the shared secret for a secondary TACACS+ server, specify **secondary**.

Do not use the encrypted keyword to set the shared secret. The encrypted keyword prevents the display of the shared secret in the `show configuration` command output.

#### *Enabling and Disabling the TACACS+ Client Service*

The TACACS+ client service can be enabled or disabled without affecting the client configuration. When the client service is disabled, the client does not communicate with the TACACS+ server, so authentication must take place through the another service such as the local database or a RADIUS server.

#### **Note**

You cannot use RADIUS and TACACS+ at the same time.

- To enable the TACACS+ client service, use the following command: `enable tacacs`
- To disable the TACACS+ client service, use the following command: `disable tacacs`

#### *Requiring the Privilege Level Attribute for Authentication*

You can require that the privilege level attribute (`priv-lvl`) must be specified for TACACS authentication to occur. Setting the privilege level attribute as required does not change any behavior associated with values received in the `priv-lvl` attribute, only the presence/absence of the attribute.

To require that the `priv-lvl` is set to allow authentication, use the following command:

```
configure tacacs priv-lvl [required | optional]
```

### TACACS+ Configuration Example

This section provides a sample TACACS+ client configuration that:

- Specifies the primary TACACS+ server.
- Specifies the shared secret for the primary TACACS+ server.
- Specifies the secondary TACACS+ server.
- Specifies the shared secret for the secondary TACACS+ server.
- Enables the TACACS+ client on the switch.
- Configures an IPv6 server as the primary TACACS+ server.

All other client configuration features use the default settings as described [Configuring the TACACS+ Client for Authentication and Authorization](#) on page 1540 or in the [Switch Engine v33.3.1 Command References](#).

```
configure tacacs primary server 10.201.31.238 client-ip 10.201.31.85 vr "VR-Default"
configure tacacs primary shared-secret purple
configure tacacs secondary server 10.201.31.235 client-ip 10.201.31.85 vr "VR-Default"
configure tacacs secondary shared-secret purple
enable tacacs
```

IPv6 servers can be configured similarly using the following commands:

```
configure tacacs primary server 2111::220 client-ip 2111::85 vr "VR-Default"
configure tacacs primary shared-secret purple
configure tacacs secondary server 2111::210 client-ip 2111::85 vr "VR-Default"
configure tacacs secondary shared-secret purple
configure tacacs primary server 1111::220 client-ip 1111::170 vr vr-mgmt
```

To display the TACACS+ client configuration, use the `show tacacs` command. Below is sample output from this command:

```
TACACS+: enabled
TACACS+ Authorization: disabled
TACACS+ Accounting : disabled
TACACS+ Server Connect Timeout sec: 3
Primary TACACS+ Server:
 Server name :
 IP address : 10.201.31.238
 Server IP Port: 49
 Client address: 10.201.31.85 (VR-Default)
 Shared secret : purple
Secondary TACACS+ Server:
 Server name :
 IP address : 10.201.31.235
 Server IP Port: 49
 Client address: 10.201.31.85 (VR-Default)
 Shared secret : purple
TACACS+ Acct Server Connect Timeout sec: 3
Primary TACACS+ Accounting Server:Not configured
Secondary TACACS+ Accounting Server:Not configured
```

## Configuring the TACACS+ Client for Accounting

### Specifying the Accounting Server Addresses

Before the TACACS+ client software can communicate with a TACACS+ accounting server, you must specify the server address in the client software. You can specify up to

two accounting servers, and you can use either an IP address or a host name to identify each server.

- To specify TACACS+ accounting servers, use the following command:

```
configure tacacs-accounting [primary | secondary] server [host_ipaddr
| host_ipV6addr | hostname] {tcp_port} client-ip [client_ipaddr |
client_ipV6addr] {vr vr_name}
```

To configure the primary TACACS+ accounting server, specify **primary**. To configure the secondary TACACS+ accounting server, specify **secondary**.

#### *Configuring the TACACS+ Client Accounting Timeout Value*

- To configure the timeout if a server fails to respond, use the following command:  
`configure tacacs-accounting timeout seconds`

To detect and recover from a TACACS+ accounting server failure when the timeout has expired, the switch makes one authentication attempt before trying the next designated TACACS+ accounting server or reverting to the local database for authentication. In the event that the switch still has IP connectivity to the TACACS+ accounting server, but a TCP session cannot be established, (such as a failed TACACS+ daemon on the accounting server), failover happens immediately regardless of the configured timeout value. If the user does not have a local account or the user is disabled locally, the user's login will fail.

For example, if the timeout value is set for three seconds (the default value), it takes three seconds to failover from the primary TACACS+ accounting server to the secondary TACACS+ accounting server. If both the primary and the secondary servers fail or are unavailable, it takes approximately six seconds to revert to the local database for authentication.

#### *Configuring the Shared Secret Password for TACACS+ Accounting Servers*

The shared secret is a password that is configured on each network device and TACACS+ accounting server. The shared secret is used to verify communication between network devices and the server.

- To configure the shared secret for client communications with TACACS+ accounting servers, use the following command:

```
configure tacacs-accounting [primary | secondary] shared-secret
{encrypted} string
```

To configure the primary TACACS+ accounting server, specify **primary**. To configure the secondary TACACS+ accounting server, specify **secondary**.

Do not use the encrypted keyword to set the shared secret. The encrypted keyword prevents the display of the shared secret in the `show configuration` command output.

#### *Enabling and Disabling TACACS+ Accounting*

After you configure the TACACS+ client with the TACACS+ accounting server information, you must enable accounting in the TACACS+ client before the switch begins transmitting the information. You must enable TACACS+ authentication in

the client for accounting information to be generated. You can enable and disable accounting without affecting the current state of TACACS+ authentication.

- To enable TACACS+ accounting, use the following command:  
`enable tacacs-accounting`
- To disable TACACS+ accounting, use the following command:  
`disable tacacs-accounting`

### *TACACS+ Accounting Configuration Example*

This section provides a sample TACACS+ client configuration for TACACS+ accounting that:

- Specifies the primary TACACS+ accounting server.
- Specifies the shared secret for the primary TACACS+ accounting server.
- Specifies the secondary TACACS+ accounting server.
- Specifies the shared secret for the secondary TACACS+ accounting server.
- Enables TACACS+ accounting on the switch.
- Configures an IPv6 server as the primary TACACS+ accounting server.

All other client configuration features use the default settings as described [Configuring the TACACS+ Client for Authentication and Authorization](#) on page 1540 or in the *Switch Engine v33.3.1 Command References*.

```
configure tacacs-accounting primary server 10.201.31.238 client-ip 10.201.31.85 vr "VR-Default"
configure tacacs-accounting primary shared-secret purple
configure tacacs-accounting secondary server 10.201.31.235 client-ip 10.201.31.85 vr "VR-Default"
config tacacs-accounting secondary shared-secret purple
enable tacacs-accounting
```

IPv6 server can be configured using the following commands:

```
configure tacacs-accounting primary server 2111::220 client-ip 2111::85 vr "VR-Default"
configure tacacs-accounting primary shared-secret purple
configure tacacs-accounting secondary server 2111::210 client-ip 2111::85 vr "VR-Default"
configure tacacs-accounting secondary shared-secret purple
configure tacacs-accounting primary server 1111::220 client-ip 1111::170 vr vr-mgmt
```

To display the TACACS+ client accounting configuration, use the `show tacacs` or the `show tacacs-accounting` command. The following is sample output from the `show tacacs` command:

```
TACACS+: enabled
TACACS+ Authorization: enabled
TACACS+ Accounting : enabled
TACACS+ Server Connect Timeout sec: 3
Primary TACACS+ Server:
 Server name :
 IP address : 10.201.31.238
 Server IP Port: 49
 Client address: 10.201.31.85 (VR-Default)
 Shared secret : purple
Secondary TACACS+ Server:
 Server name :
 IP address : 10.201.31.235
 Server IP Port: 49
```

```
Client address: 10.201.31.85 (VR-Default)
Shared secret : purple
TACACS+ Acct Server Connect Timeout sec: 3
Primary TACACS+ Accounting Server:
 Server name :
 IP address : 10.201.31.238
 Server IP Port: 49
 Client address: 10.201.31.85 (VR-Default)
 Shared secret : purple
Secondary TACACS+ Accounting Server:
 Server name :
 IP address : 10.201.31.235
 Server IP Port: 49
 Client address: 10.201.31.85 (VR-Default)
 Shared secret : purple
```

## Authenticating Management Sessions Through a RADIUS Server

You can use a Remote Authentication Dial In User Service (*RADIUS*) server to authenticate management sessions for multiple switches. A RADIUS server allows you to centralize the authentication database, so that you do not have to maintain a separate local database on each switch. RADIUS servers provide the following services for management sessions:

- Username and password authentication
- Command authorization (the RADIUS server validates whether the user is authorized to execute each command)

### Note

Command usage that should be restricted for a user account by RADIUS with CLI authorization may not occur when users are logged in by Chalet or when using the XML API directly.

- Accounting service (tracks authentication and authorization events)

### Note

You can use a local database on each switch as a backup authentication service if the RADIUS service is unavailable. When the RADIUS service is operating, privileges defined on the RADIUS server take precedence over privileges configured in the local database.

To use RADIUS server features, you need the following components:

- RADIUS client software, which is included in the ExtremeXOS software.
- A RADIUS server, which is a third-party product.

### Note

RADIUS provides many of the same features provided by TACACS+. You cannot use RADIUS and TACACS+ at the same time.

RADIUS is a communications protocol (RFC 2865) that is used between client and server to implement the RADIUS service.

The RADIUS client component of the ExtremeXOS software should be compatible with any RADIUS compliant server product.

**Note**

The switch allows local authentication when the client IP is excluded in RADIUS server.

The following sections provide more information on management session authentication:

- [How Extreme Switches Work with RADIUS Servers](#) on page 1547
- [Configuration Overview for Authenticating Management Sessions](#) on page 1548

## How Extreme Switches Work with RADIUS Servers

When configured for use with a *RADIUS* server, an ExtremeXOS switch operates as a RADIUS client. In RADIUS server configuration, the client component is configured as a client or as a Network Access Server (NAS). Typically, an ExtremeXOS NAS provides network access to supplicants such as PCs or phones.

When a supplicant requests authentication from a switch that is configured for RADIUS server authentication, the following events occur:

1. The switch sends an authentication request in the form of a RADIUS Access-Request message.
2. The RADIUS server looks up the user in the users file.
3. The RADIUS server accepts or rejects the authentication and returns a RADIUS Access-Accept or Access-Reject message.

**Note**

A user rejected by the Radius/TACACS server can not be authenticated via local database.

4. If authentication is accepted, the Access-Accept message can contain standard RADIUS attributes and Vendor Specific Attributes (VSAs) that can be used to configure the switch.
5. If authentication is accepted, the Access-Accept message can enable command authorization for that user on the switch. Command authorization uses the RADIUS server to approve or deny the execution of each command the user enters.

The ExtremeXOS switch initiates all communications with the RADIUS server. For basic authentication, the switch sends the Access-Request message, and communications with the RADIUS server is complete when the switch receives the Access-Accept or Access-Reject message. For command authorization, communications starts each time a user configured for command authorization enters a switch command. RADIUS server communications ends when command use is allowed or denied.

A key component of RADIUS server management is the attributes and VSAs that the RADIUS server can be configured to send in Access-Accept messages. VSAs are custom attributes for a specific vendor, such as Extreme Networks. These attributes store information about a particular user and the configuration options available to

the user. The RADIUS client in ExtremeXOS accepts these attributes and uses them to configure the switch in response to authentication events. The RADIUS server does not process attributes; it simply sends them when authentication is accepted. It is the switch that processes attributes.

User authentication and attributes are managed on a RADIUS server by editing text files. On the FreeRADIUS server, the user ID, password, attributes, and VSAs are stored in the users file, and VSAs are defined in the dictionary file. The dictionary file associates numbers with each attribute. When you edit the users file, you specify the text version of each attribute you define. When the RADIUS server sends attributes to the switch, it sends the attribute type numbers to reduce the network load. Some attribute values are sent as numbers too.

Command authorization is also managed on a RADIUS server by editing text files. On a FreeRADIUS server, the profiles file is divided into sections called *profiles*. Each profile lists command access definitions. In the users file, you can use the Profile-Name attribute to select the command profile that applies to each user managed by command authorization.

The ExtremeXOS software supports backup authentication and authorization by eight total servers for redundancy.

RADIUS servers can be optionally configured to work with directory services such as LDAP or Microsoft Active Directory. Because ExtremeXOS switches operate with RADIUS servers, they can benefit from the pairing of the RADIUS server and a directory service. Some guidelines for configuring FreeRADIUS with LDAP are provided later in this chapter. Since the use of the directory service requires configuration of the RADIUS server and directory service, the appropriate documentation to follow is the documentation for those products.

## Configuration Overview for Authenticating Management Sessions

To configure the switch *RADIUS* client and the RADIUS server to authenticate management sessions, do the following:

1. Configure the switch RADIUS client for authentication as described in [Configuring the RADIUS Client for Authentication and Authorization](#) on page 1557.
2. If you want to use RADIUS accounting, configure the switch RADIUS accounting client as described in [Configuring the RADIUS Client for Accounting](#) on page 1558.
3. Configure the RADIUS server for authentication as described in [Configuring User Authentication \(Users File\)](#) on page 1560.
4. If you want to use RADIUS accounting, configure a RADIUS accounting server as described in the documentation for your RADIUS product.

## Authenticating Network Login Users Through a RADIUS Server

You can use a *RADIUS* server to authenticate network login users and supply configuration data that the switch can use to make dynamic configuration changes to accommodate network login users.

A RADIUS server allows you to centralize the authentication database, so that you do not have to maintain a separate local database on each switch. RADIUS servers provide the following services for network login sessions:

- Username and password authentication
- Standard RADIUS attributes and Extreme Networks VSAs that the switch can use for dynamic configuration
- Accounting service (tracks authentication and authorization events)

To use RADIUS server features, you need the following components:

- RADIUS client software, which is included in the ExtremeXOS software.
- A RADIUS server, which is a third-party product.

**Note**

RADIUS provides many of the same features provided by TACACS+, but the network login feature does not work with TACACS+.

The following sections provide more information on network login session authentication:

- [Differences Between Network Login Authentication and Management Session Authentication](#) on page 1549
- [Configuration Overview for Authenticating Network Login Users](#) on page 1550

## Differences Between Network Login Authentication and Management Session Authentication

Network login authentication is very similar to management session authentication.

The differences are:

- Network login authentication grants network access to devices connected to a switch port, and management session authentication grants management access to the switch for configuration and management.
- The user name for network login authentication can be a MAC address.
- Standard *RADIUS* attributes and Extreme Networks VSAs can be used with the network login and universal port features to configure switch ports and general switch configuration parameters.
- Command authorization is not applicable because network login controls network access, not management session access.

Except for the above differences, network login authentication is the same as described in [How Extreme Switches Work with RADIUS Servers](#) on page 1547.

## Configuration Overview for Authenticating Network Login Users

To configure the switch *RADIUS* client and the RADIUS server to authenticate network login users, do the following:

1. Configure the switch RADIUS client for authentication as described in [Configuring the RADIUS Client for Authentication and Authorization](#) on page 1557.
2. If you want to use RADIUS accounting, configure the switch RADIUS accounting client as described in [Configuring the RADIUS Client for Accounting](#) on page 1558.
3. Configure network login on the switch as described in [Security](#).
4. Configure the RADIUS server for authentication and Extreme Networks VSAs as described in [Configuring User Authentication \(Users File\)](#) on page 1560.
5. If you want to use the universal port feature to run configuration scripts at authentication, configure the switch universal port feature as described in [Universal Port](#) on page 2066.
6. If you want to use RADIUS accounting, configure a RADIUS accounting server as described in the documentation for your RADIUS product.

## Authentication

Entire packets (as opposed to individual TLVs in a packet) can be authenticated. If authentication fails on a packet, the entire packet is discarded. Multi-part packets are authenticated separately. Routers are not required to support authentication. The ExtremeXOS software provides optional support for plain-text authentication.

## Authentication Retransmission Algorithm

Two retransmission algorithms are used in combination: Back-off Round Robin, and simple Round Robin. The focus of this retransmission algorithm is to provide for server redundancy.

### Note

The reason for using a combination of back-off and round-robin rather than the standard back-off algorithm where all configured transmissions occur to server 1 before transmitting to server 2 is to allow for more than one server to be tried prior to 802.1x timeout when EAP authentication is occurring.

The standard algorithm is as described in [Figure 195](#) and is a combination of back-off and round-robin. This algorithm always uses the highest priority server first regardless of past transaction history. If the highest priority server can handle the entire load all, transactions will go to that server. Consider three *RADIUS* servers – 1, 2 and 3 with the configurable number of retries set to 2:

**Figure 195: Authentication Retransmission Algorithm for a Single RADIUS Transaction (No Servers Responding 1)**

This figure shows the entire retransmission algorithm for a single RADIUS transaction if none of the servers were to respond. No more transmissions will occur for this transaction if a response is received by the RADIUS client software within the configurable timeout period.

The round-robin retransmission algorithm is depicted in [Figure 196](#) and is simply round-robin.

The configurable round-robin retransmission algorithm for RADIUS authentication aims to spread the load among all the configured servers. In large-scale deployments with high rates of authentication this algorithm will provide for better performance than the default algorithm. The initial transmission for each potential authentication will go to the next server in the list. If 999 sessions were to be authenticated across three servers and no timeouts were to occur, then 333 responses would be sent to each server.

Consider three RADIUS servers: 1, 2 and 3 with the configurable number of retries set to 2 and where the prior session sent its initial request to server 1:

**Figure 196: Authentication Retransmission Algorithm for a Single RADIUS Transaction (No Servers Responding 2)**

This figure shows the entire retransmission algorithm for a single RADIUS transaction if none of the servers were to respond. No more transmissions will occur for this transaction if a response is received by the RADIUS client software within the configurable timeout period. All servers are considered the same priority when using this transmission algorithm with each server taking its turn receiving the initial transmission.

## Accounting

Accounting Start and Stop requests are sent for user sessions in accordance with RFC 2866 (7).

### Accounting Retransmission Algorithm

The *RADIUS* client accounting software uses the standard back-off retransmission algorithm. Since accounting transactions generally do not require timeliness this algorithm focuses on redundancy rather than expediency. The highest priority server

is always tried first regardless of past transaction history. Consider three accounting servers – 1, 2 and 3 each with the configurable number of retries set to 2:

**Figure 197: Accounting Retransmission Algorithm (No Servers Responding)**

This figure shows the entire retransmission algorithm for a single RADIUS accounting transaction if none of the servers were to respond. All of the transactions to each of the servers are attempted before another server is attempted. If the initial server can handle the entire accounting transmission load, then all transactions will go to that server.

## Authentication NMS Realm

The NMS realm type is supported in addition to the management and network realms. These servers are used for the Extreme Network Virtualization or Virtual Machine Tracking feature. This realm only supports the existing subset of two servers (primary and secondary).

## Per Realm Authentication Enable/Disable

*RADIUS* authentication can be enabled on a per realm basis for the management and network realms.

## Supported RADIUS Attributes

The following is a list of *RADIUS* attributes.

### Note

Although this is the list of attributes that is supported by the RADIUS software, usage of these attributes is dependent on the features provided by the system as a whole.

Table Legend:

- PRQ—PAP Authentication Request
- CRQ—CHAP Authentication Request
- EARQ—EAP Authentication Request
- AC—Access Challenge
- AA—Access Accept
- AR—Access Reject

**Table 143: Authentication Attributes**

| Attribute Name     | RFC  | Attr # | PRQ | CRQ | EARQ | AC | AA | AR |
|--------------------|------|--------|-----|-----|------|----|----|----|
| User-Name          | 2865 | 1      | X   | X   | X    |    | X  | X  |
| User-Password      | 2865 | 2      | X   |     |      |    |    |    |
| CHAP-Password      | 2865 | 3      |     | X   |      |    |    |    |
| NAS-IP-Address     | 2865 | 4      | X   | X   | X    |    |    |    |
| NAS-Port           | 2865 | 5      | X   | X   | X    |    |    |    |
| Service-Type       | 2865 | 6      | X   | X   | X    |    | X  |    |
| Framed-Protocol    | 2865 | 7      |     | X   | X    |    |    |    |
| Filter-ID          | 2865 | 11     |     |     |      |    | X  |    |
| Framed-MTU         | 2865 | 12     | X   | X   | X    |    |    |    |
| State              | 2865 | 24     |     |     | X    | X  |    |    |
| Class              | 2865 | 25     |     |     |      |    | X  |    |
| Session-Timeout    | 2865 | 27     |     |     |      |    | X  |    |
| Idle-Timeout       | 2865 | 28     |     |     |      |    | X  |    |
| Termination-Action | 2865 | 29     |     |     |      |    | X  |    |
| Called-Station-ID  | 2865 | 30     | X   | X   | X    |    |    |    |
| Calling-Station-ID | 2865 | 31     | X   | X   | X    |    |    |    |
| NAS-Identifier     | 2865 | 32     | X   | X   | X    |    |    |    |

**Table 143: Authentication Attributes (continued)**

| Attribute Name                 | RFC  | Attr # | PRQ | CRQ | EARQ | AC | AA | AR |
|--------------------------------|------|--------|-----|-----|------|----|----|----|
| CHAP-Challenge                 | 2865 | 60     |     | X   |      |    |    |    |
| NAS-Port-Type                  | 2865 | 61     | X   | X   | X    |    |    |    |
| Tunnel-Type                    | 2868 | 64     |     |     |      |    | X  |    |
| Tunnel-Medium                  | 2868 | 65     |     |     |      |    | X  |    |
| Message-Authenticator          | 2869 | 80     |     |     | X    | X  | X  | X  |

## Configuring the RADIUS Client

For information on installing, configuring, and managing a *RADIUS* server, see the product documentation for that server and the guidelines in [RADIUS Server Configuration Guidelines](#) on page 1560.

## Configuring the RADIUS Client for Authentication and Authorization

### Specifying the RADIUS Server Addresses

Before the *RADIUS* client software can communicate with a RADIUS server, you must specify the server address in the client software. You can specify up to 32 RADIUS servers, and you can use either an IP address or a host name to identify each server.

- To configure the RADIUS servers in the client software, use the following command:

```
configure radius {mgmt-access | netlogin} [primary | secondary |
index] server [host_ipaddr | host_ipV6addr | hostname] {udp_port}
client-ip [client_ipaddr | client_ipV6addr] {vr vr_name} {shared-
secret {encrypted} secret}
```

#### Note

It is recommended to enable loopback mode on the *VLAN* associated with RADIUS if the radius connectivity is established via a front panel port on a SummitStack.

The default port value for authentication is 1812. The client IP address is the IP address used by the RADIUS server for communicating back to the switch.

To configure the primary RADIUS server, specify *primary*. To configure the secondary RADIUS server, specify *secondary*.

By default, switch management and network login use the same primary and secondary RADIUS servers for authentication. To specify one pair of RADIUS servers for switch management and another pair for network login, use the *mgmt-access* and *netlogin* keywords.

### Configuring the RADIUS Client Timeout Value

- To configure the timeout if a server fails to respond, use the following command:

```
configure radius {mgmt-access {primary | secondary} | netlogin
{primary | secondary} | index } timeout sec
```

If the timeout expires, another authentication attempt is made. After three failed attempts to authenticate, the alternate server is used. After six failed attempts, local user authentication is used. If the user does not have a local account or the user is disabled locally, the user's login will fail.

If you do not specify the *mgmt-access* or *netlogin* keyword, the timeout interval applies to both switch management and *netlogin* *RADIUS* servers.

### Configuring the Shared Secret Password for RADIUS Communications

The shared secret is a password that is configured on each network device (*RADIUS* client) and RADIUS server. The shared secret is used to verify communication between network devices and the server.

- To configure the shared secret for client communications with RADIUS servers, use the following command:

```
configure radius {mgmt-access | netlogin} [primary | secondary]
shared-secret {encrypted} string
```

To configure the shared secret for a primary RADIUS server, specify **primary**. To configure the shared secret for a secondary RADIUS server, specify **secondary**.

If you do not specify the **mgmt-access** or **netlogin** keyword, the secret applies to both the primary and secondary switch management and network login RADIUS servers.

Do not use the **encrypted** keyword to set the shared secret. The **encrypted** keyword prevents the display of the shared secret in the **show configuration** command output.

### Enabling and Disabling the RADIUS Client Service

The *RADIUS* client service can be enabled or disabled without affecting the client configuration. When the client service is disabled, the client does not communicate with the RADIUS server, so authentication must take place through the another service such as the local database or a TACACS+ server.

#### Note

You cannot use RADIUS and TACACS+ at the same time.

- To enable the RADIUS client service, use the following command:  

```
enable radius {mgmt-access | netlogin}
```
- To disable the RADIUS client service, use the following command:  

```
disable radius {mgmt-access | netlogin}
```

If you do not specify the **mgmt-access** or **netlogin** keywords, RADIUS authentication is enabled or disabled on the switch for both management and network login.

## Configuring the RADIUS Client for Accounting

### Specifying the RADIUS Accounting Server Addresses

Before the *RADIUS* client software can communicate with a RADIUS accounting server, you must specify the server address in the client software. You can specify up to 32 accounting servers, and you can use either an IP address or a host name to identify each server.

- To specify RADIUS accounting servers, use the following command:  

```
configure radius-accounting { mgmt-access | netlogin } [primary |
secondary | index] server [host_ipaddr | host_ipV6addr | hostname]
```

```
{udp_port} client-ip [client_ipaddr | client_ipV6addr] {vr vr_name}
{shared-secret {encrypted} secret}
```

The default port value for accounting is 1813. The client IP address is the IP address used by the RADIUS server for communicating back to the switch.

To configure the primary RADIUS accounting server, specify **primary**. To configure the secondary RADIUS accounting server, specify **secondary**.

By default, switch management and network login use the same primary and secondary RADIUS servers for accounting. To specify one pair of RADIUS accounting servers for switch management and another pair for network login, use the **mgmt-access** and **netlogin** keywords.

#### *Configuring the RADIUS Client Accounting Timeout Value*

- To configure the timeout if a server fails to respond, use the following command:  

```
configure radius-accounting {mgmt-access {primary | secondary} |
netlogin {primary | secondary} | index } timeout sec
```

If the timeout expires, another authentication attempt is made. After three failed attempts to authenticate, the alternate server is used.

#### *Configure the Shared Secret Password for RADIUS Accounting Servers*

The shared secret is a password that is configured on each network device (*RADIUS* client) and RADIUS accounting server. The shared secret is used to verify communication between network devices and the server.

- To configure the shared secret for client communications with RADIUS accounting servers, use the following command:  

```
configure radius-accounting {mgmt-access | netlogin} [primary |
secondary] shared-secret {encrypted} string
```

To configure the primary RADIUS accounting server, specify **primary**. To configure the secondary RADIUS accounting server, specify **secondary**.

If you do not specify the **mgmt-access** or **netlogin** keywords, the secret applies to both the primary and secondary switch management and network login RADIUS accounting servers.

Do not use the **encrypted** keyword to set the shared secret. The **encrypted** keyword prevents the display of the shared secret in the **show configuration** command output.

#### *Enabling and Disabling RADIUS Accounting*

After you configure the *RADIUS* client with the RADIUS accounting server information, you must enable accounting in the RADIUS client before the switch begins transmitting the information. You must enable RADIUS authentication in the client for accounting information to be generated. You can enable and disable accounting without affecting the current state of RADIUS authentication.

- To enable RADIUS accounting, use the following command:  

```
enable radius-accounting {mgmt-access | netlogin}
```

- To disable RADIUS accounting, use the following command:  
`disable radius-accounting {mgmt-access | netlogin}`  
If you do not specify a keyword, RADIUS accounting is enabled or disabled on the switch for both management and network login.

## RADIUS Server Configuration Guidelines

### Note

For information on how to use and configure your *RADIUS* server, refer to the documentation that came with your RADIUS server.

### Note

When configuring RADIUS/TACACS servers with the IP address received from a DHCP server, the IP address should be reserved for the switch in the DHCP server to avoid conflicts after rebooting.

## Configuring User Authentication (Users File)

User authentication is configured in the users file on a FreeRADIUS server. Other *RADIUS* servers might use a different name and a different syntax for configuration, but the basic components of the users file and user authentication are the same.

For Extreme Networks switches, there are three types of users file entries:

- Session management entries
- Network login user entries
- Network login MAC address entries

### Note

The “users” file is case-sensitive, and punctuation is very important for FreeRADIUS.

### *Session Management Entries*

The following is an example of a session management entry for read-write access:

```
eric
Cleartext-Password := "eric"
Service-Type = Administrative-User,
Extreme-CLI-Authorization = Enabled
```

The key components of the example above are the user name, password, service-type, and Extreme-CLI-Authorization VSA. For simple authentication, you only need to enter the user name ("eric" in this example) and a password as described in the *RADIUS* server documentation.

Enter the attributes for each user and separate them from the others with commas as described in the RADIUS server documentation.

For more information on the Extreme-CLI-Authorization VSA, see [Extreme Networks VSAs](#) on page 1564.

### Network Login User Entries

The following is an example of a network login user entry:

```
Jim Auth-Type := EAP, Cleartext-Password == "12345"
 Session-Timeout = 60,
 Termination-Action = 1,
 Extreme-Security-Profile = "user-auth LOGOFF-PROFILE=avaya-
 remove;qos=\"QP1\";",
 Extreme-Netlogin-Vlan = voice-avaya
```

The key components of the example above are the user name, password, attributes, and Extreme Networks VSAs. For simple authentication, you only need to enter the user name (Jim in this example) and a password as described in the [RADIUS](#) server documentation.

Enter the attributes for each user and separate them from the others with commas as described in the RADIUS server documentation.

In the example above, the Session-Timeout and Termination-Action attributes are examples of standard RADIUS attributes, and these are described in [Standard RADIUS Attributes Used by Extreme Switches](#) on page 1562.

The Extreme-Security-Profile and Extreme-Netlogin-Vlan attributes are examples of Extreme Networks VSAs and are described in [Extreme Networks VSAs](#) on page 1564.

### Network Login MAC Address Entries

The following is an example of a network login MAC address entry:

```
00040D9D12AF
Auth-Type := Local,
Cleartext-Password == "00040D9D12AF"
Session-Timeout = 60,
Termination-Action = 1,
Extreme-Security-Profile = "user-auth LOGOFF-PROFILE=avaya remove;qos=\"QP1\";",
Extreme-Netlogin-Vlan = voice-avaya
```

The key components of the example above are the MAC address, password (which is set to the MAC address), attributes, and Extreme Networks VSAs. For simple authentication, you only need to enter the MAC address (00040D9D12AF in this example) and a password as described in the [RADIUS](#) server documentation.

Enter the attributes for each user and separate them from the others with commas as described in the RADIUS server documentation.

In the example above, the Session-Timeout and Termination-Action attributes are examples of standard RADIUS attributes, and these are described in [Standard RADIUS Attributes Used by Extreme Switches](#) on page 1562.

The Extreme-Security-Profile and Extreme-Netlogin-VLAN attributes are examples of Extreme Networks VSAs and are described in [Extreme Networks VSAs](#) on page 1564.

### Standard RADIUS Attributes Used by Extreme Switches

The ExtremeXOS software uses standard [RADIUS](#) attributes to send information in an Access-Request message to a RADIUS server.

The software also accepts some standard RADIUS attributes in the Access-Accept message that the RADIUS server sends to the switch after successful authentication. The switch ignores attributes that it is not programmed to use.

[Table 145](#) lists the standard RADIUS attributes used by the ExtremeXOS software.

**Table 145: Standard RADIUS Attributes Used by Network Login**

| Attribute             | RFC      | Attribute Type | Format    | Sent-in                                                            | Description                                                                                                          |
|-----------------------|----------|----------------|-----------|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| User-Name             | RFC 2138 | 1              | String    | Access-Request                                                     | Specifies a user name for authentication.                                                                            |
| Calling-Station-ID    | RFC 2865 | 31             | String    | Access-Request                                                     | Identifies the phone number for the supplicant requesting authentication.                                            |
| EAP-Message           | RFC 3579 | 79             | String    | Access-Request, Access-Challenge, Access-Accept, and Access Reject | Encapsulates EAP packets.                                                                                            |
| Login-IP-Host         | RFC 2138 | 14             | Addresses | Access-Request and Access-Accept                                   | Specifies a host to log into after successful authentication.                                                        |
| Message-Authenticator | RFC 3579 | 80             | String    | Access-Request, Access-Challenge, Access-Accept, and Access Reject | Contains a hash of the entire message that is used to authenticate the message.                                      |
| NAS-Port-Type         | RFC 2865 | 61             | Integer   | Access-Request                                                     | Identifies the port type for the port through which authentication is requested.                                     |
| Service-Type          | RFC 2138 | 6              | String    | Access-Accept                                                      | Specifies the granted service type in an Access-Accept message. See <a href="#">Attribute 6: Service Type</a> below. |
| Session-Timeout       | RFC 2865 | 27             | Integer   | Access-Accept, Access-Challenge                                    | Specifies how long the user session can last before authentication is required.                                      |

**Table 145: Standard RADIUS Attributes Used by Network Login (continued)**

| Attribute               | RFC      | Attribute Type | Format          | Sent-in                          | Description                                                                                                                                                                                                                                                                                                            |
|-------------------------|----------|----------------|-----------------|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| State                   | RFC 2865 | 24             | String          | Access-Challenge, Access-Request | Site specific.                                                                                                                                                                                                                                                                                                         |
| Termination-Action      | RFC 2865 | 29             | Integer         | Access-Accept                    | Specifies how the switch should respond to service termination.                                                                                                                                                                                                                                                        |
| Tunnel-Medium-Type      | RFC 2868 | 65             | Integer         | Access-Accept                    | Specifies the transport medium used when creating a tunnel for protocols (for example, VLANs) that can operate over multiple transports.                                                                                                                                                                               |
| Tunnel-Private-Group-ID | RFC 2868 | 81             | Integer /String | Access-Accept                    | Specifies the <u>VLAN</u> ID of the destination VLAN after successful authentication; used to derive the VLAN name. Usually, the Integer VLAN ID (1-4094) is used. However, if the desired VLAN is statically configured and bound to a specific VLAN ID, the VLAN name string can be used for this attribute as well. |
| Tunnel-Type             | RFC 2868 | 64             | Integer         | Access-Accept                    | Specifies the tunneling protocol that is used.                                                                                                                                                                                                                                                                         |
| User-Password           | RFC 2138 | 2              | String          | Access-Request                   | Specifies a password for authentication.                                                                                                                                                                                                                                                                               |

**Attribute 6: Service Type**

During authentication, ExtremeXOS, in conformance with *RFC 2865*, sends the following values for the following authentication methods:

- Web-Auth—"Login"
- MAC-Auth—"Call Check"
- Dot1x—"Framed"

Extreme Networks switches have two levels of user privilege:

- read-only
- read-write

Because no command line interface (CLI) commands are available to modify the privilege level, access rights are determined when you log in. For a RADIUS server to identify the administrative privileges of a user, Extreme Networks switches expect a

RADIUS server to transmit the Service-Type attribute in the Access-Accept packet, after successfully authenticating the user.

Extreme Networks switches grant a RADIUS-authenticated user read-write privilege if a Service-Type value of 6 is transmitted as part of the Access-Accept message from the RADIUS server. Other Service-Type values or no value, result in the switch granting read-only access to the user. Different implementations of RADIUS handle attribute transmission differently. You should consult the documentation for your specific implementation of RADIUS when you configure users for read-write access.

#### Extreme Networks VSAs

**Table 146** contains the Vendor Specific Attribute (VSA) definitions that a *RADIUS* server can send to an Extreme switch after successful authentication.

These attributes must be configured on the RADIUS server along with the Extreme Networks Vendor ID, which is 1916.

**Table 146: VSA Definitions for Web-Based, MAC-Based, and 802.1X Network Login**

| VSA                        | Attribute Type | Format  | Sent-in       | Description                                                                                                                                                                                                                                                                                     |
|----------------------------|----------------|---------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Extreme-CLI-Authorization  | 201            | Integer | Access-Accept | Specifies whether command authorization is to be enabled or disabled for the user on the ExtremeXOS switch.                                                                                                                                                                                     |
| Extreme-Netlogin-VLAN-Name | 203            | String  | Access-Accept | Name of destination VLAN after successful authentication (must already exist on switch).                                                                                                                                                                                                        |
| Extreme-Netlogin-URL       | 204            | String  | Access-Accept | Destination web page after successful authentication.                                                                                                                                                                                                                                           |
| Extreme-Netlogin-URL-Desc  | 205            | String  | Access-Accept | Text description of network login URL attribute.                                                                                                                                                                                                                                                |
| Extreme-Netlogin-Only      | 206            | Integer | Access-Accept | Indication of whether the user can authenticate using other means, such as telnet, console, SSH, or Vista. A value of "1" (enabled) indicates that the user can only authenticate via network login. A value of "0" (disabled) indicates that the user can also authenticate via other methods. |
| Extreme-User-Location      | 208            | String  |               |                                                                                                                                                                                                                                                                                                 |
| Extreme-Netlogin-VLAN-ID   | 209            | Integer | Access-Accept | ID of destination VLAN after successful authentication (except for dynamic VLANs, must already exist on switch).                                                                                                                                                                                |

**Table 146: VSA Definitions for Web-Based, MAC-Based, and 802.1X Network Login (continued)**

| VSA                            | Attribute Type | Format  | Sent-in       | Description                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------|----------------|---------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Extreme-Netlogin-Extended-VLAN | 211            | String  | Access-Accept | Name or ID of the destination VLAN after successful authentication (must already exist on switch).<br><br><b>Note:</b> When using this attribute, specify whether the port should be moved tagged or untagged to the VLAN. See the guidelines listed in the section <a href="#">VSA 211: Extreme-Netlogin-Extended-Vlan</a> on page 1568 for more information. |
| Extreme-Security-Profile       | 212            | String  | Access-Accept | Specifies a universal port profile to execute on the switch. For more information, see <a href="#">Universal Port</a> on page 2066.                                                                                                                                                                                                                            |
| EXTREME_VM_NAME                | 213            | String  | Access-Accept | Specifies the name of the VM that is being authenticated . Example: MyVM1                                                                                                                                                                                                                                                                                      |
| EXTREME_VM_VPP_NAME            | 214            | String  | Access-Accept | Specifies the VPP to which the VM is to be mapped. Example: nvpp1                                                                                                                                                                                                                                                                                              |
| EXTREME_VM_IP_ADDR             | 215            | String  | Access-Accept | Specifies the IP address of the VM . Example: 11.1.1.254                                                                                                                                                                                                                                                                                                       |
| EXTREME_VM_CT ag               | 216            | Integer | Access-Accept | Specifies the ID or tag of the destination VLAN for the VM . Example: 101                                                                                                                                                                                                                                                                                      |
| EXTREME_VM_VR_Name             | 217            | String  | Access-Accept | Specifies the VR in which the destination VLAN is to be placed. Example : UserVR1                                                                                                                                                                                                                                                                              |

The examples in the following sections are formatted for use in the FreeRADIUS users file. If you use another RADIUS server, the format might be different.

**Note**

For information on how to use and configure your RADIUS server, refer to the documentation that came with your RADIUS server.

For untagged VLAN movement with 802.1X netlogin, you can use all current Extreme Networks VLAN VSAs: VSA 203, VSA 209, and VSA 211.

**VSA 201: Extreme-CLI-Authorization**

This attribute specifies whether command authorization is to be enabled or disabled for the user on the ExtremeXOS switch.

If command authorization is disabled, the user has full access to all CLI commands. If command authorization is enabled, each command the user enters is accepted or rejected based on the contents of the profiles file on the RADIUS server.

When added to the RADIUS users file, the following example enables command authorization for the associated user:

**Extreme: Extreme-CLI-Authorization = enabled**

When added to the RADIUS users file, the following example disables command authorization for the associated user:

```
Extreme: Extreme-CLI-Authorization = disabled
```

**VSA 203: Extreme-Netlogin-VLAN-Name**

This attribute specifies a destination VLAN name that the RADIUS server sends to the switch after successful authentication.

The VLAN must already exist on the switch. When the switch receives the VSA, it adds the authenticated user to the VLAN.

The following describes the guidelines for VSA 203:

- For untagged VLAN movement with 802.1X netlogin, you can use all current Extreme Networks VLAN VSAs: VSA 203, VSA 209, and VSA 211.
- To specify the VLAN name, use an ASCII string.
- When using this VSA, do not specify whether the VLAN is tagged or untagged.

Because the RADIUS server can identify a target VLAN with multiple attributes, the switch selects the appropriate VLAN or VLANs using the order:

- Extreme-Netlogin-Extended-VLAN (VSA 211)
- Extreme-Netlogin-VLAN-Name (VSA 203)
- Extreme-Netlogin-VLAN-ID (VSA 209)
- Tunnel-Private-Group-ID, but only if Tunnel-Type == VLAN(13) and Tunnel-Medium-Type == 802 (6) (see [Standard RADIUS Attributes Used by Extreme Switches](#) on page 1562)

If none of the previously described attributes are present ISP mode is assumed, and the client remains in the configured VLAN.

When added to the RADIUS users file, the following example specifies the destination VLAN name, purple, for the associated user:

```
Extreme: Extreme-Netlogin-VLAN-Name = purple
```

**VSA 204: Extreme-Netlogin-URL**

The Extreme-*NetLogin*-Url attribute specifies a web page URL that the RADIUS server sends to the switch after successful authentication. When the switch receives the attribute in response to a web-based network login, the switch redirects the web client to display the specified web page. If a login method other than web-based is used, the switch ignores this attribute.

The following describes the guidelines for VSA 204:

- To specify the URL to display after authentication, use an ASCII string.
- If you do not specify a URL, the network login infrastructure uses the default redirect page URL, , or the URL that you configured using the `configure netlogin redirect-page` command.
- VSA 204 applies only to the web-based authentication mode of Network Login.

The following example specifies the redirection URL to use after successful authentication.

To configure the redirect URL as `http://www.myhomepage.com`, add the following line:

```
Extreme: Netlogin-URL = http://www.myhomepage.com
```

#### **VSA 205: Extreme-Netlogin-URL-Desc**

The Extreme-NetLogin-Url-Desc attribute provides a redirection description that the RADIUS server sends to the switch after successful authentication. When the switch receives this attribute in response to a web-based network login, the switch temporarily displays the redirect message while the web client is redirected to the web page specified by attribute 204. If a login method other than web-based is used, the switch ignores this attribute.

The following describes the guidelines for VSA 205:

- To let the user know where they will be redirected to after authentication (specified by VSA 204), use an ASCII string to provide a brief description of the URL.
- VSA 205 applies only to the web-based authentication mode of Network Login.

The following example specifies a redirect description to send to the switch after successful authentication:

```
Extreme: Netlogin-URL-Desc = "Authentication successful. Stand by for the home page."
```

#### **VSA 206: Extreme-Netlogin-Only**

The Extreme-Netlogin-Only attribute can be used to allow normal authentication or restrict authentication to only the network login method.

When this attribute is assigned to a user and authentication is successful, the RADIUS server sends the configured value back to the switch. The configured value is either disabled or enabled.

The Extreme switch uses the value received from the RADIUS server to determine if the authentication is valid. If the configured value is disabled, all normal authentication processes are supported (Telnet and SSH, for example), so the switch accepts the authentication. If the configured value is enabled, the switch verifies whether network login was used for authentication. If network login was used for authentication, the switch accepts the authentication. If an authentication method other than network login was used, the switch rejects the authentication.

Add the following line to the RADIUS server users file for users who are not restricted to network login authentication:

```
Extreme:Extreme-Netlogin-Only = Disabled
```

Add the following line to the RADIUS server users file for users who are restricted to network login authentication:

```
Extreme:Extreme-Netlogin-Only = Enabled
```

To reduce the quantity of information sent to the switch, the RADIUS server sends either a 1 for the enabled configuration or a 0 for the disabled configuration.

These values must be configured in the RADIUS dictionary file as shown in [Configuring the Dictionary File](#) on page 1571.

#### **VSA 209: Extreme-Netlogin-VLAN-ID**

This attribute specifies a destination VLAN ID (or VLAN tag) that the RADIUS server sends to the switch after successful authentication.

The VLAN must already exist on the switch. When the switch receives the VSA, it adds the authenticated user to the VLAN.

The following describes the guidelines for VSA 209:

- For untagged VLAN movement with 802.1X netlogin, you can use all current Extreme Networks VLAN VSAs: VSA 203, VSA 209, and VSA 211.
- To specify the VLAN ID, use an ASCII string.
- When using this VSA, do not specify whether the VLAN is tagged or untagged.

Because the RADIUS server can identify a target VLAN with multiple attributes, the switch selects the appropriate VLAN or VLANs using the order:

- Extreme-Netlogin-Extended-VLAN (VSA 211)
- Extreme-Netlogin-VLAN-Name (VSA 203)
- Extreme-Netlogin-VLAN-ID (VSA 209)
- Tunnel-Private-Group-ID, but only if Tunnel-Type == VLAN(13) and Tunnel-Medium-Type == 802 (6) (see [Standard RADIUS Attributes Used by Extreme Switches](#) on page 1562)

If none of the previously described attributes are present ISP mode is assumed, and the client remains in the configured VLAN.

When added to the RADIUS users file, the following example specifies the destination VLAN ID, 234, for the associated user:

```
Extreme:Extreme-Netlogin-VLAN-ID = 234
```

#### **VSA 211: Extreme-Netlogin-Extended-Vlan**

This attribute specifies one or more destination VLANs that the RADIUS server sends to the switch after successful authentication.

You can specify VLANs by VLAN name or ID (tag). The VLANs may either already exist on the switch or, if you have enabled dynamic VLANs and a non-existent VLAN tag is given, the VLAN is created.

When the switch receives the VSA, it does the following:

- Unauthenticates the user on all VLANs where it is currently authenticated during reauthentication.
- Authenticates the user on all VLANs in the VSA, or none of them.

In cases where the client is already authenticated, if a single VLAN move fails from a list of VLANs in the VSA and the move-fail-action is authenticate, then it is left as-is. If the client is not already authenticated (first time authentication), then it is authenticated on learnedOnVlan if possible. If move-fail-action is deny then the client is unauthenticated from all the VLANs where it is currently authenticated. There is no partial success.

**Note**

If there is one or more invalid VLAN in the VSA, the supplicant is not authenticated on any one of them.

For example, if the VSA is Uvoice;Tdata and the VLAN data does not have a tag or the VLAN does not exist, then the port movement fails. Even if a single VLAN in the list is invalid the entire list is discarded and the action taken is based on move-fail-action configuration.

The following describes the guidelines for VSA 211:

- For tagged VLAN movement with 802.1X netlogin, you must use VSA 211.
- To specify the VLAN name or the VLAN ID, use an ASCII string; however, you cannot specify both the VLAN name and the VLAN ID at the same time. If the string only contains numbers, it is interpreted as the VLAN ID.
- A maximum of 10 VLANs are allowed per VSA.
- For tagged VLANs, specify **T** for tagged before the VLAN name or VLAN ID.
- For untagged VLANs, specify **U** for untagged before the VLAN name or VLAN ID.
- For movement based on the incoming port's traffic, specify the wildcard \* before the VLAN name or VLAN ID. The behavior can be either tagged or untagged, based on the incoming port's traffic, and mimics the behavior of VSA 203 and VSA 209, respectively.
- Multiple VLAN names or VLAN IDs are separated by semicolons. When multiple vlans are defined in single VSA 211, the wildcard \* is not allowed.
- There cannot be more than one untagged VLAN in a single VSA.
- The same VLAN cannot be both untagged and tagged in a single VSA.
- A client or supplicant can be authenticated in a only one untagged VLAN.
- The ports configured for an untagged VLAN different from the netlogin VLAN can never be added tagged to the same VLAN.
- A port can be in more than one untagged VLAN when MAC-based VLANs are enabled.

When added to the RADIUS users file, the following examples specify VLANs for the switch to assign after authentication:

```
Extreme-Netlogin-Extended-VLAN = Tvoice (Tagged VLAN named voice)
Extreme-Netlogin-Extended-VLAN = Udata (Untagged VLAN named data)
Extreme-Netlogin-Extended-VLAN = *orange (VLAN named orange, tagging dependent on
incoming traffic)
Extreme-Netlogin-Extended-VLAN = T229 (Tagged VLAN with ID 229)
Extreme-Netlogin-Extended-VLAN = U4091 (Untagged VLAN with ID 4091)
Extreme-Netlogin-Extended-VLAN = *145 (VLAN with ID 145, tagging dependent on incoming
traffic)
in FreeRADIUS, a tagged VLAN voice and a tagged VLAN mktg would be configured as the
following:
Extreme-Netlogin-Extended-VLAN = "Tvoice;Tmktg;"
```

An untagged VLAN data and a tagged VLAN mktg is configured as the following:

```
Extreme-Netlogin-Extended-VLAN = "Udata;Tmktg;"
```

A tagged VLAN with VLAN ID 229 and a tagged VLAN with VLAN ID 227 is configured in FreeRADIUS as the following:

```
Extreme-Netlogin-Extended-VLAN = "T229;T227;"
```

An untagged VLAN with VLAN ID 4091 and a tagged VLAN with VLAN ID 2001 is configured as the following:

```
Extreme-Netlogin-Extended-VLAN = "U4091;T2001;"
```

### VSA 212: Extreme-Security-Profile

This attribute specifies a profile name that the RADIUS server sends to the switch after successful authentication. The switch uses this profile name to run a special type of script called a *profile*. The profile is stored on the switch and can be used to modify the switch configuration in response to authentication. Profiles are created using the Universal Port feature, which is described in [Universal Port](#) on page 2066.

The following describes the guidelines for VSA 212:

- This VSA must contain a profile name.
- This VSA can include optional variables for use in profile execution.
- The variable entry format is: <var1>=<value1>;<var2>=<value2>;...
- Each profile variable must be separated from the others by a semicolon.

When added to the RADIUS users file, the following example provides to the switch the profile name p1, variable QOS=QP8, and variable LOGOFF-PROFILE=P2:

```
EXTREME-SECURITY-PROFILE= "p1 QOS=\"QP8\";LOGOFF-PROFILE=P2;"
```

### VSA 213: EXTREME\_VM\_NAME

This VSA is used in context with the [Extreme Network Virtualization \(XNV\)](#) feature, especially with the NMS authentication of VMs. Use this VSA to specify the name of the VM that is being authenticated. An example would be: MyVM1

**VSA 214: EXTREME\_VM\_VPP\_NAME**

This VSA is used in context with the XNV feature, especially with the NMS authentication of VMs. Use this VSA to specify the VPP to which the VM is to be mapped. An example would be: nvpp1

**VSA 215: EXTREME\_VM\_IP\_ADDR**

This VSA is used in context with the XNV feature, especially with the NMS authentication of VMs. Use this VSA to specify the IP address of the VM. An example would be: 11.1.1.254

**VSA 216: EXTREME\_VM\_VLAN\_ID**

This VSA corresponds to XNV with Dynamic VLANs. Use this VSA to specify the ID or tag of the destination VLAN for the VM. An example would be: 101

**VSA 217: EXTREME\_VM\_VR\_NAME**

This VSA corresponds to XNV with Dynamic VLANs. Use this VSA to specify the VR in which the destination VLAN is to be placed. An example would be: UserVR1

## Configuring the Dictionary File

Before you can use Extreme Networks VSAs on a *RADIUS* server, you must define the VSAs.

On the FreeRADIUS server, you define the VSAs in the dictionary file in the /etc/raddb directory. You must define the vendor ID for Extreme Networks, each of the VSAs you plan to use, and the values to send for the VSAs. The following example shows the entries to add to a FreeRADIUS server dictionary file for Extreme Networks VSAs:

|                     |                                |          |         |         |  |
|---------------------|--------------------------------|----------|---------|---------|--|
| VENDOR              | Extreme                        | 1916     |         |         |  |
| ATTRIBUTE           | Extreme-CLI-Authorization      | 201      | integer | Extreme |  |
| ATTRIBUTE           | Extreme-Shell-Command          | 202      | string  | Extreme |  |
| ATTRIBUTE           | Extreme-Netlogin-Vlan          | 203      | string  | Extreme |  |
| ATTRIBUTE           | Extreme-Netlogin-Url           | 204      | string  | Extreme |  |
| ATTRIBUTE           | Extreme-Netlogin-Url-Desc      | 205      | string  | Extreme |  |
| ATTRIBUTE           | Extreme-Netlogin-Only          | 206      | integer | Extreme |  |
| ATTRIBUTE           | Extreme-User-Location          | 208      | string  | Extreme |  |
| ATTRIBUTE           | Extreme-Netlogin-Vlan-Tag      | 209      | integer | Extreme |  |
| ATTRIBUTE           | Extreme-Netlogin-Extended-Vlan | 211      | string  | Extreme |  |
| ATTRIBUTE           | Extreme-Security-Profile       | 212      | string  | Extreme |  |
| ATTRIBUTE           | Extreme-Policy-ACL             | 232      | string  | Extreme |  |
| VALUE               | Extreme-CLI-Authorization      | Disabled | 0       |         |  |
| VALUE               | Extreme-CLI-Authorization      | Enabled  | 1       |         |  |
| VALUE               | Extreme-Netlogin-Only          | Disabled | 0       |         |  |
| VALUE               | Extreme-Netlogin-Only          | Enabled  | 1       |         |  |
| # End of Dictionary |                                |          |         |         |  |

The lines that begin with VALUE provide the integers that the RADIUS server sends to the switch when the corresponding text is configured in the RADIUS users file. For example, if the Extreme-CLI-Authorization attribute is set to Enabled for a particular user, the RADIUS server sends the value 1 to the switch (which reduces total bytes transferred). The ExtremeXOS software is designed to interpret the integer values as shown above, so be sure to use these values.

## Change-of-Authorization (Dynamic Authorization) Overview

The *RADIUS* protocol, defined in (RFC2865), does not support unsolicited messages sent from the RADIUS server to the Network Access Server (NAS). However, it may be desirable for changes to be made to session characteristics, without requiring the NAS to initiate the exchange. For example, it may be desirable for administrators to be able to terminate user session(s) in progress. Alternatively, if the user changes authorization level, this may require that authorization attributes be added/deleted from user session(s). To overcome these limitations, several vendors have implemented additional RADIUS commands to enable unsolicited messages to be sent to the NAS. These extended commands provide support for Disconnect and Change-of-Authorization (CoA) packets.

### *Disconnect Request*

Disconnect Requests are sent from the DA initiator to the DA controller when it is determined that a session will be terminated. The request is sent to UDP port 3799.

When a Disconnect Request packet is received, it is determined whether it is an authorized request from a configured server. The source IP address of the packet is used to check for a match of the configured Dynamic Authorization Servers. If the source IP address has not been configured, then the request is immediately dropped with no further validation. If the IP address is present in the configuration, a validation of the Message-Authenticator attribute occurs as indicated in RFC2869. If validation is not successful, then the packet is dropped with no further processing. If it is determined that this is a retry, the packet is also dropped with no further processing.

The authorized request indicates which DA controller the message is for, as well as which session should be terminated. If the DA controller indicated by the included attributes in the packet does not match the receiver, then the request is responded to with a Disconnect-NAK. The appropriate DA controller receiving this *RADIUS* extension packet identifies the session using the attributes provided and immediately terminates the session.

#### **Note**

In order to use CoA/Disconnect, ONEPolicy must be enabled with NetLogin.

### **NAS Identification**

These attributes provided by the *RADIUS* extension packets are used to determine the DA Controller that is to disconnect the session:

- **NAS-IP-Address**—This IPV4 address must match the primary IP address of the default interface for a match to occur.

If all of these attributes do not match, the request is responded to with a Disconnect-NAK response.

Starting with ExtremeXOS 31.3, the `nas-ip` option can ignore this requirement using the `ignore` variable.

## User Session Identification

The following attributes are used to determine the Layer 2 sessions that are to be terminated:

- **NAS-Port**—the interface index of the port that the session is connected to.
- **Calling-Station-Id**—The ASCII representation of the MAC address of the session to be terminated. If no NAS-Port attribute is present, then all sessions with the specified MAC address are terminated regardless of what port(s) the sessions are connected to.
- **Enterasys Auth-Client-Type**—One or more of these vendor-specific attributes (VSA) can be specified to indicate which authentication clients are to be affected. Valid values are: 1-dot1x, 2-pwa, 3-macauth. If this attribute is not present, then all sessions with the specified MAC address and/or port are affected.

All included attributes must match for the request to be processed. Additional attributes that are not understood by the DA controller in this context cause a failure of this disconnect request.

## Disconnect Responses

If the Disconnect Request is determined to be of appropriate format and matching session(s) are present and terminated appropriately, then a Disconnect-Ack is sent in response. If all the attributes in the packet are not understood within this context or do not result in a matching DA controller and session, then the DA controller sends a Disconnect-NAK in response. If the DA controller is unable to appropriately terminate the matching session(s) for some reason, a Disconnect-NAK is sent in response.

## Security

Using the [RADIUS](#) protocol to push both changes and terminations of existing sessions does have some security issues.

### Caution

In this implementation in ExtremeXOS of RFC5176, some level of trust is required on the upstream portion of the local network. Network administrators should not enable this functionality if they are not comfortable with this level of security. See [Limitations](#) on page 510.

## Limitations

The following features of Change-of-Authorization (RFC5176) are not implemented in ExtremeXOS:

- **Reverse Path Forwarding Check**—Typically this is used in a proxy scenario. This check is used to determine if the IP address indicated by the [RADIUS](#) attributes is a routable destination address for a request sent by the switch software.
- **IPSEC encryption**—End-to-end encryption of both the RADIUS requests and responses.
- **Disconnect-Request and Change-of-Authorization packets** identifying sessions with anything other than the Calling-Station-Id attribute containing a properly formatted MAC address. In addition to the Calling-Station-ID attribute, you can also use a NAS-

Port attribute, which indicates the index of the specific port the session is connected to.

- Acct-Session-Id attribute—This is an alternate means of session identification. Sessions are currently uniquely identified by port and MAC address pair.
- Retransmissions of Disconnect-Request or Change-of-Authorization ACK and NAK packets—Retransmissions of packets is the responsibility of the device initiating the dynamic authorization transactions.

### *Change of Authorization*

Change of Authorization requests are sent from the DA initiator to the DA controller when it is determined that a session's authorization parameters will be changed. The request is sent to UDP port 3799.

When a Change-of-Authorization (CoA) packet is received, it is determined whether it is an authorized request from a configured server. The source IP address of the packet is used to check for a match of the configured Dynamic Authorization Servers. If the source IP address has not been configured, then the request is immediately dropped with no further validation. If the IP address is present in the configuration, a validation of the Message-Authenticator attribute occurs as indicated in RFC2869. If validation is not successful, then the packet is dropped with no further processing. If it is determined that this is a retry, the packet is also dropped with no further processing.

The message indicates which DA controller the message is for, as well as, which session should be terminated. If the DA controller indicated by the included attributes in the packet does not match the receiver, then the request is responded to with a Change-of-Authorization-NAK. The appropriate DA controller receiving this *RADIUS* extension packet identifies the session(s) using the attributes provided and attempts to change the authorization level of the user as newly defined in the request packet.

#### **DA Controller Identification**

The DA controller is identified for CoA Requests in the same way that Disconnect Request identification occurs.

#### **User Session Identification**

Session identification for CoA occur in the same way that Disconnect Request identification does.

#### **Supported Authorization Attributes**

Policy authorization levels can be changed using this functionality. These attributes are the same ones that are used to define the initial authorization level of a session when authenticated by the DA controller. The processing of these attributes will result in the same authorization conditions that would have occurred if they were to have been received as the initial authorization level.

- Filter-Id —The filter ID identifies the name of the policy profile that is used for the session.
- RFC3580 Attributes—Three attributes are used to determine the RFC3580 authorization levels: Tunnel-Type, Tunnel-Medium-Type, and Tunnel-Private-Group-Id.

These values are used in concert with local policy settings to determine both the correct policy profile and [VLAN](#) settings for the session.

### Change-of-Authorization Responses

If the CoA request is determined to be of appropriate format, matching session(s) are found, and their authorization levels are changed appropriately, then a Change-Of-Authorization-Ack is sent in response. If all the attributes in the packet are not understood within this context or do not result in a matching DA controller and session, then the DA controller sends a Change-Of-Authorization-NAK in response. If the DA controller is unable to appropriately change the matching session(s) authorization level for some reason, a Change-Of-Authorization-NAK is sent in response.

### Retry Detection

To minimize the potential for replay attacks, the DA controller needs to support retry detection. This involves remembering source UDP port and [RADIUS](#) packet identifier pairs that have been received on a per DA Initiator basis. This information needs to be remembered for a reasonable period of time so that an attacker resending an identical frame to the DA controller does not cause undue harm to the switch. This functionality used in conjunction with the Event-Timestamp attribute limits the validity of replay attacks.

### Change-of-Authorization Mandatory Attributes

The following is a list of Change-of-Authorization CoA mandatory attributes.

- Calling-Station-ID = "session-id Hyponated"
- NAS-IP-Address = <SWITCH MGMT IP>
- Filter-ID = <Policy Profile Name>
- Tunnel-Medium-Type = IEEE-802
- Tunnel-Type = VLAN
- Tunnel-Private-Group-Id = <Tunnel-ID>

#### Note

Filter-ID and Tunnel attributes are mandatory based on the configuration used in the switch. Filter-ID is mandatory if the map table response is policy. Tunnel is mandatory if map table response is tunnel. Attributes shown in [Table 147](#) on page 1576 are optional attributes.

### Limitations

Optional attributes may or may not be present in the CoA/disconnect. If all the received values are correct, then further processing occurs; otherwise, you may get an ACK/NAK, but the packet is not processed further.

*New Attribute Support*

**Table 147: New CoA Attribute Support**

| Name                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Defining RFC |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|
| Event-Timestamp       | The Event-Timestamp attribute is used to minimize the effect of network replay attacks. RFC5176 recommends incorporating this attribute when not using more complex security measures to encrypt the <i>RADIUS</i> packet data. The DA controller does not process Disconnect Request or CoA requests that do not include this attribute. The timestamp sent in this attribute must be within 300 seconds of the current time for the request to be processed. Response frames to either Disconnect request or CoA requests contain this attribute. | RFC2869      |
| Proxy-State           | When one or more of these attributes are included in either Disconnect request or request frames they must be included unedited in the responses to those packets.                                                                                                                                                                                                                                                                                                                                                                                  | RFC2865      |
| Message-Authenticator | The Message-Authenticator attribute is used to both authenticate and integrity check RADIUS packets. It is used in lieu of more complex security measures to authorize and/or encrypt the RADIUS control packets. The DA controller does not process packets with invalid Message-Authenticator attribute values.                                                                                                                                                                                                                                   | RFC2869      |
| Error-Cause           | The Error-Cause attribute is used to give the DA Initiator more information regarding the cause of the failure to process either a Disconnect request or a CoA request. The DA controller uses this attribute when it responds with the Disconnect-Request-NAK or the Change-Of-Authorization-NAK messages.                                                                                                                                                                                                                                         | RFC5176      |

**Table 147: New CoA Attribute Support (continued)**

| Name                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Defining RFC           |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| Enterasys Auth-Client-Type | The Enterasys Auth-Client-Type vendor-specific attribute (VSA) is used to indicate which authentication client sessions are to be affected by either the CoA or Disconnect Requests. The vendor ID used for this VSA is the IANA assigned private enterprise number for Enterasys—5624. The Enterasys attribute type number for this attribute is 1. Valid values are: 1- dot1x, 2-pwa, 3-macauth, 4-cep, 5-radsnoop, 6-auto-tracking and 7-quarantine-agent. | N/A                    |
| NAS-Port                   | The interface index of the port that a session is connected to. Representation of port 5 in standalone switches will be like this: 1005, stack port 3:5 will be 3005, and vpex port 100:5 will be like this NAS-Port = 101005.                                                                                                                                                                                                                                | RFC2865                |
| Extreme-Policy-ACL         | See <a href="#">Dynamic ACLs</a> on page 353.                                                                                                                                                                                                                                                                                                                                                                                                                 | EXTREME-VSA 232 String |

### *RADIUS Port Bounce*

Port bouncing is the process of temporarily disabling and re-enabling a network port, which enables the clients connected to an authenticator to reinitiate a DHCP request. RADIUS port bounce occurs only when there is a change in the authenticator VLAN and when a CoA request is received from a RADIUS server with VSA port bounce. You can enable or disable port bounce using the command line interface, but first you must do the following:

- Start an active Netlogin session on an authenticator port.
- Create Policy.
- Enable Dynamic Authentication.

The following command configures the port bounce feature:

```
configure radius port bounce [on | off]
```

## Additional RADIUS Configuration Examples

### *Installing and Testing the FreeRADIUS Server*

RADIUS is a client/server protocol based on UDP.

The example presented in this section describes a RADIUS server that is a daemon process running on a Linux server.

The following example shows how to install and test a FreeRADIUS server:

```
tar -zxvf freeradius-1.0.2.tar.gz (extract with gunzip and tar)
./configure
make
make install (run this command as root)
radiusd (start RADIUS server, or...)
radiusd -X (start RADIUS server in debug mode)
radtest test test localhost 0 testing123 (test RADIUS server)
```

If radtest receives a response, the FreeRADIUS server is up and running.

#### Note

RADIUS server software can be obtained from several sources. This solution uses the FreeRADIUS software available on the following URLs: [www.freeradius.org](http://www.freeradius.org) and [www.redhat.com](http://www.redhat.com). Another free tool, NTRadPing, can be used to test authentication and authorization requests from Windows clients. NTRadPing displays detailed responses such as attribute values sent back from the RADIUS server.

### Configuring the FreeRADIUS Server

Configuring the *RADIUS* server involves configuring the RADIUS server and the RADIUS client (for authentication and authorization). FreeRADIUS configuration files are usually stored in the `/etc/raddb` folder. The following example demonstrates how to configure the FreeRADIUS server for authentication and LDAP support:

1. Modify the `radiusd.conf` file global settings:

```
log_auth = yes (log authentication requests to the log file)
log_auth_badpass = no (don't log passwords if request rejected)
log_auth_goodpass = no (don't log passwords if request accepted)
```

2. Modify LDAP Settings:

```
modules {
 ldap {
 server = "ldaptest.extremenetworks.com"
 basedn = "o=ldaptestdemo,dc=extremenetworks,dc=com"
 filter = "(cn=%{Stripped-User-Name:-%{User-Name}})"
 base_filter = "(objectclass=radiusprofile)"
 start_tls = no
 dictionary_mapping = ${raddbdir}/ldap.attrmap
 authtype = ldap
 ldap_connections_number = 5
 timeout = 4
 timelimit = 3
 net_timeout = 1
 }
}
```

3. Uncomment LDAP from the authorize section:

```
authorize {
 preprocess
 chap
 mschap
 suffix
 ldap
 eap
}
```

```
files
}
```

#### 4. Uncomment LDAP from the authenticate section:

```
authenticate {
 Auth-Type PAP {
 pap
 }
 Auth-Type CHAP {
 chap
 }
 Auth-Type MS-CHAP {
 mschap
 }
 unix
 ldap
 eap
}
```

An Extreme Networks edge switch serves as a network access server (NAS) for workstations and as a RADIUS client for the RADIUS server.

RADIUS clients are configured in `/etc/raddb/clients.conf`. There are two ways to configure RADIUS clients. Either group the NAS by IP subnet or list the NAS by host name or IP address.

#### 5. Configure the RADIUS client using the second method.

```
client 192.168.1.1 {
 secret = extremel
 shortname = ldap-demo
}
```

### Configuring the RADIUS-to-LDAP Attribute Mappings

Attributes are configured in `/etc/freeradius/ldap.attrmap`. This file maps RADIUS attributes to LDAP attributes. Samba has NT/LM password hashes. Hence, the default mapping for LM-Password and NT-Password must be changed.

- Configure attribute mappings.

```
checkItem User-Password userPassword.
checkItem LMPassword sambaLMPassword
checkItem NTPassword sambaNTPassword
replyItem Tunnel-Type radiusTunnelType
replyItem Tunnel-Medium-Type radiusTunnelMediumType
replyItem Tunnel-Private-Group-Id radiusTunnelPrivateGroupId
```

### Configuring Additional Attributes Mappings

Attributes are configured in `/etc/freeradius/ldap.attrmap`:

```
Attributes for Extreme Networks Vendor-Specific RADIUS
replyItem Extreme-Security-Profile radiusExtremeSecurityProfile
replyItem Extreme-Netlogin-Vlan-Tag radiusExtremeNetloginVlanTag
replyItem Extreme-Netlogin-Extended-Vlan radiusExtremeNetloginExtendedVlan
```

### Modifying the RADIUS Schema

Additional attributes for *RADIUS* must be configured to extend the RADIUS-LDAP-V3.schema under the /etc/openldap directory.

- Use the following commands to modify the RADIUS schema:

```
attributetype
(1.3.6.1.4.1.3317.4.3.1.61
NAME 'radiusExtremeSecurityProfile'
DESC ''
EQUALITY caseIgnoreIA5Match
SYNTAX 1.3.6.1.4.1.1466.115.121.1.26
)
attributetype
(1.3.6.1.4.1.3317.4.3.1.62
NAME 'radiusExtremeNetloginVlanTag'
DESC ''
EQUALITY caseIgnoreIA5Match
SYNTAX 1.3.6.1.4.1.1466.115.121.1.26
)
attributetype
(1.3.6.1.4.1.3317.4.3.1.63
NAME 'radiusExtremeNetloginExtendedVlan'
DESC ''
EQUALITY caseIgnoreIA5Match
SYNTAX 1.3.6.1.4.1.1466.115.121.1.26
)
```

### Configuring the Authentication Method for Supplicants

The authentication method is configured in /etc/raddb/eap.conf. The authentication method used by FreeRADIUS is the PEAP (Protected EAP) method. To activate PEAP, a TLS tunnel is required to encrypt communication between supplicant and *RADIUS* server. This means that server certificates are required.

- Configure the authentication method.

```
peap {
default_eap_type = mschapv2
}
tls {
private_key_password = whatever
private_key_file = ${raddbdir}/certs/cert-srv.pem
certificate_file = ${raddbdir}/certs/cert-srv.pem
CA_file = ${raddbdir}/certs/demoCA/cacert.pem
dh_file = ${raddbdir}/certs/dh
random_file = ${raddbdir}/certs/random
fragment_size = 1024
include_length = yes
}
```

### Starting the FreeRADIUS Server

- Start *RADIUS* in the foreground with debugging enabled.  
radiusd -X -f

## Implementation Notes for Specific RADIUS Servers

### *Cistron RADIUS*

Cistron Radius is a popular server, distributed under GPL. Cistron Radius can be found at:

When you configure the Cistron server for use with Extreme switches, you must pay close attention to the users file setup. The Cistron Radius dictionary associates the word Administrative-User with Service-Type value 6, and expects the Service-Type entry to appear alone on one line with a leading tab character.

The following is a user file example for read-write access:

```
adminuser Auth-Type = System
Service-Type = Administrative-User,
Filter-Id = "unlim"
```

### *RSA Ace*

For users of Cistron's RSA SecureID® product, RSA offers *RADIUS* capability as part of their RSA/Ace Server® server software. It is mandatory to configure a matching shared-secret key on the switch and RSA Ace server for successful authentication.

### *Steel-Belted Radius*

For users who have the Steel-Belted Radius (SBR) server from Juniper Networks, it is possible to limit the number of concurrent login sessions using the same user account. This feature allows the use of shared user accounts, but limits the number of simultaneous logins to a defined value. Using this feature requires Steel-Belted Radius for *RADIUS* authentication and accounting. To limit the maximum concurrent login sessions under the same user account:

1. Configure RADIUS and RADIUS-Accounting on the switch.

The RADIUS and RADIUS-Accounting servers used for this feature must reside on the same physical RADIUS server. Standard RADIUS and RADIUS-Accounting configuration is required as described earlier in this chapter.

2. Modify the SBR vendor.ini file and user accounts.

- a. To configure the SBR server, the file vendor.ini must be modified to change the Extreme Networks configuration value of ignore-ports to yes as shown in the example below:

```
vendor-product = Extreme Networks
dictionary = Extreme
ignore-ports = yes
port-number-usage = per-port-type
help-id = 2000
```

- b. After modifying the vendor.ini file, the desired user accounts must be configured for the Max-Concurrent connections. Using the SBR Administrator application, enable the check box for Max-Concurrent connections and fill in the desired number of maximum sessions.

*Microsoft IAS*

To use Extreme Networks VSAs with the Internet Authentication Service (IAS) in Microsoft® Windows Server™ 2003, you must first create a Remote Access Policy and apply it so that user authentication occurs using a specific authentication type such as EAP-TLS, PEAP, or PAP. The following procedure assumes that the Remote Access Policy has already been created and configured and describes how to define Extreme Networks VSAs in Microsoft IAS:

1. Open the IAS administration GUI application.
2. In the left window pane, select the **Remote Access Policies** section of the tree.
3. In the right window pane, double-click the desired Remote-Access policy name so you can edit it.
4. Click the **Edit-Profile** button in the lower-left corner, and then select the **Advanced** tab.
5. If any attributes already appear in the **Parameters** window, remove them by selecting the attribute and clicking the **Remove** button.
6. When the **Parameters** window is empty, proceed to the next step.
7. Click the **Add** button, which brings up the **Add Attributes** dialog window.
8. Scroll down the displayed list of *RADIUS* attributes and select the attribute named **Vendor-Specific**.
9. Double-click the **Vendor-Specific** attribute or click the **Add** button.

The **Multivalued Attribute Information** dialog box should appear.

10. Click the **Add** button, which brings up the **Vendor-Specific Attribute Information** dialog window.
  - a. Select the first radio button for **Enter Vendor Code** and enter the Extreme Networks vendor code value of 1916 in the text-box.
  - b. Select the second radio button for **Yes, It conforms**.
  - c. Verify both settings, and click the **Configure Attribute** button to proceed.

The **Configure VSA (RFC compliant)** dialog window should now appear.

The settings for this dialog window varies, depending on which product and attribute you wish to use in your network.

- d. In the first text-box enter the Extreme Networks VSA number for the attribute you want to configure (see [Extreme Networks VSAs](#) on page 1564).
- e. Use the pull-down menu to select the **Attribute** format, which is the same as the attribute Type listed in [Extreme Networks VSAs](#) on page 1564.

**Note**

For values of format integer you will have to select the type **Decimal** from the pull-down menu.

- f. Configure the desired value for the attribute.
  - g. Once the desired values have been entered, click **OK**.
11. Click **OK** two more times to return to the **Add Attributes** dialog window.
  12. Select **Close**, and then click **OK** twice to complete the editing of the Remote Access Policy profile.

13. To apply the configuration changes, stop and restart the Microsoft IAS service.

After restarting the IAS service, new authentications should correctly return the Extreme Networks VSA after successful authentication. Users who were previously authenticated have to re-authenticate to before the new VSAs apply to them.

14. If you experience problems with the newly configured VSAs, use the following troubleshooting guidelines:

- a. If you have multiple IAS Remote Access Policies, verify that the user is being authenticated with the correct policy.
- b. Check the IAS System Log events within Microsoft Event Viewer to verify the user is authenticated through the policy where VSA settings are configured.
- c. Check whether the VSA configuration performed above is correct.  
A mismatch in any of the VSA settings could cause authentication or VSA failure.
- d. Verify that attributes such as "VLAN tag" or "VLAN name" correctly match the configuration of your ExtremeXOS switch and overall network topology.  
Invalid, or incorrect values returned in the VSA could prevent authenticated users from accessing network resources.

## Setting Up Open LDAP

To integrate an ExtremeXOS switch in an LDAP environment, a RADIUS server must be configured to communicate with the LDAP database. The following components are required to install the access control solution:

- Linux server with Linux Red Hat 4.0
- FreeRADIUS 1.1.x
- OpenLDAP 2.3.x
- Extreme Networks switches
- Windows 7/Windows 8 clients

To configure Universal Port for use in an LDAP environment, use the following procedure:

1. Install and configure a RADIUS server on an existing Linux server as described in [Installing and Testing the FreeRADIUS Server](#) on page 1577.
2. Install and configure OpenLDAP as described later in this section.
3. Add vendor specific attributes to the RADIUS and LDAP servers as described in [Installing and Testing the FreeRADIUS Server](#) on page 1577 and later in this section.
4. Configure the edge switches as described in this guide.
5. Configure each supplicant as described in [Configuring a Windows 7/Windows 8 Supplicant for 802.1X Authentication](#) on page 1588.

For complete instructions on setting up an LDAP server, see the product documentation for the LDAP server.

### Installing OpenLDAP

OpenLDAP software is an open source implementation of Lightweight Directory Access Protocol. This can be obtained from the site: [www.openldap.org](http://www.openldap.org). To install OpenLDAP packages:

1. Verify the Red Hat Linux installed releases.

The release number is stored in the `/etc/redhat-release` file.

2. Verify the version of OpenLDAP currently installed by entering the command `rpm -qa | grep openldap` at the Linux prompt.

```
rpm -qa |grep openldap
openldap-2.3.xx-x
openldap-clients-2.3.xx-x
openldap-servers-2.3.xx-x
```

3. If you have a default Red Hat Linux installation, there is at least one OpenLDAP Red Hat Package Manager (RPM) installed.

The LDAP RPMs can be found on the Red Hat CD or downloaded from one of the following RPM download sources:

[www.rpmfind.net](http://www.rpmfind.net) and search for **openldap** and select the RPM based on the distribution

[www.redhat.com](http://www.redhat.com) and select **Download**, and then search for **openldap**.

4. After downloading the RPMs to the Linux server, change to the download directory and start the installation using the `rpm` command:

```
rpm -ivh openldap*
```

5. Verify that the OpenLDAP RPMs have been installed with the `rpm -qa | grep openldap` command at the Linux prompt.

```
rpm -qa | grep openldap
openldap-2.3.xx-x
openldap-clients-2.3.xx-x
openldap-servers-2.3.xx-x
```

### Configuring OpenLDAP

Once the build is complete, the `slapd` and `slurpd` daemons are located in `/usr/local/libexec`.

The config files are in `/etc/openldap` and ready to start the main server daemon, `slapd`.

### Configuring slapd for Startup

Before you start `slapd`, edit `/etc/openldap/slapd.conf` to include the location to store the data and details on who is allowed to access the data.

The following configuration changes need to be made:

- Change the suffix.
- Change the rootDN.
- Use `slappasswd` to generate rootpw.
- Add rootpw entry.

Use the following commands to configure slapd for startup:

```
database (use default)
suffix "dc=xxxxxx,dc=org"
rootdn "cn=xxxx,dc=xxxxxx,dc=org"
rootpw {SSHA}c5Pem01KWqz0254r4rnFVmxKA/evs4Hu
directory /var/lib/ldap
allow bind_v2
pidfile /var/run/slapd.pid
```

### Adding New Schemas

The *RADIUS* schema and Samba schema for PEAP authentication must be included into the `slapd.conf` file. After modifying the file, the LDAP server must be restarted to load the new schemas.

- Use the following commands to add new schemas:

```
cp /usr/share/doc/freeradius-1.0.1/RADIUS-LDAPv3.schema /etc/openldap/schema/
```

```
cp /usr/share/doc/samba-3.0.10/LDAP/samba.schema /etc/openldap/schema
```

- Use the following commands to modify `slapd.conf`:

```
include/etc/openldap/schema/RADIUS-LDAPv3.schema
include/etc/openldap/schema/samba.schema
```

### Populating the LDAP Database with Organization and User Entries

- Use the following commands to make the user entry in the LDAP directory (`slapd.conf`):

```
dn: uid=newperson3,o=ldaptestdemo,dc=extremenetworks,dc=com
objectClass: top
objectClass: person
objectClass: radiusprofile << Defined in the RADIUS-LDAPv3 schema
objectClass: sambaSamAccount
sn: ldaptestdemo
uid: newperson3 <<< This username given in the Odyssey client
cn: newperson3
radiusTunnelMediumType: IEEE-802
radiusTunnelType: VLAN
radiusTunnelPrivateGroupId: 2 <<< Value of the VLAN tag
sambaNTPassword: A3A685F89364D4A5182B028FBE79AC38
sambaLMPassword: C23413A8A1E7665FC2265B23734E0DAC
userPassword:: e1NIQX00MXZzNXNYbTRPaHNwUjBFUU9raWdxblidySW89
sambaSID: S-1-0-0-28976
```

The Samba-related attributes can be populated in the LDAP server already if there is an LDAP-enabled Samba infrastructure in place.

#### Note

If the Samba related entries are not present, then the values for `sambaNTPassword` and `sambaNMPPassword` can be created by running the `mkntpwd` command.

```
cd /usr/share/doc/samba-3.0.10/LDAP/smbldap-tools/mkntpwd
make
./mkntpwd -L <password> (provides value for sambaLMPassword attribute)
./mkntpwd -N <password> (provides value for sambaNTPassword attribute)
```

### Restarting the LDAP Server

- Use the following syntax to stop and start LDAP services:

```
service ldap restart
```

For phone authentication (which uses EAP based md5 authentication), the password is stored in clear text in the UserPassword field for the phone entries in LDAP.

### LDAP Configuration Example

This configuration example is for ExtremeSwitching switches

Use the following commands to activate the switch for 802.1X port-based authentication:

```
create vlan voice
create vlan data
create vlan ldap
configure voice tag 10
configure data tag 20
configure ldap ipaddress 192.168.1.1/24
enable ipforwarding
create vlan nvlan
en netlogin dot1x
en netlogin port 13-24 dot1x
configure radius netlogin primary server 192.168.1.2 1812 client-ip 192.168.1.1 vr VR-Default
configure radius netlogin primary shared-secret extremel
enable radius netlogin
enable netlogin dot1x
```

Configure the ports to run a script when a user is authenticated through [RADIUS](#) and LDAP:

```
configure upm event user-authenticate profile a-avaya ports 1-23
LDAP UID entries:
```

In the LDAP phone UID entry in the users file, use the following attribute to specify a profile to run on the switch:

```
Extreme-Security-Profile
```

To add the port as tagged in the voice [VLAN](#), use the following attribute in the users file:

```
Extreme-Netlogin-Extended-Vlan = TVoice (use UData for a PC)
```

#### Note

It depends on the end-station to determine the fields required for authentication; XP uses EAP-PEAP and must have encrypted fields for the UID password. Avaya phones authenticate with MD-5 and must have an unencrypted field in LDAP.

### Scripts

The following a-avaya script tells the phone to configure itself in the voice VLAN, and to send tagged frames.

The script also informs the phone of the file server and call server:

```
create upm profile a-avaya
create log message Starting_UPM_Script_AUTH-AVAYA
set var callServer 10.147.12.12
set var fileServer 10.147.10.3
set var voiceVlan voice
set var CleanupProfile CleanPort
set var sendTraps false
#
create log message Starting_UPM_AUTH-AVAYA_Port_${EVENT.USER_PORT}
#*****
adds the detected port to the device "unauthenticated" profile port list
#*****
create log message Updating_Unauthenticated_Port_List_Port_${EVENT.USER_PORT}
#configure upm event user-unauthenticated profile CleanupProfile ports ${EVENT.USER_PORT}
#*****
Configure the LLDP options that the phone needs
#*****
configure lldp port ${EVENT.USER_PORT} advertise vendor-specific dot1 vlan-name vlan
${voiceVlan}
configure lldp port ${EVENT.USER_PORT} advertise vendor-specific avaya-extreme call-server
${callServer}
configure lldp port ${EVENT.USER_PORT} advertise vendor-specific avaya-extreme file-server
${fileServer}
configure lldp port ${EVENT.USER_PORT} advertise vendor-specific avaya-extreme dot1q-
framing tagged
configure lldp port ${EVENT.USER_PORT} advertise vendor-specific med capabilities
#configure lldp port ${EVENT.USER_PORT} advertise vendor-specific med policy application
voice vlan ${voiceVlan} dscp 46
If port is PoE capable, uncomment the following lines
#*****
Configure the POE limits for the port based on the phone requirement
#*****
configure lldp port ${EVENT.USER_PORT} advertise vendor-specific med power-via-mdi
#configure inline-power operator-limit ${EVENT.DEVICE_POWER} ports ${EVENT.USER_PORT}
create log message UPM_Script_A-AVAYA_Finished_Port_${EVENT.USER_PORT}
```

#### Note

Parts of the scripts make use of the QP8 profile. This is NOT recommended because the QP8 profile is used by EAPS. For voice, use QP7 for QOS.

This script uses tagging for the phone and the ports for the voice VLAN. This is NOT necessary; use multiple supplicant and untagged for the phones.

## Configuring a Windows 7/Windows 8 Supplicant for 802.1X Authentication

This section provides an overview procedure for configuring a Windows 7/Windows 8 supplicant. For complete instructions on setting up a Windows 7/Windows 8 supplicant, see the product documentation for Microsoft Windows XP.

### Note

For enhanced security, install the FreeRADIUS server CA certificate (the CA that signed the certificate installed in eap.conf).

1. Open the network configuration panel, select the network card, enter the properties.
2. Click the **Authentication** tab.  
The Authentication dialog appears.
3. Enable 802.1X and disable authenticate as computer.
4. Choose EAP type of Protected EAP, then click **Properties**.
5. Deselect the Validate server certificate and select eap-mschapv2 as the authentication method.
6. Click **Configure**.
7. Select or clear the check box depending on whether you want to use the logon name and password, then click **OK**.

## Hypertext Transfer Protocol

The Hypertext Transfer Protocol (HTTP) is a set of rules for transferring and exchanging information (data, voice, images, and so on) on the World Wide Web. HTTP is based on a request-response model. An HTTP client initiates requests by establishing a TCP connection to a port on a remote host (port 80 by default). An HTTP server listening on that port waits for and then responds to the request; in many instances, the client is requesting a specific URL or IP address. Upon receiving a request, the destination server sends back the associated file or files and then closes the connection.

The web server in ExtremeXOS allows HTTP clients to access the switch on port 80 (by default) as well as the network login page without additional encryption or security measures. For information about secure HTTP transmission, including Secure Socket Layer (SSL), see [Secure Socket Layer](#) on page 1621.

By default, HTTP is enabled on the switch.

- If you disabled HTTP access, you can re-enable HTTP access on the default port (80) using the following command:  

```
enable web http
```
- To disable HTTP, use the following command:  

```
disable web http
```

Starting in Switch Engine 32.7.1, HTTPS is also enabled by default under certain conditions so that both HTTP and HTTPS are active and available for use. HTTPS is enabled in::

- New switches with Switch Engine 32.7.1 installed.
- Old switches that are not configured and are booting with Switch Engine 32.7.1 (the switch does not have a configuration file).
- Old switches that are upgrading to Switch Engine 32.7.1 that have a configuration file where HTTPS is disabled and there is no switch key or certificate.

At the time that HTTPS is enabled, a new SSL key and self-signed certificate are automatically generated. with the following parameters:

Key length: 2048  
Country-code: "US"  
Org name: "Extreme Networks"  
Common name: "\*.extremenetworks.com"  
State: "NC"  
Locality: "Morrisville"  
Org unit: "EXOS"

The **show configuration** command shows that HTTPS is enabled.

When upgrading to Switch Engine 32.7.1, HTTPS is not enabled when:

- HTTPS is disabled and a switch key by itself is present
- HTTPS is disabled and a certificate by itself is present
- HTTPS is disabled and both a switch key and a certificate is present
- HTTPS is enabled

## Secure Shell 2

---

Secure Shell 2 (SSH2) is a feature of the ExtremeXOS software that allows you to encrypt session data between a network administrator using SSH2 client software and the switch or to send encrypted data from the switch to an SSH2 client on a remote system.

Configuration, image, public key, and policy files can be transferred to the switch using the Secure Copy Protocol 2 (SCP2).

The ExtremeXOS SSH2 switch application works with the following clients: Putty, SSH2 (version 2.x or later) from SSH Communication Security, and OpenSSH (version 2.5 or later).

## SSH Server Overview

SSH server in ExtremeXOS device listens for incoming connections. The server uses various services in ExtremeXOS including AAA for authentication, Policy Manager for access control, Session Manager for session reporting, and EMS for logging.

### Understanding SSH Server

A 2,048-bit RSA Host key for the SSH server on the ExtremeXOS device is generated. Once the key is generated, the SSH server is started and listens for connections. Password and public key authentication methods are supported.

The client's public keys are configurable through the CLI. A maximum of 100 keys can be created. A specific key can hold a maximum of 16 users, and a single user can be added to a maximum of 16 keys.

For password authentication, the configuration should be done in the AAA module, where an account must be created for the user, either as an admin or a user, and the corresponding password should be configured. The same will be used for validating the user, when `exsshd` (SSH server daemon/process) contacts AAA for authenticating the user.

Upon receiving a connection, it will be first validated with [ACL/Policy](#), if configured. If the source-address from which the connection has been established, and is configured for a deny action in the acl, the connection is closed.

If the ACL permits the source-address of the client, the server proceeds with authentication steps. As part of authentication, the versions are exchanged between the client and the server. ExtremeXOS SSH server supports protocol version 2. If the client has a protocol version 1.99 or above, the same is accepted. Otherwise, the connection is rejected. Once the versions of both the ends are accepted, key exchange algorithms proposal of server and client are matched. Openssh-7.5p1 supports Diffie-Hellman group 1, 14, 16, and 18 as part of the key exchange algorithms (see [Diffie-Hellman Overview](#) on page 1620). The minimal supported Diffie-Hellman group is 14 by default in Default mode, since group 1 is considered weaker. After the key exchange algorithm is agreed upon, the ciphers are exchanged and agreed upon. Openssh-7.5p1 supports the following ciphers and MACs.

- **Ciphers:** aes128-cbc, aes192-cbc, aes256-cbc, rijndael-cbc@lysator.liu.se, aes128-ctr, aes192-ctr, aes256-ctr, chacha20-poly1305@openssh.com
- **MACs:** hmac-md5-etm@openssh.com, hmac-sha1-etm@openssh.com, hmac-sha2-256-etm@openssh.com, hmac-sha2-512-etm@openssh.com, hmac-sha1-96-etm@openssh.com, hmac-md5-96-etm@openssh.com, hmac-md5, hmac-sha1, hmac-sha2-256, hmac-sha2-512, hmac-sha1-96, hmac-md5-96

After the key exchanges, the local authentication methods that are supported (public key and password authentication) are tried first. If there is a matching key or password, the AAA authentication will be tried out. Else, the user will be considered to be unknown, and the session will be terminated.

Below are the steps that are involved between the client and the server while establishing the connection.

**Figure 198: SSH Client /Server Connection Steps**

Upon disabling SSH using the command `disable ssh2`, the server stops listening for new connections, but the existing connections continue to be active. When you enable the SSH server again, the key is not regenerated by default. Specific sessions or all the sessions can be closed through `clear session` command through CLI. The sessions are closed once the idle-timeout expires. By default the idle timeout is 3,600 seconds for SSH. The same can be configured through the CLI. If the session is left idle for more than the configured/default idle-timeout value in seconds, then the session is closed by the server. The idle timeout will be on per session basis. In other words, the idle timeout that is configured when the session is established, will be the one used for that particular session. If the user changes the idle timeout after the session is established, that will not be reflected on the existing sessions, but will be used for new sessions.

#### *SSH Default Enabled Parameters During Installation*

When you install Switch Engine for the first time, the following SSH parameters are enabled by default:

In Default, FIPS, and Secure mode:

- **Diffie-Hellman groups:** 14 (2,048 bits), 16 (4,096 bits), 18 (8192 bits)
- **Public key algorithms:** ssh-rsa, x509v3-sign-rsa, x509v3-sign-dss

In Default mode:

- **Ciphers:** aes128-ctr, aes192-ctr, aes256-ctr, chacha20-poly1305@openssh.com
- **MACs:** hmac-sha1-etm@openssh.com, hmac-sha2-256-etm@openssh.com, hmac-sha2-512-etm@openssh.com, hmac-sha1, hmac-sha2-256, hmac-sha2-512

Other OpenSSH 7.5p1 supported MACs and ciphers listed in [Understanding SSH Server](#) on page 1590 are disabled by default.

### RSA and SHA256 for Host Key Algorithm

Version 32.5 adds support for two new host key algorithms: rsa-sha2-256 and rsa-sha2-512. While the default algorithm remains ssh-rsa, this SHA-1 algorithm is weak and not recommended. In version 32.5, you can use the CLI to select the host key algorithm from the list of three options.

During an upgrade to version 32.5, the ssh-rsa type host key present in the switch is used, but the following EMS log will be generated when the switch starts:

```
04/25/2023 08:19:25.67 <Noti:exsshd.CfgHostKeyAlgWeak> The configured host key
algorithm(s),
 ssh-rsa, is/are weaker than what is recommended.
```

The switch will continue to generate an ssh-rsa type key until you use the **configure ssh2 key algorithm** command. Once you use the command to make a selection, the new algorithm chosen will take effect when you run **disable/enable ssh2** or **sshd restart**, as displayed in the following example output:

```
configure ssh2 key algorithm rsa-sha2-256
New key algorithm will be usable after disable and enable SSH or 'restart process exsshd'.

Warning: Legacy clients that do not support this algorithm will not connect with the
switch's SSH server.
```

The following command configures the host key algorithm:

```
configure ssh2 key algorithm [ssh-rsa | rsa-sha2-256 | rsa-sha2-512]
```

Use the **show ssh2** command to display current and configured algorithms.

## Enabling SSH2 for Inbound Switch Access

You must enable SSH2 on the switch before you can connect to the switch using an external SSH2 client.

Enabling SSH2 involves two steps:

1. Generate or specify an authentication key for the SSH2 sessions (see [Standard Key Authentication](#) on page 1593 and [User Key-Based Authentication](#) on page 1593).

2. Enable SSH2 access by specifying a TCP port to be used for communication and specifying on which SSH2 is enabled (see [Enabling SSH2](#) on page 1603).
3. If desired, specify a timeout period for a login attempts by using the command:  
`configure ssh2 login-grace-timeout seconds`

### Standard Key Authentication

An authentication key must be generated before the switch can accept incoming SSH2 sessions. This can be done automatically by the switch, or you can enter a previously generated key.

- To have the key generated by the switch, use the following command:

```
configure ssh2 key
```

The key generation process can take up to one minute.

For the switch to use the newly generated key, the `exsshd` process needs to be restarted using the `restart process [class cname | name {msm slot}]` command with "exsshd" for *name*.

- To use a key that has been previously created, use the following command:

```
configure ssh2 key {pregenerated}
```

The switch prompts you to enter the pregenerated key.

#### Note

The pregenerated key must be one that was generated by the switch. To get such a key, you can use the command `show ssh2 private-key` to display the key on the console. Copy the key to a text editor and remove the carriage return/line feeds. Finally, copy and paste the key into the command line. The key must be entered as one line.

The key generation process generates the SSH2 private host key. The SSH2 public host key is derived from the private host key and is automatically transmitted to the SSH2 client at the beginning of an SSH2 session.

### User Key-Based Authentication

Public key authentication is an alternative method to password authentication that SSH uses to verify identity. You can generate a key pair consisting of a private key and a public key. The public key is used by the ExtremeXOS SSH server to authenticate the user.

In ExtremeXOS, user public keys are stored in the switch's configuration file; these keys are then associated (or bound) to a user.

The keys are configured on the switch in one of two ways:

- By copying the key to the switch using `scp2/sftp2` with the switch acting as the server.
- By configuring the key using the CLI.

RSA and DSA encryption keys are both supported.

The public key can be loaded onto the switch using SCP or SFTP, where the switch is the server. The administrator can do this by using the SCP2 or SFTP2 client software to connect to and copy the key file to the switch. The public key file must have the extension `ssh`; for example, `id_dsa_2048.ssh`. When the `.ssh` file is copied to the switch, the key is loaded into the memory. The loaded public keys are saved to the configuration file (`*.cfg`) when the `save` command is issued via the CLI.

The key name is derived from the file name. For example, the key name for the file `id_dsa_2048.ssh` will be `id_dsa_2048`. The file name of the key or the keyname is restricted to 32 characters in length.

The key is associated with a user either implicitly, by pre-pending the user name to the file or explicitly using the CLI.

In order for a key to be bound or associated to a user, the user must be known. In other words, that user must have an entry in the local database on the switch. Once the user is authenticated, the user's rights (read-only or read/write) are obtained from the database.

The key can be associated with a user by pre-pending the user name to the file name. For example, `admin.id_dsa_2048.ssh`.

If the user specified in the file name does not exist on the switch, the key is still accepted, but is not associated to any user. Once the user is added, the key can be associated with the user using the CLI. If the user name is not pre-pended to the file name, the key is accepted by the switch but is not associated with any user. The key can be then be associated with the user using the command `configure sshd2 user-key key_name add user user_name`.

You can also enter or paste the key using the command `configure ssh2 key {pregenerated}` using the `pregenerated` keyword. There cannot be any carriage returns or new lines in the key. For more information, see the `configure ssh2 key {pregenerated}` command in the [Switch Engine v33.3.1 Command References](#)

The host and user public keys can be written to a file in the `config` directory using the `create sshd2 key-file {host-key | user-key} key_name` command. This enables the administrator to copy the public key to an outside server.

### *Public-Key Infrastructure (PKI) in Secure Shell (SSH) Overview*

The major disadvantage with user-key-based authentication is scalability. As the number of users increases, a greater number of keys must be copied and stored in the switch. This problem can be solved with the Public-Key Infrastructure (PKI). Moreover, PKI has its own advantages of added security, certificate revocation checking, avoiding manual mapping of keys with users, etc.

For the details about configuring PKI, see [Using Public-Key Infrastructure \(PKI\) in Your Network](#) on page 1626.

**Figure 199: Public-Key Infrastructure Login Flow Overview**

In [Figure 199](#), Callout 1 is the initial series of message exchanges initiated by the Secure Shell (SSH) client. The ExtremeXOS device is providing the SSH client with the list of supported authentication methods, one of which is public key. The SSH client responds with its public key certificate.

At Callout 2, the ExtremeXOS device verifies if the extended key usage of client certificate contains 'client authentication'. If not, the SSH PKI connection is not established. Next, the ExtremeXOS device extracts the Common-Name field from the public key certificate and validates it against the local-accounts present/configured in the switch. If there is no matching accounts/user-name, then the SSH PKI connection is not established. Next, it checks to ensure the certificate signature from SSH client matches a trusted certificate authority's certificate present on the ExtremeXOS device.

At Callout 3, the ExtremeXOS device sends an Online Certificate Status Protocol (OCSP) request to the OCSP responder to check the validity of the Clients X.509 certificate. If the OCSP responder determines that the certificate has not been revoked by the certificate authority, the server sends back a GOOD response. After the preceding steps are completed, then the user is logged in automatically using SSH with X509, which can be seen using the command `show session {{detail}} {sessID}} {history}` with the output shown as follows (the Auth field has a value of x509v3, which indicates that this is a SSH login using PKI):

```
show session
```

| #  | Login Time               | User     | Type | Auth   | CLI Auth Location |
|----|--------------------------|----------|------|--------|-------------------|
| *5 | Tue Oct 18 12:24:12 2016 | samar .. | ssh2 | x509v3 | dis 10.127.3.143  |

### Limitations

- Certificate-based authentication is supported only for ExtremeXOS Secure Shell (SSH) server, not for ExtremeXOS SSH client.
- Revocation check is done only for the SSH client-end certificate using OCSP only at the time of login. There are no periodic revocation checks.
- The SSH client certificate must have client authentication purpose in the extendedKeyUsage field.
- Username must be present in CommonName (CN) in the subject of the certificate. The login username and this CN must match for access to be granted.
- Supports only RSA, DSA-based SSH client certificates.
- Beginning with Release 32.2, if X.509v3 authentication fails due to an invalid key or certificate, then the connection request will be rejected. The next authentication method will not be attempted.

### Example: Configuring PKI for SSH Secure Login Using X509v3 Certificates

The following is an example on how to use the ExtremeXOS PKI for SSH secure login using X509v3 certificates.

For example purposes, the following has been considered:

- OpenSSL is used to generate the trusted CA certificates and SSH client certificates.
- CommonIssuerModel is used for OCSP.
- OpenSSL's OCSP utility is used.
- Roumenpetrov's "PKIX-SSH" with X.509 v3 certificate support is used as an SSH client.

See the following topics for an example:

- [Generating Certificates Using OpenSSL](#) on page 1596
- [Downloading the Trusted Certificate to the ExtremeXOS PKI and Configuring the User Accounts](#) on page 1599
- [Using OpenSSL OCSP Utility](#) on page 1599
- [Using Roumenpetrov's "PKIX-SSH" SSH Client for Logging](#) on page 1599
- [The openssl.cnf file Used in This Example](#) on page 1600

### Generating Certificates Using OpenSSL

The following steps should be followed on a Linux server with OpenSSL installed to generate the X509v3 certificates.

```
$ mkdir certs crl newcerts serial private
$ touch index.txt
$ echo "01" > serial

$ openssl req -x509 -nodes -days 365 -newkey rsa:2048 -subj "/C=US/ST=NC/L=Raleigh/O=Extr/
OU=Exos/CN=CA-EXOS/emailAddress=ca-exos@extremenetworks.com" -keyout exosCAkey.pem -out
exosCAcert.crt
Generating a 2048 bit RSA private key
.+++
.....+++
writing new private key to 'exosCAkey.pem'
```

```

$ openssl x509 -in exosCAcert.crt -text
Certificate:
 Data:
 Version: 3 (0x2)

-----END CERTIFICATE-----

```

The next steps are to create a X509v3 certificate for a user that is signed by the above generated CA certificate "exosCAcert.crt".

In the following command, a user certificate signing request with RSA 2048 bit key, commonName as "exos-admin" is generated:

```

$ openssl req -nodes -days 365 -newkey rsa:2048 -new -subj "/C=US/ST=NC/L=Raleigh/
O=Extr/OU=Exos/CN=exos-admin/emailAddress=exos-admin@extremenetworks.com" -keyout exos-
admin-key.pem -out exos-admin-req.csr
Generating a 2048 bit RSA private key
.....+++
.....+++
writing new private key to 'exos-admin-key.pem'

```

In the following command, the user certificate-signing-request that was generated in the preceding command is being signed using the CA certificate "exosCAcert.crt":

```

$ openssl ca -config openssl.cnf -extensions usr_cert -days 365 -keyfile exosCAkey.pem
-cert exosCAcert.crt -in exos-admin-req.csr -out exos-admin-cert.crt
Using configuration from openssl_A.cnf
Check that the request matches the signature
Signature ok
Certificate Details:
 Serial Number: 1 (0x1)

```

## Downloading the Trusted Certificate to the ExtremeXOS PKI and Configuring the User Accounts

The previously generated trusted CA certificate needs to be downloaded from a TFTP server using the following command. "10.127.3.236" is the TFTP server IP address:

```

DUT1_switch_model.3 # download ssl 10.127.3.236 certificate trusted-ca /certs/
exosCAcert.crt
DUT1_switch_model.4 #
DUT1_switch_model.4 # sh ssl trusted-ca exosCAcert.crt
===== exosCAcert.crt =====
Certificate:
 Data:
 Version: 3 (0x2)
 Serial Number:
 f1:4d:fe:e9:6f:e3:b8:6f
 Signature Algorithm: sha256WithRSAEncryption
 Issuer: C=US, ST=NC, L=Raleigh, O=Extr, OU=Exos, CN=CA-EXOS/emailAddress=ca-
exos@extremenetworks.com
 Validity
 Not Before: Oct 20 07:12:47 2016 GMT
 Not After : Oct 20 07:12:47 2017 GMT
 Subject: C=US, ST=NC, L=Raleigh, O=Extr, OU=Exos, CN=CA-EXOS/emailAddress=ca-
exos@extremenetworks.com

```

The user needs to be created on the ExtremeXOS device with appropriate privileges. The name of the account would be the value present in the "commonName" field of the user-certificate that was generated (that is: exos-admin-cert.crt):

```
DUT1_switch_model.1 # create account admin exos-admin exospassword
```

## Using OpenSSL OCSP Utility

As mentioned previously, OpenSSL's OCSP utility is used for example purposes, and the example uses the "Common Issuer Model".

The following command should be entered in the Linux Server for OCSP Responder:

```
$openssl ocsp -port 2561 -text -index index.txt -CA exosCAcert.crt
-rkey exosCAkey.pem -rsigner exosCAcert.crt
```

## Using Roumenpetrov's "PKIX-SSH" SSH Client for Logging

To use the user-certificate for logging into the ExtremeXOS SSH server, you need to concatenate the key file and certificate file as a single file, and also ensure that the file does not have a very open permission level (that is, accessible by others).

```
$ cat exos-admin-key.pem exos-admin-cert.crt > exosadmincert.crt
$ chmod 0600 exosadmincert.crt

$ ssh -i exosadmincert.crt exos-admin@10.127.6.57

subjectKeyIdentifier = hash
authorityKeyIdentifier = keyid,issuer
keyUsage = critical, digitalSignature
extendedKeyUsage = critical, OCSPSigning

```

### SSH X.509v3 Authentication Using RADIUS

Version 32.2 introduces support for SSH X.509v3 Authentication Using RADIUS. When enabled, the SSH server requests a password from the client during X.509v3 key-certificate authentication. The user name and password received is then sent to Authentication, Authorization, and Accounting (AAA) for authentication. AAA sends these credentials to the RADIUS server for authentication. If the RADIUS server is not configured or is not reachable, then AAA will validate the user name and password through local authentication. You can use the following command to enable or disable the RADIUS password authentication feature:

```
configure ssh2 x509v3 radius-password-auth [on | off]
```

For authentication, you can use Principal Name as the user name in the client's certificate. The 'principalName' (OID: 1.3.18.0.2.4.318) is displayed below the 'otherName' identifier in the 'SubjectAltName' (SAN) extension of the X509v3 key-certificate.

The following is an example of openssl.cnf to generate X509v3 certificate with SAN extension having 'principalName':

```
[usr_cert]
Extensions for client certificates (`man x509v3_config`).
basicConstraints = CA:FALSE
#nsCertType = client, email
#nsComment = "OpenSSL Generated Client Certificate"
subjectKeyIdentifier = hash
authorityKeyIdentifier = keyid,issuer:always
keyUsage = critical, nonRepudiation, digitalSignature, keyEncipherment
extendedKeyUsage = clientAuth, emailProtection
authorityInfoAccess = OCSP;URI:http://ocspserver.extremenetworks.com:2561
subjectAltName = otherName:1.3.18.0.2.4.318;UTF8:exos-admin@sustaining.com
```

### Overwrite

The configure `ssh2 x509v3 username overwrite [on | off]` command is used to enable or disable using Principal Name as the username for authentication. If 'principalName' is not found, then Common Name in the certificate will be used as the username. This command can only be used if `radius-password-auth` is enabled.

### Strip Domain

The configure `ssh2 x509v3 username strip-domain [on | off]` command is used to specify using the 'principalName' without its domain name. This command can only be used if `radius-password-auth` and `overwrite` are enabled.

### Use Domain

The configure `ssh2 x509v3 username use-domain [domain_name | none]` command is used to add a domain name to the username for authentication. This command can only be used if `radius-password-auth`, `overwrite`, and `strip-domain` are enabled.

## Enabling SSH2

- To enable SSH2, use the following command:

```
enable ssh2 {access-profile [access_profile | none]} {port
tcp_port_number} {vr [vr_name | all | default]}
```

You can also specify a TCP port number to be used for SSH2 communication. The TCP port number is 22 by default. The switch accepts IPv6 connections.

Before you initiate a session from an SSH2 client, ensure that the client is configured for any non-default access list or TCP port information that you have configured on the switch. After these tasks are accomplished, you may establish an SSH2-encrypted session with the switch. Clients must have a valid user name and password on the switch in order to log in to the switch after the SSH2 session has been established.

Up to eight active SSH2 sessions can run on the switch concurrently. If you enable the idle timer using the `enable cli idle-timeout` command, the SSH2 connection times out after 20 minutes of inactivity by default. If you disable the idle timer using the `disable cli idle-timeout` command, the SSH2 connection times out after 60 minutes of inactivity by default. This timeout value can be modified using the `configure ssh2 idletimeout minutes` command wherein *minutes* can be from 1 to 240 ". For more information please refer to the command help for "configure ssh2".

After SSH2 has enabled, TCP port 22 is available on all virtual routers by default .

General technical information is also available at <http://www.openssh.com/specs.html>.

### *Setting SSH2 Rekeying Interval*

Data transmission between server and client in each SSH2 session is encrypted using session keys.

Session keys are generated after negotiation between server and client using Diffie-Hellman algorithm (see [Diffie-Hellman Overview](#) on page 1620). Cryptanalysis experts advise that it is unsafe to use the same session key to encrypt data over long periods of time. With enough captured data you could analyze the traffic and compromise the key, so it is advisable to keep changing the session keys after a certain interval.

You can configure the SSHv2 session rekeying interval by specifying a time interval and/or a data limit. After the configured time interval, the SSH server forces the client to perform a key negotiation for a new session key. This new key is used for SSH communication until the next rekeying. After configuring the SSH session rekeying time interval, configured SSH idle-timeout is disabled, so the idle-timeout occurs at the globally configured idle-timeout, instead of SSH configured idle-timeout.

Default value for data limit varies depending upon the encryption algorithm being used. For algorithms with a block size of 128-bits, data-limit is 4GB; for algorithms with a block size of 64-bits, the data limit is 1GB. This is the limitation by OpenSSH. For example, if the communication is through 3-DES algorithm and the data limit is configured at 4GB, rekeying occurs after 1GB of data is transferred. If the communication is using AES algorithm with same configuration, rekeying occurs after 4GB data is transferred. This issue does not occur if you limit the range to 1GB, instead of 4GB for the data limit.

To set the rekey interval, use the following command:

```
configure ssh2 rekey [time-interval [time_interval | none] | data-limit [data_size | default]]
```

To view your selections for rekeying, use the following commands:

```
show ssh2
```

or

```
show management
```

### Enabling/Disabling DSA and X509v3 Public Key Algorithms

You can selectively enable and disable DSA/RSA X509 public key-based algorithms: ssh-rsa, ssh-dss, x509v3-sign-rsa, x509v3-sign-dss.

To enable DSA/RSA X509 public key-based algorithms, use the following command:

```
configure ssh2 enable {pk-alg [pkalg_name | all]}
```

To disable DSA/RSA X509 public key-based algorithms, use the following command:

```
configure ssh2 disable {pk-alg [pkalg_name | all]}
```

To view which public key-based algorithms are currently enabled, use the following command:

```
show ssh2
```

## Viewing SSH2 Information

- To view the status of SSH2 sessions on the switch, use the following command:

```
show ssh2
```

The `show switch management` command displays information about the switch including the enable/disable state for SSH2 sessions and whether a valid key is present.

## Using ACLs to Control SSH2 Access

You can restrict SSH2 access by creating and implementing an [ACL](#) policy.

You configure an ACL policy to permit or deny a specific list of IP addresses and subnet masks for the SSH2 port.

The two methods to load ACL policies to the switch are:

- Use the `edit policy` command to launch a VI-like editor on the switch. You can create the policy directly on the switch.
- Use the `tftp` command to transfer a policy that you created using a text editor on another system to the switch.

For more information about creating and implementing ACLs and policies, see [Security](#) and [ACLs](#) on page 325.

### Sample SSH2 Policies

The following are sample policies that you can apply to restrict SSH2 access.

In the following example, named `MyAccessProfile.pol`, the switch permits connections from the subnet 10.203.133.0/24 and denies connections from all other addresses:

```
MyAccessProfile.pol
Entry AllowTheseSubnets {
if {
source-address 10.203.133.0 /24;
```

```
}
Then
{
permit;
}
}
```

In the following example, named `MyAccessProfile.pol`, the switch permits connections from the subnets `10.203.133.0/24` or `10.203.135.0/24` and denies connections from all other addresses:

```
MyAccessProfile.pol
Entry AllowTheseSubnets {
 if match any {
 source-address 10.203.133.0 /24;
 source-address 10.203.135.0 /24;
 }
 Then
 {
 permit;
 }
}
```

In the following example, named `MyAccessProfile_2.pol`, the switch does not permit connections from the subnet `10.203.133.0/24` but accepts connections from all other addresses:

```
MyAccessProfile_2.pol
Entry dontAllowTheseSubnets {
 if {
 source-address 10.203.133.0 /24;
 }
 Then
 {
 deny;
 }
}
Entry AllowTheRest {
 If {
 ; #none specified
 }
 Then
 {
 permit;
 }
}
```

In the following example, named `MyAccessProfile_2.pol`, the switch does not permit connections from the subnets `10.203.133.0/24` or `10.203.135.0/24` but accepts connections from all other addresses:

```
MyAccessProfile_2.pol
Entry dontAllowTheseSubnets {
 if match any {
 source-address 10.203.133.0 /24;
 source-address 10.203.135.0 /24
 }
 Then
 {
 deny;
 }
}
```

```

Entry AllowTheRest {
If {
; #none specified
}
Then
{
permit;
}
}

```

### Configuring SSH2 to Use ACL Policies

This section assumes that you have already loaded the policy on the switch. For more information about creating and implementing [ACLs](#) and policies, see [Security](#) and [ACLs](#).

- To configure SSH2 to use an ACL policy to restrict access, use the following command:

```
enable ssh2 {access-profile [access_profile | none]} {port
tcp_port_number} {vr [vr_name | all | default]}
```

Use the none option to remove a previously configured ACL.

In the ACL policy file for SSH2, the source-address field is the only supported match condition. Any other match conditions are ignored.

### Using SCP2 from an External SSH2 Client

In ExtremeXOS, the SCP2 protocol is supported for transferring configuration, image and public key policy files to the switch from the SCP2 client. The user must have administrator-level access to the switch. The switch can be specified by its switch name or IP address. ExtremeXOS only allows SCP2 to transfer to the switch files named as follows:

- \*.cfg—ExtremeXOS configuration files
- \*.pol—ExtremeXOS policy files
- \*.xos—ExtremeXOS core image files
- \*.xmod—ExtremeXOS modular package files
- \*.ssh—Public key files

In the following examples, you are using a Linux system to move files to and from the switch at 192.168.0.120, using the switch administrator account admin. You are logged into your Linux system as user.

- To transfer the primary configuration file from the switch to your current Linux directory using SCP2, use the following command:

```
[user@linux-server]# scp2 admin@192.168.0.120:primary.cfg primary.cfg
```

- To copy the policy filename test.pol from your Linux system to the switch, use the following command:

```
[user@linux-server]# scp2 test.pol admin@192.168.0.120:test.pol
```

- To copy the image file test.xos from your Linux system to the switch, use the following command:

```
[user@linux-server]# scp2 test.xos admin@192.168.0.120:test.xos
```

Now you can use the command `install image test.xos` to install the image in the switch.

- To copy the SSH image file `test.xmod` from your Linux system to the switch, use the following command:

```
[user@linux-server]# scp2 test.xmod admin@192.168.0.120:test.xmod
```

Now you can use the command `install image test.xmod` to install the image in the switch.

- To load the public key `id_rsa.pub` from your Linux system to the switch, use the following command:

```
[user@linux-server]# scp2 id_rsa.pub admin@192.168.0.120:test.ssh
```

This command loads the key into memory, which can be viewed with the command `show sshd2 user-key`.

## Understanding the SSH2 Client Functions on the Switch

An Extreme Networks switch can function as an SSH2 client. This means you can connect from the switch to a remote device running an SSH2 server and send commands to that device. You can also use SCP2 to transfer files to and from the remote device.

### Note

ExtremeXOS 15.7.1 upgraded from `openssh-3.9p1` to `openssh-6.5p1`. ExtremeXOS 21.1 adds the `openssl-fips-ecp-2.0.9` open source library. ExtremeXOS 22.5 upgraded from `openssh-6.5p1` to `openssh-7.5p1`. ExtremeXOS 30.7 upgraded from `openssh-7.5p1` to `openssh-8.1p1`

Support for following ciphers and macs are removed in ExtremeXOS 30.7, since these are not supported in `openssh 8.1p1`:

- **Ciphers:** `blowfish-cbc`, `cast128-cbc`, `arcfour`, `arcfour256`, `arcfour128`
- **MACs:** `hmac-ripemd160-etm@openssh.com`, `hmac-ripemd160`, `hmac-ripemd160@openssh.com`

### Note

When upgrading to ExtremeXOS 30.7, if unsupported ciphers/MACs are:

- Enabled in the saved configuration, the configuration is ignored during configuration load. The dirty bit is set and an error message appears: `<Error:exsshd.LoadCfgCipherUnsuprt>`  
`<Error:exsshd.LoadCfgMACUnsuprt>`.
- Disabled (by default or intentional) in the saved configuration, the configuration is ignored silently during configuration load. The dirty bit is set and an error messages do not appear.

You do not need to enable SSH2 or generate an authentication key to use the SSH2 and SCP2 commands from the ExtremeXOS CLI.

#### Note

User-created VRs are supported only on the platforms listed for this feature in the [Switch Engine v33.3.1 Licensing Guide](#) document.

- To send commands to a remote system using SSH2, use the following command:

```
ssh2 {cipher [cipher] {mac mac} {compression [on | off]} {port port}
{user username} {vr vr_name} user@host {remote_command}
```

The remote commands can be any command acceptable by the remote system. You can specify the login user name as a separate argument or as part of the user@host specification. If the login user name for the remote system is the same as your user name on the switch, you can omit the username parameter entirely.

For example, to obtain a directory listing from a remote Linux system with IP address 10.10.0.2 using SSH2, enter the following command: `ssh2 admin@10.10.0.2 ls`

- To initiate a file copy from a remote system to the switch using SCP2, use the following command:

```
scp2 {cipher cipher} {mac mac} {compression [on | off]} {port port}
{vr vr_name} [user@host:file local-file | local-file user@host:file]
```

For example, to copy the configuration file test.cfg on host system1 to the switch, enter the following command:

```
scp2 admin@system1:test.cfg localtest.cfg
```

- To initiate a file copy to a remote system from the switch using SCP2, use the following command:

```
scp2 {cipher cipher} {mac mac} {compression [on | off]} {port port}
{vr vr_name} [user@host:file local-file | local-file user@host:file]
```

For example, to copy the configuration file engineering.cfg from the switch to host system1, enter the following command:

```
scp2 engineering.cfg admin@system1:engineering.cfg
```

#### SSH/SCP Client Upgrade Limitations

- Only password-based authentication is supported for SSH/SCP client.
- SCP client will not support upload of Image or BootROM files (i.e, \*.xos, \*.xmod, and \*.xtr).
- SCP client will not support download of Image or BootRom files (like \*.xos, \*.xmod, and \*.xtr) from ExtremeXOS SCP server.
- Only supports transfer of files such as \*.cfg, \*.xsf, \*.py, \*.pol and \*.ssh files to/from the switch.
- Keyboard interactive authentication will not be supported.
- Host key algorithms are not configurable.

## Using SFTP from an External SSH2 Client

The SFTP protocol is supported for transferring configuration, and policy files to the switch from the SFTP client. You must have administrator-level access to the switch. The switch can be specified by its switch name or IP address.

ExtremeXOS requires that SFTP transfer to the switch files named as follows:

- \*.cfg—ExtremeXOS configuration files
- \*.pol—ExtremeXOS policy files
- \*.xos—ExtremeXOS core image file
- \*.xmod—ExtremeXOS modular package file
- \*.ssh—Public key files

In the following examples, you are using a Linux system to move files to and from the switch at 192.168.0.120, using the switch administrator account admin. You are logged into your Linux system as account user.

- To transfer the primary configuration file from the switch to your current Linux directory using SCP2, use the following command:

```
user@linux-server]# sftp admin@192.168.0.120
password: <Enter password>
sftp> put primary.cfg
```

- To copy the policy filename test.pol from your Linux system to the switch, use the following command:

```
user@linux-server]# sftp admin@192.168.0.120
password: <Enter password>
sftp> put test.pol
```

- To copy the image file image.xos from your Linux system to the switch, use the following command:

```
user@linux-server]# sftp admin@192.168.0.120
password: <Enter password>
sftp> put image.xos
```

- To load the public key id\_rsa.pub from your Linux system to the switch, use the following command:

```
user@linux-server]# sftp admin@192.168.0.120
password: <Enter password>
sftp> put id_rsa.pub id_rsa.ssh
```

For image file transfers, only one image file at a time can be available for installation. If you need to install an additional image (xmod):

- a. Transfer image.xos into the switch using scp/sftp
- b. Install the image.xos image using the "install image" command
- c. Transfer the xmod into the switch using scp/sftp
- d. Install the xmod modular package file using `install image [inactive | filename | local-file] {partition} {slot slotid}{reboot}` command.

- For image file transfers using SFTP or SCP (with the switch acting as the server), once the image is copied to the switch, validation of image is done by the switch, as indicated by the following log message:

```
<Info:AAA.LogSsh> Validating Image file, this could take approximately
30 seconds..image.xos
```

You must receive the following log message before you can proceed with the installation of the image:

```
<Info:AAA.LogSsh> Image file successfully validated
```

In stacking switches, you must receive the following log message from all slots before proceeding with the installation.

For example, in a four-switch stack, the installation can be proceed only after the following log messages are received:

```
04/19/2007 17:41:09.71 <Info:AAA.LogSsh> Slot-1: Sent file "image.xos" info to backup
04/19/2007 17:41:09.71 <Info:AAA.LogSsh> Slot-1: Sent file "image.xos" info to standby
slot 3
04/19/2007 17:41:09.71 <Info:AAA.LogSsh> Slot-1: Sent file "image.xos" info to standby
slot 4
```

## Disabling Unapproved Crypto Algorithms

ExtremeXOS provides a way to administratively disable unapproved crypto algorithms. This allows you to enable and disable ciphers and MAC algorithms to be used by the SSH server.

### *Disabling Unapproved Crypto Algorithms*

SSH works on three security modes default-mode, FIPS-mode, and Secure-Mode (see [Security Mode Overview](#) on page 1482). In each mode, you can configure the required ciphers and MACs from a list using the CLI. Different modes support a different list of

ciphers. By default, all available ciphers and MACs in the modes are configured unless otherwise indicated (see [Table 148](#)).

**Table 148: Supported Ciphers and MACs**

| Mode           | Ciphers                                                                                                                                                                                                           | MACs                                                                                                                                                                                                                                                                                                                                        |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b> | <i>Enabled by default:</i><br>aes128-ctr, aes192-ctr, aes256-ctr,<br>chacha20-poly1305@openssh.com<br><i>Disabled by default:</i><br>3des-cbc, aes128-cbc, aes192-cbc,<br>aes256-cbc, rijndael-cbc@lysator.liu.se | <i>Enabled by default:</i><br>hmac-sha1-etm@openssh.com,<br>hmac-sha2-256-etm@openssh.com,<br>hmac-sha2-512-etm@openssh.com;<br>hmac-sha1, hmac-sha2-256, hmac-sha2-512<br><i>Disabled by default:</i><br>hmac-md5, hmac-md5-96,<br>hmac-md5-etm@openssh.com,<br>hmac-md5-96-etm@openssh.com,<br>hmac-sha1-96, hmac-sha1-96-etm@openssh.com |

| <b>Secure</b>  | aes128-ctr, aes192-ctr, aes256-ctr                                                                                                                                                                                | hmac-sha1; hmac-sha2-256; hmac-sha2-512                                                                                                                                                                                                                                                                                                     |

By default, weaker ciphers/MACs are disabled, while the remaining ciphers/MACs are enabled (see Default mode in [Table 148](#)). This is the default mode of operation. A switch can move from this default mode to FIPS mode. Changing from default mode to FIPS mode requires switch reboot. Until reboot, all the SSH connections use default mode configurations. Since the configuration is already changed by the user (here FIPS mode), updated configuration is displayed. On reboot, only FIPS mode ciphers/MACs are available in SSH for configuration. Again, disabling FIPS mode requires a system reboot. Until reboot, SSH server supports only FIPS mode ciphers/MACs. Since the user configured disabling FIPS mode, the corresponding updated configuration appears. It is recommended to update the FIPS mode once all the operations are completed. None of the security related configurations are supposed to be changed after updating the FIPS mode. This is because the behavior is undefined in those scenarios.

SSH supports Secure-Mode, which allows only highly secure ciphers/MACs. Secure-Mode is a feature of SSH alone. This has no effect on other modules that use cryptograph like FIPS-mode. Configuring Secure-Mode does not require a switch reboot. The changes are immediate. Secure-mode and FIPS-mode are not mutually exclusive. Secure-Mode supports fewer ciphers/MACs than FIPS mode, so you only have Secure-Mode ciphers/MACs available for configuration with both Secure-Mode and FIPS-Mode are enabled. Internally, Secure-Mode uses FIPS library for cryptography instead of OpenSSL library. Once Secure-Mode is disabled, the SSH server moves to either default-mode or FIPS-mode, based on FIPS-Mode configuration. However, those ciphers/MACs that are configured before enabling/disabling Secure-Mode are lost. So, for each mode update, SSH server configuration of ciphers/MACs is reset. You have to configure ciphers/MACs each time if you configured SSH server for using particular

ciphers/MACs. From the list of available ciphers/MACs, you can configure the required ciphers/MACs, and disable the ciphers/MACs that are not required.

Disabling all the ciphers/MACs does not allow any incoming connection from the clients. This happens because the incoming connections are not able to negotiate for a common cipher/MAC.

### Configuring Unapproved Crypto Algorithms

- To configure the required ciphers/MACs with SSHv2, use the following command:  
`configure ssh2 enable [cipher [cipher | all] | mac [ mac | all]]`
- To disable ciphers/Message Authentication Codes (MACs) for use with SSHv2, use the following command:  
`configure ssh2 disable [cipher [cipher | all] | mac [ mac | all]]`
- To display the configured SSHv2 ciphers and MACs, use the following command:  
`show ssh2 {ciphers | macs}`

### Enabling/Disabling Ciphers and MACs Configuration Examples

#### Configuration Example: Enable/Disable Ciphers in Default Mode

```
show ssh2
SSH module configuration details:
SSH Access : Disabled
Key validity : Invalid
Key type : RSA 2048
Key algorithm :
 Current : rsa-sha2-256
 Configured : rsa-sha2-256
TCP port : 22
VR : all
Access profile : not set
Secure Mode : Off
Diffie-Hellman Groups : 14 (2048 bits), 16 (4096 bits), 18 (8192 bits)
Max Auth Tries : 3
Idle time : 60 minutes
Rekey Interval : 4096 MB and no time limit
Ciphers : aes128-cbc, aes192-cbc, aes256-cbc, rijndael-cbc@lysator.liu.se,
aes128-ctr, aes192-ctr, aes256-ctr, chacha20-poly1305@openssh.com
Macs : hmac-md5-etm@openssh.com, hmac-sha1-etm@openssh.com, hmac-
sha2-256-etm@openssh.com, hmac-sha2-512-etm@openssh.com, hmac-sha1-96-etm@openssh.com,
hmac-md5-96-etm@openssh.com, hmac-md5, hmac-sha1, hmac-sha2-256, hmac-sha2-512, hmac-
sha1-96, hmac-md5-96
Public key algorithms : ssh-rsa, ssh-dss, x509v3-sign-rsa, x509v3-sign-dss
Login grace timeout : 100 seconds

show ssh2 ciphers
Ciphers : aes128-cbc, aes192-cbc, aes256-cbc, rijndael-cbc@lysator.liu.se,
aes128-ctr, aes192-ctr, aes256-ctr, chacha20-poly1305@openssh.com

configure ssh2 disable cipher aes128-cbc

show ssh2 ciphers
Ciphers : aes192-cbc, aes256-cbc, rijndael-cbc@lysator.liu.se, aes128-ctr,
aes192-ctr, aes256-ctr, chacha20-poly1305@openssh.com

show ssh2
SSH module configuration details:

```

## Key Exchange Algorithms—Diffie-Hellman

### Diffie-Hellman Overview

Diffie-Hellman (DH) is a public-key cryptography protocol that allows two parties to establish a shared secret over an unsecure communications channel. This method allows two computer users to generate a shared private key with which they can then exchange information across an insecure channel.

ExtremeXOS supports Diffie-Hellman group 1, 14, 16, and 18 as part of the key exchange algorithms. In compliance with the Network Device collaborative Protection Profile (NDPP) of Common Criteria, the TSF (Target Security Function) ensures that diffie-hellman-group14-sha1 is the only minimal allowed key exchange method used for the SSH protocol.

ExtremeXOS uses group 14 by default as the minimal supported Diffie-Hellman group as 14 to avoid using the weaker Diffie-Hellman group 1 in an SSH server.

### Configuring the Diffie-Hellman Minimal Supported Group

- To configure the minimal supported Diffie-Hellman group, use the following command:

```
configure ssh2 dh-group minimum [1 | 14 | 16 | 18]
```

- To show the SSH configuration details, including minimal supported Diffie-Hellman group, use the following command:

```
show ssh2
```

### Diffie-Hellman Minimal Supported Group Configuration Examples

#### Configuration Example: DH-16 Key-Exchange Algorithm

```
show ssh2
SSH module configuration details:
SSH Access : Disabled
Key validity : Invalid
Key type : RSA 2048
TCP port : 22
VR : all
Access profile : not set
Secure Mode : Off
Diffie-Hellman Groups : 14 (2048 bits), 16 (4096 bits), 18 (8192 bits)
Max Auth Tries : 3
Idle time : 60 minutes
Rekey Interval : 4096 MB and no time limit
Ciphers : aes128-ctr, aes192-ctr, aes256-ctr, aes128-cbc, aes192-cbc,
aes256-cbc, rijndael-cbc@lysator.liu.se
Macs : hmac-sha1, hmac-sha2-256, hmac-sha2-512
Public key algorithms : ssh-rsa, ssh-dss, x509v3-sign-rsa, x509v3-sign-dss
```

```
configure ssh2 dh-group minimum 16

show ssh2
SSH module configuration details:
SSH Access : Disabled
Key validity : Invalid
Key type : RSA 2048
TCP port : 22
VR : all
Access profile : not set
Secure Mode : Off
Diffie-Hellman Groups : 16 (4096 bits), 18 (8192 bits)
Max Auth Tries : 3
Idle time : 60 minutes
Rekey Interval : 4096 MB and no time limit
Ciphers : aes128-ctr, aes192-ctr, aes256-ctr, aes128-cbc, aes192-cbc,
aes256-cbc, rijndael-cbc@lysator.liu.se
Macs : hmac-sha1, hmac-sha2-256, hmac-sha2-512
Public key algorithms : ssh-rsa, ssh-dss, x509v3-sign-rsa, x509v3-sign-dss
```

### Configuration Example: DH-1 Key-Exchange Algorithm

```
configure ssh2 dh-group minimum 1
Notice: The configured key exchange algorithm(s), DH group 1, is/are weaker than what is
recommended.

show ssh2
SSH module configuration details:
SSH Access : Disabled
Key validity : Invalid
Key type : RSA 2048
TCP port : 22
VR : all
Access profile : not set
Secure Mode : Off
Diffie-Hellman Groups : 1 (1024 bits), 14 (2048 bits), 16 (4096 bits), 18 (8192 bits)
Max Auth Tries : 3
Idle time : 60 minutes
Rekey Interval : 4096 MB and no time limit
Ciphers : aes128-ctr, aes192-ctr, aes256-ctr, aes128-cbc, aes192-cbc,
aes256-cbc, rijndael-cbc@lysator.liu.se
Macs : hmac-sha1, hmac-sha2-256, hmac-sha2-512
Public key algorithms : ssh-rsa, ssh-dss, x509v3-sign-rsa, x509v3-sign-dss
```

## Secure Socket Layer

Secure Socket Layer (SSLv3) is a feature of ExtremeXOS that allows you to authenticate and encrypt data over an SSL connection to provide secure communication.

The existing web server in ExtremeXOS allows HTTP clients to access the network login page. By using HTTPS on the web server, clients securely access the network login page using an HTTPS enabled web browser. Since SSL encrypts the data exchanged between the server and the client, you protect your data, including network login credentials, from unwanted exposure.

HTTPS access is provided through SSL and the Transport Layer Security (TLS1.2). These protocols enable clients to verify server authenticity to prevent network intruders.

You must upload or generate a certificate for SSL server use. Before you can upload a certificate, you must purchase and obtain an SSL certificate from an Internet security vendor. The following security algorithms are supported:

- RSA for public key cryptography (generation of certificate and public-private key pair, certificate signing). RSA key size between 1,024 and 4,096 bits.
- Symmetric ciphers (for data encryption): RC4.
- Message Authentication Code (MAC) algorithms: RSA Data Security, Inc. *MD5* Message-Digest Algorithm and SHA.

Version 32.3 adds a security enhancement that auto-generates an SSL certificate on enabling web HTTPS if an SSL certificate is not already created via the CLI. The certificate is generated with default configurations for the following:

- Key length
- Country-code
- Organization name
- Common name
- State
- Locality
- Organization unit
- Email

Once the certificate is successfully generated, the HTTPS login will be granted. The generation and validation of the certificate and key behaves in the same way as those that are generated through the command line.

## Enabling and Disabling SSL

This section describes how to enable and disable SSL on your switch.

To use SSL with web-based login (secure HTTP access, HTTPS) you must specify the HTTPS protocol when configuring the redirect URL.

- To enable SSL and allow secure HTTP (HTTPS) access on the default port (443), use the following command:

```
enable web https
```

- To disable SSL and HTTPS, use the following command:

```
disable web https
```

## Creating Self-Signed Certificates and Private Keys

When you generate a certificate, the certificate is stored in the configuration file, and the private key is stored in the EEPROM. The certificate generated is in PEM format. By default ExtremeXOS uses the SHA-512 hashing algorithm to create the certificate. The certificate hashing algorithm can be configured using command `configure ssl certificate hash-algorithm hash-algorithm`. ExtremeXOS supports *MD5*, SHA-224, SHA-256, SHA-384 and SHA-512. The configured algorithm are used to create

certificates from next time onwards. Use the `show ssl` command to check the currently configured Signature hashing algorithm.

- To create a self-signed certificate and private key that can be saved in the EEPROM, use the following command:

```
configure ssl certificate privkeylen length country code organization
org_name common-name name
```

Make sure to specify the following:

- Country code (maximum size of 2 characters)
- Organization name (maximum size of 64 characters)
- Common name (maximum size of 64)

Any existing certificate and private key is overwritten.

The size of the certificate depends on the RSA key length (**privkeylen**) and the length of the other parameters (country, organization name, and so forth) supplied by the user. For an RSA key length of 4,096, the certificate length is approximately 2 Kb, and the private key length is approximately 3 Kb.

#### *Downloading a Certificate Key from a TFTP Server*

You can download a certificate key from files stored in a TFTP server. If the operation is successful, any existing certificate is overwritten. After a successful download, the software attempts to match the public key in the certificate against the private key stored. If the private and public keys do not match, the switch displays a warning message similar to the following: Warning: The Private Key does not match with the Public Key in the certificate. This warning acts as a reminder to also download the private key.

Downloaded certificates and keys are not saved across switch reboots unless you save your current switch configuration. After you use the `save` command, the downloaded certificate is stored in the configuration file and the private key is stored in the EEPROM.

- To download a certificate key from files stored in a TFTP server, use the following command:

```
download ssl ipaddress certificate {ssl-cert | trusted-ca | ocsp-
signature-ca | {csr-cert {ocsp [on | off]}}
```

#### **Note**

For security measures, you can only download a certificate key in the VR-Mgmt.

- To see whether the private key matches with the public key stored in the certificate, use the following command:

```
show ssl {detail}
```

This command also displays:

- HTTPS port configured. This is the port on which the clients will connect.
- Length of the RSA key (the number of bits used to generate the private key).

- Basic information about the stored certificate.

#### *Downloading a Private Key from a TFTP Server*

For security reasons, when downloading private keys, we recommend obtaining a pre-generated key rather than downloading a private key from a TFTP server. See [Configuring Pregenerated Certificates and Keys](#) on page 1624 for more information.

- To download a private key from files stored in a TFTP server, use the following command:

```
download ssl ipaddress privkey key_file
```

If the operation is successful, the existing private key is overwritten. After the download is successful, a check is performed to find out whether the private key downloaded matches the public key stored in the certificate. If the private and public keys do not match, the switch displays a warning message similar to the following: `Warning: The Private Key does not match with the Public Key in the certificate.` This warning acts as a reminder to also download the corresponding certificate.

Downloaded certificates and keys are not saved across switch reboots unless you save your current switch configuration. After you use the `save` command, the downloaded certificate is stored in the configuration file and the private key is stored in the EEPROM.

#### *Configuring Pregenerated Certificates and Keys*

- To get the pregenerated certificate from the user, use the following command:

```
configure ssl certificate pregenerated
```

You can copy and paste the certificate into the command line followed by a blank line to end the command.

This command is also used when downloading or uploading the configuration. Do not modify the certificate stored in the uploaded configuration file because the certificate is signed using the issuer's private key.

The certificate and private key file should be in PEM format and generated using RSA as the cryptography algorithm.

- To get the pregenerated private key from the user, use the following command:

```
configure ssl privkey pregenerated
```

You can copy and paste the key into the command line followed by a blank line to end the command.

This command is also used when downloading or uploading the configuration. The private key is stored in the EEPROM.

The certificate and private key file should be in PEM format and generated using RSA as the cryptography algorithm.

### Support for x509v3-rsa2048-sha256 host key

Version 33.2.1 adds support for the x509v3-rsa2048-sha256 host key. The SSH server can present its x509v3 certificate (host key) to clients, and external SSH clients can authenticate the SSH server with the server's x509v3 certificate.

#### Supported Platforms

All platforms.

#### New CLI Command

```
configure ssh2 x509v3 key algorithm
```

#### Example

The following command configures the x509v3-rsa2048-sha256 key algorithm:

```
configure ssh2 enable x509v3 key algorithm x509v3-rsa2048-sha256
```

#### Modified CLI Command

The [configure ssl csr](#), [download ssl certificate](#), [show ssl](#), and [show ssl csr](#) commands add the ssh keyword to the syntax:

- `configure ssl csr {ssh} privkeylen length country code organization org_name common-name name`
- `download ssl ip_address certificate csr-cert {ssh} file_name {ocsp [on | off]}`
- `show ssl {manufacturing} {certificate {ssh} | detail}`

## Creating Certificate Signing Requests and Private Keys

Secure Socket Layer (SSL) allows you to:

- Generate self-signed certificates, which generate private keys and self-signed X509 certificates.
- Download SSL private key/certificate using `download ssl ipaddress certificate {ssl-cert | trusted-ca | ocsp-signature-ca | {csr-cert {ocsp [on | off]}}` `file_name` command (generally used to download CA signed certificate).
- Obtain an SSL private-key/certificate using the `configure ssl certificate pregenerated { csr-cert } pregenerated {ocsp {on | off}}` command (generally used to obtain the CA signed certificate for copying).

Additionally, you can create certificate signing requests (CSRs)/private key pairs. The CSR can then be taken to a Certificate Authority (CA) for signing. The CA then provides the signed certificate, which can be downloaded to the switch using either of the commands listed previously.

To create a CSR, use the following command:

```
configure ssl csr privkeylen length country code organization org_name common-name name
```

To view the CSR any time after creating it, use the following command:

```
show ssl csr
```

#### Note

For enhanced security, the minimum private key length is 2,048 (previously it was 1,024). This length is enforced in both private key/self-signed certificate pairs and private key/CSR pairs.

## Displaying SSL Information

- To display whether the switch has a valid private and public key pair and the state of HTTPS access, use the following command:

```
show ssl {[trusted-ca | ocsp-signature-ca] [file_name | all]}
{manufacturing}{certificate | detail}
```

- To display a certificate signing request (CSR), use the following command:

```
show ssl csr
```

## Using Public-Key Infrastructure (PKI) in Your Network

The ExtremeXOS implementation of public-key infrastructure (PKI) supports the secure authentication of Syslog server and SSH client to an Extreme Networks XOS device using an X.509 certificate. Below are primary aspects of a PKI configuration (for more information about each command listed in this topic, see [Switch Engine v33.3.1 Command References](#)):

#### Note

All the certificates mentioned below should be in PEM format.

- Trusted CA—The X509v3 certificates of Certificate Authority (CA) should be downloaded using the CLI: `download ssl ipaddress certificate {ssl-cert | trusted-ca | ocsp-signature-ca | {csr-cert {ocsp [on | off]}}` *file\_name* using the **trusted-ca** option. The CA certificate must satisfy the following criteria to successfully download:
  - Basic constraints: CA = true
  - Key usage must contain: KeyCertSign
- Peer Certificate—X509v3 certificate of the peer, signed by one of the above trusted CAs. The following criteria must be met for successful authentication:
  - Syslog server certificate: Extended key usage must contain 'Server Authentication'
  - SSH Client certificate:
    - Common name (CN) of the certificate subject must be same as the username with which SSH session is tried out.
    - Extended key usage must contain 'Client Authentication.'
- OCSP—Online Certificate Status Protocol used to find the revocation status of the peer certificate in the following scenarios:
  - Syslog server certificate's OCSP status is identified when a TLS session is to be established with the Syslog server. Only if the OCSP status is GOOD is the session established.

- SSH Client certificate's OCSP status is identified as part of authentication. Only if the OCSP status is GOOD is the session established.

### Note

OCSF processes intermediate CA certificates iteratively, one by one.

The OCSP Server's address must be configured in the Authority Information Access (AIA) of the peer certificate. Otherwise, the PKI authentication fails. The supported OCSP responder models are: common issuer model, delegated trusted responder model, trusted responder model.

- **OCSP Signature CA**—The certificates of OCSP responders must be configured as OCSP signature CA and trusted CA. To support Trusted Responder Model (TRM) of OCSP, the X509v3 certificate of the OCSP responder should be downloaded using the CLI: `download ssl ipaddress certificate {ssl-cert | trusted-ca | ocsp-signature-ca | {csr-cert {ocsp [on | off]}}` *file\_name* using the `ocsp-signature-ca` and `trusted-ca` options. For example:

```
download ssl 10.120.89.79 certificate trusted-ca cacert.pem
```

The OCSP signature CA is only required for TRM; it is not used for DTM and common issuer. This certificate must contain a trusted use extension that permits OCSP signing. A “trusted use extension” can be appended to a certificate using OpenSSL.

The following example appends a trusted use extension specifying an original file and the trusted file: `ocsp-sig-ca.pem` is the original certificate file and the output file `trusted-ocsp-sig-ca.pem` is the trusted file: `% openssl x509 -in ocsp-sig-ca.pem -addtrust OCSPSigning -out trusted-ocspsig-ca.pem`

The following is an example of an original certificate followed by the OpenSSL command output trusted certificate:

```

```

- ExtremeXOS X509v3 certificate—The certificate of the ExtremeXOS device. This is shared to the Syslog server to perform authentication there. Use the commands: `download ssl ipaddress certificate {ssl-cert | trusted-ca | ocspp-signature-ca | {csr-cert {ocsp [on | off]}} file_name` with the `ssl-cert` option, and `download ssl ipaddress privkey key_file`.
- Beginning with software release 32.2, you can configure SSH x509v3 OCSP attributes (enable/disable, nonce, override, and ocsp-nocheck, respectively) using the following commands:
  - `configure ssh2 x509v3 ocsp [on | off]`
  - `configure ssh2 x509v3 ocsp nonce [on | off]`
  - `configure ssh2 x509v3 ocsp override [url | none]`
  - `configure ssh2 x509v3 ocsp signer ocsp-nocheck [on | off]`

OCSP nonce cryptographically binds an OCSP request and an OCSP response with an `id-pkix-ocsp-nonce` extension to prevent replay attacks.

OCSP override configures one HTTP Online Certificate Status Protocol (OCSP) override URL for an SSH2 x509v3 server.

When OCSP-nocheck is done for a peer certificate, ExtremeXOS sends the OCSP request to the OCSP server. The OCSP response is signed by the OCSP responder/signer. The response also comes along with the certificate of the OCSP signer. When ExtremeXOS receives the response, it only verifies that the status of the peer certificate is not revoked.

## Setting Up PKI

The following is the sequential workflow involved in the session establishment using PKI:

1. Generate the involved X509v3 certificates: CA certificates, OCSP Signature CA certificate, Peer certificate (for example: Syslog server or SSH client), ExtremeXOS device certificate.
2. Download the CA certificates and OCSP Signature CA certificates to the ExtremeXOS device.
3. Download the ExtremeXOS device certificate and key to ExtremeXOS device (required for establishing TLS session with Syslog server).
4. Configure the peer (Syslog server or SSH client) as required to use its own X509v3 certificate in the connection request.
5. Initiate the connection request from peer (Syslog server or SSH client) to ExtremeXOS device.

6. The ExtremeXOS device performs the following tasks on the received peer's certificate and accepts or rejects the connection request:
  - Certificate chain verification
  - Validity checks on certificate extensions
  - OCSP

## PKI Limitations

- All certificates should be in PEM format files.
- Downloading CA certificate chain is not supported.
- Individual CA certificates in a certificate chain should be downloaded one-by-one using the following command: `download ssl ipaddress certificate {ssl-cert | trusted-ca | ocsp-signature-ca | {csr-cert {ocsp [on | off]}}` *file\_name*
- Downloading CA certificate of size greater than 7.5KB is not recommended.
- Certification Revocation Lists (CRLs)—not supported.
- OCSP stapling—not supported.
- Nonce is always disabled in OCSP request.
- OCSP is not done for the OCSP responder certificate. Therefore, the OCSP responder certificate should satisfy any of following criteria, failing which the OCSP response is rejected:
  - OCSP responder certificate should be self-signed, OR
  - OCSP responder certificate should contain `id-pkix-ocsp-nocheck` extension.

## ExtremeXOS Image Integrity Check

If the ExtremeXOS image integrity check feature is enabled, during bootup, the system checks the integrity of the ExtremeXOS image, and notifies you if it has been compromised or not (error is reported in the Syslog).

## Configuring ExtremeXOS Image Integrity Check

To enable or disable the ExtremeXOS image integrity check feature, use the following command:

```
configure switch integrity-check image [on | off]
```

To view the status and configuration of the ExtremeXOS image integrity check feature, use the following command:

```
show switch management
```

This command shows one of the following values:

- **On (Valid)**—the feature is enabled, and the check was successful.
- **On (Not Checked)**—the feature is enabled, but the image has not been checked. This occurs immediately after enabling the feature, but before rebooting, which will initiate the integrity check.
- **On (Invalid)**—the feature is enabled, and the check failed. The ExtremeXOS image is corrupted.
- **On (Failed)**—the feature is enabled, and the integrity check failed to run due to failures.
- **Off**—the feature is disabled.

## ExtremeXOS Image Integrity Check Syslog Messages

If an integrity failure occurs, the following error message is logged:

```
<ERROR> INTEGRITY: File <file-path> has invalid hash; expected <expected-hash> actual
<calculate-hash>.
```

If all critical files have expected hash values (passed integrity check), the following messages are logged:

```
<INFO> INTEGRITY: INTEGRITY-CHECK-VALID
<INFO> INTEGRITY: Image Integrity verification passed (<hash-algorithm>).
```

If one or more critical files have unexpected hash values (failed integrity check), the following error messages are logged:

```
<INFO> INTEGRITY: INTEGRITY-CHECK-INVALID
<INFO> INTEGRITY: Image Integrity verification failed (<hash-algorithm>).
```

## Secure Boot

Secure Boot is a mechanism to ensure the integrity of firmware and software running on a hardware platform by establishing a chain-of-trust relationship in the boot process. The chain-of-trust is established by cryptographic checks at each stage of the boot process to validate the integrity and authenticity of the next stage before it can execute.

The first link in the chain-of-trust is called the “Hardware Root of Trust” (HWROT), which is always trusted and protected against any alterations once programmed. For this version of Secure Boot, the chain-of-trust is established between HWROT, bootloader(s) (ARM systems)/BIOS (X86 systems). The HWROT comprises hardware components ASP NOR Flash, TPM, the firmware ‘Secondary Program Loader’ (SPL), and the recovery bootloader.

If the UBOOT image verification fails during boot-up, the switch halts and enters the recovery bootloader.

## Supported Platforms

ExtremeSwitching 5420, 5520, 5720, 7520, and 7720 series switches.

## Verifying Secure Boot

The following two commands show you the Secure Boot status in the **Trusted Delivery** field:

```
show switch {detail}
```

```
show system
```

The **Trusted Delivery** field has the following states:

- Boot Image Verification Failed
- Boot Image Verified

# Software Upgrade and Boot Options

---

[ExtremeXOS Upgrade Process](#) on page 1632  
[Installing a Modular Software Package](#) on page 1646  
[Configuration Changes](#) on page 1647  
[Using TFTP to Upload the Configuration](#) on page 1654  
[Using TFTP to Download the Configuration](#) on page 1655  
[Synchronizing Nodes](#) on page 1656  
[Upgrading the Bootrom](#) on page 1657  
[Upgrading the Firmware](#) on page 1658  
[Displaying the BootROM and Firmware Versions](#) on page 1659

This chapter provides instructions for upgrading ExtremeXOS software and firmware, including how to download and install a new image, perform a hitless upgrade, upload and download the configuration using TFTP, and synchronize nodes.

To upgrade your ExtremeXOS images and modules, start with [ExtremeXOS Upgrade Process](#) on page 1632.

To install modules on top of an existing ExtremeXOS image that will not be upgraded, see [Installing a Modular Software Package](#) on page 1646.

## ExtremeXOS Upgrade Process

---

Upgrading your ExtremeXOS image and modules uses the following process:

1. Backup all configuration files (see [Creating a Backup Configuration File](#) on page 1635).
2. Download ExtremeXOS and module package images from the Extreme Networks support portal (see [Downloading a New Image](#) on page 1639).

### Note

Beginning with ExtremeXOS 16.1, there are two methods available for the upgrade process:

- `download url filename` - provides a means of downloading multiple files at the same time over TFTP, HTTP, or anonymous FTP.
- `download image filename` - downloads a single .xos or .xmod file from a TFTP server.

3. Place the image files on a server that your switch can locate (see [Installing a Core Image](#) on page 1642).

4. Discover your inactive partition (see [Finding the Inactive Partition](#) on page 1641).
5. Use the `download image` command to install each image on the inactive partition (see [Installing a Core Image](#) on page 1642).
6. Reboot the switch (see [Reboot Options](#) on page 1643).

## Upgrade Example

We recommend upgrading software images and any modular packages at the same time. The following example shows an ExtremeSwitching 5720 image `onie-32.2.0.416.x86_64.xos` being installed before rebooting the switch:

```
show switch

## Creating a Backup Configuration File

Before upgrading ExtremeXOS on a switch, it is highly recommended that you create a backup copy of the configuration. Creating a copy of the "Config Booted" configuration file, with the version number of the ExtremeXOS image included in the name of the backup copy, is the simplest method.

To do this:

1. Save the configuration to the database so the switch can reapply the configuration after the switch reboot using the `save` command.
2. Enter `y` at the prompt to save your changes.
3. Execute the `show switch` command to view the "Config Booted" file. The following output is displayed:

```

show switch
SysName: XXXXX
SysLocation:
SysContact: support@extremenetworks.com, +1 888 257 3000
System MAC: 00:04:96:51:FE:E2
System Type: XXXXXX

SysHealth check: Enabled (Normal)
Recovery Mode: All
System Watchdog: Enabled

Current Time: Thu Sep 4 00:57:18 2014
Timezone: [Auto DST Disabled] GMT Offset: 0 minutes, name is UTC.
Boot Time: Wed Sep 3 20:07:11 2014
Boot Count: 402
Next Reboot: None scheduled
System UpTime: 4 hours 50 minutes 7 seconds

Current State: OPERATIONAL

```

```
Image Selected: primary
Image Booted: primary
Primary ver: 15.7.1.4
Secondary ver: 15.7.1.5

Config Selected: ssh-privatekey.cfg
Config Booted: ssh-privatekey.cfg
 ssh-privatekey.cfg Created by ExtremeXOS version
15.7.1.5
 219131 bytes saved on Mon Jul 14 23:03:08 2014
```

4. Using the ExtremeXOS version shown in the "Config Booted:" line, enter the "copy" command as shown:

```
cp config selected config-booted-exos_ver
```

For example: `cp ssh-privatekey.cfg ssh-privatekey-15_7_1_5`

**Note**

For more information about version strings, see [Understanding the Image Version String](#) on page 1644.

For more information about ExtremeXOS configuration files, see [Configuration Changes](#) on page 1647.

## Download URL Method

ExtremeXOS 21.1 provides an enhancement to the download CLI command so that it now accepts a URL as the name of the file to download.

**Note**

This feature is not available unless you are currently running ExtremeXOS 21.1 or later.

URL protocols can be TFTP, HTTP, or anonymous FTP. The format of a URL is:

- <http://10.10.10.1/filename.xos>
- <tftp://10.10.10.1/filename.xos>
- <ftp://10.10.10.1/filename.xmod>

In addition to accepting a URL that ends in .xos or .xmod, the URL filename can now end in .lst.

A .lst file contains filenames at the same location as the .lst file URL and will be downloaded, and then installed one after the other. The .lst file method can define bundles of downloads for:

- Large image file sizes
- Files ending in '.cfg', '.xsf', '.pol', '.xlic', '.py', '.ssh'
- Any additional .lst files so that you can create lists of lists
- Any bundling that makes it easier to download with a single command

The .lst file allows you to download .xos, .xmods, and other files at the same time. Once downloaded as a list, simply reboot and the files become active. This feature allows for better organization of downloads across switches.

All of the filenames in any .lst must be available at the same URL path provided in the download command.

Any .xos and .xmod files are installed to the inactive partition.

For any other file types, the /usr/local/cfg directory is used.

See the following for an example of .lst files

#### *Example*

An HTTP server on 10.68.9.7 for directory 16.1/xxxx/xxxx/release:

This example shows how the .lst file can contain filenames ending in .lst to get a list of lists (of lists etc...)

#### **cat big.lst – big.lst contains other list file names**

xos.lst

xmod.lst

script.lst

**cat xos.lst – xos.lst contains an ExtremeXOS image**

summitX-16.1.0.18.xos

**cat xmod.lst – xmod.lst contains a number of .xmod filenames**

summitX-16.1.0.18-debug.xmod

summitX-16.1.0.18-LegacyCLI.xmod

summitX-16.1.0.18-reachnxt-1.8.1.8.xmod

summitX-16.1.0.18-techSupport.xmod

**cat script.lst – script.lst contains a number of python scripts the user wants to download to a switch**

jsonrpc.py

jsontest.py

otst.py

ping.py

readvr.py

A single download command downloads all of the above files. Example uses big.lst:

```
download url http://10.68.9.7/big.lst
http://10.68.9.7/xos.lst
Downloading http://10.68.9.7/summitX-16.1.0.18.xos

```

## Downloading a New Image

The ExtremeXOS core image (.xos) file contains the executable code that runs on the switch and is preinstalled at the factory. An ExtremeXOS module image (.xmod) supplements the core image. Note that the version number of the core image and the module must match. As new versions of this image are released, you should upgrade both the software and modular packages running on your system.

To find and install image files:

1. Point your browser to <http://esupport.extremenetworks.com> and log in with your eSupport account.

If you do not have an eSupport account, you can request one with the **Request Web Login** link.

### Note

You can also download release notes from the eSupport site. The [ExtremeXOS Release Notes](#) will always have the most current download and install instructions.

2. Find the ExtremeXOS image and all modules you wish to upgrade. Later you will install all files on the image at the same time.
3. Save the files to a TFTP server on the network. You can also store them on a USB 2.0 device.
4. When you have all images downloaded and saved, proceed to [Finding the Inactive Partition](#) on page 1641.

### *Image Integrity Checking*

This feature adds digital signature verification in ExtremeXOS image and XMOD modules. Image integrity is checked against the digital signature before actual installation.

#### **Digital Signature**

Prior to ExtremeXOS 16.1, the ExtremeXOS image or XMOD modules downloaded to the switch were only protected by CRC check. This is sufficient for checking corrupted image. However, it cannot prevent malicious attacks. For example, an attacker can de-package the image, replace certain fields, recompute CRC and then repackage the image.

Digital signature is commonly used to demonstrate of the authenticity of a digital message, in this case, the image downloaded to the switch. Only images with digital signature validated on the switch can be installed. Otherwise, the installation should be aborted.

This features uses the Public Key Infrastructure (PKI) approach. Specifically, with the RSA algorithm, two keys, the private key and the public key are generated using openssl utility. The ExtremeXOS image or XMOD module is digitally signed with the private key. The public key is installed on the switch in the format of a X.509 certificate, which is verified before being used.

When building the image, the signature is computed for the ExtremeXOS image or XMOD module, then included in the final image provided to the customer. On the switch, during downloading process, the signature is verified against the image using the public key previously installed.

In order to deliver the public key to the customer securely, it is also digitally signed and it is distributed in the format of a X.509 certificate. In order to do so, another set of keys are generated to sign this certificate. A self-signed root certificate is also installed on the switch to verify the certificate containing the image signing public key.

All these keys and certificates are generated offline and the private keys should be stored safely.

Transition from an image without signature to one with needs two steps, the first step is to download the ExtremeXOS image and install the public key certificates. At this time, the signature cannot be verified because there is no key to validate the image. But after the first installation, all subsequent downloaded images can be validated using the installed key.

The certificates are only included in the ExtremeXOS image; XMOD modules do not need to include certificates.

Downgrading from an ExtremeXOS version supporting digital signature to one that does not is allowed. No special handling is needed. A warning message is printed on the console to remind the user that the image is not digitally signed. The user does have the choice to either proceed with downgrading or not.

### Hash Verification

Currently, each ExtremeXOS image or XMOD is posted along side with an MD5 (*Message-Digest algorithm 5*) hash checksum, which can be verified using any offline tools. As of ExtremeXOS 16.1, an enhancement now provides a stronger SHA256 hash checksum is generated for you to verify offline.

## Finding the Inactive Partition

A switch can store up to two core images: an active and inactive. When downloading a new image, you must select on which partition to install the new image. You must install the software image to the inactive partition, and must specify that partition while downloading the image to the switch.

To find the inactive partition:

1. From the CLI, enter the command `show switch` (or `show slot detail on SummitStack`).

```
show switch
SysName: XXXXXXXX
SysLocation:
SysContact: support@extremenetworks.com, +1 888 257 3000
System MAC: 00:04:96:51:FE:E2
System Type: XXXXXXXX

SysHealth check: Enabled (Normal)
Recovery Mode: All
System Watchdog: Enabled

Current Time: Thu Sep 4 00:57:18 2014
Timezone: [Auto DST Disabled] GMT Offset: 0 minutes, name is UTC.
Boot Time: Wed Sep 3 20:07:11 2014
Boot Count: 402
Next Reboot: None scheduled
System UpTime: 4 hours 50 minutes 7 seconds

Current State: OPERATIONAL
Image Selected: primary
Image Booted: primary
Primary ver: 15.7.1.4
Secondary ver: 15.7.1.5

Config Selected: ssh-privatekey.cfg
Config Booted: ssh-privatekey.cfg
 ssh-privatekey.cfg Created by ExtremeXOS version
 15.7.1.5

 219131 bytes saved on Mon Jul 14 23:03:08 2014
```

2. Locate the `Image Booted:` line. If it indicates `primary`, you will know to install the images on the secondary partition. If it indicates `secondary`, you will know to install the images on the primary partition.

For help with versions and image filenames, refer to the following:

- [Understanding the Image Version String](#) on page 1644
- [Image Types and Image Filename Prefixes](#)
- [Software Signatures](#) on page 1645

When you know the inactive partition, proceed to [Installing a Core Image](#) on page 1642.

## Installing a Core Image

Once .xos and .xmod files are stored on a network server (see [Downloading a New Image](#) on page 1639), download the image to the switch using the following procedure:

1. Use a login session on the master node of the SummitStack to verify which connects to your server. Use one of the following ping commands to confirm which virtual router reaches your server:

```
ping vr vr-Mgmt host
ping vr vr-Default host
```

At least one of these commands must successfully reach your server for you to download the image. After verifying the virtual router that reaches your server, specify that virtual router when you download the image.

2. Download the new image to the switch using the command:

```
download [url url {vr vrname} | image [active | inactive] [[hostname |
ipaddress] filename {{vr} vrname} {block-size block_size}] {partition}
{install {reboot}}]
```

### Note

If you configure the switch to write core dump (debug) files to the internal memory card and attempt to download a new software image, you might have insufficient space to complete the image download. If this occurs, you will need to move or delete the core dump files from the internal memory. You will be asked during the download process if you want to remove these files. For more information, see [Understanding Core Dump Messages](#) on page 1645.

3. Before the download begins, the switch asks if you want to install the image immediately after the download is finished. Enter *y* to install the image after download.  
  
If you enter *n* to install the image at a later time, the image is still downloaded and saved to the switch, but you must use the [install image](#) command when ready to install the image.
4. Install .xmod images to the inactive partition using the same command shown above.
5. After installing the .xos and all .xmod iamges, reboot the switch (see [Reboot Options](#) on page 1643).

For information about installing a new BootROM image on an ExtremeSwitching series switch, see [Upgrading the Bootrom](#) on page 185.

### Installing a Core Image with NMS

You can either load the new image to the NMS server on your network or configure it to automatically poll and download newly released images to the server. Follow the instructions described in the NMS documentation to appropriately configure the server for your network environment.

For more information about installing the NMS client and server, configuring it, and the platforms the NMS supports, refer to the NMS documentation that comes with

the product or the documentation available from the Extreme Networks website at [www.extremenetworks.com/documentation/](http://www.extremenetworks.com/documentation/).

## Copying an Image from the Active to Inactive Partition

To copy the image on the active partition to the inactive partition, use the following command:

```
install image inactive {slot slot}
```

## Reboot Options

### Reboot the Switch

- To reboot the switch immediately, use the following command  
`reboot`

#### Note

The reboot occurs immediately and any previously schedule reboots are cancelled.

On SummitStack, the `reboot` command reboots the *active* topology and can be run from the master node only.

- To schedule a time to reboot the switch, use the command:  
`reboot {[time mon day year hour min sec] | cancel} {slot slot-number}  
| node-address node-address | stack-topology {as-standby} | all} |  
rolling}`

The options use the following format:

- **date** — in mm dd yyy format
- **time** — 24-hour clock in hh mm ss format

#### Note

When you configure a timed reboot of the switch, you can use the `show switch` command to see the scheduled time.

- To reboot the entire stack topology, use the command:  
`reboot stack-topology {as-standby}`

#### Note

This command can be run on any node and can be used to eliminate the dual master condition manually.

- To cancel a previously scheduled reboot, use the **cancel** option of the `reboot` command.

### Reboot a Node in a SummitStack

To reboot a single node in the SummitStack, use the command:

```
reboot {[time mon day year hour min sec] | cancel} {slot slot-number}
| node-address node-address | stack-topology {as-standby} | all} |
rolling}
```

The `reboot slot` command works only on the active master node for other slots, and on an active non-master node for its own slot.

The `reboot stack-topology {as-standby}` command can also be used to reboot a single node by specifying the MAC address of the node.

The `reboot node-address` command reboots the specified node from any node.

## Understanding the Image Version String

The image version string contains build information for each version of ExtremeXOS.

You can use the `show version` and `show switch` commands to display the ExtremeXOS version running on your switch. The output will be structured as one of the following:

- ExtremeXOS Version <major>.<minor>.<sustaining>.<build>

In the case of a patch release, the version structure is ExtremeXOS Version <major>.<minor>.<sustaining>.<build>-patchX-Y where X is the patch type and Y is the build number for the patch.

- <major>.<minor>.<sustaining>.<build>patchX-Y

Table 149 describes the image version fields.

**Table 149: Image Version Fields**

| Field      | Description                                         |
|------------|-----------------------------------------------------|
| major      | Specifies the ExtremeXOS major version number.      |
| minor      | Specifies the ExtremeXOS minor version number.      |
| sustaining | Specifies the ExtremeXOS sustaining version number. |
| build      | Specifies the ExtremeXOS build number.              |
| patch      | Identifies a specific patch release.                |

The `show version` command also displays information about the firmware (BootROM) images running on the switch. For more information, see [Displaying the BootROM and Firmware Versions](#) on page 1659.

## Image Types and Image Filename Prefixes

The software image file can be an .xos file, which contains a Switch Engine core image, or an .xmod file, which contains a Switch Engine modular software package.

### Filename Prefixes

You can identify the appropriate image or module for your platform based on the filename prefix of the image.

**Table 150: Switch Engine Image Types (Prefixes)**

| Switches                                | Image File Type (Prefix)                       |
|-----------------------------------------|------------------------------------------------|
| 4120, 5120                              | rzg2<br>Example: rzg2-33.1.1.x.xos             |
| 4220, ExtremeSwitching 5320, 5420, 5520 | summit_arm<br>Example: summit_arm-31.3.1.x.xos |
| ExtremeSwitching 5720, 7520, 7720       | onie<br>Example: onie-32.1.1.6.x86_64.xos      |

For additional installation requirements see the sections, [#unique\\_2471](#) and [#unique\\_2472](#).

## Software Signatures

Each ExtremeXOS image contains a unique signature.

The BootROM checks for signature compatibility and denies an incompatible software upgrade. In addition, the software checks both the installed BootROM and software and also denies an incompatible upgrade.

## Understanding Core Dump Messages

If you configure the switch to write core dump (debug) files to internal memory (/usr/local/tmp) and attempt to download a new software image, you might have insufficient space to complete the image download.

If this occurs, move or delete the core dump files from the internal memory. For example, if the switch supports a USB 2.0 storage device and space is available, transfer the files to the storage device. On switches without removable storage devices, transfer the files from internal memory to a TFTP server. This frees up space on the internal memory card while keeping the core dump files.

The switch displays a message similar to the following and prompts you to take action:

```
Core dumps are present in internal-memory and must be removed before this download can
continue.
(Please refer to documentation for the "configure debug core-dumps" command for
additional information)
Do you want to continue with download and remove existing core dumps? (y/n)
```

Type **y** to remove the core dump files and download the new software image. Type **n** to cancel this action and transfer the files before downloading the image.

For information about configuring and sending core dump information, see the `configure debug core-dumps [ off | directory_path ]` and `save debug tracefiles directory_path` commands.

## Installing a Modular Software Package

In addition to the functionality available in the ExtremeXOS core image, you can add functionality to your switch by installing modular software packages or feature packs. A complete listing of these feature packs can be found with their availability requirements in the [Switch Engine v33.3.1 Licensing Guide](#) document.

Modular software packages are contained in files named with the file extension `.xmod`, while the core images use the file extension `.xos`.

Modular software packages are built at the same time as core images and are designed to work in concert with the core image, so the `<major>.<minor>.<patch>` field of a modular software package must match the `<major>.<minor>.<patch>` field of the core image that it will be running with. For example, the modular software package for tech support named:

```
summitX-21.1.1.4-techSupport.xmod
```

Can run only with the core image named:

```
summitX-21.1.1.4.xos
```

You can install a modular software package on the active or inactive partition. You would install on the active partition if you want to add the package functionality to the currently running core image without having to reboot the switch. You would install on the inactive partition if you want the functionality available after a switch reboot.

To install the package on the inactive partition, you use the same process that you use to install a new core image. Follow the process described in [Installing a Core Image](#) on page 1642.

Activate the installed modular software package either by rebooting the switch or by issuing the following command: `run update`

You can uninstall packages by issuing the following command:

```
uninstall image fname partition {msm slotid} {reboot}
```

### Note

Do not terminate a process that was installed since the last reboot unless you have saved your configuration. If you have installed a software module and you terminate the newly installed process without saving your configuration, your module may not be loaded when you attempt to restart the process with the `start process` command.

## Upgrading a Modular Software Package

When Extreme Networks introduces a new core software image, a new feature pack or modular software package is also available. If you have a software module installed and upgrade to a new core image, you need to upgrade to the corresponding feature pack at the same time (see [ExtremeXOS Upgrade Process](#) on page 1632).

If you wish to upgrade your existing module software package *without* upgrading your ExtremeXOS image, two methods are available. Regardless of which method you choose, you must terminate and restart the processes associated with the software module.

### 1. Method One

- a. Terminate the processes associated with the software module using one of the following commands:

```
terminate process name [forceful | graceful] (modular switches)
```

```
terminate process name [forceful | graceful] {slot slot}
```

(SummitStack)

- b. Download the software module from your TFTP server, compact flash card, or USB 2.0 storage device using the following command:

```
download [url url {vr vrname} | image [active | inactive] [[hostname
| ipaddress] filename {{vr vrname} {block-size block_size}}
{partition} {install {reboot}}
```

- c. Activate the installed modular package, if installed on the active partition, using the following command: `run update`

- d. Restart the processes associated with the software module using one of the following commands:

```
start process name {msm slot} (modular switches)
```

```
start process name {slot slot} (SummitStack)
```

### 2. Method Two

- a. Download the software module from your TFTP server, compact flash card, or USB 2.0 storage device using the following command:

```
download [url url {vr vrname} | image [active | inactive] [[hostname
| ipaddress] filename {{vr vrname} {block-size block_size}}
{partition} {install {reboot}}
```

- b. Activate the installed modular package, if installed on the active partition, using the following command: `run update`

- c. Terminate and restart the processes associated with the software module using one of the following commands:

```
restart process [class cname | name {msm slot}] (modular switches)
```

```
restart process [class cname | name {slot slot}] (SummitStack)
```

## Configuration Changes

### Image Configuration Overview

The configuration is the customized set of parameters that you have selected to run on the switch. As you make configuration changes, the new settings are stored in run-time

memory. Settings that are stored in run-time memory are not retained by the switch when the switch is rebooted. To retain the settings and have them loaded when you reboot the switch, you must save the configuration to nonvolatile storage.

The switch can store multiple user-defined configuration files, each with its own filename. By default, the switch has two prenamed configurations: a primary and a secondary configuration. When you save configuration changes, you can select to which configuration you want the changes saved or you can save the changes to a new configuration file. If you do not specify a filename, the changes are saved to the configuration file currently in use. Or if you have never saved any configurations, you are asked to save your changes to the primary configuration.

**Note**

Configuration files have a .cfg file extension. When you enter the name of the file in the CLI, the system automatically adds the .cfg file extension.

If you have made a mistake or you must revert to the configuration as it was before you started making changes, you can tell the switch to use the backup configuration on the next reboot.

Each filename must be unique and can be up to 32 characters long. Filenames are also case sensitive. For information about filename restrictions, see the specific command in the [Switch Engine v33.3.1 Command References](#).

- First, save the configuration using the command:

```
save configuration {primary | secondary | existing-config | new-config}
```

Where the options are:

- **primary** — Specifies the primary saved configuration
  - **secondary** — Specifies the secondary saved configuration
  - **existing-config** — Specifies an existing user-defined configuration (displays a list of available user-defined configuration files)
  - **new-config**—Specifies a new user-defined configuration
- You are prompted to save the changes. Enter *y* to save the changes or enter *n* to cancel the process.
  - Next, use the configuration command:

```
use configuration file-name
```

Where the options are:

- **primary** — Specifies the primary saved configuration
- **secondary** — Specifies the secondary saved configuration
- **file\_name** — Specifies an existing user-defined configuration (displays a list of available user-defined configuration files)

The configuration takes effect on the next reboot.

**Note**

When a switch boots up after executing this command, examine the log to determine if a subsequent save and a reboot of the switch or slot is necessary for the configuration to be correctly applied.

**Note**

If the switch is rebooted while in the middle of saving a configuration, the switch boots to factory default settings if the previously saved configuration file is overwritten. The configuration that is not in the process of being saved is unaffected.

## Automatic Saving of Configuration Files

The currently running switch configuration can be configured to be saved at automatic intervals. This feature is turned off by default, but can be enabled and configured to save at specified time intervals and to a designated file.

To configure automatic configuration saving, use the command `save configuration automatic {every minutes {primary | secondary | existing-config | new-config} | never}` .

**Note**

Automatic save of the running configuration on system reboot, irrespective of the interval between saves is handled for only immediate reboot, not for scheduled reboots or rebooting through other techniques such as [\*SNMP \(Simple Network Management Protocol\)\*](#).

## View a Configuration

- To view the current configuration, enter the command: on the switch.

```
show configuration {module-name} {detail}
```

You can also view just that portion of the configuration that applies to a particular module (for example, [\*SNMP\*](#)) by using the `module-name` parameter.

Beginning with ExtremeXOS 12.1, when you specify `show configuration only`, the switch displays configuration information for each of the switch modules excluding the default data.

You can send output from the `show configuration {module-name} {detail}` command to the [Extreme Networks Technical Support](#) for problem-solving purposes. The output maintains the command line interface (CLI) format of the current configuration on the switch.

## Comparing Configurations

You can view the differences between switch configuration files or a configuration file with the running configuration using the command:

```
show configuration difference { from-config-file {to-config-file} }
{module-name} {detail} {context lines}
```

When using the `save configuration automatic {every minutes {primary | secondary | existing-config | new-config} | never}` command this can be especially helpful for comparing what changed between the running (or "startup") configuration and the most recently autosaved configuration.

## Restore Factory Defaults

The following two procedures restore the switch to factory defaults and reboot the switch. Use the first procedure when you can log in to the switch and issue a CLI command and the second when you cannot.

- When you can log in to the switch, use the following command:

```
unconfigure switch
```

This command resets most of the configuration, with the exception of user-configured user accounts and passwords, the date, and the time. On SummitStack, the command also preserves stacking-specific parameters so the stack can be formed after reboot.

- Unset the currently selected configuration image, reset all switch parameters, and reboot the switch .

```
unconfigure switch all
```

- If you cannot log in because the switch is in a continuous booting loop, use the following procedure:

- a. Reboot the switch while pressing the space bar. This puts the switch in Bootstrap mode.
- b. From the Bootstrap prompt, type `boot` and then press **[Enter]** and press the spacebar. This puts the switch in BootROM mode.
- c. From the BootROM prompt, type `config none`.

The following appears:

```
Configuration selected: none
```

- d. From the BootROM prompt, enter `reboot`. The switch reboots and restores the factory defaults.

## Uploading ASCII-Formatted Configuration Files

You can upload your current configuration in ASCII format to a TFTP server.

The uploaded ASCII file retains the CLI format and allows you do the following:

- View and modify the configuration using a text editor, and later download a copy of the file to the same switch or to one or more different switches.

- Send a copy of the configuration file to [Extreme Networks Technical Support](#) for problem-solving purposes.

### Summary of Tasks

The following summary describes only the CLI involved to transfer the configuration and load it on the switch; it is assumed that you know how to modify the configuration file with a text editor. As previously described, to use these commands, use the .xsf file extension, as these steps are not applicable to configurations that use the .cfg file extension.

To work with an ASCII-formatted configuration file, complete the following tasks:

1. Upload the configuration to a network TFTP server using the following command:

```
upload configuration [hostname | ipaddress] filename {vr vr-name}
{block-size block_size}
```

After the configuration file is on the TFTP server, use a text editor to enter the desired changes, and rename the file if necessary so it has the .xsf extension.

2. Download the configuration from the TFTP server to the switch using one of the `tftp` and `tftp get` commands.
3. Verify the configuration file is on the switch using the `ls` command
4. Load and restore the new configuration file on the switch using the following command:

```
load script filename {arg1} {arg2} ... {arg9}
```

5. Save the configuration to the configuration database so the switch can reapply the configuration after switch reboot using the following command:

```
save configuration {primary | secondary | existing-config | new-config}
```

When you save the configuration file, the switch automatically adds the .cfg file extension to the filename. This saves the ASCII configuration as an XML-based configuration file.

#### Note

Configuration files are forward compatible only and not backward compatible. That is, configuration files created in a newer release, such as ExtremeXOS 15.5, might contain commands that do not work properly in an older release, such as ExtremeXOS 15.3.

### Upload the ASCII Configuration File To a TFTP Server

To upload the current switch configuration as an ASCII-based file to the TFTP server, use the `upload configuration` command and save the configuration with the .xsf file extension.

For example, to transfer the current switch configuration as an ASCII-based file named `meg_upload_config1.xsf` to the TFTP server with an IP address of 10.10.10.10, do the following:

```
upload configuration 10.10.10.10 meg_upload_config1.xsf
```

If you successfully upload the configuration to the TFTP server, the switch displays a message similar to the following:

```
Uploading meg_upload_config1.xsf to 10.10.10.10 ... done!
```

### Download the ASCII Configuration File to the Switch

To download the configuration from the TFTP server to the switch, use the `tftp` or `tftp get` command.

For example, to retrieve the configuration file named `meg-upload_config1.xsf` from a TFTP server with an IP address of `10.10.10.10`, you can use one of the following commands:

```
tftp 10.10.10.10 -g -r meg_upload_config1.xsf
tftp get 10.10.10.10 meg_upload_config1.xsf
```

If you successfully download the configuration to the switch, the switch displays a message similar to the following:

```
Downloading meg_upload_config1.xsf to switch... done!
```

### Verify that the ASCII Configuration File is on the Switch

To confirm that the ASCII configuration file is on the switch, use the `ls` command. The file with an `.xsf` extension is the ASCII configuration.

The following sample output contains an ASCII configuration file:

```
-rw-r--r-- 1 root 0 98362 Nov 2 13:53 Nov022005.cfg
-rw-r--r-- 1 root 0 68 Oct 26 11:17 mcastgroup.pol
-rw-r--r-- 1 root 0 21203 Dec 13 15:40 meg_upload_config1.xsf
-rw-r--r-- 1 root 0 119521 Dec 6 14:35 primary.cfg
-rw-r--r-- 1 root 0 96931 Nov 11 11:01 primary_11_11_05.cfg
-rw-r--r-- 1 root 0 92692 Jul 19 16:42 secondary.cfg
```

### Load the ASCII Configuration File

After downloading the configuration file, you must load the new configuration on the switch.

To load and restore the ASCII configuration file, use the command:

```
load script filename {arg1} {arg2} ... {arg9}
```

After issuing this command, the ASCII configuration quickly scrolls across the screen.

The following is an example of the type of information displayed when loading the ASCII configuration file:

```
script.meg_upload_config1.xsf.389 # enable snmp access
script.meg_upload_config1.xsf.390 # enable snmp traps
script.meg_upload_config1.xsf.391 # configure mstp region purple
script.meg_upload_config1.xsf.392 # configure mstp revision 3
script.meg_upload_config1.xsf.393 # configure mstp format 0
script.meg_upload_config1.xsf.394 # create stpd s0
```

Instead of entering each command individually, the script runs and loads the CLI on the switch.

### Save the Configuration

After you load the configuration, save it to the configuration database for use by the switch. This allows the switch to reapply the configuration after a switch reboot.

- To save the configuration, use the command;  
`save configuration {primary | secondary | existing-config | new-config}`

When you save the configuration file, the switch automatically adds the .cfg file extension to the filename. This saves the ASCII configuration as an XML-based configuration file.

You can use any name for the configuration.

For example, after loading the file `meg_upload_config1.xsf`, you need to save it to the switch.

To save the configuration as `configuration1.cfg`, enter the command:

```
save configuration configuration1
```

### Using Autoconfigure and Autoexecute Files

Two features allow you automatically execute scripts that can manage the switch configuration.

#### Autoconfigure:

Configuration commands placed in the `default.xsf` file are executed by the switch as it comes up and is unable to find its usual configuration file or if the switch is unconfigured or if the configuration file cannot be determined due to a corrupt NVRAM.

This returns the switch to some basic configuration. When `default.xsf` is executed, the `show switch` command shows `default.xsf` as the booted configuration file.

The `default.xsf` file can have any CLI commands as long as they are all executed within 500 seconds.

The script is aborted when the commands are not executed within that time. When the file is loaded, the results can be seen by executing the `show script output default` command.

#### Autoexecute:

Configuration commands placed in the `autoexec.xsf` file are executed after a switch loads its configuration.

The file is not executed when a `default.xsf` file has been executed. Use the file to execute commands after a switch is up and running and also to revert changes made to the configuration by UPM scripts that run persistent commands. The commands must be executed within 500 seconds or the script execution is aborted.

When an `autoexec.xsf` file is executed, the results can be seen by executing the `show script output autoexec` command.

## Using TFTP to Upload the Configuration

You can upload the current configuration to a TFTP server on your network. Using TFTP, the uploaded configuration file retains your system configuration and is saved in XML format. This allows you to send a copy of the configuration file to [Extreme Networks Technical Support](#) for problem-solving purposes.

- To view your current switch configuration, use the `show configuration {module-name} {detail}` command available on your switch. Do not use a text editor to view or modify your XML-based switch configuration files.

To view your current switch configuration in ASCII-format, see [Uploading ASCII-Formatted Configuration Files](#) on page 1650 for more information about uploading and downloading ASCII-formatted configuration files.

For more information about TFTP, see [Using the Trivial File Transfer Protocol](#) on page 82.

- To upload the configuration from the switch to a TFTP server, you can use either the `tftp` or the `tftp put` command:

```
tftp [ip-address | host-name] { -v vr_name } { -b block_size } [-g | -p] [-l local-file { -r remote-file } | -r remote-file { -l localfile }]
```

Where the options are:

- `host-name` — Specifies the host name of the TFTP server
- `ip-address` — Specifies the IP address of the TFTP server
- `-p` — Puts the specified file from the local host and copies it to the TFTP server
- `-l local-file` — Specifies the name of the configuration file that you want to save to the TFTP server
- `-r remote-file` — Specifies the name of the configuration file on the TFTP server

```
tftp put [ip-address | host-name] {vr vr_name} {block-size block_size} local-file { remote-file}
```

Where the options are:

- `put` — Puts the specified file from the local host and copies it to the TFTP server
- `host-name` — Specifies the host name of the TFTP server
- `ip-address` — Specifies the IP address of the TFTP server
- `local-file` — Specifies the name of the configuration file that you want to save to the TFTP server
- `remote-file` — Specifies the name of the configuration file on the TFTP server

If you upload a configuration file and see the following message:

```
Error: No such file or directory
```

Check to make sure that you entered the filename correctly, including the `.cfg` extension, and that you entered the correct host name or IP address for the TFTP server.

If your upload is successful, the switch displays a message similar to the following:

```
Uploading megtest1.cfg to TFTPHost ... done!
```

You can also upload the current configuration in ASCII format from the switch to a TFTP server on your network. For more information, see [Uploading ASCII-Formatted Configuration Files](#) on page 1650.

## Using TFTP to Download the Configuration

You can download previously saved XML formatted XOS configuration files from a TFTP host to the switch to modify the switch configuration. Do not use a text editor to view or modify your switch configuration files; modify your switch configurations directly in the CLI.

To view your current switch configuration in ASCII-format, see [Uploading ASCII-Formatted Configuration Files](#) on page 1650 for more information about uploading and downloading ASCII-formatted configuration files.

For more information about TFTP, see [Using the Trivial File Transfer Protocol](#) on page 82.

### Note

By default, if you transfer a file with a name that already exists on the system, the switch prompts you to overwrite the existing file. For more information, see the `tftp get` command in the [Switch Engine v33.3.1 Command References](#).

- To download the configuration from a TFTP host to the switch, you can use either the `tftp` or the `tftp get` command:

```
tftp [ip-address | host-name] { -v vr_name } { -b block_size } [-g | -p] [-l local-file { -r remote-file } | -r remote-file { -l localfile }]
```

Where the options are:

- **host-name** — Specifies the host name of the TFTP server
- **ip-address** — Specifies the IP address of the TFTP server
- **-p** — Puts the specified file from the local host and copies it to the TFTP server
- **-l local-file** — Specifies the name of the configuration file that you want to save to the TFTP server
- **-r remote-file** — Specifies the name of the configuration file on the TFTP server

```
tftp get [ip-address | host-name] { vr vr_name } { block-size block_size } remote-file local-file { force-overwrite }
```

Where the options are:

- **get** — Gets the specified file from the TFTP server and copies it to the local host
- **host-name** — Is the host name of the TFTP server
- **ip-address** — Is the IP address of the TFTP server
- **remote\_file** — Specifies the name of the configuration file that you want to retrieve from the TFTP server

- *local-file* — Specifies the name of the configuration file on the switch
- **force-overwrite** — Specifies the switch to automatically overwrite an existing file

If you download a configuration file and see the following message:

```
Error: Transfer timed out
```

Make sure that you entered the filename correctly, including the .cfg extension, and that you entered the correct host name or IP address for the TFTP server.

If your download is successful, the switch displays a message similar to the following:

```
Downloading megtest2.cfg to switch... done!
```

Configurations are downloaded and saved into the switch nonvolatile memory. The configuration is applied after you reboot the switch.

If the configuration currently running in the switch does not match the configuration that the switch used when it originally booted, an asterisk (\*) appears before the command line prompt when using the CLI.

You can also download the current configuration in ASCII format from a TFTP server on your network to the switch. For more information, see [Uploading ASCII-Formatted Configuration Files](#) on page 1650.

## Synchronizing Nodes

Before synchronizing nodes on a SummitStack, confirm that all nodes are active nodes and running ExtremeXOS 12.0 or later, so as to support the [synchronize](#) command.

On a SummitStack with redundancy, you can take the primary node configurations and images and replicate them on the backup node using the [save configuration](#) command.

### Caution

During a synchronization on a SummitStack, the active stack briefly alternates between a ring and daisy-chain topology. When the primary node finishes replicating its configurations and images to the backup node, the full the stack ring is restored.

In addition to replicating the configuration settings and images, this command also replicates which configuration or image the node should use on subsequent reboots. This command does not replicate the run-time configuration. You must use the `save configuration {primary | secondary | existing-config | new-config}` command to store the run-time configuration first.

On a SummitStack, you can synchronize an active node in the stack with the primary or non-primary slots using the following command:

```
synchronize {slot slotid} {file_name}
```

**Note**

You cannot synchronize a master switch running a version earlier than ExtremeXOS 22.2 to a target node running ExtremeXOS 22.2 or later. The command fails and the following error message appears: Error: the target slot's partitions are not compatible with the Master's for synchronize.

## Automatic Synchronization of Configuration Files

On a SummitStack where redundancy is in use, ExtremeXOS automatically synchronizes all of the configuration files from the primary node to the backup node if the switch detects that the backup node's configuration file contents are different from the primary node.

You cannot configure this behavior.

The switch deletes the old configuration files on the backup node only upon a successful file synchronization. If an error occurs, the switch does not delete the old configuration files on the backup node. For example, if you install a backup node that contains different configuration files from the primary node, the old configuration files are deleted after a successful bootstrap of the backup node.

To see a complete listing of the configuration files on your system, use the `ls` command.

For more detailed information, see [Replicating Data Between Nodes](#) on page 86.

## Upgrading the Bootrom

The ExtremeSwitching series switches have a two-stage bootROM. The first stage, called bootstrap, does basic initialization of the switch processor and loads one of two second-stage bootloaders (called primary and secondary).

If the switch does not boot properly, both the bootstrap and the bootloader allow you to access the boot options using the CLI.

If necessary, the bootloader can be updated after the switch has booted, using TFTP. You can upgrade the bootROM from a TFTP server on the network after the switch has booted and only when asked to do so by an Extreme Networks technical representative.

For information about loading an image to a TFTP server and verifying which VR connects to your TFTP server, see [Installing a Core Image](#) on page 1642.

To download to a single stacking node, you need to specify the slot parameter:

[download bootrom](#)**Note**

User-created VRs are supported only on the platforms listed for this feature in the licensing guide.

For ExtremeSwitching switches (except 5720 switches, which use ONIE), you can upgrade the bootROM with the version packaged in the ExtremeXOS .xos image file using the `from-exos` option: This command uses the bootROM image from the booted ExtremeXOS image. After reboot, the new bootROM image is used.

[install bootrom](#)

When you download and install new version of ExtremeXOS image, the system automatically compares the currently installed bootROM image against the bootROM image contained in the new ExtremeXOS image. If the installed version is older version, the system automatically upgrades bootROM to the version contained in new ExtremeXOS image. To view which version bootROM is on each partition, use the [show version](#) command.

If the bootROM image is invalid, this command shows 0.0.0.0. If the primary bootROM is invalid, the bootROM upgrade will be canceled. To fix this, re-install the bootROM on the primary partition.

## Upgrading the Firmware

---

Firmware images are bundled with ExtremeXOS and Switch Engine software images. The bundled firmware images include system FPGA and PLD images. When you download and install a new version of ExtremeXOS, ExtremeXOS automatically compares the existing firmware image against the firmware images bundled with the ExtremeXOS image, and prompts to install the firmware if there is a new version. If the firmware install is skipped during an ExtremeXOS install, firmware can be installed later by following the procedure below using the `install firmware` command.

After a firmware image upgrade, messages are sent to the log.

To view the current firmware version, use the `show version detail` command:

```
show version detail
Switch : 800906-00-02 1907F-10042 Rev 02 IMG: 30.2.0.34
 FPGA: 1.1.34 CPLD: 1.1.13

Image : ExtremeXOS version 30.2.0.34 by release-manager
 on Wed Mar 27 20:36:16 EDT 2019
Diagnostics : 1.1.6
Certified Version : EXOS Linux 4.14.107, FIPS fips-ecp-2.0.16

Build Tools Version : exos-x32-sdk-2.5.1.1.3
```

1. To install the firmware bundled with the ExtremeXOS image, use the `install firmware {force} {slot slot-number}` command.

If the bundled firmware image is newer than the existing firmware image, the switch prompts you to confirm the upgrade.

2. At the prompt:

- Type **y** to upgrade the firmware.
- Type **n** to cancel the firmware upgrade for the specified hardware, and continue scanning for other hardware that needs to be upgraded.

3. Press **Enter** to cancel the upgrade.

During the firmware upgrade, the switch also prompts you to save your configuration changes to the current, active configuration.

4. To save your configuration changes to the current, active configuration, type **y** or to discard your changes, type **n**.

The new firmware overwrites the older version.

You must reboot the switch to load the newly installed firmware. However, you do not need to do this immediately after a firmware upgrade. Use the [reboot](#) command to reboot the switch and activate the new firmware. During the firmware upgrade, do not turn off or disrupt the power to the switch. During the firmware upgrade, do not cycle down or disrupt the power to the switch. If a power interruption occurs, the installed firmware may be corrupted. In this case, the switch uses a backup version, and you can run the upgrade again to install the latest version.

## Displaying the BootROM and Firmware Versions

To display the bootROM (firmware) version on the switch and on all of the modules and PSU controllers, use the [show version](#) command.

The following is a sample for an 4120 Series switch:

```
4120-48MW-4Y-SwitchEngine.8 = show version
Switch : 801187-00-AA FF022335G-00007 Rev AA BootROM: 4.6.0.3 IMG: 32.7.1.22

- [Using sFlow](#) on page 1705
- [Using RMON](#) on page 1712
- [Monitoring CPU Utilization](#) on page 1716

Viewing statistics on a regular basis allows you to see how well your network is performing. If you keep simple daily records, you can see trends emerging and notice problems arising before they cause major network faults. In this way, statistics can help you get the best out of your network.

The status monitoring facility provides information about the switch.

This information may be useful for your technical support representative if you have a problem. ExtremeXOS software includes many command line interface (CLI) show commands that display information about different switch functions and facilities.

## Note

For more information about show commands for a specific ExtremeXOS feature, see the appropriate chapter in this guide.

## Viewing Port Statistics

---

ExtremeXOS software provides a facility for viewing port statistical information. The summary information lists values for the current counter for each port in the system. The switch automatically refreshes the display (this is the default behavior).

You can also display a snapshot of the real-time port statistics at the time you issue the command and view the output in a page-by-page mode. This setting is not saved; therefore, you must specify the *no-refresh* parameter each time you want a snapshot of the port statistics.

Values are displayed to nine digits of accuracy.

- View port statistics with the following command:

```
show ports {port_list | stack-ports stacking-port-list} statistics
{no-refresh}
```

The switch collects the following port statistical information:

- Link State—The current state of the link. Options are:
  - Active (A)—The link is present at this port.
  - Ready (R)—The port is ready to accept a link.
  - Loopback (L)—The port is configured for WANPHY loopback.
- Transmitted Packet Count (TX Pkt Count)—The number of packets that have been successfully transmitted by the port.
- Transmitted Byte Count (TX Byte Count)—The total number of data bytes successfully transmitted by the port.
- Received Packet Count (RX Pkt Count)—The total number of good packets that have been received by the port.
- Received Byte Count (RX Byte Count)—The total number of bytes that were received by the port, including bad or lost frames. This number includes bytes contained in the Frame Check Sequence (FCS), but excludes bytes in the preamble.
- Received Broadcast (RX Bcast)—The total number of frames received by the port that are addressed to a broadcast address.
- Received Multicast (RX Mcast)—The total number of frames received by the port that are addressed to a multicast address.
- View port statistics for SummitStack stacking ports with the following command:

```
show ports stack-ports {stacking-port-list} statistics {no-refresh}
```

## Viewing Port Errors

The switch keeps track of errors for each port and automatically refreshes the display (this is the default behavior). You can also display a snapshot of the port errors at the time you issue the command and view the output in a page-by-page mode. This setting is not saved; therefore, you must specify the *no-refresh* parameter each time you want a snapshot of the port errors.

- View port transmit errors with the following command:

```
show ports {port_list | stack-ports stacking-port-list} txerrors {no-
refresh}
```

The switch collects the following port transmit error information:

- Port Number—The number of the port.

- Link State—The current state of the link. Options are:
  - Active (A)—The link is present at this port.
  - Ready (R)—The port is ready to accept a link.
  - Loopback (L)—The port is configured for WANPHY loopback.
- Transmit Collisions (TX Coll)—The total number of collisions seen by the port, regardless of whether a device connected to the port participated in any of the collisions.
- Transmit Late Collisions (TX Late Coll)—The total number of collisions that have occurred after the port's transmit window has expired.
- Transmit Deferred Frames (TX Deferred)—The total number of frames that were transmitted by the port after the first transmission attempt was deferred by other network traffic.
- Transmit Errored Frames (TX Errors)—The total number of frames that were not completely transmitted by the port because of network errors (such as late collisions or excessive collisions).
- Transmit Lost Frames (TX Lost)—The total number of transmit frames that do not get completely transmitted because of buffer problems (FIFO underflow).
- Transmit Parity Frames (TX Parity)—The bit summation has a parity mismatch.
- View port receive errors with the command:

```
show ports {port_list | stack-ports stacking-port-list} rxerrors {no-
refresh}
```

The switch collects the following port receive error information:

- Port Number
- Link State—The current state of the link. Options are:
  - Active (A)—The link is present at this port.
  - Ready (R)—The port is ready to accept a link.
  - Loopback (L)—The port is in Loopback mode.
- Receive Bad CRC Frames (RX CRC)—The total number of frames received by the port that were of the correct length but contained a bad FCS value.
- Receive Oversize Frames (RX Over)—The total number of good frames received by the port greater than the supported maximum length of 1,522 bytes.
- Receive Undersize Frames (RX Under)—The total number of frames received by the port that were less than 64 bytes long.
- Receive Fragmented Frames (RX Frag)—The total number of frames received by the port that were of incorrect length and contained a bad FCS value.
- Receive Jabber Frames (RX Jabber)—The total number of frames received by the port that were greater than the support maximum length and had a Cyclic Redundancy Check (CRC) error.
- Receive Alignment Errors (RX Align)—The total number of frames received by the port with a CRC error and not containing an integral number of octets.
- Receive Frames Lost (RX Lost)—The total number of frames received by the port that were lost because of buffer overflow in the switch.

- For SummitStack stacking ports, you can also view transmit and receive errors with the following commands:

```
show ports stack-ports stacking-port-list txerrors {no-refresh}
```

```
show ports stack-ports {stacking-port-list} rxerrors {no-refresh}
```

Information displayed is identical to the details displayed for non-stacking ports.

## Port Link-Flap Detection

---

This feature detects excessive link flapping (link going up and down rapidly) on a physical port and can take the following actions:

- **Disables port**—After the port is disabled due to excessive link flapping, the port either stays down for the configured disable time value or can be re-enabled manually.
- **Reports issue to Syslog**—Adds an entry in the log for a link down event (see [Link-Flap Detection Syslog Messages](#) on page 1666).
- **Generates SNMP trap**—SNMP trap generated for a link down event (see [SNMP Traps](#) on page 1666).

You can configure the interval, threshold (maximum number of link down events), and disable time, and which of the preceding actions to take on a per port basis.

## Link-Flap Detection Threshold Value Dependencies

### *Dependency on Hardware Link Scan Interval*

The maximum value configurable for threshold depends on the link-flap interval value and the link scan interval. For example, if the link scan interval is 50 ms (default link-scan interval on most platforms), maximum link down/up events detectable by the hardware is 20 per second. Thus the maximum number of link-flaps detectable per second is 10. If the link-flap interval is 20 seconds, the maximum configurable threshold value is  $20 * 10 = 200$ .

Thus, the maximum configurable value for threshold = link-flap interval (seconds) \* maximum link-flaps detectable/second.

### *Dependency on Debounce Timer*

The debounce timer is implemented at the chip level. Since the link-flap algorithm is implemented at a higher level in the [VLAN \(Virtual LAN\)](#) manager application, any link-flaps within the debounce timer are not reported to HAL nor the VLAN manager. For example, if the debounce timer is configured to be 400 ms, then any link-flaps within that interval are not reported to HAL and hence they are not counted.

## Link-Flap Detection Syslog Messages

If you've configured link-flap detection to send log messages, the following messages are sent after excessive flapping:

- If the threshold is exceeded, and the log action is set, and the disable port action is not set, then a log message similar to the following appears:

```
03/31/2016 15:56:36.52 <Noti:vlan.msgs.PortLinkFlapActLogEvent> Port 1 link-flap
detection operational status is UP. Link has flapped more than 3 times in 60 seconds.
```

- If the log action and disable port action are set, and the threshold is exceeded, then a log message similar to the following appears:

```
03/31/2016 15:51:13.61 <Noti:vlan.msgs.PortLinkFlapActLogEvent> Port 2 link-flap
detection operational status is DOWN. Link has flapped more than 3 times in 60
seconds.
```

- This log message appears when all of the following conditions are met:
  - Disable port action is set on a port.
  - The number of link-flaps on the port exceeds the threshold.
  - You issue the command `enable log debug-mode`.
  - You add the event to the log filter (for example: "conf log filter "DefaultFilter" add events vlan.msgs.PortLinkFlapActDsblPort")

```
03/31/2016 15:51:13.61 <Summ:vlan.msgs.PortLinkFlapActDsblPort> Port 2 is disabled for
excessive link flapping. Link has flapped more than 3 times in 60 seconds.
```

## SNMP Traps

If configured, after excessive link flapping an *SNMP (Simple Network Management Protocol)* trap notification is generated for link up or down events. The trap notification "etsysLinkFlapViolation" includes the following information regarding the port in violation of threshold:

- Interface index
- Interface name
- Operation status (up or down)

## Port Link-Flap Statistics

| Statistics         | Description                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------|
| Current Lin- Flaps | Number of link-flaps in the current interval before the threshold is exceeded.                                             |
| Total Link-Flaps   | Total number of link-flaps accumulated for this port since the feature was turned on.                                      |
| Time Elapsed       | Time in seconds that has passed in the current interval.                                                                   |
| Threshold Exceeded | Number of times a given port has exceeded the threshold value for the maximum number of tolerated link-flaps per interval. |

## Configuring Port Link-Flap Detection

To turn on or off port link-flap detection, use the following command:

```
configure ports [port_list | all] link-flap-detection [on | off]
```

To set interval, threshold (maximum number of link down events), and disable time values for link-flap detection, use the following command:

```
configure ports [port_list | all] link-flap-detection [{interval
[interval | indefinitely]} {threshold threshold} {disable-time
[disable_time | until-cleared]}]
```

To reset interval, threshold (maximum number of link down events), and disable time to defaults for link-flap detection, use the following command.

```
unconfigure ports [port_list | all] link-flap-detection {interval}
{threshold} {disable-time}
```

To add or delete actions (disabling ports, logging events, generating *SNMP* traps) to be taken when excessive link-flapping is detected, use the following command:

```
configure ports [port_list | all] link-flap-detection action [add |
delete] [{disable-port} {log} {trap}] | all-actions]
```

To manually enable ports that have been disabled due to excessive link flapping, use the following command:

```
clear ports [port_list | all] link-flap-detection status
```

To clear the counters related to port link flapping, use the following command.

```
clear ports [port_list | all] link-flap-detection counters
```

To display the link-flap detection status for ports, use the following command:

```
show ports [port_list | all] link-flap-detection [disabled-ports |
configuration | counters {refresh | no-refresh}]
```

## Using the Port Monitoring Display Keys

[Table 151](#) on page 1667 describes the keys used to control the displays that appear if you use any of the show ports commands without specifying the **no-refresh** parameter (this is the default behavior).

**Table 151: Port Monitoring Display Keys with Auto-Refresh Enabled**

| Key(s) | Description                          |
|--------|--------------------------------------|
| [U]    | Displays the previous page of ports. |
| [D]    | Displays the next page of ports.     |
| [Esc]  | Exits from the screen.               |

**Table 151: Port Monitoring Display Keys with Auto-Refresh Enabled (continued)**

| Key(s)  | Description                                                                                                                                                                                                                                                           |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [0]     | Clears all counters.                                                                                                                                                                                                                                                  |
| [Space] | Cycles through the following screens: <ul style="list-style-type: none"> <li>• Packets per second</li> <li>• Bytes per second</li> <li>• Percentage of bandwidth</li> </ul> <p><b>Note:</b> Available only using the <code>show ports utilization</code> command.</p> |

Table 152 describes the keys used to control the displays that appear if you use any of the `show ports` commands and specify the **no-refresh** parameter.

**Table 152: Port Monitoring Display Keys with Auto-Refresh Disabled**

| Key     | Description                      |
|---------|----------------------------------|
| [Q]     | Exits from the screen.           |
| [Space] | Displays the next page of ports. |

## Viewing VLAN Statistics

ExtremeXOS software provides the facility for configurable VLAN statistics gathering and display of packet and byte counters on the port level and on the VLAN level.

## Configuring VLAN Statistics

- Configure the switch to start counting VLAN statistics with the commands:  

```
clear counters
configure ports [port_list|all] monitor vlan vlan_name {rx-only | tx-only}
```
- View VLAN statistics at the port level with the command:  

```
show ports {port_list} vlan statistics {no-refresh}
```

The switch collects and displays the following statistics:

- Port—The designated port.
- VLAN—The associated VLANs.
- Rx Frames Count—The total number of frames successfully received by the port on the designated VLAN.
- Rx Byte Count—The total number of bytes that were received by the port on the designated VLAN.
- Tx Frame Count—The total number of frames that were transmitted by the port on the designated VLAN.
- Tx Byte Count—The total number of bytes that were transmitted by the port on the designated VLAN.

Frame and byte counters are also displayed through [SNMP](#).

- View VLAN statistics at the VLAN level with the command:

```
show ports {port_list} vlan statistics {no-refresh}
```

The switch collects and displays the following statistics:

- VLAN—The designated VLAN.
  - Rx Total Frames—The total number of frames successfully received by the port.
  - Rx Byte Count—The total number of bytes that were received by the port.
  - Tx Total Frames—The total number of frames that were transmitted by the port.
  - Tx Byte Count—The total number of bytes that were transmitted by the port.
- Stop counting VLAN statistics.

```
unconfigure ports [port_list |all] monitor vlan vlan_name
```

#### Note

While using VLAN statistics, traffic also matching egress [ACL \(Access Control List\)](#) counters will cause the VLAN statistics Tx counter to not increment.

## Guidelines and Limitations

The following describes guidelines for this feature.

- Support for VMAN statistics are provided in the same manner as [VLAN](#) statistics. CLI commands use the same syntax as used with monitoring VLANs including the use of the `vlan` keyword in CLI commands. [SNMP](#) access uses the same MIB objects as used for VLAN statistics.

Statistics for VLANs encapsulated within VMANs are not supported.

- ExtremeSwitching series switches provide support only for byte counters.
- All of the counters supported are 64 bit counters. No indication of counter rollover is supported.
- Packets originating from the switch's CPU or forwarded by the CPU may not be reflected in transmit statistics.

## Performing Switch Diagnostics

The switch provides a facility for running normal or extended diagnostics.

In simple terms, a normal routine performs a simple ASIC and packet loopback test on all ports, and an extended routine performs extensive ASIC, ASIC-memory, and packet loopback tests. By running and viewing the results from diagnostic tests, you can detect and troubleshoot any hardware issues.

On ExtremeSwitching series switches, you run the diagnostic routine on the switch or on the stacking ports. Running the switch or stacking port diagnostic routine affects system operation; the switch is unavailable during the diagnostic test.

**Note**

Before running diagnostics, you must power on the External Power Supply (EPS) when it is connected to the switch.

When you run diagnostics, the switch verifies that the:

- Registers can be written to and read from correctly.
- Memory addresses are accessed correctly.
- Application-Specific Integrated Circuit (ASICs) and Central Processing Unit (CPUs) operate as required.
- External ports can send and receive packets.
- Sensors, hardware controllers, and LEDs are working correctly.

When you run diagnostics on the SummitStack stacking ports, the switch completes a hardware test to ensure that the stacking ports are operational.

**Note**

No ExtremeSwitching Universal switches include the diagnostic image in the main ExtremeXOS core software image (.xos). Instead, they have a separate diagnostic image that is upgraded using an XMOD file. For information about how to install an XMOD file, see [Installing a Modular Software Package](#) on page 1646.

## Running Diagnostics

If you run the diagnostic routine, the switch reboots and then performs the diagnostic test.

During the test, traffic to and from the ports on the switch is temporarily unavailable. When the diagnostic test is complete, the switch reboots and becomes operational again.

To run the diagnostic routine on the stack ports, you need a dedicated stacking cable that connects stack port 1 to stack port 2, which are located at the rear of the switch. The stacking cable is available from Extreme Networks. The switch performs a hardware test to confirm that the stack ports are operational; traffic to and from the ports on the switch is temporarily unavailable. This Bit Error Rate Test (BERT) provides an analysis of the number of bits transmitted in error.

After the switch runs the diagnostic routine, test results saved to the switch's EEPROM and messages are logged to the syslog.

- Run diagnostics with the following command:  

```
run diagnostics [extended | normal | stack-port] {slot [slot | A | B]}
```

Where the following is true:

extended—Reboots the switch and performs extensive ASIC, ASIC-memory, and packet loopback tests. Extended diagnostic tests take a maximum of five minutes. The CPU is not tested.

- normal—Reboots the switch and performs a simple ASIC and packet loopback test on all ports.
- stack-port—Performs a BERT on the stacking ports and reboots the switch.

## LED Behavior During Diagnostic Testing

Table 153 describes the LED behavior during a diagnostic test.

**Table 153: ExtremeSwitching Switch LED Behavior**

| LED  | Color          | Indicates                      |
|------|----------------|--------------------------------|
| MGMT | Green blinking | Normal operation is occurring. |
|      | Amber blinking | Diagnostic test in progress.   |

While diagnostic tests are running, the MGMT LED blinks amber. If a diagnostic test fails, the MGMT LED continues to blink amber. During normal operation, the MGMT LED blinks green.

## Displaying Diagnostic Test Results

- Display the status of the last diagnostic test run on the switch.

```
show diagnostics {slot [slot_number]} {boot-time}
```

*Example*

The following example displays the results of boot-time diagnostics on a specific stack slot:

```
show diagnostics slot 2 boot-time

Slot-2: 5520-48SE-ACDC
Time: Thu May 23 19:04:11 2024

Component Result Details
=====
CPU PASS
Memory PASS
Storage PASS
Power PASS PSU-1: Powered On, PSU-2: Empty
Mgmt interface PASS Mgmt interface present, Link Up
```

## Using the System Health Checker

The system health checker is a useful tool to monitor the overall health of your system.

The software performs a proactive, preventive search for problems by polling and reporting the health of system components, including power supplies, power supply controllers, and fans. By isolating faults to a specific module, backplane connection,

control plane, or component, the system health checker notifies you of a possible hardware fault.

The system health checker polls and reads the switch fabric and CPU registers.

Polling is always enabled on the system and occurs in the background every 10 seconds; the polling value is not a user-configured parameter.

System health check errors are reported to the Syslog. If you see an error, contact Extreme Networks Technical Support (see [Help and Support](#)). There are no health checking tests related to the stacking links in a SummitStack.

To display the system health check setting, including polling and how ExtremeXOS software handles faults on the switch, use the command: `show switch`

The system health check setting, displayed as SysHealth check, shows the polling setting and how ExtremeXOS handles faults. The polling setting appears as Enabled, and the fault handling setting appears in parenthesis next to the polling setting.

---

## Using ELSM

Extreme Link Status Monitoring (ELSM) is an Extreme Networks proprietary protocol that monitors network health by detecting CPU and remote link failures.

ELSM is available only on Extreme Networks devices and operates on a point-to-point basis. You can configure ELSM on the ports that connect to other network devices and on both sides of the peer connection.

## About ELSM

ELSM monitors network health by exchanging various hello messages between two ELSM peers.

ELSM uses an open-ended protocol, which means that an ELSM-enabled port expects to send and receive hello messages from its peer. The Layer 2 connection between ports determines the peer connection. Peers can be either directly connected or separated by one or more hubs. If there is a direct connection between peers, they are considered neighbors.

If ELSM detects a failure, the ELSM-enabled port responds by blocking traffic on that port. For example, if a peer stops receiving messages from its peer, ELSM brings down that connection by blocking all incoming and outgoing data traffic on the port and notifying applications that the link is down.

In some situations, a software or hardware fault may prevent the CPU from transmitting or receiving packets, thereby leading to the sudden failure of the CPU. If the CPU is unable to process or send packets, ELSM isolates the connections to the faulty switch from the rest of the network. If the switch fabric sends packets during a CPU failure, the switch may appear healthy when it is not. For example, if hardware forwarding is active and software forwarding experiences a failure, traffic forwarding may continue. Such failures can trigger control protocols such as *ESRP (Extreme*

*Standby Router Protocol*) or *EAPS (Extreme Automatic Protection Switching)* to select different devices to resume forwarding. This recovery action, combined with the CPU failure, can lead to loops in a Layer 2 network.

## ELSM Hello Messages

ELSM uses two types of hello messages to communicate the health of the network to other ELSM ports. The following describes the hello messages:

- Hello+ — The ELSM-enabled port receives a hello message from its peer and no problem is detected.
- Hello- — The ELSM-enabled port has not received a hello message from its peer.

In addition to the ELSM port states described in the next section, ELSM has hello transmit states. The hello transmit states display the current state of transmitted ELSM hello messages and can be one of the following:

- HelloRx(+)—The ELSM-enabled port is up and receives Hello+ messages from its peer. The port remains in the HelloRx+ state and restarts the HelloRx timer each time it receives a Hello+ message. If the HelloRx timer expires, the hello transmit state enters HelloRx(-). The HelloRx timer is 6 \* hello timer, which by default is 6 seconds.
- HelloRx(-)—The ELSM-enabled port either transitions from the initial ELSM state or is up but has not received hello messages because there is a problem with the link or the peer is missing.

For information about displaying ELSM hello messages and hello transmit states, see [Displaying ELSM Information](#) on page 1680.

## ELSM Port States

Each ELSM-enabled port exists in one of the following states:

- Up—Indicates a healthy remote system and this port is receiving Hello+ messages from its peer.

If an ELSM-enabled port enters the Up state, the up timer begins. Each time the port receives a Hello+ message from its peer, the up timer restarts and the port remains in the Up state. The up timer is 6 \* hello timer, which by default is 6 seconds.

- Down—Indicates that the port is down, blocked, or has not received Hello+ messages from its peer.

If an ELSM-enabled port does not receive a hello message from its peer before the up timer expires, the port transitions to the Down state. When ELSM is down, data packets are neither forwarded nor transmitted out of that port.

- Down-Wait—Indicates a transitional state.

If the port enters the Down state and later receives a Hello+ message from its peer, the port enters the Down-Wait state. If the number of Hello+ messages received is greater than or equal to the hold threshold (by default, two messages), the port

transitions to the Up state. If the number of Hello+ messages received is less than the hold threshold, the port enters the Down state.

- Down-Stuck—Indicates that the port is down and requires user intervention.

If the port repeatedly flaps between the Up and Down states, the port enters the Down-Stuck state. Depending on your configuration, there are two ways for a port to transition out of this state:

By default, automatic restart is enabled, and the port automatically transitions out of this state. For more information, see the `enable elsm ports port_list auto-restart` command.

If you disabled automatic restart, and the port enters the Down-Stuck state, you can clear the stuck state and enter the Down state by using one of the following commands:

- `clear elsm ports port_list auto-restart`
- `enable elsm ports port_list auto-restart`

#### Note

If you reboot the peer switch, its ELSM-enabled peer port may enter the Down-Stuck state. If this occurs, clear the stuck state using one of the following commands:

- `clear elsm ports port_list auto-restart`
- `enable elsm ports port_list auto-restart`

For information about displaying ELSM port states, see [Displaying ELSM Information](#) on page 1680.

## Link States

The state of the link between ELSM-enabled (peer) ports is known as the *link state*. The link state can be one of the following:

- Ready—Indicates that the port is enabled but there is no physical link
- Active—Indicates that the port is enabled and the physical link is up
- View the state of the link between the peer ports using the commands:

```
show elsm ports all | port_list
show ports {port_list} information {detail}
```

If you use the `show elsm ports all | port_list` command, the Link State row displays link state information.

If you use the `show ports {port_list} information` command, the Link State column displays link state information.

If you use the `show ports {port_list} information` command and specify the detail option, the ELSM Link State row displays ELSM link state information. For more information, see [ELSM Link States](#) on page 1675.

For more information about these show commands, see [Displaying ELSM Information](#) on page 1680.

## ELSM Link States

The state of the ELSM logical link is known as the ELSM link state. The ELSM link state can be one of the following:

- ELSM is enabled and the ELSM peer ports are up and communicating
- ELSM is enabled but the ELSM peer ports are not up or communicating
- ELSM is disabled
- View the current state of ELSM on the switch using the commands:

- `show elsm`

```
show elsm ports all | port_list
```

```
show ports {port_list} information {detail}
```

If you use the `show elsm` commands, the following terms display the ELSM link state:

- Up—Indicates that ELSM is enabled and the ELSM peer ports are up and communicating; the ELSM link state is up. In the up state, the ELSM-enabled port sends and receives hello messages from its peer.
- Down—Indicates that ELSM is enabled, but the ELSM peers are not communicating; the ELSM link state is down. In the down state, ELSM transitions the peer port on this device to the down state. ELSM blocks all incoming and outgoing switching traffic and all control traffic except ELSM PDUs.

If ELSM is disabled, the switch does not display any information.

If you use the `show ports {port_list} information {detail}` command, the following columns display the current state of ELSM on the switch:

- Flags
  - L—Indicates that ELSM is enabled on the switch
  - - —Indicates that ELSM is disabled on the switch
- ELSM
  - up—Indicates that ELSM is enabled and the ELSM peer ports are up and communicating; the ELSM link state is up. In the up state, the ELSM-enabled port sends and receives hello messages from its peer.
  - dn—Indicates that ELSM is enabled, but the ELSM peers are not communicating; the ELSM link state is down. In the down state, ELSM transitions the peer port on this device to the down state. ELSM blocks all incoming and outgoing switching traffic and all control traffic except ELSM PDUs.
  - - —Indicates that ELSM is disabled on the switch.

If you specify the optional detail parameter, the following ELSM output is called out in written explanations versus displayed in a tabular format:

- ELSM Link State (displayed only if ELSM is enabled on the switch)
  - Up—Indicates that ELSM is enabled and the ELSM peer ports are up and communicating; the ELSM link state is up. In the up state, the ELSM-enabled port sends and receives hello messages from its peer.
  - Down—Indicates that ELSM is enabled, but the ELSM peers are not communicating; the ELSM link state is down. In the down state, ELSM transitions the peer port on this device to the down state. ELSM blocks all incoming and outgoing switching traffic and all control traffic except ELSM PDUs.
- ELSM
  - Enabled—Indicates that ELSM is enabled on the switch
  - Disabled—Indicates that ELSM is disabled on the switch

For more information about these show commands, see [Displaying ELSM Information](#) on page 1680.

## ELSM Timers

To determine whether there is a CPU or link failure, ELSM requires timer expiration between the ELSM peers. Depending on the health of the network, the port enters different states when the timers expire. For more information about the ELSM port states, see [ELSM Port States](#) on page 1673.

Table 154 describes the ELSM timers. Only the hello timer is user-configurable; all other timers are derived from the hello timer. This means that when you modify the hello timer, you also modify the values for down, up, and HelloRx timers.

**Table 154: ELSM Timers**

| Timer   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hello   | The ELSM hello timer is the only user-configurable timer and specifies the time in seconds between consecutive hello messages. The default value is 1 second, and the range is 100 milliseconds to 255 seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Down    | <p>The ELSM down timer specifies the time it takes the ELSM port to cycle through the following states:</p> <ul style="list-style-type: none"> <li>Down—Indicates that the port is down, blocked, or has not received Hello+ messages from its peer.</li> <li>Down-Wait—Indicates a transitional state.</li> <li>Up—Indicates a healthy remote system and this port is receiving Hello+ messages from its peer.</li> </ul> <p>By default, the down timer is <math>(2 + \text{hold threshold}) * \text{hello timer}</math>, which is 4 seconds. If the hold threshold is set to 2 and the hello timer is set to 1 second, it takes 4 seconds for the ELSM port receiving messages to cycle through the states.</p> <p>After the down timer expires, the port checks the number of Hello+ messages against the hold threshold. If the number of Hello+ messages received is greater than or equal to the configured hold threshold, the ELSM receive port moves from the Down-Wait state to the Up state.</p> <p>If the number of Hello+ messages received is less than the configured hold threshold, the ELSM receive port moves from the Down-Wait state back to the Down state and begins the process again.</p> |
| Up      | <p>The ELSM up timer begins when the ELSM-enabled port enters the UP state. Each time the port receives a Hello+ message, the timer restarts.</p> <p>Up timer is the UpTimer threshold * hello timer. It is configurable and the range is 3 to 60 seconds.</p> <p>By default, the UpTimer threshold is 6. Therefore, the default up timer is 6 seconds <math>(6 * 1)</math>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| HelloRx | <p>The ELSM HelloRx timer specifies the time in which a hello message is expected. If the port does not receive a hello message from its peer, there is the possibility of a CPU or link failure.</p> <p>By default the HelloRx timer <math>6 * \text{hello timer}</math>, which is 6 seconds.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Configuring ELSM on a Switch

This section describes the commands used to configure ELSM on the switch.

### Note

ELSM and mirroring are mutually exclusive. You can enable either ELSM, or mirroring, but not both.

### Note

ELSM is not to be configured on ports at either end of an MLAG.

### Enabling ELSM

ELSM works between two connected ports (peers), and each ELSM instance is based on a single port. The Layer 2 connection between the ports determines the peer. You can have a direct connection between the peers or hubs that separate peer ports. In the first instance, the peers are also considered neighbors. In the second instance, the peer is not considered a neighbor.

- Enable ELSM on one or more ports with the command:

```
enable elsm ports port_list
```

When you enable ELSM on a port, ELSM immediately blocks the port and it enters the Down state. When the port detects an ELSM-enabled peer, the peer ports exchange ELSM hello messages. At this point, the ports enter the transitional Down-Wait state. If the port receives Hello+ messages from its peer and does not detect a problem, the peers enter the Up state. If a peer detects a problem or there is no peer port configured, the port enters the Down state.

For more information about the types of ELSM hello messages, see [ELSM Hello Messages](#) on page 1673. For information about configuring the ELSM hello timer, see the next section.

### Configuring the ELSM Hello Timer

The ELSM hello timer is the only user-configurable timer and specifies the time in seconds between consecutive hello messages. The default value is 1 second, and the range is 1 to 128 seconds. Although other timers rely on the hold timer for their values, you do not explicitly configure the down, up, or HelloRx timers. If you modify the hello timer on one port, we recommend that you use the same hello timer value on its peer port.

A high hello timer value can increase the time it takes for the ELSM-enabled port to enter the Up state. The down timer is  $(2 + \text{hold threshold}) * \text{hello timer}$ . Assuming the default value of 2 for the hold threshold, configuring a hello timer of 128 seconds creates a down timer of  $(2 + 2) * 128$ , or 512 seconds. In this scenario it would take 512 seconds for the port to transition from the Down to the Up state.

- Configure the ELSM hello timer with the command:

```
configure elsm ports port_list hellotime hello_time
```

### Configuring the ELSM Hold Threshold

The ELSM hold threshold determines the number of Hello+ messages the ELSM peer port must receive to transition from the Down-Wait state to the Up state. For example, a threshold of 1 means the ELSM port must receive at least one Hello+ message to transition from the Down-Wait state to the Up state. The default is two messages, and the range is one to three messages.

After the down timer expires, the port checks the number of Hello+ messages against the hold threshold. If the number of Hello+ messages received is greater than or equal to the configured hold threshold, the ELSM receive port moves from the Down-Wait state to the Up state.

If the number of Hello+ messages received is less than the configured hold threshold, the ELSM receive port moves from the Down-Wait state back to the Down state and begins the process again.

If you modify the hold threshold on one port, we recommend that you use the same hold threshold value on its peer port.

You must configure the hold threshold on a per-port basis, not on a per-switch basis.

- Configure the ELSM hold threshold with the command:

```
configure elsm ports port_list hold-threshold hold_threshold
```

### *Configure Automatic Restart*

You must explicitly configure automatic restart on each ELSM-enabled port; this is not a global configuration. By default, ELSM automatic restart is enabled. If an ELSM-enabled port goes down, ELSM bypasses the Down-Stuck state and automatically transitions the down port to the Down state, regardless of the number of times the port goes up and down. For information about the port states, see [ELSM Port States](#) on page 1673.

If you disable ELSM automatic restart, the ELSM-enabled port can transition between the following states multiple times: Up, Down, and Down-Wait. When the number of state transitions is greater than or equal to the sticky threshold, the port enters the Down-Stuck state. The ELSM sticky threshold specifies the number of times a port can transition between the Up and Down states. The sticky threshold is not user-configurable and has a default value of 1. That means a port can transition only one time from the Up state to the Down state. If the port attempts a subsequent transition from the Up state to the Down state, the port enters the Down-Stuck state.

The following user events clear or re-set the sticky threshold:

- Enabling automatic restart on the port using the following command:  

```
enable elsm ports port_list auto-restart
```
- Clearing the port that is in the Down-Stuck state using the following command:  

```
clear elsm ports port_list auto-restart
```
- Disabling and re-enabling the port using the following commands:
  - ```
disable ports [port_list|all]
```
 - ```
enable ports [port_list|all]
```
- Disabling ELSM on the port using the following command:  

```
disable elsm ports port_list
```

We recommend that you use the same automatic restart configuration on each peer port.

- If the port enters the Down-Stuck state, you can clear the stuck state and enter the Down state by using one of the following commands:

```
clear elsm ports port_list auto-restart
enable elsm ports port_list auto-restart
```

If you use the `enable elsm ports port_list auto-restart` command, automatic restart is always enabled; you do not have to use the `clear elsm ports port_list auto-restart` command to clear the stuck state.

- Disable automatic restart with the command:  
`disable elsm ports port_list auto-restart`
- Re-enable automatic restart with the command:  
`enable elsm ports port_list auto-restart`

We recommend that you use the same automatic restart configuration on each peer port.

### Disabling ELSM

- Disable ELSM on one or more ports with the command:  
`disable elsm ports port_list`

When you disable ELSM on the specified ports, the ports no longer send ELSM hello messages to their peers and no longer maintain ELSM states.

## Displaying ELSM Information

- Display summary information for all of the ELSM-enabled ports on the switch with the command:

```
show elsm
```

This command displays in a tabular format the operational state of ELSM on the configured ports.

If ports are configured for ELSM (ELSM is enabled), the switch displays the following information:

- Port—The port number of the ELSM-enabled port.
- ELSM State—The current state of ELSM on the port. For information about the port states, see [ELSM Port States](#) on page 1673.
- Hello time—The current value of the hello timer, which by default is 1 second. For information about configuring the hello timer, see [Configuring the ELSM Hello Timer](#) on page 1678.

If no ports are configured for ELSM (ELSM is disabled), the switch does not display any information.

- Display detailed information for one or more ELSM-enabled ports on the switch.  
`show elsm ports all | port_list`

In addition to the port, ELSM state, and hello timer information, this command displays in a tabular format the following:

- Link State—The state of the link between ELSM-enabled ports. For information about the link states, see [Link States](#) on page 1674.
- ELSM Link State—The current state of the ELSM logical link on the switch. For more information, see [ELSM Link States](#) on page 1675.

- Hello Transmit State—The current state of ELSM hello messages being transmitted.
- Hold Threshold—The number of Hello+ messages required by the ELSM-enabled port to transition from the Down-Wait state to the Up state within the hold threshold.
- UpTimer Threshold—The number of hello times that span without receiving Hello+ packets before a port changes its ELSM state from Up to Down.
- Auto Restart—The current state of ELSM automatic restart on the port.
- Sticky Threshold—The number of times a port can transition between the Up and Down states. The sticky threshold is not user-configurable and has a default value of 1.
- Sticky Threshold Counter—The number of times the port transitions from the Up state to the Down state.
- Down Timeout—The actual waiting time (msecs or secs) before a port changes its ELSM state from Down to Up after receiving the first Hello+ packet. It is equal to  $[\text{Hello Time} * (\text{Hold Threshold} + 2)]$ .
- Up Timeout—The actual waiting time (msecs or secs) before a port changes its ELSM state from Up to Down after receiving the last Hello+ packets. It is equal to  $[\text{Hello Time} * \text{UpTimer Threshold}]$ .

The remaining output displays counter information.

- Use the counter information to determine the health of the ELSM peers and how often ELSM has gone up or down.

The counters are cumulative.

- Rx Hello+—The number of Hello+ messages received by the port.
- Rx Hello- —The number of Hello- messages received by the port.
- Tx Hello+—The number of Hello+ messages sent by the port.
- Tx Hello- —The number of Hello- messages sent by the port.
- ELSM Up/Down Count—The number of times ELSM has been up or down.
- Display summary port information in a tabular format for one or more ELSM-enabled ports with the command:

```
show ports {port_list} information {detail}
```

This command displays the following ELSM information:

- Flags
  - L—ELSM is enabled on the switch
  - - —ELSM is disabled on the switch
- ELSM (For more information, see [ELSM Link States](#) on page 1675.)
  - up—ELSM is enabled and the ELSM link state is up.
  - dn—ELSM is enabled and the ELSM link state is down.
  - - —ELSM is disabled on the switch.
- Display summary port information called out in written explanations versus displayed in a tabular format, use the detail parameter.

```
show ports {port_list} information {detail}
```

This command displays the following ELSM information:

- ELSM Link State (displayed only if ELSM is enabled on the switch). For more information, see [ELSM Link States](#) on page 1675.
  - Up—ELSM is enabled and the ELSM link state is up.
  - Down—ELSM is enabled and the ELSM link state is down.
- Link State—The state of the link between ELSM-enabled ports. For information about the link states, see [Link States](#) on page 1674.
- ELSM
  - Enabled—ELSM is enabled on the switch.
  - Disabled—ELSM is disabled on the switch.

### Clearing ELSM Counters

Before clearing the ELSM counters, you should use the `show elsm` and `show elsm ports` commands to view the ELSM information.

- Clear only the ELSM-related counters gathered by the switch using the command:

```
clear elsm {ports port_list} counters
```

You can also use the `clear counters` command, which clears all of the counters on the device, including those associated with ELSM.

## Using ELSM with Layer 2 Control Protocols

You can use ELSM with Layer 2 control protocols such as *STP (Spanning Tree Protocol)*, *ESRP*, *EAPS*, and so on to improve the recovery of Layer 2 loops in the network.

ELSM detects remote link failures if the established link is through a Layer 2 transport cloud and the ELSM endpoints traverse the Layer 2 cloud in a point-to-point fashion, as shown in [Figure 200](#) on page 1682.

**Figure 200: ELSM Through a Layer 2 Cloud**

A sudden failure of the switch CPU may cause the hardware to continue forwarding traffic. For example, ESRP may select a second device for forwarding traffic thereby creating a Layer 2 loop in the network. If you configure ELSM and the CPU fails, ELSM closes the connection to the faulty device to prevent a loop.

## ELSM Configuration Example

The following example configures ELSM on two ports connected directly to each other and assumes the following:

### Note

In the following sample configurations, any lines marked (Default) represent default settings and do not need to be explicitly configured.

#### Switch A Configuration

- ELSM-enabled port—Port 1
- Hello timer—2 seconds
- Hello threshold—2 hello messages

```
enable elsm ports 1
configure elsm ports 1 hellotime 2
configure elsm ports 1 hold-threshold 2 (Default)
```

#### Switch B Configuration

- ELSM-enabled port—Slot 2, port 1
- Hello timer—2 seconds
- Hello threshold—2 hello messages

```
enable elsm ports 2:1
configure elsm ports 2:1 hellotime 2
configure elsm ports 2:1 hold-threshold 2 (Default)
```

After you enable ELSM on the ports, the peers exchange hello messages with each other as displayed in [Figure 201](#).

**Figure 201: Extreme Networks Switches with ELSM-Enabled Ports Exchanging Hello Messages**

To configure ELSM with *LAG (Link Aggregation Group)*, enable ELSM on each port member of the LAG, as shown in the following example:

```
enable sharing 7 grouping 7-9, 41 algorithm address-based L2
enable elsm port 7
enable elsm port 8
enable elsm port 9
enable elsm port 41

sh elsm
Port ELSM State Hello Time
==== =====
7 Up 1 (secs)
8 Down 1 (secs)
9 Down 1 (secs)
41 Up 1 (secs)
```

## Viewing Fan Information

You can view detailed information about the fans installed in your switch. Depending on your switch model, different information may be displayed.

- View detailed information about the health of the fans with the command: `show fans`

The switch collects and displays the following fan information:

- State—The current state of the fan. Options are:
  - Empty: There is no fan installed.
  - Failed: The fan failed.
  - Operational: The fan is installed and working normally.
- NumFan—The number of fans in the fan tray.
- Fan Name, displayed as Fan-1, Fan-2, and so on—Specifies the individual state for each fan in a fan tray and its current speed in revolutions per minute (rpm).

## Viewing the System Temperature

Depending on your switch model, you can view the temperature in Celsius for the power controllers, power supplies, and fan trays installed in your switch. In addition, depending on the software version running on your switch, additional or different temperature information might be displayed, such as the inlet air temperature of a switch using an Extreme-supplied USB dongle temperature sensor for version 33.3.1 and later.

You can view the system temperature with the command: `show temperature`

## System Temperature Output

### *SummitStack*

The following output shows a sample display from a SummitStack.

```
Slot-3 Stack.1 # show temperature
Field Replaceable Units Temp (C) Status Min Normal Max

Slot-1 :
Slot-2 : SummitX 34.50 Normal -10 0-54 59
Slot-3 : SummitX 36.50 Normal -10 0-66 67
Slot-4 :
Slot-5 :
Slot-6 :
Slot-7 :
Slot-8 :
Slot-3 Stack.2 #
```

### ExtremeSwitching Switches Only

On ExtremeSwitching series switches, the output includes the current temperature, operating status of the switch, and inlet air temperature. The following shows a sample display from a switch:

```
show temperature
Field Replaceable Units Temp (C) Status Min
Normal Max

Switch : 5520-24W 68.38 Normal 0
10-100 110
Switch : Inlet Air 21.50
```

The switch monitors its temperature and generates a warning if the temperature exceeds the normal operating range. If the temperature exceeds the maximum limit, the `show switch` output indicates the switch in an OPERATIONAL (Overheat) mode, and the `show temperature` output indicates an error state due to overheat.

For the inlet air temperature readings, for switch models that support two USB ports, the sensor works in either port, but only one sensor will work at a time if two are plugged in. If two are installed and one is removed, the second one must be re-seated for the kernel/operating system to detect and use it.

## Using the Event Management System/Logging

We use the general term *event* for any type of occurrence on a switch that could generate a log message or require an action.

For example, a link going down, a user logging in, a command entered on the command line, or the software executing a debugging statement, are all events that might generate a log message. The system for saving, displaying, and filtering events is called the EMS. With EMS, you have many options about which events generate log messages, where the messages are sent, and how they are displayed.

Using EMS you can:

- Send event messages to a number of logging targets (for example, syslog host and NVRAM).
- Filter events per target, by:
  - Component, subcomponent, or specific condition (for example, *BGP (Border Gateway Protocol)* messages, *IGMP (Internet Group Management Protocol)*, Snooping messages, or the IP.Forwarding.SlowPathDrop condition).
  - Match expression (for example, any messages containing the string “user 5”).
  - Matching parameters (for example, only messages with source IP addresses in the 10.1.2.0/24 subnet).
  - Severity level (for example, only messages of severity critical, error, or warning).
- Change the format of event messages (for example, display the date as “12-May-2005” or “2005-05-12”).
- Display log messages in real time and filter the messages that are displayed, both on the console and from Telnet sessions.

- Display stored log messages from the memory buffer or NVRAM.
- Upload event logs stored in memory buffer or NVRAM to a TFTP server.
- Display counts of event occurrences, even those not included in filter.
- Display debug information using a consistent configuration method.

EMS supports IPv6 as a parameter for filtering events.

## Sending Event Messages to Log Targets

You can specify seven types of targets to receive log messages:

- Console display
- Current session (Telnet or console display)
- Memory buffer (can contain 200 to 20,000 messages)
- NVRAM (messages remain after reboot)
- Primary node (for SummitStack)
- Backup node (for SummitStack)
- Syslog server, supports IPv6 address family as of ExtremeXOS 21.1

The first six targets exist by default; but before enabling any syslog host, you must add the host's information to the switch using the `configure syslog` command.

By default, the memory buffer and NVRAM targets are already enabled and receive messages.

- To start sending messages to the targets, use the following command:

```
enable log target [console | memory-buffer | nvram | primary-
node|backup-node| session | syslog [all | ipaddress udp-port
{udp_port} | ipPort | ipaddress tls_port {tls_port}] {vr vr_name}
{local0...local7}]]
```

After you enable this feature, the target receives the messages for which it is configured. See [Target Configuration](#) on page 1687 for information on viewing the current configuration of a target. The memory buffer can contain only the configured number of messages, so the oldest message is lost when a new message arrives, when the buffer is full.

- To stop sending messages to the target, use the following command:

```
disable log target [console | memory-buffer | nvram |primary-node |
backup-node | session | syslog [all | ipaddress udp-port {udp_port}
| ipPort | ipaddress tls_port {tls_port}] {vr vr_name} {local0 ...
local7}]]
```

Refer to your UNIX documentation for more information about the syslog host facility.

### *Primary and Backup Systems—SummitStack Only*

A system with primary and backup nodes (SummitStack) keeps the two systems synchronized by executing the same commands on both.

However, the full data between the EMS servers is not synchronized. The reason for this design decision is to make sure that the control channel is not overloaded when a high number of log messages are generated.

To capture events generated by the primary node onto the backup node, two additional targets are shown in the target commands—one called `primary-node` and one called `backup-node`. The first target is active only on the non-primary (backup) EMS server and is used to send matching events to the primary EMS server. The other target is active only on the primary EMS server and is used to send matching events to all other EMS servers.

If the condition for the backup target is met by a message generated on the primary node, the event is sent to the backup node. When the backup node receives the event, it detects if any of the local targets (NVRAM, memory, or console) are matched. If so that event gets processed. The session and Syslog targets are disabled on the backup node, as they are handled on the primary. If the condition for the primary target is met by a message generated on the backup, the event is sent to the primary node.

Note that the backup target is active only on the primary node, and the primary target is active only on the backup node.

## Filtering Events Sent to Targets

Not all event messages are sent to every enabled target. Each target receives only the messages for which it is configured.

### Target Configuration

To specify the messages to send to an enabled target, you can set a message severity level, a filter name, and a match expression. These items determine which messages are sent to the target. You can also configure the format of the messages in the targets. For example, the console display target is configured to get messages of severity info and greater, the NVRAM target gets messages of severity warning and greater, and the memory buffer target gets messages of severity debug-data and greater. All the targets are associated by default with a filter named `DefaultFilter` that passes all events at or above the default severity threshold. All the targets are also associated with a default match expression that matches any messages (the expression that matches any message is displayed as `Match : (none)` from the command line). And finally, each target has a format associated with it.

- To display the current log configuration of the targets, use the following command:

```
show log configuration target {console | memory-buffer | nvram |
primary-node | backup-node | session | syslog {ipaddress {udp-port
{udp_port }} | ipPort | ipaddress tls-port {tls_port}} {vr vr_name}
{[local0...local7]}}
```

- To configure a target, you use specific commands for severity, filters, and formats, use the following command:

```
configure log target [console | memory-buffer | nvram |primary-
node |backup-node | session | syslog [all | ipaddress {udp-port
{udp_port}} | ipPort | ipaddress tls-port {tls_port}] {vr vr_name}
{local0...local7 }] {severity severity {only}}
```

In addition, you can configure the source IP address for a syslog target. Configuring the source IP address allows the management station or syslog server to identify from which switch it received the log messages.

- To configure the source IP address for a syslog target, use the following command.  

```
configure log target syslog [all | ipaddress {udp-port {udp_port}} | ipPort | ipaddress tls-port {tls_port}] {vr vr_name} {local0...local7} from source-ip-address
```

#### Note

The address family (i.e IPv4 or IPv6) of the specified source IP address must be the same as the address family of the syslog server.

## Severity

Messages are issued with one of the following severity levels: Critical, Error, Warning, Notice, Info, Debug-Summary, Debug-Verbose, or Debug-Data, which are described in [Table 155](#).

When a message is sent to a syslog target, the severity is mapped to a corresponding syslog priority value (see RFC 3164).

The three severity levels for extended debugging—Debug-Summary, Debug-Verbose, and Debug-Data—require that log debug mode be enabled (which may cause a performance degradation).

See [Displaying Debug Information](#) on page 1700 for more information about debugging.

**Table 155: Severity Levels Assigned by the Switch**

| Level                   | Description                                                                                                                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Critical                | A serious problem has been detected that is compromising the operation of the system; the system cannot function as expected unless the situation is remedied. The switch may need to be reset.          |
| Error                   | A problem has been detected that is interfering with the normal operation of the system; the system is not functioning as expected.                                                                      |
| Warning                 | An abnormal condition, not interfering with the normal operation of the system, has been detected that indicate that the system or the network in general may not be functioning as expected.            |
| Notice                  | A normal but significant condition has been detected, which signals that the system is functioning as expected.                                                                                          |
| Info<br>(Informational) | A normal but potentially interesting condition has been detected, which signals that the system is functioning as expected; this level simply provides potentially detailed information or confirmation. |
| Debug-Summary           | A condition has been detected that may interest a developer seeking the reason underlying some system behavior.                                                                                          |

**Table 155: Severity Levels Assigned by the Switch (continued)**

| Level         | Description                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Debug-Verbose | A condition has been detected that may interest a developer analyzing some system behavior at a more verbose level than provided by the debug summary information. |
| Debug-Data    | A condition has been detected that may interest a developer inspecting the data underlying some system behavior.                                                   |

### Configuring Severity Level

You can use more than one command to configure the severity level of the messages sent to a target.

- The most direct way to set the severity level of all the sent messages is to use the following command:

```
configure log target [console | memory-buffer | nvram | primary-
node | backup-node | session | syslog [all | ipaddress {udp-port
{udp_port}} | ipPort | ipaddress tls-port {tls_port}] {vr vr_name}
{local0...local7 }] {severity severity {only}}
```

When you specify a severity level, messages of that severity level and greater are sent to the target. If you want only those messages of the specified severity to be sent to the target, use the keyword **only**. For example, specifying severity warning will send warning, error, and critical messages to the target, but specifying severity warning only sends only warning messages.

- You can also use the following command to configure severity levels, which associate a filter with a target:

```
configure log target [console | memory-buffer | | primary-node | |
backup-node | nvram | session | syslog [all | ipaddress {udp-port
{udp_port}} | ipPort | ipaddress tls-port {tls_port}] {vr vr_name}
{local0...local7}] filter filter-name {severity severity {only}}
```

When you specify a severity level as you associate a filter with a target, you further restrict the messages reaching that target. The filter may allow only certain categories of messages to pass. Only the messages that pass the filter and then pass the specified severity level reach the target.

Finally, you can specify the severity levels of messages that reach the target by associating a filter with a target. The filter can specify exactly which message it will pass. Constructing a filter is described in [Filtering By Components and Conditions](#) on page 1691.

### Components and Conditions

The event conditions detected by ExtremeXOS are organized into components and subcomponents.

- To get a listing of the components and subcomponents in your release of ExtremeXOS, use the following command:

```
show log components {event component } {version}
```

For example, to get a list of the components and subcomponents in your system, use the following command: `show log components`

The following is partial output from this command:

| Severity<br>Component | Title                        | Threshold |
|-----------------------|------------------------------|-----------|
| ...                   |                              |           |
| ...                   |                              |           |
| STP                   | Spanning-Tree Protocol (STP) | Error     |
| InBPDU                | STP In BPDU subcomponent     | Warning   |
| OutBPDU               | STP Out BPDU subcomponent    | Warning   |
| System                | STP System subcomponent      | Error     |
| ...                   |                              |           |
| ...                   |                              |           |

The display above lists the components, subcomponents, and the severity threshold assigned to each. In EMS, you use a period (.) to separate component, subcomponent, and condition names. For example, you can refer to the InBPDU subcomponent of the *STP* component as STP.InBPDU. On the CLI, you can abbreviate or **[Tab]** complete any of these.

A component or subcomponent typically has several conditions associated with it.

- To see the conditions associated with a component, use the following command:  
`show log events [event condition | [all | event component] {severity severity {only}}] {details}`

For example, to see the conditions associated with the STP.InBPDU subcomponent, use the following command: `show log events stp.inbpdu`

The following is sample output from this command:

| Comp | SubComp | Condition | Severity      | Parameters |
|------|---------|-----------|---------------|------------|
| STP  | InBPDU  | Drop      | Error         | 2 total    |
| STP  | InBPDU  | Dump      | Debug-Data    | 3 total    |
| STP  | InBPDU  | Trace     | Debug-Verbose | 2 total    |
| STP  | InBPDU  | Ign       | Debug-Summary | 2 total    |
| STP  | InBPDU  | Mismatch  | Warning       | 2 total    |

The display above lists the five conditions contained in the STP.InBPDU component, the severity of the condition, and the number of parameters in the event message. In this example, the severities of the events in the STP.InBPDU subcomponent range from error to debug-summary.

When you use the **details** keyword, you see the message text associated with the conditions.

- For example, if you want to see the message text and the parameters for the event condition STP.InBPDU.Trace, use the following command: `show log events stp.inbpdu.trace details`

The following is sample output from this command:

| Comp                | SubComp | Condition | Severity      | Parameters |
|---------------------|---------|-----------|---------------|------------|
| STP                 | InBPDU  | Trace     | Debug-Verbose | 2 total    |
| 0 - string          |         |           |               |            |
| 1 - string (printf) |         |           |               |            |
| Port=%0%: %1%       |         |           |               |            |

The Comp heading shows the component name, the SubComp heading shows the subcomponent (if any), the Condition heading shows the event condition, the Severity heading shows the severity assigned to this condition, the Parameters heading shows the parameters for the condition, and the text string shows the message that the condition will generate. The parameters in the text string (for example, %0% and %1% above) will be replaced by the values of these parameters when the condition is encountered and displayed as the event message.

### Filtering By Components and Conditions

You may want to send the messages that come from a specific component that makes up ExtremeXOS or to send the message generated by a specific condition. For example, you might want to send only those messages that come from the *STP* component, or send the message that occurs when the IP.Forwarding.SlowPathDrop condition occurs. Or you may want to exclude messages from a particular component or event. To do this, you construct a filter that passes only the items of interest, and you associate that filter with a target.

1. The first step is to create the filter using the `create log filter` command.

You can create a filter from scratch, or copy another filter to use as a starting point. (It may be easiest to copy an existing filter and modify it.)

2. To create a filter, use the following command:

```
create log filter name {copy filter_name}
```

If you create a filter from scratch, that filter initially blocks all events until you add events (either the events from a component or a specific event condition) to pass. You might create a filter from scratch if you want to pass a small set of events and to block most events. If you want to exclude a small set of events, use the default filter that passes events at or above the default severity threshold (unless the filter has been modified), named DefaultFilter, that you can copy to use as a starting point for your filter.

3. After you create your filter, you configure filter items that include or exclude events from the filter.

Included events are passed; excluded events are blocked.

4. To configure your filter, use the following command:

```
configure log filter name [add | delete] {exclude} events [event-
condition | [all | event-component] {severity severity {only}}]
```

For example, if you create the filter myFilter from scratch, use the following command to include events:

```
configure log filter myFilter add events stp
```

All STP component events of at least the default threshold severity passes myFilter (for the STP component, the default severity threshold is error). You can further modify this filter by specifying additional conditions.

For example, assume that myFilter is configured as before, and assume that you want to exclude the STP.CreatPortMsgFail event.

5. To add that condition, use the following command:

```
configure log filter myFilter add exclude events stp.creatportmsgfail
```

6. You can also add events and subcomponents to the filter.

For example, assume that myFilter is configured as before, and you want to include the STP.InBPDU subcomponent. To add that condition, use the following command:

```
configure log filter myFilter add events stp.inbpdu
```

7. You can continue to modify this filter by adding more filter items.

The filters process events by comparing the event with the most recently configured filter item first. If the event matches this filter item, the incident is either included or excluded, depending on whether the exclude keyword was used. If necessary, subsequent filter items on the list are compared. If the list of filter items is exhausted with no match, the event is excluded and is blocked by the filter.

8. To view the configuration of a filter, use the following command:

```
show log configuration filter {filter_name}
```

The following is sample output from this command (for the earlier filter):

```
Log Filter Name: myFilter
I/
E Comp. Sub-comp. Condition Severity
- -
I STP InBPDU
E STP CreatPortMsgFail -E-----
I STP
Include/Exclude: I - Include, E - Exclude
Component Unreg: * - Component/Subcomponent is not currently registered
Severity Values: C - Critical, E - Error, W - Warning, N - Notice, I - Info
Debug Severity : S - Debug-Summary, V - Debug-Verbose, D - Debug-Data
+ - Debug Severities, but log debug-mode not enabled
If Match parameters present:
Parameter Flags: S - Source, D - Destination, (as applicable)
I - Ingress, E - Egress, B - BGP
Parameter Types: Port - Physical Port list, Slot - Physical Slot #
MAC - MAC address, IP - IP Address/netmask, Mask - Netmask
VID - Virtual LAN ID (tag), VLAN - Virtual LAN name
L4 - Layer-4 Port #, Num - Number, Str - String
Nbr - Neighbor, Rtr - Routerid, EAPS - EAPS Domain
Proc - Process Name
```

```
Strict Match : Y - every match parameter entered must be present in the event
N - match parameters need not be present in the event
```

The `show log configuration filter` command shows each filter item, in the order that it will be applied and whether it will be included or excluded. The above output shows the three filter items, one including events from the STP.InBPDU component, one excluding the event STP.CreatPortMsgFail, and the next including the remaining events from the STP component. The severity value is shown as "\*", indicating that the component's default severity threshold controls which messages are passed. The Parameter(s) heading is empty for this filter because no match is configured for this filter. Matches are described in [Matching Expressions](#) on page 1693.

Each time a filter item is added to or deleted from a given filter, the specified events are compared against the current configuration of the filter to try to logically simplify the configuration. Existing items will be replaced by logically simpler items if the new item enables rewriting the filter. If the new item is already included or excluded from the currently configured filter, the new item is not added to the filter.

### Matching Expressions

You can configure the switch so messages reaching the target match a specified match expression.

The message text is compared with the configured match expression to determine whether to pass the message on. To require that messages match a match expression, use the following command:

```
configure log target [console | memory-buffer | nvram | primary-node |
backp-node | session | syslog [all | ipaddress {udp-port {udp_port}}
| ipPort | ipaddress tls-port {tls_port}] {vr vr_name} {local0 ...
local17}] match [any |match-expression]
```

The messages reaching the target will match the match-expression, a simple regular expression. The formatted text string that makes up the message is compared with the match expression and is passed to the target if it matches. This command does not affect the filter in place for the target, so the match expression is compared only with the messages that have already passed the target's filter. For more information on controlling the format of the messages, see [Formatting Event Messages](#) on page 1696.

### Simple Regular Expressions

A simple regular expression is a string of single characters including the dot character (.), which are optionally combined with quantifiers and constraints. A dot matches any single character, while other characters match only themselves (case is significant). Quantifiers include the star character (\*) that matches zero or more occurrences of the immediately preceding token. Constraints include the caret character (^) that matches at the beginning of a message and the currency character (\$) that matches at the end of a message. Bracket expressions are not supported. There are a number of sources available on the Internet and in various language references describing the

operation of regular expressions. The following table shows some examples of regular expressions.

**Table 156: Simple Regular Expressions**

| Regular Expression | Matches                                                 | Does Not Match                                    |
|--------------------|---------------------------------------------------------|---------------------------------------------------|
| port               | port 2:3<br>import cars<br>portable structure           | poor<br>por<br>pot                                |
| ..ar               | baar<br>bazaar<br>rebar                                 | bar                                               |
| port.*vlan         | port 2:3 in vlan test<br>add ports to vlan<br>port/vlan |                                                   |
| myvlan\$           | delete myvlan<br>error in myvlan                        | myvlan port 2:3<br>ports 2:4,3:4 myvlan link down |

### Matching Parameters

Rather than using a text match, EMS allows you to filter more efficiently based on the parameter values of the message.

In addition to event components and conditions and severity levels, each filter item can also use parameter values to further limit which messages are passed or blocked. The process of creating, configuring, and using filters has already been described in [Filtering By Components and Conditions](#) on page 1691, so this section describes matching parameters with a filter item.

To configure a parameter match filter item, use the following command:

```
configure log filter name [add | delete] {exclude} events [event-
condition | [all | event-component] {severity severity {only}}] [match
| strict-match] type value
```

Each event in ExtremeXOS is defined with a message format and zero or more parameter types.

The `show log events` all command can be used to display event definitions (the event text and parameter types). Only those parameter types that are applicable given the events and severity specified are exposed on the CLI. The syntax for the parameter types (represented by *type* in the command syntax above) is:

```
[address-family [ipv4-multicast | ipv4-unicast | ipv6-multicast | ipv6-
unicast] | bgp-neighbor ip address | bgp-routerid ip address | eaps eaps
domain name | {destination | source} [ipaddress ip address | L4-port
L4-port | mac-address mac-address] | esrp esrp domain name | {egress |
ingress} [slot slot number | ports portlist] | ipaddress ip address |
L4-port L4-port | mac-address mac_address | netmask netmask | number
```

*number* | **port** *portlist* | **process** *process name* | **slot** *slotid* | **string** *exact string to be matched* | **vlan** *vlan name* | **vlan tag** *vlan tag*]

You can specify the `ipaddress` type as IPv4 or IPv6, depending on the IP version.

The following examples show how to configure IPv4 addresses and IPv6 addresses:

#### IPv4 address

- To configure an IP address, with a mask of 32 assumed, use the following command:  

```
configure log filter myFilter add events all match ipaddress 12.0.0.1
```
- To configure a range of IP addresses with a mask of 8, use the following command:  

```
configure log filter myFilter add events all match ipaddress 12.0.0.0/8
```

#### IPv6 address

- To configure an IPv6 address, with a mask of 128 assumed, use the following command:  

```
configure log filter myFilter add events all match ipaddress 3ffe::1
```
- To configure a range of IPv6 addresses with a mask of 16, use the following command:  

```
configure log filter myFilter add events all match ipaddress 3ffe::/16
```

#### IPv6 scoped address

- IPv6 scoped addresses consist of an IPv6 address and a VLAN. The following examples identify a link local IPv6 address.

To configure a scoped IPv6 address, with a mask of 128 assumed, use the following command:

```
configure log filter myFilter add events all match ipaddress fe80::1%Default
```

To configure a range of scoped IPv6 addresses with a mask of 16, use the following command:

```
configure log filter myFilter add events all match ipaddress fe80::/16%Default
```

To configure a scoped IPv6 address with any VLAN, use the following command:

```
configure log filter myFilter add events all match ipaddress fe80::/16%*
```

To configure any scoped IPv6 address with a specific VLAN, use the following command:

```
configure log filter myFilter add events all match ipaddress fe80::/0%Default
```

#### Note

In the previous example, if you specify the VLAN name, it must be a full match; wild cards are not allowed.

The *value* depends on the parameter type specified.

As an example, an event may contain a physical port number, a source MAC address, and a destination MAC address. To allow only those RADIUS (Remote Authentication

*Dial In User Service*) incidents, of severity notice and above, with a specific source MAC address, use the following command:

```
configure log filter myFilter add events aaa.radius.requestInit severity notice match
source mac-address 00:01:30:23:C1:00
```

The string type is used to match a specific string value of an event parameter, such as a user name. The exact string is matched with the given parameter and no regular expression is supported.

### Match Versus Strict-Match

The **match** and **strict-match** keywords control the filter behavior for those incidents with event definition that does not contain all the parameters specified in a `configure log filter events match` command.

This is best explained with an example. Suppose an event in the XYZ component, named XYZ.event5, contains a physical port number, a source MAC address, but no destination MAC address. If you configure a filter to match a source MAC address and a destination MAC address, XYZ.event5 will match the filter when the source MAC address matches regardless of the destination MAC address because the event contains no destination MAC address. If you specify the **strict-match** keyword, then the filter will never match event XYZ.event5 because this event does not contain the destination MAC address.

In other words, if the **match** keyword is specified, an incident will pass a filter so long as all parameter values in the incident match those in the match criteria, but all parameter types in the match criteria need not be present in the event definition.

### Formatting Event Messages

Event messages are made up of a number of items. The individual items can be formatted; however, EMS does not allow you to vary the order of the items.

- Format the messages for a particular target.

```
configure log target format
```

Using the default format for the session target, an example log message might appear as:

```
06/25/2004 22:49:10.63 <Info:dm.Info> MSM-A: PowerSupply:4 Powered On
```

If you set the current session format using the following command:

```
configure log target session format timestamp seconds date mm-dd-yyyy event-name
component
```

The same example would appear as:

```
06/25/2004 22:49:10 <dm> PowerSupply:4 Powered On
```

- Provide some detailed information to technical support, set the current session format.

```
configure log target session format timestamp hundredths date mmm-dd event-name
condition process-name source-line
```

The same example then appears as:

```
Jun 25 22:49:10.63 <dm.info> devmgr: (dm.c:134) PowerSupply:4 Powered On
```

## Displaying Real-Time Log Messages

You can configure the system to maintain a running real-time display of log messages on the console display or on a (Telnet) session.

- Turn on the log display on the console with the command:

```
enable log target console
```

This setting may be saved to the FLASH configuration and is restored on boot-up (to the console display session).

- Turn on log display for the current session with the command:

```
enable log target session
```

This setting only affects the current session and is lost when you log off the session.

The messages that are displayed depend on the configuration and format of the target. For information on message filtering, see [Filtering Events Sent to Targets](#) on page 1687. For information on message formatting, see [Formatting Event Messages](#) on page 1696.

## Displaying Event Logs

The log stored in the memory buffer and the NVRAM can be displayed on the current session (either the console display or Telnet).

- Display the log using the command:

```
show log {messages [memory-buffer | nvr]} {events {event-condition |
event-component}} {severity severity {only}} {starting [date date time
time | date date | time time]} {ending [date date time time | date
date | time time]} {match regex} {chronological}
```

You can use many options to select those log entries of interest. You can select to display only those messages that conform to the specified:

- Severity
- Starting and ending date and time
- Match expression

The displayed messages can be formatted differently from the format configured for the targets, and you can choose to display the messages in order of newest to oldest or in chronological order (oldest to newest).

### Log Buffer Threshold Alert

ExtremeXOS 16.1 now supports the ability to generate syslog message or trigger a SNMP trap when the log memory buffer is filled up to 90% of configured log lines. SNMP/SNMP trap is not supported by ExtremeXOS EMS module at this point. The feature provides that an alert in the form of log message will be generated when the log memory buffer is filled up to a certain percentage threshold. A new command has

been added to allow you to configure the memory buffer alert. The alert will be based on the percentage used of the memory buffer. By default, the alert is disabled.

The new command can be used to enable the alert and to specify the percentage threshold that triggers alerts. When the percentage threshold is set to a value in the allowed range, the memory buffer alert is enabled. When the percentage threshold is set to none, the memory buffer alert is disabled. The alert triggered will be a log message with Notice severity.

If the alert is enabled, a log message will be generated in the following three scenarios:

1. When the actual use of the memory buffer first exceeds the configured percentage threshold.
2. When the configured memory buffer size is changed and the actual use of the buffer exceeds the configured percentage threshold.
3. When the configured percentage threshold is changed and the actual use of the buffer exceeds the re-configured percentage threshold.

When you execute the command `clear log`, the memory buffer will be emptied. When the new logs re-fill up to the configured percentage threshold, the log message will be re-generated. Output of `show log configuration` will be modified as well to include the information of memory buffer alert configuration and current memory buffer usage.

## Uploading Event Logs

The log stored in the memory buffer and the NVRAM can be uploaded to a TFTP server.

- Use the following command to upload the log:

```
upload log [ipaddress | hostname] {vr vr_name} {block-size
block_size} filename {messages [memory-buffer | nvram] } {severity
severity {only}} {match regex} {chronological}
```

You must specify the TFTP host and the filename to use in uploading the log.

There are many options you can use to select the log entries of interest. You can select to upload only those messages that conform to the specified:

- Severity
- Match expression

The uploaded messages can be formatted differently from the format configured for the targets, and you can choose to upload the messages in order of newest to oldest or in chronological order (oldest to newest).

## Displaying Counts of Event Occurrences

EMS adds the ability to count the number of occurrences of events. Even when an event is filtered from all log targets, the event is counted.

- Display the event counters.

```
show log counters {event condition | [all | event component]} {include
| notified | occurred} {severity severity {only}}
```

The system displays two counters. One counter displays the number of times an event has occurred, and the other displays the number of times that notification for the event was made to the system for further processing. Both counters reflect totals accumulated since reboot or since the counters were cleared using the `clear log counters` or `clear counters` command.

The `show log counters` command also displays an included flag (the column titled In in the output). The included flag is set to Y(es) if one or more targets are receiving notifications of this event without regard to matching parameters.

The keywords `include`, `notified`, and `occurred` display events only with non-zero counter values for the corresponding counter.

The output of the command:

```
show log counters stp.inbpdu severity debug-summary
```

is similar to the following:

| Comp | SubComp | Condition | Severity      | Occurred | In | Notified |
|------|---------|-----------|---------------|----------|----|----------|
| STP  | InBPDU  | Drop      | Error         | 0        | Y  | 0        |
| STP  | InBPDU  | Ign       | Debug-Summary | 0        | N  | 0        |
| STP  | InBPDU  | Mismatch  | Warning       | 0        | Y  | 0        |

Occurred : # of times this event has occurred since last clear or reboot  
 Flags : (\*) Not all applications responded in time with there count values  
 In(cluded): Set to Y(es) if one or more targets filter includes this event  
 Notified : # of times this event has occurred when 'Included' was Y(es)

The output of the command:

```
show log counters stp.inbpdu.drop
```

is similar to the following:

| Comp | SubComp | Condition | Severity | Occurred | In | Notified |
|------|---------|-----------|----------|----------|----|----------|
| STP  | InBPDU  | Drop      | Error    | 0        | Y  | 0        |

Occurred : # of times this event has occurred since last clear or reboot  
 Flags : (\*) Not all applications responded in time with there count values  
 In(cluded): Set to Y(es) if one or more targets filter includes this event  
 Notified : # of times this event has occurred when 'Included' was Y(es)

## Displaying Debug Information

By default, a switch does not generate events of severity Debug-Summary, Debug-Verbose, and Debug-Data unless the switch is in debug mode. Debug mode causes a performance penalty, so it should only be enabled for specific cases where it is needed.

- Place the switch in debug mode using the command:

```
enable log debug-mode
```

When the switch is in debug-mode, any filters configured for your targets still affect which messages are passed on or blocked.

## Logging Configuration Changes

ExtremeXOS allows you to record all configuration changes and their sources that are made using the CLI by way of Telnet or the local console. These configuration changes are noted in the log as event entries. Each log entry includes the user account name that performed the change and the source IP address of the client (if Telnet was used). Configuration logging applies only to commands that result in a configuration change. CLI configuration logging is disabled by default.

- To enable configuration logging, use the following command:

```
enable cli config-logging
```

- To disable configuration logging, use the following command:

```
disable cli config-logging
```

You can specify that logged commands appear in fully expanded form, rather than the abbreviations you may have used when entering them in the command line.

For example, with command expansion enabled, a command entered in abbreviated format, such as

```
config por 33 auto of spee 10000 duplex ful
```

appears in the log as:

```
configure ports 33 auto off speed 10000 duplex full
```

- To enable command expansion, use the following command:

```
enable cli-config-logging expansion
```

- To disable command expansion, use the following command:

```
disable cli-config-logging expansion
```

## Securing Syslog Transport Layer Security Sessions

By default, the following ciphers are enabled for Syslog Transport Layer Security (TLS) sessions:

aes128-sha, aes128-sha256; aes256-sha256; dhe-rsa-aes128-sha256; dhe-rsa-aes256-sha256

You can selectively enable and disable ciphers using the following command:

```
configure syslog tls cipher [[cipher | all] on | cipher off]
```

To see which ciphers are enabled or disabled for Syslog TLS sessions, use the following command:

```
show log configuration
```

## Avoiding Potential Loss of TLS Syslog Logging

For Linux, by default, it takes about 15 minutes for kernel to end a TCP connection when transmitted data remains unacknowledged. This results in a potential loss of logs to TLS Syslog server during the 15 minutes window due to link down.

To reduce this time window, use the following command:

```
configure syslog tls tcp-user-timeout [seconds | default]
```

To view the value set for Syslog TLS TCP user timeout, use the following command:

```
show log configuration
```

## Disabling OCSP for TLS Connections to Remote Syslog Servers

For compliance with *RFC 6960* (X.509 Internet Public Key Infrastructure Online Certificate Status Protocol – OCSP), you can disable the OCSP check for Transport Layer Security (TLS) connections to remote Syslog servers by using the following command:

```
configure syslog tls ocsp [on | off]
```

To see the status of OCSP checking, use the following command:

```
show log configuration
```

### Note

Be sure you understand the ramifications of turning off OCSP if you chose to do so.

## Syslog TLS OCSP Attribute Configuration

Beginning with version 32.2, you can configure Syslog TLS OCSP attributes (nonce, override, and ocsp-nocheck, respectively) using the following commands:

- `configure syslog tls ocsp nonce [on | off]`
- `configure syslog tls tls override [url | none]`
- `configure syslog tls ocsp signer ocsp-nocheck [on | off]`

OCSP nonce cryptographically binds an OCSP request and an OCSP response with an `id-pkix-ocsp-nonce` extension to prevent replay attacks.

OCSP override configures one HTTP Online Certificate Status Protocol (OCSP) override URL for TLS connections to a remote Syslog server.

#### *OCSP-nocheck*

If this configuration is turned on, then the operating system assumes the OCSP signer certificate contains the ocsf-nocheck extension, whether it has the extension or not. This results in the system accepting the OCSP responses from this OCSP signer. By default, this configuration is off to maintain backward compatibility, but can be turned on or off per application. This is also applicable for both the override server and AIA servers.

## Using the XML Notification Client

---

### Introduction

This feature allows an event such as a configuration change, a fault, a change in status, the crossing of a threshold, or an external input to the system, to be sent as an asynchronous message or event notification to external web servers.

The only ExtremeXOS modules that support XML notification as targets are Identity Management and EMS.

XML notification does not provide any event filtering capability. However, in the case of EMS, the target Web server can be configured with log filters and conditions. The XML notification feature establishes and checks the connectivity with the web server only when an event is ready to be pushed. State transitions take place if required. Statistics are updated accordingly and can be monitored.

The Web servers must be configured and enabled using ExtremeXOS CLI with an IP address, port, protocol type, user authentication, session information, if any, and other web server configuration.

A maximum of four web servers can be configured at a time.

The XML schemas are defined using Web Services Description Language (WSDL) in the XML SDK.

### HTTP Client Interface

The event notifications are sent in XML format, using SOAP transport protocol and HTTP/HTTPS.

The XML notification client can communicate with the external HTTP/HTTPS server. HTTP/HTTPS client interfaces maintain persistent connections with external Web servers as long as the target is activated on the switch.

The HTTP URL format for the server is `http://<ip-address>:<port>/<service>`. The default HTTP port number 80 is used if a port number is not configured.

HTTP basic access authentication method (Base64 algorithm) is used to encrypt the user name and password when making a request. HTTP cookies are not supported in this release.

Create a server certificate that can be used by the HTTPS server. To generate the secure certificate on a ExtremeXOS switch, see the configuration guidelines of the HTTP server, (see [Secure Socket Layer](#) on page 1621 for more information).

## Configuring XML Notification

- Create a web server target on an XML client using the command:  

```
create xml-notification target new-target url url {vr vr_name} {user [none | user]} {encrypted-auth encrypted-auth} {queue-size queue-size}
```
- Configure a web server target on an XML client using the command:  

```
configure xml-notification target target [url url {vr vr_name} | user [none | user] | [encrypted-auth encrypted-auth] | [queue-size queue-size]]
```
- Add or delete an ExtremeXOS application to a web server target (EMS or Identity Management) using the command:  

```
configure xml-notification target target [add | delete] module
```
- Enable or disable web server target(s) using the command:  

```
[enable|disable] xml-notification [all | target]
```
- Delete a web server target on an XML client process using the command:  

```
delete xml-notification target target
```
- Unconfigure an XML client process using the command:  

```
unconfigure xml-notification
```
- Unconfigure and reset all statistics counters using the command:  

```
clear counters xml-notification {all | target}
```

## Displaying XML Notification

- Display the configuration of a web server target using the command:  

```
show xml-notification configuration {target}
```
- Display the connection status, enable status, and event statistics of the target web server using the command:  

```
show xml-notification statistics {target}
```
- Display information on the stored certificate using the command:  

```
show ssl {detail}
```

## Configuring Log Target in EMS

The following commands support the EMS XML target.

- Create a web server XML target using the command:  
`create log target xml-notification [ target_name | xml_target_name ]`
- Configure the web server target with an EMS filter using the command:  
`configure log target xml-notification xml_target_name filter filter-name {severity [[severity] {only}}`
- Enable the web server target using the command:  
`enable log target xml-notification xml_target_name`
- Disable the web server target using the command:  
`disable log target xml-notification xml_target_name`
- Delete the web server target XML target using the command:  
`delete log target xml-notification xml_target_name`
- Display XML target information using the command:  
`show log configuration target xml-notification {xml_target_name}`

## Examples

Below are examples of configuring web server targets in a XML Notification module.

*Scenario 1: Push filtered EMS events to external web server in a well-defined XML format.*

Create a Web Server Target test1, create a log target and a filter in EMS, and attach the filter to the web target. Enable the target in both EMS and XML-Notification module.

```
create XML-notification target test1 url http://10.255.129.22:8080/xos/webservice user
admin
create log target xml-notification "test1"
create log filter xmlc_filter_1
configure log filter "xmlc_filter_1" add events idmgr
configure log target xml-notification "test1" filter "xmlc_filter-1"
enable log target xml-notification "test1"
enable XML-notification test1
```

*Scenario 2: Push user identity events to the external web server without EMS module in a well defined (XML Schema) XML format.*

Create a web server target and attach an idmgr module. Idmgr modules use an XML-notification backend library to trigger events. In this case, no special filters are supported.

```
create xml-notification target test2 url http://10.255.129.22:8080/xos/webservice user
admin
configure xml-notification target test2 add module idmgr
enable xml-notification test2
```

*Scenario - 3: XMLC notifications using HTTPS*

Install the SSH module. If not installed, refer to [Understanding System Redundancy](#) on page 83 for details on SSH and [Secure Socket Layer](#) on page 1621 for details on SSL.

```
configure ssl certificate privkeylen 1024 country us organization extreme common-name
name1
```

```
create xml-notification target test3 url https://10.120.91.64:8443/xos/webservice
configure xml-notification target "test3" user admin
configure xml-notification target "test3" add "ems"
enable xml-notification "test3"
```

## Using sFlow

sFlow is a technology for monitoring traffic in data networks containing switches and routers. It relies on statistical sampling of packets from high-speed networks, plus periodic gathering of the statistics. A *UDP (User Datagram Protocol)* datagram format is defined to send the information to an external entity for analysis. sFlow consists of a *MIB (Management Information Base)*, and a specification of the packet format for forwarding information to a remote agent. For details on sFlow specifications, see RFC 3176; and for more general information, go to [www.sflow.org](http://www.sflow.org).

The ExtremeXOS implementation is based on sFlow version 5, which is an improvement from the revision specified in RFC 3176.

Additionally, the switch software also allows you to set the individual port sampling rates, so that you can fine-tune sFlow statistics.

sFlow and mirroring are not mutually exclusive on ExtremeSwitching series switches, whether or not they are included in a SummitStack. You can enable them simultaneously.

However, be aware that the following limitations are present in the ExtremeXOS implementation:

- Generic port statistics are reported to the sFlow collector
- Non-extended data
- Only port-based sampling
- No MIB support

## Sampling Mechanisms

ExtremeSwitching series switches support hardware-based sampling at a programmed interval.

With hardware-based sampling, the data path for a packet that traverses the switch does not require processing by the CPU. Fast path packets are handled entirely by ASICs and are forwarded at wire speed rate.

Both ingress and egress sFlow sampling can be enabled simultaneously on a port. The **enable sflow port** command provides an option to enable sFlow on ingress, or egress, or both directions. The default value is ingress. The sample rate is maintained on a per-port basis, so a given port has the same sample rate for ingress and egress traffic. Ingress and egress sFlows sample both unicast and multicast egress flows. The global enable/disable control of sFlow is common to both ingress and egress. When the global option is enabled, the port level sFlow parameter is applied to hardware.

When sFlow sampling is enabled on a port, the sFlow agent samples the traffic on that port, processed in slow path and passed on to the collector. You can configure the rate at which the packets are sampled.

ExtremeXOS 22.5 expands upon sFlow's capability by providing support for additional data structures that an sFlow agent can use to report table utilization statistics in sFlow counter samples (see [Displaying sFlow Information](#) on page 1712).

## Limitations of Egress sFlow

The following limitations apply to the egress sFlow feature:

- Due to the hardware limitation, destination port information is not supported for multicast traffic. The output interface index is populated as 0.
- Egress sFlow sampling does not support de-duplication of packets.
- For multicast traffic, the sampling rate, sample pool of the egress sFlow sampled datagram is populated as 0, because the source ID of the egress sampled multicast packet is unknown.
- For L3 unicast traffic, an unmodified packet is sampled and the destination port is supplied if the L3 traffic is a flow within single chip. When the egress port and ingress port are in different chips, then a modified packet is sampled and the destination ports are supplied. For L3 multicast traffic, unmodified packet is sampled and destination port is populated as zero.
- Packets dropped due to egress [ACL](#) are sampled.
- In cases of unicast and multicast flooding, the packets are sampled before packet replication. If the ingress and member ports are in the same chip, then a single copy of the packet is sampled even though the egress sFlow is enabled on more than one member's ports. If the member ports are spread across different chip, then packets are sampled on a per-chip basis.
- In flooding cases, the least configured sampling rate among the member ports on a port group is considered as a sample rate. Even if you configure different sample rates on a member ports, egress sampling is based on the least configured sample rate among the member ports on a chip.

## sFlow Destination Port

Currently, when a packet is sampled from the ingress traffic, the output interface index is populated as 0. This is applicable for both unicast and multicast traffic. As part of the egress sFlow, the output interface index is populated with the destination port information for unicast packets sampled in both ingress and egress directions. Multicast packet samples still have an output interface index as 0.

Table 157 illustrates the expected output of the ifIndex when based on traffic type, and sampling direction.

**Table 157: IfIndex Traffic Type Sampling Direction**

| Case # | Ingress/Egress Unicast/Multicast | Scenario                                                                                                                        |
|--------|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| 1      | Ingress/unicast                  | sFlow sample includes both ingress and egress port (ifindex).                                                                   |
| 2      | Egress/unicast                   | sFlow sample includes both ingress and egress port information.                                                                 |
| 3      | Ingress/multicast                | Egress port information cannot be provided because of hardware limitation. Egress ifindex is 0 and ingress ifindex is supplied. |
| 4      | Egress/multicast                 | Egress port information cannot be provided because of hardware limitation. Egress ifindex is 0 and ingress ifindex is supplied. |

## Configuring sFlow

ExtremeXOS allows you to collect sFlow statistics on a per port basis.

An agent residing locally on the switch sends data to a collector that resides on another machine. You configure the local agent, the address of the remote collector, and the ports of interest for sFlow statistics gathering. You can also modify default values for how frequently on an average a sample is taken and the maximum number of samples allowed before throttling the sample gathering.

To configure sFlow on a switch:

- Configure the local agent
- Configure the addresses of the remote collectors
- Enable sFlow globally on the switch
- Enable sFlow on the desired ports

Optionally, you may also change the default values of the following items:

- How often the statistics are collected
- How frequently a sample is taken, globally or per port
- How many samples per second can be sent to the CPU

### Configuration Tasks

Use the following commands to configure the sFlow feature:

- `enable sflow ports all | port_list {ingress | egress | both}`

The keyword options enable you to configure sFlow types on a given set of ports. If you do not configure an sFlow type, then ingress sFlow sampling is enabled as the default configuration.

Use the following commands to display the type of sFlow configured on the physical interface, and various statistics about sFlow sampling:

- `show sflow configuration`
- `show sflow statistics`

The following fields are displayed:

- Received frames—Number of frames received on sFlow enabled ports.
- Sampled Frames—Number of packets that have been sampled by sFlow.
- Transmitted Frames—Number of UDP packets sent to remote collector(s).
- Broadcast Frames—Number of broadcast frames received on sFlow enabled ports.
- Multicast Frames—Number of multicast frames received on sFlow enabled ports.
- Packet Drops—Number of samples dropped.

### *Configuring the Local Agent*

The local agent is responsible for collecting the data from the samplers and sending that data to the remote collector as a series of UDP datagrams. The agent address is stored in the payload of the sFlow data, and is used by the sFlow collector to identify each agent uniquely. By default, the agent uses the management port IP address as its IP address.

- Change the agent IP address using the command:  
`configure sflow agent {ipaddress} ipaddress`
- Unconfigure the agent using the command:  
`unconfigure sflow agent`

### *Configuring the Remote Collector Address*

You can specify up to four remote collectors to send the sFlow data to. Typically, you would configure the IP address of each collector. You may also specify a UDP port number different from the default value of 6343, and/or a different from the default of [VR-Mgmt](#). When you configure a collector, the system creates a database entry for that collector that remains until the collector is unconfigured. All the configured collectors are displayed in the command: `show sflow {configuration}`.

- Configure the remote collector using the command:  
`configure sflow collector {ipaddress} ipaddress {port udp-port-number} {vr vr_name}`
- Unconfigure the remote collector and remove it from the database using the command:  
`unconfigure sflow collector {ipaddress} ipaddress {port udp-port-number} {vr vr_name}`

### *Enabling sFlow Globally on the Switch*

Before the switch starts sampling packets for sFlow, you must enable sFlow globally on the switch.

- Enable sFlow globally using the command:

```
enable sflow
```

- Disable sFlow globally using the command:

```
disable sflow
```

When you disable sFlow globally, the individual ports are also put into the disabled state. If you later enable the global sFlow state, individual ports return to their previous state.

### *Enabling sFlow on the Desired Ports*

- Enable sFlow on specific ports using the command:

```
enable sflow ports port_list {ingress | egress | both}
```

The ingress option allows you to configure the sFlow type on a given set of ports. This option is configured on the port by default.

You may enable and disable sFlow on ports irrespective of the global state of sFlow, but samples are not taken until both the port state and the global state are enabled.

- Disable sFlow on ports using the command:

```
disable sflow ports port_list
```

## Additional sFlow Configuration Options

You can configure three global options to different values from the defaults. These options affect how frequently the sFlow data is sent to the remote collector, how frequently packets are sampled, and the maximum number of sFlow samples that could be processed in the CPU per second.

You can also configure how frequently packets are sampled per port.

### *Polling Interval*

Each port counter is periodically polled to gather the statistics to send to the collector. If there is more than one counter to be polled, the polling is distributed in such a way that each counter is visited once during each polling interval, and the data flows are spaced in time. For example, assume that the polling interval is 20 seconds and there are 40 counters to poll. Two ports will be polled each second, until all 40 are polled.

- Configure the polling interval using the command:

```
configure sflow poll-interval seconds
```

### Global Sampling Rate

The global sampling rate is the rate set on newly enabled sFlow ports. Changing this rate does not affect currently enabled sFlow ports. The default sample rate is 8192, so sFlow samples one packet out of every 8192 received.

- Use the following command to configure the switch to use a different sampling rate.

```
configure sflow sample-rate number
```

For example, if you set the sample rate number to 16384, the switch samples one out of every 16384 packets received. Higher numbers mean fewer samples and longer times between samples. If you set the number too low, the number of samples can be very large, which increases the load on the switch. Do not configure the sample rate to a number lower than the default unless you are sure that the traffic rate on the source is low.

The Global Sampling Rate applies to all ExtremeSwitching platforms.

#### Note

The minimum rate that these platforms sample is 1 out of every 256 packets. If you configure a rate to be less than 256, the switch automatically rounds up the sample rate to 256.

### Per Port Sampling Rate

The per port sampling rate overrides the system-wide value.

The rate is rounded off to the next power of two, so if 400 is specified, the sample rate is configured as 512. The valid range is [256-536870912].

- Set the sampling rate on individual ports.

```
configure sflow ports port_list sample-rate number
```

### Maximum CPU Sample Limit

A high number of samples can cause a heavy load on the switch CPU. To limit the load, there is a CPU throttling mechanism to protect the switch.

#### Note

Sflow sampling is limited to 2000 packets per second in the CPU. Any packets sent at a rate greater than 2000 pps are dropped.

On a stand-alone switch, whenever the limit is reached, the sample rate value is doubled on the ports from which the maximum number of samples are received. For ports that are sampled less frequently, the sampling rate is not changed; the sub-sampling factor is adjusted downward.

- Configure the maximum CPU sample limit.

```
configure sflow max-cpu-sample-limit rate
```

### Unconfiguring sFlow

- Reset the configured values for sFlow to their default values and remove from sFlow any configured collectors and ports using the following ocmmand:

```
unconfigure sflow
```

## sFlow Configuration Example

In a service provider environment, you can configure sFlow to sample packets at the edge of the network to determine the hourly usage for each IP address in the data center.

You can capture web traffic, FTP traffic, mail traffic, and all bits of data that travel across service providers' edge routers to their customers' (end users') servers.

The example in this section assumes that you already have an sFlow data collector installed somewhere in your network. In many environments, the sFlow data collector is on a network PC.

The following sFlow configuration example performs the following tasks in a service provider environment:

- Configures the IP address of the sFlow data collector.

#### Note

In many environments, the sFlow data collector is not directly connected to the switch. Make sure to specify the VR used to forward traffic between the sFlow collector and the switch. In most cases the VR is *VR-Mgmt*.

- Configures the sampling rate on an edge port.
- Enables sFlow on the edge port.
- Enables sFlow globally on the switch.

```
configure sflow collector 10.127.11.88 vr vr-mgmt
configure sflow ports 5:21 sample-rate 8192
enable sflow ports 5:21 egress
enable sflow
```

Here is sample output for the configuration:

```
SFLOW Global Configuration
Global Status: enabled
Polling interval: 20
Sampling rate: 8192
Maximum cpu sample limit: 2000
SFLOW Configured Agent IP: 0.0.0.0
Operational Agent IP: 10.127.11.88
Collectors
SFLOW Port Configuration Port Status Sample-rate Subsampling Sflow-type
Config / Actual factor Ingress/Egress
5:21 enabled 8192 / 8192 1 Disabled / Enabled
```

## Displaying sFlow Information

- To display the current configuration of sFlow, use the following command:  
`show sflow {configuration}`
- To display the sFlow statistics, use the following command:  
`show sflow statistics`
- To display the sFlow hardware table utilization statistics, use the following command:  
`show sflow hardware-utilization {slot [slot_num | all]}`

## Using RMON

---

Using the Remote Monitoring (RMON) capabilities of the switch allows network administrators to improve system efficiency and reduce the load on the network.

### Note

You can use the RMON features of the system only if you have an RMON management application and have enabled RMON on the switch.

## About RMON

RMON is the common abbreviation for the Remote Monitoring Management Information Base (MIB) system defined by the Internet Engineering Task Force (IETF) documents RFC 1757 and RFC 2021, which allows you to monitor LANs remotely.

A typical RMON setup consists of the following two components:

- [RMON agent](#)
- [Management workstation](#)

### *RMON Agent*

An RMON agent is an intelligent software agent that continually monitors port statistics and system variables.

The agent transfers the information to a management workstation on request, or when a predefined threshold is crossed.

Information collected by RMON includes Ethernet port statistics and history and the software version and hardware revision of the device. RMON generates alarms when threshold levels are met and then logs those events to the log. RMON can also send traps to the destination address configured by the management workstation. You can also use RMON to trigger a system reboot.

### *Management Workstation*

A management workstation communicates with the RMON agent and collects the statistics from it.

The workstation does not have to be on the same network as the RMON agent and can manage the agent by in-band or out-of-band connections.

If you enable RMON on the switch, you can use a management workstation to review port statistics and port history, no configuration of the management workstation is necessary. However, you must use a management workstation to configure the alarm and event entries.

## Supported RMON Groups of the Switch

The IETF defines nine groups of Ethernet RMON statistics. The switch supports the following four of these groups, as defined in RFC 1757:

- [Statistics](#)
- [History](#)
- [Events](#)

The switch also supports the following parameters for configuring the RMON agent and the trap destination table, as defined in RFC 2021:

- probeCapabilities
- probeSoftwareRev
- probeHardwareRev
- probeDateTime
- probeResetControl
- trapDestTable

The following sections describe the supported groups, the RMON probe configuration parameters, and the trap destination parameter in greater detail.

### *Statistics*

Per virtual network and per remote endpoint counters are supported. Both byte and packet counts are available.

Virtual network counters display the sum of all counters from all remote endpoints associated with the virtual network. Packets that arrived encapsulated on the VXLAN network port are counted on the virtual network as Rx bytes/packets (network side), and also, are counted as Tx bytes/packets (access side). For example, if 10 packets are received from remote endpoint 1.1.1.2 on virtual network vnet44, Rx Frames are 10, since 10 frames are received on the virtual network from the network interface (VXLAN encapsulated packets). Also, TX frames are 10, since 10 frames are transmitted on the virtual network tenant interface (native, non-VXLAN encapsulated packets). Similarly, on the other direction.

Remote endpoint counters display the sum of all counters from all virtual networks associated with the remote endpoint. Currently, it is not possible to display the counters for a given virtual network/remote endpoint pair.

### *History*

The History group provides historical views of network performance by taking periodic samples of the counters supplied by the Statistics group.

The group features user-defined sample intervals and bucket counters for complete customization of trend analysis.

The group is useful for analysis of traffic patterns and trends on an Ethernet port, and for establishing baseline information indicating normal operating parameters.

### *Events*

The Events group creates entries in an event log and/or sends *SNMP* traps to the management workstation.

An event is triggered by an RMON alarm. The action taken can be configured to ignore it, to log the event, to send an SNMP trap to the receivers listed in the trap receiver table, or to both log and send a trap. The RMON traps are defined in RFC 1757 for rising and falling thresholds.

Effective use of the Events group saves you time. Rather than having to watch real-time graphs for important occurrences, you can depend on the Events group for notification. Through the SNMP traps, events can trigger other actions, which provides a mechanism for an automated response to certain occurrences.

### *RMON Probe Configuration Parameters*

The RMON probe configuration parameters supported in ExtremeXOS are a subset of the probe configuration group as defined in RFC 2021. The probe configuration group controls and defines the operation of the RMON agent.

You can configure the following objects:

- probeCapabilities—View the RMON MIB groups supported on at least one interface by the probe.
- probeSoftwareRev—View the current software version of the monitored device.
- probeHardwareRev—View the current hardware version of the monitored device.
- probeDateTime—View the current date and time of the probe. For example, Friday December 31, 2004 at 1:30:15 PM EST is displayed as: 2004-12-31,13:30:15.0

If the probe is aware of time zones, the display also includes the Greenwich Mean Time (GMT) offset. For example, Friday, December 31, 2004, 1:30:15 PM EST with the offset known is displayed as: 2004-12-31,13:30:15.0, -4.0

If time information is unavailable or unknown, the time is not displayed.

- probeResetControl—Restart a managed device that is not running normally. Depending on your configuration, you can do one of the following:
  - Warm boot—A warm boot restarts the device using the current configuration saved in non-volatile memory.
  - Cold boot—A cold boot causes the device to reset the configuration parameters stored in non-volatile memory to the factory defaults and then restarts the device using the restored factory default configuration.

### *trapDestTable*

The trapDestTable contains information about the configured trap receivers on the switch and stores this information in non-volatile memory.

To configure one or more trap receivers, see [Using the Simple Network Management Protocol](#) on page 105.

### *Extreme-RtStats-MIB*

The extremeRtStatsTable provides the user with all the common measurement/monitoring attributes in a single table.

It includes measurements like utilization, error, and collision levels.

The extreme RtStatsUtilization variable gives an accurate measurement of segment utilization. ExtremeRtStatsCollisions is included in the segment utilization calculation for more accuracy. Collision statistics are collected periodically, and the segment utilization is calculated with a sampling interval of 5 minutes (300 seconds).

The extremeRtStatsTotalErrors variable is calculated by adding the following counters:

- extremeRtStatsCRCAlignErrors (receive errors)
- extremeRtStatsFragments (receive errors)
- extremeRtStatsJabbers (receive errors)
- extremeRtStatsCollisions (transmit errors)

## Configuring RMON

RMON requires one probe per LAN segment, and stand-alone RMON probes traditionally have been expensive. Therefore, the approach taken by Extreme Networks has been to build an inexpensive RMON probe into the agent of each system. This allows RMON to be widely deployed around the network without costing more than traditional network management. The switch accurately maintains RMON statistics at the maximum line rate of all of its ports.

By default, RMON is disabled. However, even in the disabled state, the switch collects etherStats and you can configure alarms and events.

RMON saves the history, alarm, and event configurations to the configuration file. Runtime data is not stored in the configuration file and is subsequently lost after a system restart.

- Enable or disable the collection of RMON statistics on the switch using the commands:

```
enable rmon
disable rmon
```

By enabling RMON, the switch begins the processes necessary for collecting switch statistics.

## Event Actions

The actions that you can define for each alarm are shown in [Table 158](#).

**Table 158: Event Actions**

| Action       | High Threshold                                             |
|--------------|------------------------------------------------------------|
| no action    |                                                            |
| log          | Sends a log message.                                       |
| log-and-trap | Sends both a log message and a trap to all trap receivers. |
| snmp-trap    | Sends a trap to all trap receivers.                        |

To be notified of events using [SNMP](#) traps, you must configure one or more trap receivers, as described in [Using the Simple Network Management Protocol](#) on page 105.

## Display RMON Information

- View the status of RMON polling on the switch (the enable/disable state for RMON polling) using the command:  

```
show switch management
```
- View the RMON memory usage statistics for a specific RMON feature (for example, statistics, events, logs, or history) or for all features using the command:  

```
show rmon memory {detail | memoryType}
```

## SMON

SMON is the common abbreviation for the Switch Network Monitoring Management Information Base (MIB) system defined by the Internet Engineering Task Force (IETF) document RFC 2613.

SMON is a set of MIB extensions for RMON that allows monitoring of switching equipment from a [SNMP](#) Manager in greater detail. The supported MIB tables are described in [Supported Standards, Protocols, and MIBs](#) on page 1786; smonPrioStatsControlTable and smonPrioStatsTable cannot be supported due to hardware limitations.

### Note

When you delete all the mirroring filters through the portCopyConfigTable, the mirroring is disabled automatically.

## Monitoring CPU Utilization

You can monitor the CPU utilization and history for all of the processes running on the switch.

By viewing this history on a regular basis, you can see trends emerging and identify processes with peak utilization. Monitoring the workload of the CPU allows you to troubleshoot and identify suspect processes before they become a problem. By default, the switch monitors CPU utilization every five seconds. In addition, when CPU utilization of a process exceeds 90% of the regular operating basis, the switch logs an error message specifying the process name and the current CPU utilization for the process.

## Disabling CPU Monitoring

- Disable CPU monitoring using the command:

```
disable cpu-monitoring
```

This command disables CPU monitoring on the switch; it does not clear the monitoring interval. Therefore, if you altered the monitoring interval, this command does not return the monitoring interval to five seconds. The next time you enable CPU monitoring, the switch uses the existing configured interval.

## Enable CPU Monitoring

By default, CPU monitoring is enabled and occurs every five seconds. The default CPU threshold value is 90%.

- Enable CPU monitoring using the command:

```
enable cpu-monitoring {interval seconds} {threshold percent}
```

Where the following is true:

- *seconds*—Specifies the monitoring interval. The default interval is 5 seconds, and the range is 5 to 60 seconds. We recommend the default setting for most network environments.
- *threshold*—Specifies the CPU threshold value. CPU usage is measured in percentages. The default is 90%, and the range is 0% to 100%.

## Displaying CPU Utilization History

- Display the CPU utilization history of one or more processes using the command:

```
show cpu-monitoring {process name} {slot slotid}
```

Where the following is true:

- *name*—Specifies the name of the process.
- *slot*—On a SummitStack, specifies the slot number of the target node. The number is a value from one (1) to eight (8).

Output from this command includes the following information:

- *Process*—The name of the process.
- *Range of time* (five seconds, ten seconds, and so forth)—The CPU utilization history of the process or the system. The CPU utilization history goes back only 1 hour.

- Total User/System CPU Usage—The amount of time recorded in seconds that the process spends occupying CPU resources. The values are cumulative meaning that the values are displayed as long as the system is running. You can use this information for debugging purposes to see where the process spends the most amount of time: user context or system context.
- Clear the utilization history stored in the switch and reset the statistics to zero using the command:

```
clear cpu-monitoring {process name} {slot slotid}
```

The following is sample truncated output from a switch:

```
5420F-48P-4XE.1 # show cpu-monitoring
```

| CPU Utilization Statistics - Monitored every 5 seconds |      |      |      |      |      |      |      |      |             |           |
|--------------------------------------------------------|------|------|------|------|------|------|------|------|-------------|-----------|
| Process                                                | 5    | 10   | 30   | 1    | 5    | 30   | 1    | Max  | Total       |           |
|                                                        | secs | secs | secs | min  | mins | mins | hour |      | User/System |           |
|                                                        | util | util | util | util | util | util | util | util | CPU Usage   |           |
|                                                        | (%)  | (%)  | (%)  | (%)  | (%)  | (%)  | (%)  | (%)  | (secs)      |           |

Using the [\*STP \(Spanning Tree Protocol\)\*](#) functionality of the switch makes your network more fault tolerant. This chapter explains more about STP and the STP features supported by ExtremeXOS.

## Note

STP is a part of the 802.1D bridge specification defined by the IEEE Computer Society. To explain STP in terms used by the IEEE 802.1D specification, the switch will be referred to as a [\*bridge\*](#).

ExtremeXOS version 12.0 and later supports the new edition of the IEEE 802.1D standard (known as IEEE 802.1D-2004 ) for STP, which incorporates enhancements from the IEEE 802.1t-2001, IEEE 802.1W, and IEEE 802.1y standards. The IEEE 802.1D-2004 standard is backward compatible with the IEEE 802.1D-1998 standard. For more information, see [Compatibility Between IEEE 802.1D-1998 and IEEE 802.1D-2004 STP Bridges](#) on page 1720.

## Spanning Tree Protocol Overview

---

[\*STP\*](#) is a bridge-based mechanism for providing fault tolerance on networks.

STP allows you to implement parallel paths for network traffic and to ensure that redundant paths are:

- Disabled when the main paths are operational.

- Enabled if the main path fails.

**Note**

STP and *ESRP (Extreme Standby Router Protocol)* cannot be configured on the same *VLAN (Virtual LAN)* simultaneously.

**Note**

If you are transitioning from EOS to ExtremeXOS, please note that ExtremeXOS blocks on a more granular (VLAN) level, instead of at the port level as EOS does.

## Compatibility Between IEEE 802.1D-1998 and IEEE 802.1D-2004 STP Bridges

The IEEE 802.1D-2004 compliant bridges interoperate with the IEEE 802.1D-1998 compliant bridges.

To ensure seamless operation of your *STP* network, read this section before you configure STP on any Extreme Networks device running ExtremeXOS 11.6 or later.

Differences in behavior between the two standards include the:

- Default port path cost
- Bridge priority
- Port priority
- Edge port behavior

This section describes the bridge behavior differences in more detail.

### *Default Port Path Cost*

The 802.1D-2004 standard modified the default port path cost value to allow for higher link speeds.

A higher link speed can create a situation whereby an 802.1D-1998 compliant bridge could become the more favorable transit path.

For example, in [Figure 202](#), bridge A is the root bridge running the new 802.1D-2004 standard, bridges B and C are running the old 802.1D-1998 standard, and bridges D, E, and F are running the new 802.1D-2004 standard. In addition, all ports are 100 Mbps links. The ports on bridges B and C have a default path cost of 19, and the ports on bridge A, D, E, and F have a default path cost of 200,000.

**Figure 202: 802.1D-1998 and 802.1D-2004 Mixed Bridge Topology**

If you use the default port path costs, bridge D blocks its port to bridge E, and all traffic between bridges D and E must traverse all of bridges in the network. Bridge D blocks its port to bridge E because the path cost to the root bridge is less by going across bridges B and C (with a combined root cost of 38) compared with going across bridge E (with a root cost of 200,000). In fact, if there were 100 bridges between bridges B, C, and D running the old 802.1D-1998 standard with the default port path costs, bridge D would still use that path because the path cost is still higher going across bridge E.

As a workaround and to prevent this situation, configure the port path cost to make links with the same speed use the same path host value. In the example described above, configure the port path cost for the 802.1D-2004 compliant bridges (bridges A, D, E, and F) to 19.

**Note**

You cannot configure the port path cost on bridges B and C to 200,000 because the path cost range setting for 802.1D-1998 compliant bridges is 1 to 65,535.

To configure the port path cost, use the following command:

```
configure stpd stpd_name ports cost [auto | cost] port_list
```

### Bridge Priority

By configuring the *STPD (Spanning Tree Domain)* bridge priority, you make the bridge more or less likely to become the root bridge.

Unlike the 802.1D-1998 standard, the 802.1D-2004 standard restricts the bridge priority to a 16-bit number that must be a multiple of 4,096. The new priority range is 0 to

61,440 and is subject to the multiple of 4,096 restriction. The old priority range was 0 to 65,535 and was not subject to the multiple of 4,096 restriction (except for *MSTP* (*Multiple Spanning Tree Protocol*) configurations). The default bridge priority remains the same at 32,768.

If you have an ExtremeXOS 11.5 or earlier configuration that contains an *STP* or RSTP bridge priority that is not a multiple of 4,096, the switch rejects the entry and the bridge priority returns to the default value while loading the structure. The MSTP implementation in ExtremeXOS already uses multiples of 4,096 to determine the bridge priority.

To configure the bridge priority, use the following command:

```
configure stpd stpd_name priority priority
```

For example, to lower the numerical value of the priority (which gives the priority a higher precedence), you subtract 4,096 from the default priority:  $32,768 - 4,096 = 28,672$ . If you modify the priority by a value other than 4,096, the switch automatically changes the priority to the lower priority value. For example, if you configure a priority of 31,000, the switch automatically changes the priority to 28,672.

### Spanning Tree Protocol (STP) Bridge Priority Incrementing/Decrementing by One

This feature allows you to configure all *STP* modes (RSTP/*MSTP*) bridge priority in increments of 1 or 4,096. Allowing this level of granularity of the priority allows a large range of priority values for the backup root functionality.

After priority reaches 0, backup root is unable to provide for rapid recovery in a lost root situation. In that case, priority returns to its initial configured (or default) value, and the process starts again.

Loss of root should be a rare event, but this feature setting provides a buffer in situations where network downtime to reset the root is not often available.

#### Supported Platforms

All ExtremeSwitching platforms.

### STP Loss of Root Bridge Example

The backup root bridge becomes the root bridge when something goes wrong with the primary root bridge: root bridge failure, root bridge malfunction, or administrative errors, and the backup root bridge loses connectivity with the root bridge. If the priority of the root bridge is zero and backup root loses the connectivity to the root bridge, then automatic assignment of the priority value for the backup root becomes the initial configured value.

In the following example, Switch1 is the root bridge with priority 32,768. Switch2, Switch3, and Switch4 are configured with priority as 49,152, 36,864, and 40,960, respectively. When the physical link between Switch1 and Switch2 goes down, then Switch2 becomes the root bridge by changing its configured bridge priority, which will be less than Switch1's 32,768 (operational priority); in this case its priority will be 28,672

(32,768 - 4,096). When the priority value reaches 0, then automatic assignment of the priority value returns to the configured value.

**Figure 203: STP Root Bridge Loss Example**

#### Configuring STP Bridge Priority Incrementing/Decrementing by One

To set *STP* bridge priority values, use the following command with the priority-mode set to dot1d:

```
configure stpd stpd_name priority-mode [dot1d | dot1t]
```

#### Port Priority

The port priority value is always paired with the port number to make up the 16-bit port identifier, which is used in various *STP* operations and the STP state machines.

Unlike the 802.1D-1998 standard, the 802.1D-2004 standard uses only the four most significant bits for the port priority and it must be a multiple of 16. The new priority range available is 0 to 240 and is subject to the multiple of 16 restriction. The 802.1D-1998 standard uses the eight most significant bits for the port priority. The old priority range was 0 to 31 and was not subject to the multiple of 16 restriction.

To preserve backward compatibility and to use ExtremeXOS 11.5 or earlier configurations, the existing `configure stpd ports priority` command is available. If you have an ExtremeXOS 11.5 or earlier configuration, the switch interprets the port priority based on the 802.1D-1998 standard. If the switch reads a value that is not supported in ExtremeXOS 11.6 or later, the switch rejects the entry.

When you save the port priority value, the switch saves it as the command `configure stpd ports port-priority` with the corresponding change in value.

For example, if the switch reads the `configure stpd ports priority 16` command from an ExtremeXOS 11.5 or earlier configuration, (which is equivalent to the command `configure stpd ports priority 8` entered through CLI), the switch saves the value as `configure stpd ports port-priority 128`.

#### Edge Port Behavior

In ExtremeXOS 11.5 or earlier, Extreme Networks had two edge port implementations: edge port and edge port with safeguard.

The 802.1D-2004 standard has a bridge detection state machine, which introduced a third implementation of edge port behavior. The following list describes the behaviors of the different edge port implementations:

- Edge port (ExtremeXOS 11.5 and earlier):
  - The port does not send bridge protocol data units (BPDUs).
  - The port does not run a state machine.
  - If BPDUs are received, the port discards the BPDU and enters the blocking state.
  - If subsequent BPDUs are not received, the port remains in the forwarding state.
- Edge port with safeguard configured (ExtremeXOS 11.5 and 11.4 only):
  - The port sends BPDUs.
  - When configured for *MSTP*, the port runs a partial state machine.
  - If BPDUs are received, the port enters the blocking state.
  - If subsequent BPDUs are not received, the port attempts to enter the forwarding state.
- Edge port running 802.1D-2004 with safeguard enabled:
  - The port sends BPDUs.
  - The port runs a state machine.
  - If BPDUs are received, the port behaves as a normal RSTP port by entering the forwarding state and participating in RSTP.
  - If subsequent BPDUs are not received, the port attempts to become the edge port again.

Edge port with safeguard prevents accidental or deliberate misconfigurations (loops) by having edge ports enter the blocking state upon receiving a BPDU. The 802.1D-2004 standard implements a bridge detection mechanism that causes an edge port to transition to a non-edge port upon receiving a BPDU; however, if the former edge port does not receive any subsequent BPDUs during a pre-determined interval, the port attempts to become an edge port.

If an 802.1D-2004 compliant safeguard port (edge port) connects to an 802.1D-1998 compliant edge port with safeguard configured, the old safeguard port enters the blocking state. Although the new safeguard port becomes a designated port, the link is not complete (and thus no loop is formed) because one side of the link is blocked.

### *Restricted Role*

In a large metro environment, to prevent external bridges from influencing the spanning tree active topology, the following commands have been introduced for Rapid Spanning Tree Protocol (RSTP) and *MSTP*.

- `configure stpd stpd_name ports restricted-role enable port_list`
  - This command enables restricted role on a specified port in the core network to prevent external bridges from influencing the spanning tree active topology.
  - Restricted role should not be enabled with edge mode.
  - `stpd_name`—Specifies an *STPD* name on the switch.
  - `port_list`—Specifies one or more ports or slots and ports.

- Enabling restricted role causes a port to not be selected as a root port, even if it has the best spanning tree priority vector. Such a port is selected as an alternate port after the root port is selected. The restricted role is disabled by default. If set, it can cause a lack of spanning tree connectivity.
- A network administrator enables restricted role to prevent external bridges from influencing the spanning tree active topology.
- `configure stpd stpd_name ports restricted-role disable port_list`
  - This command disables restricted role on a specified port in the core network.
  - *stpd\_name*—Specifies an STPD name on the switch.
  - *port\_list*—Specifies one or more ports or slots and ports.
  - Restricted role is disabled by default. If set, it can cause a lack of spanning tree connectivity. A network administrator enables restricted role to prevent external bridges from influencing the spanning tree active topology.

## Loop Protect

*STP* depends on continuous reception of Type 2 BPDUs (RSTP/*MSTP*) based on the port role. The designated port transmits BPDUs and the non-designated port receives BPDUs. If one of the ports in a physical redundant topology no longer receives BPDUs, then STP assumes that the topology is loop free. This leads the blocking port from the alternate or backup port becomes designated and moves to a forwarding State causing a loop.

Loop Protect protects the network from loops. The Loop Protect feature is achieved by ports receiving BPDUs (RSTP/MSTP only) on point-to-point ISLs before their states are allowed to become forwarding. Further, if a BPDU timeout occurs on a port, its state becomes listening until a new BPDU is received. In this way, both upstream and downstream facing ports are protected. When a root or alternate port loses its path to the root bridge, due to message age expiration, it takes on the role of designated port and will not forward traffic until a BPDU is received. When a port is intended to be the designated port in an ISL, it constantly proposes and will not forward until a BPDU is received. It will revert to listening if it stops getting a response. Loop Protect also overrides the port admin setting. This protects against misconfiguration (such as disabling STP on a port) and protocol failure by the connected bridge.

Loop Protect has the capability to

- Control port forwarding state based on reception of agreement BPDUs
- Control port forwarding state based on reception of disputed BPDUs
- Disable a port based on frequency of failure events
- Communicate port non-forwarding status through traps.

### Note

Loop Protect Traps are not supported in this ExtremeXOS 15.7.

By default, Loop Protect is disabled on all ports.

### Loop Protect Port Modes

Ports work in two Loop Protect operational modes.

- If the port has the partner loop protect as capable then it works in full functional mode.
- If the port has the partner loop protect as incapable then it works limited functional mode.

In full mode, when RSTP/MSTP BPDUs is received in point-to-point link and the port is designated, a Loop Protect timer is set to 3 times hello time, when this timer expires then port will be moved to blocking state. Limited mode adds a further requirement that the flags field in the BPDU indicates a root role.

Message age expiration and the expiration of the Loop Protect timer are both events for which Loop Protect generates traps and a debug message. In addition, user can configure Loop Protect to forcefully disable port when one or more events occur. When the configured number of events happens within a given window of time, the port will be forced into disable and held there until you manually unlock it.

The following example shows the loop due to the misconfiguration in STP.

Figure 204 shows that Switch 1 is elected as Root. Switch 2 and Switch 3 elect the root port. Switch 3's port connected to Switch 2 is elected as Alternate port and its port state is in blocking state.

**Figure 204: Switch 1 Elected as Root**

Figure 205 shows that if the user accidentally disables the STP on Switch 2 port connected to Switch 3, Switch 2 will stop sending the BDPUs to Switch 3 since STP is disabled. Switch 3 assumes that neighbor is down and it changes the port to forwarding state which will eventually create a loop.

**Figure 205: STP Disabled on Switch 2**

Figure 206 shows that, with loop protect enabled switch 3 will not go to forwarding state until it receives a BPDU from switch 2 and the port state will be in discarding state.

**Figure 206: Loop Protect Enabled**

When the Loop protect feature is enabled:

- On a Point-to-point Link, BPDU must be received before going to Forwarding state.
- If a BPDU timeout occurs on a port, its state becomes DISCARDING until a BPDU is received.
- When a root or alternate port loses its path to the root bridge due to a message age expiration it takes on the role of designated port. It will not forward traffic until a BPDU is received.
- When a port is intended to be the designated port in a point-to-point link it constantly proposes and will not forward until a BPDU is received, and will revert to discarding if it fails to get a response.

- If the partner is not Loop Protect Capable (Alternate Agreement not supported), designated port will not be allowed to forward unless receiving agreements from a port with root role.
- Legacy Spanning Tree (802.1d) or shared media devices should be connected in a non-redundant fashion to avoid the possibility of looping.

You can enable the port by giving the command `enable port port-list`.

### *STP Filter Configuration*

This new ExtremeXOS 15.7.1 CLI feature includes processing and forwarding of *STP* BPDU's either by system wide or port based filter installation.

In previous releases this processing and forwarding of STP BPDUs was based only on ports, now this has been changed to system wide (default). Prior to ExtremeXOS 15.7, blocked ports transmission of the BPDU's was restricted, but for the Loop Protect feature when any proposal agreement BPDU is received in the blocked port, then reply for the proposal agreement is to be transmitted. Due to this MAC movement is reported and the packet was not processed. This feature prevents this issue.

You can roll back to the previous implementation (port-based) if any issues are encountered .

## Backup Root

When the root bridge of spanning tree instance is lost, its information may be retained in the network until the aging mechanism causes it to be removed. This leads to a delay in convergence on for the new root. This backup root feature is used to get faster convergence when the root bridge connectivity is lost.

Backup root feature enabled bridge port should be connected to Root with point to point link. When backup root bridge lost contact with the root bridge, automatically backup root bridge lowers its bridge priority (an increment below the priority of the lost root). This will cause the backup root bridge to become the new root with information superior to any information held by any bridge in the network. While save and reboot automatically changed priority will not be saved and restored. At the time of reboots it will have its priority restored to the original configured value by administrator.

If the priority of the root bridge is Zero and backup root has lost the connectivity of the root bridge then automatic assignment of the priority value for the backup root will be the initial configured value.

This backup root feature is activated only when there is loss of connectivity with the root bridge. Raising the priority on the root will not cause the Backup root feature to be activated.

### *Configuration Recommendations:*

- Enable the Backup Root feature on both the root and backup root.
- Configure all bridges except the root and backup root with the maximum bridge priority value (61440 with 802.1t).

- Configure the root and backup root to have the next lowest priority (57344 with 802.1t).
- We also recommend having multiple links between the root and backup root. This helps prevent the Backup Root feature from activating due to a simple link failure rather than a bridge failure.
- Care must be taken when this feature is used as it may result in sub-optimal traffic forwarding paths.

Consider the following topology: 10G link connected from the edge switches to the aggregation Root while the edge switches to the Backup Root switch with 1G links to reduce the cost and acts as a backup link. In this case, when the link between aggregation Root and Backup Root fails, the traffic will now use the 1G links providing reduced performance of the network. The aggregation old root is still in the network which can be used to forward the traffic. This feature has moved the root of the stp domain.

**Figure 207: Root and Backup Root Topology**

## Multisource Detection

Multisource Detection is a feature that prevents network disruption due to excessive topology changes caused by a full duplex port transmitting multiple BPDUs with different source MAC addresses, and different BPDU information. When a port is point-to-point, the received priority information comes from the most recently received BPDU. When a port is non-point-to-point, the received information reflects the best priority information out of all the received BPDUs. Typical scenarios for multisource detection are when a switch is connected to a device which has been improperly configured to forward received BPDUs out on other ports or has been configured to not run the Spanning Tree protocol and treats BPDUs as multicast packets by transmitting them out all other forwarding ports. In these situations, the connected port is acting as a shared media device. The way to detect shared media is the duplex setting. Since the port is full duplex it treats the connection as point-to-point.

When Loop Protect is configured for the port, if multisource detection is triggered, the port will go to the listening state and no longer be part of the active topology. Loop protect does not operate on shared media ports.

## Restrict Topology Change Notification

Restricted Topology Change Notification (TCN) is a Spanning Tree Protocol feature that allows/disallows TCN propagation on specified ports. When Restricted TCN is disabled, TCN propagation is allowed. The port propagates received TCNs and topology changes to other ports.

Restricted TCN is disabled by default. When Restricted TCN is enabled, the port does not propagate received TCNs and topology changes to other ports. Enable Restricted TCN to prevent unnecessary address flushing in the core region of the network caused by activation of bridges external to the core network.

A possible reason for not allowing TCN propagation is when bridges are not under the full control of the administrator or because MAC operational state for the attached or downstream LANs transitions frequently, causing disruption throughout the network. Rapid Spanning Tree responds to TCNs by selectively flushing the filter database. Persistent TCNs are disruptive, causing persistent address flushing, which in turn causes increased flooding in the network.

Restricted TCN is a useful tool when it is not possible to remove the source of the TCNs.

## BPDU Restrict on Edge Safeguard

BPDU restrict causes a port on which this feature is configured to be disabled as soon as an *STP* BPDU is received on that port, thus allowing you to enforce the STP domain borders and keep the active topology predictable.

Figure 208 shows a BPDU restrict example.

**Figure 208: BPDU Restrict**

In this figure, loops on the LAN access switches are not prevented since the ports towards the distribution switches are not running STP but Software Redundant Ports

(SRP). Currently, ExtremeXOS software cannot run STP on ports that are configured for SRP. STP on the access switch is unaware of the alternate path and therefore cannot prevent the loop that exists across the switches. Configuring a port as an edge mode port alone cannot prevent the loop between the switches because edge ports never send BPDUs. The edge safeguard feature is not able to prevent the loops because STP does not have the information about the alternate path.

To prevent the loops across the switches, the edge safeguard feature can be configured with the BPDU restrict function. When running in BPDU restrict mode, edge safeguard ports send STP BPDUs at a rate of one every two seconds. The port is disabled as soon as an STP BPDU is received on the BPDU restrict port, thereby preventing the loop. Flexibility is provided with an option to re-enable the port after a user specified time period. If a user enables a port while STP has disabled it, the port is operationally enabled; STP is notified and then stops any recovery timeout that has started.

When an *STPD* is disabled for a BPDU restrict configured port, an STP port in 802.1D operation mode begins forwarding immediately, but in the RSTP or *MSTP* operation modes, the port remains in the disabled state.

BPDU restrict is available on all of the three operational modes of STP: 802.1D, RSTP, and MSTP.

Although edge safeguard is not available in 802.1D operation mode, when you configure BPDU restrict you do so in a similar way, that is, as an extension of edge safeguard; then only BPDU restrict is available on the port and not edge safeguard.

To configure BPDU restrict, use the command:

- `configure {stpd} stpd_name ports edge-safeguard enable port_list {bpdu-restrict} {recovery-timeout {seconds}}`
- BPDU restrict can also be configured by using the following commands:
  - `configure {stpd} stpd_name ports bpdu-restrict [enable | disable] port_list {recovery-timeout {seconds}}`
  - `configure stpd stpd_name ports link-type [[auto | broadcast | point-to-point] port_list | edge port_list {edge-safeguard [enable | disable] {bpdu-restrict} {recovery-timeout seconds}}`

To include BPDU restrict functionality when configuring link types or edge safeguard, see [Configuring Link Types](#) on page 1751 and [Configuring Edge Safeguard](#) on page 1752.

The example below shows a BPDU restrict configuration:

```
configure s1 ports edge-safeguard enable 9 bpdu-restrict recovery-timeout 400.
```

The following is sample output from the `show s1 ports` command resulting from the configuration:

```
switch # show s1 ports
Port Mode State Cost Flags Priority Port ID Designated Bridge
9 EMISTP FORWARDING 20000 eDee-w-G-- 128 8009 80:00:00:04:96:26:5f:4e
Total Ports: 1
----- Flags: -----
```

```

1: e=Enable, d=Disable
2: (Port role) R=Root, D=Designated, A=Alternate, B=Backup, M=Master
3: (Config type) b=broadcast, p=point-to-point, e=edge, a=auto
4: (Oper. type) b=broadcast, p=point-to-point, e=edge
5: p=proposing, a=agree
6: (partner mode) d = 802.1d, w = 802.1w, m = mstp
7: i = edgeport inconsistency
8: S = edgeport safe guard active
s = edgeport safe guard configured but inactive

enable stpd s1

```

The following is sample output for STP operation mode dot1d from the `show configuration stp` command:

```

switch # show configuration stp
#
Module stp configuration.
#
configure mstp region region2
configure stpd s0 delete vlan default ports all
disable stpd s0 auto-bind vlan default
create stpd s1
enable stpd s0 auto-bind vlan Default
configure stpd s1 add vlan v1 ports 9 emistp
configure stpd s1 ports mode emistp 9
configure stpd s1 ports cost auto 9
configure stpd s1 ports priority 16 9
configure stpd s1 ports link-type edge 9
configure stpd s1 ports edge-safeguard enable 9 recovery-timeout 400
configure stpd s1 ports bpdu-restrict enable 9 recovery-timeout 400
enable stpd s1 ports 9
configure stpd s1 tag 10
enable stpd s1

```

## Disable Forwarding of Spanning Tree Protocol (STP) Bridge Protocol Data Units (BPDUs)

You can disable forwarding of *STP* Bridge Protocol Data Units (BPDUs) when STP is disabled on a switch. When STP is disabled globally, BPDUs received on a port are forwarded to other ports that are part of same *VLAN* causing the switch to transparently forward STP/RSTP/*MSTP* BPDUs. This transparent forwarding causes one-to-many peer in the network trouble where STP disabled. To avoid this transparent forwarding of BPDUs, you can opt to discard the BPDUs when there is no STP configuration enabled on the switch.

To disable STP BPDUs, use the command:

```
configure stpd bpdu-forwarding [on | off]
```

## Span Tree Domains

The switch can be partitioned into multiple virtual bridges. Each virtual bridge can run an independent Spanning Tree instance. Each Spanning Tree instance is called a *STPD*. Each STPD has its own root bridge and active path. After an STPD is created, one or more *VLANs* can be assigned to it.

A physical port can belong to multiple STPDs. In addition, a VLAN can span multiple STPDs.

The key points to remember when configuring VLANs and *STP* are:

- Each VLAN forms an independent broadcast domain.
- STP blocks paths to create a loop-free environment.
- Within any given STPD, all VLANs belonging to it use the same spanning tree.

- To create an STPD, use the command:

```
create stpd stpd_name {description stpd-description}
```

- To delete an STPD, use the command:

```
delete stpd stpd_name
```

User-created STPD names are not case-sensitive.

For detailed information about configuring STP and various STP parameters on the switch, see [Configuring STP on the Switch](#) on page 1777.

## Member VLANs

When you add a *VLAN* to an *STPD*, that VLAN becomes a member of the STPD. The two types of member VLANs in an STPD are:

- Carrier
- Protected

### carrier VLAN

In STP, carrier VLANs define the scope of the STPD, including the physical and logical ports that belong to the STPD as well as the 802.1Q tags used to transport EMISTP- or PVST+-encapsulated BPDUs. Only one carrier VLAN can exist in any given STPD.

### Protected VLAN

Protected VLANs are all other VLANs that are members of the STPD.

These VLANs “piggyback” on the carrier VLAN. Protected VLANs do not transmit or receive STP BPDUs, but they are affected by STP state changes and inherit the state of the carrier VLAN. Protected VLANs can participate in multiple STPDs, but any particular port in the VLAN can belong to only one STPD. Also known as non-carrier VLANs.

If you configure MSTP, all member VLANs in an MSTP region are protected VLANs. These VLANs do not transmit or receive STP BPDUs, but they are affected by STP state changes communicated by the CIST to the MSTP regions. Multiple spanning tree instances (MSTIs) cannot share the same protected VLAN; however, any port in a protected VLAN can belong to multiple MSTIs. For more information about MSTP, see [Multiple Spanning Tree Protocol](#) on page 1761.

### Specifying the Carrier VLAN

The following example:

- Creates and enables an STPD named s8.
- Creates a carrier VLAN named v5.
- Assigns VLAN v5 to STPD s8.
- Creates the same tag ID for the VLAN and the STPD (the carrier VLAN's ID must be identical to the STPD's ID).

```
create vlan v5
configure vlan v5 tag 100
configure vlan v5 add ports 1:1-1:20 tagged
create stpd s8
configure stpd s8 add vlan v5 ports all emistp
configure stpd s8 tag 100
enable stpd s8
```

Notice how the tag number for the VLAN v5 (100) is identical to the tag for STPD s8. By using identical tags, you have selected the carrier VLAN. The carrier VLAN's ID is now identical to the STPD's ID.

## STPD Modes

An STPD has three modes of operation:

- 802.1D mode

Use this mode for backward compatibility with previous STP versions and for compatibility with third-party switches using IEEE standard 802.1D. When configured in this mode, all rapid configuration mechanisms are disabled.

- 802.1w mode

Use this mode for compatibility with Rapid Spanning Tree (RSTP). When configured in this mode, all rapid configuration mechanisms are enabled. The benefit of this mode is available on point-to-point links only and when the peer is likewise

configured in 802.1w mode. If you do not select point-to-point links and the peer is not configured for 802.1w mode, the STPD fails back to 802.1D mode.

You can enable or disable RSTP on a per STPD basis only; you cannot enable RSTP on a per port basis.

For more information about RSTP and RSTP features, see [Rapid Spanning Tree Protocol](#) on page 1749.

- **MSTP mode**

Use this mode for compatibility with MSTP. MSTP is an extension of RSTP and offers the benefit of better scaling with fast convergence. When configured in this mode, all rapid configuration mechanisms are enabled. The benefit of MSTP is available only on point-to-point links and when you configure the peer in MSTP or 802.1w mode. If you do not select point-to-point links and the peer is not configured in 802.1w mode, the STPD fails back to 802.1D mode.

You must first configure a CIST before configuring any MSTIs in the region. You cannot delete or disable a CIST if any of the MSTIs are active in the system.

You can create only one MSTP region on the switch, and all switches that participate in the region must have the same regional configurations. You can enable or disable an MSTP on a per STPD basis only; you cannot enable MSTP on a per port basis.

If configured in MSTP mode, an STPD uses the 802.1D BPDU encapsulation mode by default. To ensure correct operation of your MSTP STPDs, do not configure EMISTP or PVST+ encapsulation mode for MSTP STPDs.

For more information about MSTP and MSTP features, see [Multiple Spanning Tree Protocol](#) on page 1761.

By default:

- The STPD s0 operates in MSTP CIST mode.
- The default device configuration contains a single STPD called s0.
- User-created STPDs operate in dot1d mode.
- The default VLAN is a member of STPD s0 with autobind enabled.

To configure the mode of operation of an STPD, use the following command:

```
configure stpd stpd_name mode [dot1d | dot1w | mstp [cist | msti
instance]]
```

#### Note

Starting with ExtremeXOS 22.2, STP operational mode can be changed while VLANs are associated with an STP domain. In MSTP operation mode, mode change is allowed only for CIST domains.

All STP parameters default to the IEEE 802.1D values, as appropriate.

## Encapsulation Modes

You can configure ports within an *STPD* to accept specific BPDUs encapsulations.

This *STPD* port encapsulation is separate from the STP mode of operation. For example, you can configure a port to accept the PVST+ BPDUs encapsulation while running in 802.1D mode.

An STP port has three possible encapsulation modes:

- 802.1D mode

Use this mode for backward compatibility with previous STP versions and for compatibility with third-party switches using IEEE standard 802.1D. BPDUs are sent untagged in 802.1D mode. Because of this, any given physical interface can have only one STPD running in 802.1D mode. The default port mode for user-created STP domains for Dot1d and Dot1w operation mode is Dot1d.

This encapsulation mode supports the following STPD modes of operation: 802.1D, 802.1w, and *MSTP*.

- Extreme Multiple Instance Spanning Tree Protocol (EMISTP) mode

EMISTP mode is proprietary to Extreme Networks and is an extension of STP that allows a physical port to belong to multiple STPDs by assigning the port to multiple *VLANs*. EMISTP adds significant flexibility to STP network design. BPDUs are sent with an 802.1Q tag having an STPD instance Identifier (STPD ID) in the VLAN ID field.

This encapsulation mode supports the following STPD modes of operation: 802.1D and 802.1w.

- Per VLAN Spanning Tree (PVST+) mode

This mode implements PVST+ in compatibility with third-party switches running this version of STP. The STPDs running in this mode have a one-to-one relationship with VLANs and send and process packets in PVST+ format.

This encapsulation mode supports the following STPD modes of operation: 802.1D and 802.1w.

These encapsulation modes are for STP ports, not for physical ports. When a physical port belongs to multiple STPDs, it is associated with multiple STP ports. It is possible for the physical port to run in different modes for different domains to which it belongs.

If configured in MSTP mode, an STPD uses the 802.1D BPDUs encapsulation mode by default. To ensure correct operation of your MSTP STPDs, do not configure EMISTP or PVST+ encapsulation mode for MSTP STPDs.

- To configure the BPDUs encapsulation mode for one or more STP ports, use the command:
  - `configure stpd stpd_name ports mode [dot1d | emistp | pvst-plus] port_list`

- To configure the default BPDU encapsulation mode on a per STPD basis, use the command:
  - `configure stpd stpd_name default-encapsulation [dot1d | emistp | pvst-plus]`

Instead of accepting the default encapsulation modes of dot1d for the default STPD s0 and for all other STPDs, this command allows you to specify the type of BPDU encapsulation to use for all ports added to the STPD (if not otherwise specified).

### STPD Identifier

An StpdID is used to identify each *STP* domain.

When assigning the StpdID when configuring the domain, ensure that the carrier *VLAN* of that *STPD* does not belong to another STPD. Unless all ports are running in 802.1D mode, an STPD with ports running in either EMISTP mode or PVST+ mode must be configured with an StpdID.

An StpdID must be identical to the VLAN ID of the carrier VLAN in that STP domain. For an 802.1D STPD, the VLAN ID can be either a user-defined ID or one automatically assigned by the switch.

#### Note

If an STPD contains at least one port not in 802.1D mode, you must configure the STPD with an StpdID.

*MSTP* uses two different methods to identify the STPDs that are part of the MSTP network. An instance ID of 0 identifies the CIST. The switch assigns this ID automatically when you configure the CIST STPD. An *MSTI (Multiple Spanning Tree Instances)* identifier (MSTI ID) identifies each STP domain that is part of an MSTP region. You assign the MSTI ID when configuring the STPD that participates in the MSTP region. In an MSTP region, MSTI IDs only have local significance. You can reuse MSTI IDs across MSTP regions. For more information about MSTP and MSTP features, see [Multiple Spanning Tree Protocol](#) on page 1761.

## STP States

Each port that belongs to a member *VLAN* participating in *STP* exists in one of the following states:

### Blocking

A port in the blocking state does not accept ingress traffic, perform traffic forwarding, or learn MAC source addresses. The port receives STP BPDUs. During STP initialization, the switch always enters the blocking state.

### Listening

A port in the listening state does not accept ingress traffic, perform traffic forwarding, or learn MAC source addresses. The port receives STP BPDUs. This is the first transitional state a port enters after being in the blocking state. The bridge listens for BPDUs from neighboring bridge(s) to determine whether the port should or should not be blocked.

### Learning

A port in the learning state does not accept ingress traffic or perform traffic forwarding, but it begins to learn MAC source addresses. The port also receives and processes STP BPDUs. This is the second transitional state after listening. From learning, the port will change to either blocking or forwarding.

### Forwarding

A port in the forwarding state accepts ingress traffic, learns new MAC source addresses, forwards traffic, and receives and processes STP BPDUs.

### Disabled

A port in the disabled state does not participate in STP; however, it will forward traffic and learn new MAC source addresses.

## Binding Ports

There are two ways to bind (add) ports to an *STPD*: manually and automatically. By default, ports are manually added to an STPD.

#### Note

The default *VLAN* and STPD S0 are already on the switch.

### Manually Binding Ports

- To manually bind ports, use the commands:  

```
configure stpd stpd_name add vlan vlan_name ports [all | port_list]
{[dot1d | emistp | pvst-plus]}
```

```
configure vlan vlan_name add ports [all | port_list] {tagged {} |
untagged} stpd stpd_name {[dot1d | emistp | pvst-plus]}
```

The first command adds all ports or a list of ports within the specified *VLAN* to an *STPD*. For EMISTP and PVST+, the carrier VLAN must already exist on the same set of ports. The second command adds all ports or a list of ports to the specified VLAN and STPD at the same time. If the ports are added to the VLAN but not to the STPD, the ports remain in the VLAN.

For EMISTP and PVST+, if the specified VLAN is not the carrier VLAN and the specified ports are not bound to the carrier VLAN, the system displays an error message. If you configure *MSTP* on your switch, MSTP does not need carrier VLANs.

#### Note

The carrier VLAN's ID must be identical to the ID of the *STP* domain.

If you add a protected VLAN or port, that addition inherits the carrier VLAN's encapsulation mode, unless you specify the encapsulation mode when you execute the `configure stpd add vlan` or `configure vlan add ports stpd` commands.

If you specify an encapsulation mode (dot1d, emistp, or pvst-plus), the STP port mode is changed to match; otherwise, the STP port inherits either the carrier VLAN's encapsulation mode on that port or the STPD's default encapsulation mode.

For MSTP, you do not need carrier a VLAN. A CIST controls the connectivity of interconnecting MSTP regions and sends BPDUs across the regions to communicate

region status. You must use the dot1d encapsulation mode in an MSTP environment. For more information about MSTP, see the section [Multiple Spanning Tree Protocol](#) on page 1761.

- To remove ports, use the command:

```
configure stpd stpd_name delete vlan vlan_name ports [all | port_list]
```

If you manually delete a protected VLAN or port, only that VLAN or port is removed.

If you manually delete a carrier VLAN or port, all VLANs on that port (both carrier and protected) are deleted from that STPD.

To learn more about member VLANs, see [Member VLANs](#) on page 1733. For more detailed information about these command line interface (CLI) commands, see the [Switch Engine v33.3.1 Command References](#).

### Automatically Binding Ports

- To automatically bind ports to an STPD when the ports are added to a VLAN, use the command:

```
enable stpd stpd_name auto-bind vlan vlan_name
```

The autobind feature is disabled on user-created STPDs. The autobind feature is enabled on the default VLAN that participates in the default STPD S0.

For EMISTP or PVST+, when you issue this command, any port or list of ports that you add to the carrier VLAN are automatically added to the STPD with autobind enabled. In addition, any port or list of ports that you remove from a carrier VLAN are automatically removed from the STPD. This feature allows the STPD to increase or decrease its span as ports are added to or removed from a carrier VLAN.

#### Note

The carrier VLAN's ID must be identical to the ID of the STP domain.

Enabling autobind on a protected VLAN does not expand the boundary of the STPD.

If the same set of ports are members of the protected VLAN and the carrier VLAN, protected VLANs are aware of STP state changes. For example, assume you have the following scenario:

- Carrier VLAN named v1
- v1 contains ports 3:1-3:2
- Protected VLAN named v2
- v2 contains ports 3:1-3:4

Since v1 contains ports 3:1-3:2, v2 is aware only of the STP changes for ports 3:1 and 3:2, respectively. Ports 3:3 and 3:4 are not part of the STPD, which is why v2 is not aware of any STP changes for those ports.

In addition, enabling autobind on a protected VLAN causes ports to be automatically added or removed as the carrier VLAN changes.

For MSTP, when you issue this command, any port or list of ports that gets automatically added to an MSTI are automatically inherited by the CIST. In addition, any port or list of ports that you remove from an MSTI protected VLAN are

automatically removed from the CIST. For more information, see [Automatically Inheriting Ports--MSTP Only](#) on page 1740.

- To remove ports, enter the command:

```
configure stpd stpd_name delete vlan vlan_name ports [all | port_list]
```

If you manually delete a port from the STPD on a VLAN that has been added by autobind, ExtremeXOS records the deletion so that the port does not get automatically added to the STPD after a system restart.

To learn more about the member VLANs, see [Member VLANs](#) on page 1733. For more detailed information about these CLI commands, see the [Switch Engine v33.3.1 Command References](#).

#### *Automatically Inheriting Ports--MSTP Only*

In an [MSTP](#) environment, whether you manually or automatically bind a port to an [MSTI](#) in an MSTP region, the switch automatically binds that port to the CIST.

The CIST handles BPDU processing for itself and all of the MSTIs; therefore, the CIST must inherit ports from the MSTIs in order to transmit and receive BPDUs. You can only delete ports from the CIST if it is no longer a member of an MSTI.

For more information about MSTP, see [Multiple Spanning Tree Protocol](#) on page 1761.

## Rapid Root Failover

ExtremeXOS supports rapid root failover for faster [STP](#) failover recovery times in STP 802.1D mode. If the active root port link goes down, ExtremeXOS recalculates STP and elects a new root port. The rapid root failover feature allows the new root port to immediately begin forwarding, skipping the standard listening and learning phases. Rapid root failover occurs only when the link goes down and not when there is any other root port failure, such as missing BPDUs.

The default setting for this feature is disabled.

- To enable rapid root failover, enter the command:

```
enable stpd stpd_name rapid-root-failover
```

- To display the configuration, enter the command:

```
show stpd {stpd_name | detail}
```

## STP and Hitless Failover—SummitStack Only

When you are using redundancy in a SummitStack, one node assumes the role of primary and the other node assumes the role of backup. The primary executes the switch's management functions, and the backup acts in a standby role. Hitless failover transfers switch management control from the primary to the backup and maintains

the state of [STP](#). STP supports hitless failover. You do not explicitly configure hitless failover support; rather, if you have two nodes installed, hitless failover is available.

**Note**

Not all platforms support hitless failover in the same software release. To verify if the software version you are running supports hitless failover, see the following table in [Managing the Switch](#) on page 65. For more information about protocol and platform support for hitless failover, see [Understanding Hitless Failover Support](#) on page 88.

To support hitless failover, the primary node replicates STP BPDUs to the backup, which allows the nodes to run STP in parallel. Although both primary and backup node receive STP BPDUs, only the primary transmits STP BPDUs to neighboring switches and participates in STP.

**Note**

Before initiating failover, review the section [Synchronizing Nodes](#) on page 1656 to confirm that both primary and backup nodes are running software that supports the [synchronize](#) command.

To initiate hitless failover on a network that uses STP:

1. Confirm that the nodes are synchronized and have identical software and switch configurations using the command:

```
show switch {detail}
```

The output displays the status of the primary and backup nodes, with the primary node showing MASTER and the backup node showing BACKUP (InSync).

If the primary and backup nodes are not synchronized and both nodes are running a version of ExtremeXOS that supports synchronization, proceed to [2](#).

If the primary and backup nodes are synchronized, proceed to [3](#) on page 1741.

2. If the primary and backup nodes are not synchronized, use the [synchronize](#) command to replicate all saved images and configurations from the primary to the backup.

After you confirm the nodes are synchronized, proceed to [3](#).

3. If the nodes are synchronized, use the `run failover` (formerly `run msm-failover`) command to initiate failover.

For more detailed information about verifying the status of the primary and backup nodes, and system redundancy, see [Understanding System Redundancy](#) on page 83. For more information about hitless failover, see [Understanding Hitless Failover Support](#) on page 88.

## STP Configurations

When you assign [VLANs](#) to an [STPD](#), pay careful attention to the [STP](#) configuration and its effect on the forwarding of VLAN traffic.

This section describes three types of STP configurations:

- [Basic STP](#)
- [Multiple STPDs on a single port \(which uses EMISTP\)](#)
- [A VLAN that spans multiple STPDs](#)

## Basic STP Configuration

This section describes a basic, 802.1D [STP](#) configuration. [Figure 209](#) on page 1743 illustrates a network that uses [VLAN](#) tagging for trunk connections.

The following four VLANs have been defined:

- Sales is defined on switch A, switch B, and switch M.
- Personnel is defined on switch A, switch B, and switch M.
- Manufacturing is defined on switch Y, switch Z, and switch M.
- Engineering is defined on switch Y, switch Z, and switch M.
- Marketing is defined on all switches (switch A, switch B, switch Y, switch Z, and switch M).

Two [STPDs](#) are defined:

- STPD1 contains VLANs Sales and Personnel.
- STPD2 contains VLANs Manufacturing and Engineering.

The carrier and protected VLANs are also defined:

- Sales is the carrier VLAN on STPD1.
- Personnel is a protected VLAN on STPD1.
- Manufacturing is a protected VLAN on STPD2.
- Engineering is the carrier VLAN on STPD2.
- Marketing is a member of both STPD1 and STPD2 and is a protected VLAN.

**Figure 209: Multiple STPDs**

When the switches in this configuration boot-up, STP configures each STPD such that the topology contains no active loops. STP could configure the topology in a number of ways to make it loop-free.

In [Figure 209](#), the connection between switch A and switch B is put into blocking state, and the connection between switch Y and switch Z is put into blocking state. After STP converges, all the VLANs can communicate, and all bridging loops are prevented.

The protected VLAN Marketing, which has been assigned to both STPD1 and STPD2, communicates using all five switches. The topology has no loops, because STP has already blocked the port connection between switch A and switch B and between switch Y and switch Z.

Within a single STPD, you must be extra careful when configuring your VLANs. [Figure 210](#) illustrates a network that has been incorrectly set up using a single STPD so that the STP configuration disables the ability of the switches to forward VLAN traffic.

**Figure 210: Incorrect Tag-Based STPD Configuration**

The tag-based network in the following figure has the following configuration:

- Switch 1 contains VLAN Marketing and VLAN Sales.
- Switch 2 contains VLAN Engineering and VLAN Sales.
- Switch 3 contains VLAN Marketing, VLAN Engineering, and VLAN Sales.
- The tagged trunk connections for three switches form a triangular loop that is not permitted in an STP topology.
- All VLANs in each switch are members of the same STPD.

STP can block traffic between switch 1 and switch 3 by disabling the trunk ports for that connection on each switch.

Switch 2 has no ports assigned to VLAN Marketing. Therefore, if the trunk for VLAN Marketing on switches 1 and 3 is blocked, the traffic for VLAN Marketing will not be able to traverse the switches.

**Note**

If an STPD contains multiple VLANs, all VLANs should be configured on all ports in that domain, except for ports that connect to hosts (edge ports).

## Multiple STPDs on a Port

Traditional 802.1D STP has some inherent limitations when addressing networks that have multiple VLANs and multiple STPDs.

For example, consider the sample depicted in [Figure 211](#) on page 1745.

**Figure 211: Limitations of Traditional STPD**

The two switches are connected by a pair of parallel links. Both switches run two VLANs, A and B. To achieve load-balancing between the two links using the traditional approach, you would have to associate A and B with two different STPDs, called S1 and S2, respectively, and make the left link carry VLAN A traffic while the right link carries VLAN B traffic (or vice versa). If the right link fails, S2 is broken and VLAN B traffic is disrupted.

To optimize the solution, you can use the Extreme Multiple Instance Spanning (EMISTP) mode, which allows a port to belong to multiple STPDs. EMISTP adds significant flexibility to STP network design. Referring to [Figure 211](#), using EMISTP, you can configure all four ports to belong to both VLANs.

Assuming that S1 and S2 still correspond to VLANs A and B respectively, you can fine-tune STP parameters to make the left link active in S1 and blocking in S2, while the right link is active in S2 and blocking in S1. Again, if the right link fails, the left link is elected active by the STP algorithm for S2, without affecting normal switching of data traffic.

Using EMISTP, an STPD becomes more of an abstract concept. The STPD does not necessarily correspond to a physical domain; it is better regarded as a vehicle to carry VLANs that have STP instances. Because VLANs can overlap, so do STPDs. However, even if the different STPDs share the entire topology or part of the redundant topology, the STPDs react to topology change events in an independent fashion.

## VLANs Spanning Multiple STPDs

Traditionally, the mapping from VLANs to STP instances have been one-to-one or many-to-one.

In both cases, a VLAN is wholly contained in a single instance. In practical deployment there are cases in which a one-to-many mapping is desirable. In a typical large enterprise network, for example, VLANs span multiple sites and/or buildings. Each site represents a redundant looped area. However, between any two sites the topology is usually very simple.

Alternatively, the same VLAN may span multiple large geographical areas (because they belong to the same enterprise) and may traverse a great many nodes.

In this case, it is desirable to have multiple STP domains operating in a single VLAN, one for each looped area.

The justifications include the following:

- The complexity of the STP algorithm increases, and performance drops, with the size and complexity of the network. The 802.1D standard specifies a maximum network diameter of seven hops. By segregating a big VLAN into multiple STPDs, you reduce complexity and enhance performance.
- Local to each site, there may be other smaller VLANs that share the same redundant looped area with the large VLAN. Some STPDs must be created to protect those VLANs. The ability to partition VLANs allows the large VLAN to be "piggybacked" in those STPDs in a site-specific fashion.

Figure 212 has five domains. VLANs green, blue, brown, and yellow are local to each domain. VLAN red spans all of the four domains. Using a VLAN that spans multiple STPDs, you do not have to create a separate domain for VLAN red. Instead, VLAN red is "piggybacked" onto those domains local to other VLANs.

**Figure 212: VLANs Spanning Multiple STPDs**

In addition, this configuration has these features:

- Each site can be administered by a different organization or department within the enterprise. Having a site-specific STP implementation makes the administration more flexible and convenient.
- Between the sites the connections usually traverse distribution switches in ways that are known beforehand to be "safe" with STP. In other words, the looped areas are already well defined.

## EMISTP Deployment Constraints

Although EMISTP greatly enhances STP capability, these features must be deployed with care.

This section describes configuration issues that, if not followed, could lead to an improper deployment of EMISTP. This section also provides the following restrictive principles to abide by in network design:

- Although a physical port can belong to multiple *STPDs*, any *VLAN* on that port can be in only one domain. Put another way, a VLAN cannot belong to two STPDs on the same physical port.
- Although a VLAN can span multiple domains, any LAN segment in that VLAN must be in the same STPD. VLANs traverse STPDs only inside switches, not across links. On a single switch, however, bridge ports for the same VLAN can be assigned to different STPDs. This scenario is illustrated in [Figure 213](#).

**Figure 213: VLANs Traverse Domains Inside Switches**

- The VLAN partition feature is deployed under the premise that the overall inter-domain topology for that VLAN is loop-free. Consider the case in [Figure 214](#), VLAN red (the only VLAN in the figure) spans STPDs 1, 2, and 3. Inside each domain, STP produces a loop-free topology. However, VLAN red is still looped, because the three domains form a ring among themselves.

**Figure 214: Looped VLAN Topology**

- A necessary (but not sufficient) condition for a loop-free inter-domain topology is that every two domains only meet at a single crossing point.

**Note**

You can use [MSTP](#) to overcome the EMISTP constraints described in this section.

## Per VLAN Spanning Tree

Switching products that implement Per [VLAN](#) Spanning Tree (PVST) have been in existence for many years and are widely deployed.

To support [STP](#) configurations that use PVST, ExtremeXOS has an operational mode called PVST+.

**Note**

In this document, PVST and PVST+ are used interchangeably. PVST+ is an enhanced version of PVST that is interoperable with 802.1Q STP. The following discussions are in regard to PVST+, if not specifically mentioned.

## STPD VLAN Mapping

Each [VLAN](#) participating in PVST+ must be in a separate [STPD](#), and the VLAN number (VLAN ID) must be the same as the STPD identifier (STPD ID).

As a result, PVST+ protected VLANs cannot be partitioned.

This fact does not exclude other non-PVST+ protected VLANs from being grouped into the same STPD. A protected PVST+ VLAN can be joined by multiple non-PVST+ protected VLANs to be in the same STPD.

**Note**

When PVST+ is used to interoperate with other networking devices, each VLAN participating in PVST+ must be in a separate *STP* domain.

## Native VLAN

In PVST+, the native *VLAN* must be peered with the default VLAN on Extreme Networks devices, as both are the only VLANs allowed to send and receive untagged packets on the physical port.

Third-party PVST+ devices send VLAN 1 packets in a special manner. ExtremeXOS does not support PVST+ for VLAN 1. Therefore, when the switch receives a packet for VLAN 1, the packet is dropped.

When a PVST+ instance is disabled, the fact that PVST+ uses a different packet format raises an issue. If the *STPD* also contains ports not in PVST+ mode, the flooded packet has an incompatible format with those ports. The packet is not recognized by the devices connected to those ports.

## Rapid Spanning Tree Protocol

The Rapid Spanning Tree Protocol (RSTP), originally in the IEEE 802.1w standard and now part of the IEEE 802.1D-2004 standard, provides an enhanced spanning tree algorithm that improves the convergence speed of bridged networks.

RSTP takes advantage of point-to-point links in the network and actively confirms that a port can safely transition to the forwarding state without relying on any timer configurations. If a network topology change or failure occurs, RSTP rapidly recovers network connectivity by confirming the change locally before propagating that change to other devices across the network. For broadcast links, there is no difference in convergence time between *STP* and RSTP.

RSTP supersedes legacy STP protocols, supports the existing STP parameters and configurations, and allows for seamless interoperability with legacy STP.

## RSTP Concepts

### *Port Roles*

RSTP uses information from BPDUs to assign port roles for each LAN segment. Port roles are not user-configurable. Port role assignments are determined based on the following criteria:

- A unique bridge identifier (MAC address) associated with each bridge
- The path cost associated with each bridge port
- A port identifier associated with each bridge port

RSTP assigns one of the following port roles to bridge ports in the network, as described in [Table 159](#).

**Table 159: RSTP Port Roles**

| Port Role  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Root       | Provides the shortest (lowest) path cost to the root bridge. Each bridge has only one root port; the root bridge does not have a root port. If a bridge has two or more ports with the same path cost, the port with the best port identifier (lowest MAC address) becomes the root port.                                                                                                                                                                                                                                                    |
| Designated | Provides the shortest path connection to the root bridge for the attached LAN segment. To prevent loops in the network, there is only one designated port on each LAN segment. To select the designated port, all bridges that are connected to a particular segment listen to each other's BPDUs and agree on the bridge sending the best BPDU. The corresponding port on that bridge becomes the designated port. If there are two or more ports connected to the LAN, the port with the best port identifier becomes the designated port. |
| Alternate  | Provides an alternate path to the root bridge and the root port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Backup     | Supports the designated port on the same attached LAN segment. Backup ports exist only when the bridge is connected as a self-loop or to a shared-media segment.                                                                                                                                                                                                                                                                                                                                                                             |
| Disabled   | A port in the disabled state does not participate in RSTP; however, it will forward traffic and learn new MAC source addresses.                                                                                                                                                                                                                                                                                                                                                                                                              |

When RSTP stabilizes:

- All root ports and designated ports are in the forwarding state.
- All alternate ports and backup ports are in the blocking state.

RSTP makes the distinction between the alternate and backup port roles to describe the rapid transition of the alternate port to the forwarding state if the root port fails.

To prevent a port from becoming an alternate or backup port, use the command:

```
configure stpd stpd_name ports active-role enable port .
```

To revert to the default that allows a port to be elected to any *STP* port role, use the command:

```
configure stpd stpd_name ports active-role disable port
```

To view the active-role status, use the command: `show stpd ports`.

### Link Types

With *RSTP (Rapid Spanning Tree Protocol)*, you can configure the link type of a port in an *STPD*.

RSTP tries to rapidly move designated point-to-point links into the forwarding state when a network topology change or failure occurs. For rapid convergence to occur, the port must be configured as a point-to-point link.

Table 160 describes the link types.

**Table 160: RSTP Link Types**

| Port Link Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Auto           | Specifies the switch to automatically determine the port link type. An auto link behaves like a point-to-point link if the link is in full-duplex mode or if link aggregation is enabled on the port. Otherwise, the link behaves like a broadcast link used for 802.1w configurations.                                                                                                                                                                                                                                                                                                                                                                     |
| Edge           | Specifies a port that does not have a bridge attached. An edge port is held in the <i>STP</i> forwarding state unless a BPDU is received by the port. In that case, the port behaves as a normal RSTP port. The port is no longer considered an edge port. If the port does not receive subsequent BPDUs during a pre-determined time, the port attempts to become an edge port.<br><br>ExtremeXOS 11.5 or earlier—An edge port is placed and held in the STP forwarding state unless a BPDU is received by the port. In that case, an edge port enters and remains in the blocking state until it stops receiving BPDUs and the message age timer expires. |
| Broadcast      | Specifies a port attached to a LAN segment with more than two bridges. A port with a broadcast link type cannot participate in rapid reconfiguration using RSTP or <i>MSTP</i> . By default, all ports are broadcast links.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Point-to-point | Specifies a port attached to a LAN segment with only two bridges. A port with point-to-point link type can participate in rapid reconfiguration. Used for 802.1w and MSTP configurations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### Configuring Link Types

- To configure the ports in an *STPD*, enter the command:

```
configure stpd stpd_name ports link-type [[auto | broadcast |
point-to-point] port_list | edge port_list {edge-safeguard [enable |
disable] {bpdu-restrict} {recovery-timeout seconds}}]
```

Where the following is true:

- auto—Configures the ports as auto links. If the link is in full-duplex mode or if link aggregation is enabled on the port, an auto link behaves like a point-to-point link.
- broadcast—Configures the ports as broadcast ports. By default, all ports are broadcast links.
- point-to-point—Configures the ports for rapid reconfiguration in an RSTP or *MSTP* environment.
- edge—Configures the ports as edge ports. For information about edge safeguard, see [Configuring Edge Safeguard](#) on page 1752.
- To change the existing configuration of a port in an STPD, and return the port to factory defaults, enter the command:

```
unconfigure stpd stpd_name ports link-type port_list
```

- To display detailed information about the ports in an STPD, enter the command:

```
show {stpd} stpd_name ports [{detail | port_list {detail}}]
```

## Configuring Edge Safeguard

Loop prevention and detection on an edge port configured for RSTP is called *edge safeguard*. You can configure edge safeguard on RSTP edge ports to prevent accidental or deliberate misconfigurations (loops) resulting from connecting two edge ports together or by connecting a hub or other non-*STP* switch to an edge port. Edge safeguard also limits the impact of broadcast storms that might occur on edge ports. This advanced loop prevention mechanism improves network resiliency but does not interfere with the rapid convergence of edge ports.

An edge port configured with edge safeguard immediately enters the forwarding state and transmits BPDUs. If a loop is detected, STP blocks the port. By default, an edge port without edge safeguard configured immediately enters the forwarding state but does not transmit BPDUs unless a BPDU is received by that edge port.

You can also configure edge safeguard for loop prevention and detection on an *MSTP* edge port.

- To configure an edge port and enable edge safeguard on that port, use the command:

```
configure stpd stpd_name ports link-type [[auto | broadcast |
point-to-point] port_list | edge port_list {edge-safeguard [enable |
disable] {bpdu-restrict} {recovery-timeout seconds}}]
```

- If you have already configured a port as an edge port and you want to enable edge safeguard on the port, use the following command:

```
configure {stpd} stpd_name ports edge-safeguard enable port_list
{bpdu-restrict} {recovery-timeout {seconds}}
```

- To disable edge safeguard on an edge port, enter the command:

```
configure {stpd} stpd_name ports edge-safeguard disable port_list
{bpdu-restrict} {recovery-timeout {seconds}}

configure stpd stpd_name ports link-type [[auto | broadcast |
point-to-point] port_list | edge port_list {edge-safeguard [enable |
disable] {bpdu-restrict} {recovery-timeout seconds}}]
```

In ExtremeXOS 11.5 and earlier, ports that connect to non-STP devices are edge ports. Edge ports do not participate in RSTP, and their role is not confirmed. Edge ports immediately enter the forwarding state unless the port receives a BPDU. In that case, edge ports enter the blocking state. The edge port remains in the blocking state until it stops receiving BPDUs and the message age timer expires.

ExtremeXOS 11.6 and later support an enhanced bridge detection method, which is part of the 802.1D-2004 standard. Ports that connect to non-STP devices are still considered edge ports. However, if you have an 802.1D-2004 compliant edge port, the bridge detection mechanism causes the edge port to transition to a non-edge port upon receiving a BPDU. If the former edge port does not receive a subsequent BPDU during a pre-determined interval, the port attempts to become an edge port.

In ExtremeXOS 12.0.3 and 12.1.4 onwards, STP edge safeguard disables a port when a remote loop is detected. ExtremeXOS versions prior to 12.0.3 and 12.1.4 place the port in blocking mode. The change was made because BPDUs are still processed when a port is in a blocking state. A remote loop causes BPDUs to be exponentially duplicated

which caused high CPU utilization on the switch even though the port was transitioned to a blocked state.

### Configuring Auto Edge

This feature helps to automatically determine if a port is an edge port or non-edge port. If no BPDU is received for a period of time on auto edge enabled ports, the switch marks those ports as edge ports. If BPDU is received, the switch marks those ports as non-edge ports. By default auto edge is enabled on all ports.

### RSTP Timers

For RSTP to rapidly recover network connectivity, RSTP requires timer expiration. RSTP derives many of the timer values from the existing configured *STP* timers to meet its rapid recovery requirements rather than relying on additional timer configurations.

[Table 161](#) describes the user-configurable timers, and [Table 162](#) on page 1753 describes the timers that are derived from other timers and are not user configurable.

**Table 161: User-Configurable Timers**

| Timer         | Description                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hello         | The root bridge uses the hello timer to send out configuration BPDUs through all of its forwarding ports at a predetermined, regular time interval. The default value is 2 seconds. The range is 1 to 10 seconds.                                                                                                                                                                        |
| Forward delay | A port moving from the blocking state to the forwarding state uses the forward delay timer to transition through the listening and learning states. In RSTP, this timer complements the rapid configuration behavior. If none of the rapid rules are in effect, the port uses legacy STP rules to move to the forwarding state. The default is 15 seconds. The range is 4 to 30 seconds. |

**Table 162: Derived Timers**

| Timer           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TCN             | The root port uses the topology change notification (TCN) timer when it detects a change in the network topology. The TCN timer stops when the topology change timer expires or upon receipt of a topology change acknowledgement. The default value is the same as the value for the bridge hello timer.                                                                                                                                                                            |
| Topology change | The topology change timer determines the total time it takes the forwarding ports to send configuration BPDUs. The default value for the topology change timer depends upon the mode of the port:<br>802.1D mode—The sum of the forward delay timer value (default value is 15 seconds; range of 4 to 30 seconds) and the maximum age timer value (default value is 20 seconds; range of 6 to 40 seconds).<br>802.1w mode—Double the hello timer value (default value is 4 seconds). |

**Table 162: Derived Timers (continued)**

| Timer         | Description                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Message age   | A port uses the message age timer to time out receiving BPDUs. When a port receives a superior or equal BPDU, the timer restarts. When the timer expires, the port becomes a designated port and a configuration update occurs. If the bridge operates in 1w mode and receives an inferior BPDU, the timer expires early. The default value is the same as the <i>STPD</i> bridge max age parameter. |
| Hold          | A port uses the hold timer to restrict the rate that successive BPDUs can be sent. The default value is the same as the value for the bridge hello timer.                                                                                                                                                                                                                                            |
| Recent backup | The timer starts when a port leaves the backup role. When this timer is running, the port cannot become a root port. The default value is double the hello time (4 seconds).                                                                                                                                                                                                                         |
| Recent root   | The timer starts when a port leaves the root port role. When this timer is running, another port cannot become a root port unless the associated port is put into the blocking state. The default value is the same as the forward delay time.                                                                                                                                                       |

The protocol migration timer is neither user-configurable nor derived; it has a set value of 3 seconds. The timer starts when a port transitions from STP (802.1D) mode to RSTP (802.1w) mode and vice-versa. This timer must expire before further mode transitions can occur.

## RSTP Operation

In an RSTP environment, a point-to-point link LAN segment has two bridges.

A switch that considers itself the unique, designated bridge for the attached LAN segment sends a “propose” message to the other bridge to request a confirmation of its role. The other bridge on that LAN segment replies with an “agree” message if it agrees with the proposal. The receiving bridge immediately moves its designated port into the forwarding state.

Before a bridge replies with an “agree” message, it reverts all of its designated ports into the blocking state. This introduces a temporary partition into the network. The bridge then sends another “propose” message on all of its designated ports for further confirmation. Because all of the connections are blocked, the bridge immediately sends an “agree” message to unblock the proposing port without having to wait for further confirmations to come back or without the worry of temporary loops.

Beginning with the root bridge, each bridge in the network engages in the exchange of “propose” and “agree” messages until they reach the edge ports. Edge ports connect to non-*STP* devices and do not participate in RSTP. Their role does not need to be confirmed. If you have an 802.1D-2004 compliant edge port, the bridge detection mechanism causes the edge port to transition to a non-edge port upon receiving a BPDU. If the former edge port does not receive a subsequent BPDU during a pre-determined interval, the port attempts to become an edge port.

RSTP attempts to transition root ports and designated ports to the forwarding state and alternate ports and backup ports to the blocking state as rapidly as possible.

A port transitions to the forwarding state if any of the port:

- Has been in either a root or designated port role long enough that the spanning tree information supporting this role assignment has reached all of the bridges in the network;

**Note**

RSTP is backward-compatible with STP, so if a port does not move to the forwarding state with any of the RSTP rapid transition rules, a forward delay timer starts and STP behavior takes over.

- Is now a root port and no other ports have a recent role assignment that contradicts with its root port role;
- Is a designated port and attaches to another bridge by a point-to-point link and receives an “agree” message from the other bridge port; or
- Is an edge port. An edge port is a port connected to a non-STP device and is in the forwarding state.

The following sections provide more information about RSTP behavior.

#### *Root Port Rapid Behavior*

In [Figure 215](#) on page 1756, the diagram on the left displays the initial network topology with a single bridge having the following:

- Two ports are connected to a shared LAN segment.
- One port is the designated port.
- One port is the backup port.

The diagram on the right displays a new bridge that:

- Is connected to the LAN segment.
- Has a superior STP bridge priority.
- Becomes the root bridge and sends a BPDU (Bridge Protocol Data Unit) to the LAN that is received by both ports on the old bridge.

**Figure 215: Example of Root Port Rapid Behavior**

If the backup port receives the BPDU first, STP processes this packet and temporarily elects this port as the new root port while the designated port's role remains unchanged. If the new root port is immediately put into the forwarding state, there is a loop between these two ports.

To prevent this type of loop from occurring, the recent backup timer starts. The root port transition rule does not allow a new root port to be in the forwarding state until the recent backup timer expires.

Another situation may arise if you have more than one bridge and you lower the port cost for the alternate port, which makes it the new root port. The previous root port is now an alternate port. Depending on your STP implementation, STP may set the new root port to the forwarding state before setting the alternate port to the blocking state. This may cause a loop.

To prevent this type of loop from occurring, the recent root timer starts when the port leaves the root port role. The timer stops if the port enters the blocking state. *RSTP* requires that the recent root timer stop on the previous root port before the new root port can enter the forwarding state.

#### *Designated Port Rapid Behavior*

When a port becomes a new designated port, or the *STP* priority changes on an existing designated port, the port becomes an unsynced designated port.

For an unsynced designated port to rapidly move into the forwarding state, the port must propose a confirmation of its role on the attached LAN segment (unless the port is an edge port). Upon receiving an “agree” message, the port immediately enters the forwarding state.

If the receiving bridge does not agree and it has a superior STP priority, the receiving bridge replies with its own BPDU. Otherwise, the receiving bridge keeps silent, and the proposing port enters the forwarding state and starts the forward delay timer.

The link between the new designated port and the LAN segment must be a point-to-point link. If there is a multi-access link, the “propose” message is sent to multiple recipients. If only one of the recipients agrees with the proposal, the port can erroneously enter the forwarding state after receiving a single “agree” message.

#### *Receiving Bridge Behavior*

The receiving bridge must decide whether or not to accept a proposal from a port.

Upon receiving a proposal for a root port, the receiving bridge:

- Processes the BPDU and computes the new *STP* topology.
- Synchronizes all of the designated ports if the receiving port is the root port of the new topology.
- Puts all unsynced, designated ports into the blocking state.
- Sends down further “propose” messages.
- Sends back an “agree” message through the root port.

If the receiving bridge receives a proposal for a designated port, the bridge replies with its own BPDU. If the proposal is for an alternate or backup port, the bridge keeps silent.

#### *Propagating Topology Change Information*

When a change occurs in the topology of the network, such events are communicated through the network.

In an RSTP environment, only non-edge ports entering the forwarding state cause a topology change. A loss of network connectivity is not considered a topology change; however, a gain in network connectivity must be communicated. When an RSTP bridge detects a topology change, that bridge starts the topology change timer, sets the topology change flag on its BPDUs, floods all of the forwarding ports in the network (including the root ports), and flushes the learned MAC address entries.

#### *Rapid Reconvergence*

This section describes the RSTP rapid behavior following a topology change.

In this example, the bridge priorities are assigned based on the order of their alphabetical letters; bridge A has a higher priority than bridge F.

Suppose you have a network, as shown in [Figure 216](#) on page 1758, with six bridges (bridge A through bridge F) where the following is true:

- Bridge A is the root bridge.
- Bridge D contains an alternate port in the blocking state.
- All other ports in the network are in the forwarding state.

EX\_055a

**Figure 216: Initial Network Configuration**

The network reconverges in the following way:

If the link between bridge A and bridge F goes down, bridge F detects the root port is down. At this point, bridge F:

- Immediately disables that port from the *STP*.
- Performs a configuration update.

As shown in Figure 217, after the configuration update, bridge F:

- Considers itself the new root bridge.
- Sends a BPDU message on its designated port to bridge E.

EX\_055b

**Figure 217: Down Link Detected**

- Bridge E believes that bridge A is the root bridge. When bridge E receives the BPDU on its root port from bridge F, bridge E:
  - Determines that it received an inferior BPDU.
  - Immediately begins the max age timer on its root port.
  - Performs a configuration update.

As shown in Figure 218, after the configuration update, bridge E:

- Regards itself as the new root bridge.
- Sends BPDU messages on both of its designated ports to bridges F and D, respectively.

EX\_055c

**Figure 218: New Root Bridge Selected**

As shown in [Figure 219](#), when bridge F receives the superior BPDUs and configuration update from bridge E, bridge F:

- Decides that the receiving port is the root port.
- Determines that bridge E is the root bridge.

EX\_055d

**Figure 219: Communicating New Root Bridge Status to Neighbors**

Bridge D believes that bridge A is the root bridge. When bridge D receives the BPDUs from bridge E on its alternate port, bridge D:

- Immediately begins the max age timer on its alternate port.
- Performs a configuration update.

As shown in [Figure 220](#), after the configuration update, bridge D:

- Moves the alternate port to a designated port.
- Sends a “propose” message to bridge E to solicit confirmation of its designated role and to rapidly move the port into the designated state.

EX\_055e

**Figure 220: Sending a Propose Message to Confirm a Port Role**

Upon receiving the proposal, bridge E (as shown in [Figure 221](#) on page 1760):

- Performs a configuration update.
- Changes its receiving port to a root port.

The existing designated port enters the blocking state.

Bridge E then sends:

- A “propose” message to bridge F.
- An “agree” message from its root port to bridge D.

EX\_055f

**Figure 221: Communicating Port Status to Neighbors**

To complete the topology change (as shown in [Figure 222](#)):

- Bridge D moves the port that received the “agree” message into the forwarding state.
- Bridge F confirms that its receiving port (the port that received the “propose” message) is the root port, and immediately replies with an “agree” message to bridge E to unblock the proposing port.

EX\_055g

**Figure 222: Completing the Topology Change**

Figure 223 displays the new topology.

EX\_055h

**Figure 223: Final Network Configuration**

#### Compatibility With STP (802.1D)

RSTP interoperates with legacy STP protocols; however, the rapid convergence benefits are lost when interacting with legacy STP bridges.

Each RSTP bridge contains a port protocol migration state machine to ensure that the ports in the STPD operate in the correct, configured mode. The state machine is a protocol entity within each bridge configured to run in 802.1w mode. For example, a compatibility issue occurs if you configure 802.1w mode and the bridge receives an 802.1D BPDU on a port. The receiving port starts the protocol migration timer and remains in 802.1D mode until the bridge stops receiving 802.1D BPDUs. Each time the bridge receives an 802.1D BPDU, the timer restarts. When the port migration timer expires, no more 802.1D BPDUs have been received, and the bridge returns to its configured setting, which is 802.1w mode.

## Multiple Spanning Tree Protocol

The MSTP, based on IEEE 802.1Q-2003 (formerly known as IEEE 802.1s), allows the bundling of multiple VLANs into one spanning tree topology.

This concept is not new to Extreme Networks. Like MSTP, Extreme Networks proprietary EMISTP implementation can achieve the same capabilities of sharing a virtual network topology among multiple VLANs; however, MSTP overcomes some of the challenges facing EMISTP, including enhanced loop protection mechanisms and new capabilities to achieve better scaling.

MSTP logically divides a Layer 2 network into regions. Each region has a unique identifier and contains multiple spanning tree instances (MSTIs). An *MSTI* is a spanning tree domain that operates within and is bounded by a region. MSTIs control the topology inside the regions. The Common and Internal Spanning Tree (CIST) is a single spanning tree domain that interconnects MSTP regions. The CIST is responsible for creating a loop-free topology by exchanging and propagating BPDUs across regions to form a Common Spanning Tree (CST).

MSTP uses RSTP as its converging algorithm and is interoperable with the legacy *STP* protocols: STP (802.1D) and RSTP (802.1w).

MSTP has three major advantages over 802.1D, 802.1w, and other proprietary implementations:

- To save control path bandwidth and provide improved scalability, MSTP uses regions to localize BPDU traffic. BPDUs containing information about MSTIs contained within an MSTP region do not cross that region's boundary.
- A single BPDU transmitted from a port can contain information for up to 64 STPDs. MSTP BPDU processing utilizes less resources compared to 802.1D or 802.1w where one BPDU corresponds to one *STPD*.
- In a typical network, a group of VLANs usually share the same physical topology. Dedicating a spanning tree per VLAN like PVST+ is CPU intensive and does not scale very well. MSTP makes it possible for a single STPD to handle multiple VLANs.

## MSTP Concepts

### *MSTP Regions*

An *MSTP* network consists of either individual MSTP regions connected to the rest of the network with 802.1D and 802.1w bridges or as individual MSTP regions connected to each other.

An MSTP region defines the logical boundary of the network. With MSTP, you can divide a large network into smaller areas similar to an *OSPF (Open Shortest Path First)* area or a *BGP (Border Gateway Protocol)* Autonomous System, which contain a group of switches under a single administration. Each MSTP region has a unique identifier and is bound together by one CIST that spans the entire network. A bridge participates in only one MSTP region at a time.

An MSTP region can hide its internal STPDs and present itself as a virtual 802.1w bridge to other interconnected regions or 802.1w bridges because the port roles are encoded in 802.1w and MSTP BPDUs.

By default, the switch uses the MAC address of the switch to generate an MSTP region. Since each MAC address is unique, every switch is in its own region by default. For multiple switches to be part of an MSTP region, you must configure each switch in the region with the same MSTP region identifiers. See [Configuring MSTP Region Identifiers](#) on page 1763 for information.

In Figure 224, all bridges inside MSTP regions 1 and 2 are MSTP bridges; bridges outside of the regions are either 802.1D or 802.1w bridges.

**Figure 224: Sample MSTP Topology with Two MSTP Regions**

### Configuring MSTP Region Identifiers

For multiple switches to be part of an *MSTP* region, you must configure each switch in the region with the same MSTP configuration attributes, also known as MSTP region identifiers. The following list describes the MSTP region identifiers:

- **Region Name**—This indicates the name of the MSTP region. In the Extreme Networks implementation, the maximum length of the name is 32 characters and can be a combination of alphanumeric characters and underscores ( \_ ).
- **Format Selector**—This indicates a number to identify the format of MSTP BPDUs. The default is 0.
- **Revision Level**—An unsigned integer encoded within a fixed field of 2 octets that identifies the revision of the current MST configuration. The revision number is not incremented automatically each time that the MST configuration is committed.

The switches inside a region exchange BPDUs that contain information for MSTIs.

The switches connected outside of the region exchange CIST information. By having devices look at the region identifiers, MSTP discovers the logical boundary of a region:

- To configure the MSTP region name, use the command:  
`configure mstp region regionName`

The maximum length of the region name is 32 characters and can be a combination of alphanumeric characters and underscores ( \_ ). You can configure only one MSTP region on the switch at any given time.

If you have an active MSTP region, we recommend that you disable all active STPDs in the region before renaming the region on all of the participating switches.

- To configure the number used to identify MSTP BPDUs, use the command:

```
configure mstp format format_identifier
```

By default, the value used to identify the MSTP BPDUs is 0. The range is 0 to 255.

If you have an active MSTP region, we recommend that you disable all active STPDs in the region before modifying the value used to identify MSTP BPDUs on all participating switches.

- To configure the MSTP revision level, use the command:

```
configure mstp revision revision
```

Although this command is available on the CLI, this command is reserved for future use.

### Unconfiguring an MSTP Region

Before you unconfigure an *MSTP* region, we recommend that you disable all active STPDs in the region.

To unconfigure the MSTP region on the switch, use the command:

```
unconfigure mstp region
```

After you issue this command, all of the MSTP settings return to their default values. See [Configuring MSTP Region Identifiers](#) on page 1763 for information about the default settings.

### Common and Internal Spanning Tree

*MSTP* logically divides a Layer 2 network into regions. The Common and Internal Spanning Tree (CIST) is a single spanning tree domain that interconnects MSTP regions. The CIST is responsible for creating a loop-free topology by exchanging and propagating BPDUs across regions to form a Common Spanning Tree (CST).

In essence, the CIST is similar to having a large spanning tree across the entire network. The CIST has its own root bridge that is common to all MSTP regions, and each MSTP region elects a CIST regional root that connects that region to the CIST, thereby forming a CST.

The switch assigns the CIST an instance ID of 0, which allows the CIST to send BPDUs for itself in addition to all of the MSTIs within an MSTP region. Inside a region, the BPDUs contain CIST records and piggybacked M-records. The CIST records contain information about the CIST, and the M-records contain information about the MSTIs. Boundary ports exchange only CIST record BPDUs.

All MSTP configurations require a CIST domain. You must first configure the CIST domain before configuring any MSTIs. By default, all *MSTI* ports in the region are inherited by the CIST. You cannot delete or disable a CIST if any of the MSTIs are active in the system.

## Configuring the CIST

- Configure an *STPD* as the CIST, specifying the mstp cist keywords in the following command:

```
configure stpd stpd_name mode [dot1d | dot1w | mstp [cist | msti
instance]]
```

You can enable *MSTP* on a per STPD basis only. By specifying the mstp cist keywords, you can configure the mode of operation for the STPD as MSTP and identify the STPD to be the CIST.

## CIST root bridge

In an MSTP environment, the bridge with the lowest bridge ID becomes the CIST root bridge. The bridge ID includes the bridge priority and the MAC address. The CIST root bridge can be either inside or outside an MSTP region. The CIST root bridge is unique for all regions and non-MSTP bridges, regardless of its location.

## CIST regional root bridge

Within an MSTP region, the bridge with the lowest path cost to the CIST root bridge is the CIST regional root bridge. If the CIST root bridge is inside an MSTP region, that same bridge is the CIST regional root for that region because it has the lowest path cost to the CIST root. If the CIST root bridge is outside an MSTP region, all regions connect to the CIST root through their respective CIST regional roots.

## CIST Root Port

The port on the CIST regional root bridge that connects to the CIST root bridge is the *CIST root port* (also known as the master port for MSTIs).

The CIST root port is the master port for all MSTIs in that region, and it is the only port that connects the entire region to the CIST root.

If a bridge is both the CIST root bridge and the CIST regional root bridge, there is no CIST root port on that bridge.

## Enabling the CIST

To enable the CIST, use the following command and specify the CIST domain as the *stpd\_name*:

```
enable stpd {stpd_name}
```

## Multiple Spanning Tree Instances

Multiple spanning tree instances (MSTIs) control the topology inside an *MSTP* region. An *MSTI* is a spanning tree domain that operates within and is bounded by a region; an MSTI does not exchange BPDUs with or send notifications to other regions. You must identify an MSTI on a per region basis. The MSTI ID does not have any significance outside of its region so you can reuse IDs across regions. An MSTI consists of a group of *VLANs*, which can share the same network topology. Each MSTI has its own root bridge and a tree spanning its bridges and LAN segments.

You must first configure a CIST before configuring any MSTIs in the region. You cannot delete or disable a CIST if any of the MSTIs are active in the system.

You can map multiple VLANs to an MSTI; however, multiple MSTIs cannot share the same VLAN.

### Configuring the MSTI and the MSTI ID

*MSTP* uses the *MSTI* ID, not an *Stpd* ID, to identify the spanning tree contained within the region. As previously described, the MSTI ID only has significance within its local region, so you can re-use IDs across regions.

To configure the MSTI that is inside an MSTP region and its associated MSTI ID, use the following command and specify the `mstp [msti instance]` parameters:

```
configure stpd stpd_name mode [dot1d | dot1w | mstp [cist | msti instance]]
```

The range of the MSTI instance ID is 1–4094.

MSTP STPDs use 802.1D BPDU encapsulation mode by default. To ensure correct operation of your MSTP STPDs, do not configure EMISTP or PVST+ encapsulation mode for MSTP STPDs. For more information, see [Encapsulation Modes](#) on page 1736.

### MSTI Regional Root Bridge

Each *MSTI* independently chooses its own root bridge. For example, if two MSTIs are bounded to a region, there is a maximum of two MSTI regional roots and one CIST regional root.

The bridge with the lowest bridge ID becomes the MSTI regional root bridge. The parameters that define the root bridge include the following:

- User-defined bridge priority (by default, the bridge priority is 32,768)
- MAC address

Within an *MSTP* region, the cost from a bridge to the MSTI regional root bridge is known as the MSTI internal path cost. Looking at MSTP region 1 in [CIST regional root bridge](#) on page 1765, the bridge with ID 60 has a path cost of F to the MSTI regional root bridge.

The MSTI regional root bridge can be the same as or different from the CIST regional root bridge of that region. You achieve this by assigning different priorities to the *STP* instances configured as the MSTIs and the CIST. For more information about configuring the bridge ID, see the `configure stpd priority` command in the [Switch Engine v33.3.1 Command References](#).

### MSTI Root Port

The port on the bridge that has the lowest path cost to the *MSTI* regional root bridge is the MSTI root port.

If a bridge has two or more ports with the same path cost, the port with the best port identifier becomes the root port.

## Enabling the MSTI

To enable the *MSTI*, use the following command and specify the MSTI domain as the *stpd\_name*:

```
enable stpd {stpd_name}
```

### Note

If two switches are configured for the same CIST and MSTI region, in order for them to understand that they are in the same region, both must also belong to the same *VLAN* which is added to the *STP* domain. If they belong to different VLANs, each switch believes that each belongs to a different region. When an *MSTP* BPDU is sent, it carries a VID digest created by VLAN memberships in the CIST domain and the MSTI domain.

## Boundary Ports

Boundary ports are bridge ports that are only connected to other *MSTP* regions or 802.1D or 802.1w bridges.

The ports that are not at a region boundary are called internal ports. The boundary ports exchange only CIST BPDUs. A CIST BPDU originated from the CIST root enters a region through the CIST root port and egresses through boundary ports. This behavior simulates a region similar to an 802.1w bridge, which receives BPDUs on its root ports and forwards updated BPDUs on designated ports.

[Figure 225](#) shows an MSTP network that consists of two MSTP regions. Each region has its own CIST regional root and is connected to the CIST root through master ports. The CIST regional roots in each region are the MSTP bridges having the lowest CIST external root path cost. The CIST root is the bridge with the lowest bridge ID and is an 802.1w bridge outside of either MSTP region.

**Figure 225: Sample MSTP Topology with Two MSTP Regions**

MSTP Region 1 and MSTP Region 2 are connected to the CIST root through directly connected ports, identified as master ports. The bridge with ID 100 connects to the CIST root through Region 1, Region 2, or segment B. For this bridge, either Region 1 or Region 2 can be the designated region or segment B can be the designated segment. The CIST BPDUs egressing from the boundary ports carry the CIST regional root as the designated bridge. This positions the entire MSTP region as one virtual bridge.

The CIST controls the port roles and the state of the boundary ports. A master port is always forwarding for all CIST and *MSTI* VLANs. If the CIST sets a boundary port to the discarding state, the CIST blocks traffic for all VLANs mapped to it and the MSTIs within that region. Each MSTI blocks traffic for their member VLANs and puts their internal ports into the forwarding or blocking state depending on the MSTI port roles.

#### MSTP Port Roles

*MSTP* uses the same port roles as RSTP (Root, Designated, Alternate, and Backup).

In addition to these port roles, MSTP introduces a new port role: Master. A Master port is the port that connects an *MSTI* to the CIST root.

#### MSTP Port States

*MSTP* uses the same port states as RSTP (Listening, Learning, Forwarding, and Blocking).

In the Extreme Networks MSTP implementation, the listening state is not truly implemented as *FDB (forwarding database)* learning cannot be done when the port is not in the forwarding state. Ports in the blocking state listen but do not accept ingress traffic, perform traffic forwarding, or learn MAC source address; however, the port receives and processes BPDUs.

For more information about all of the [STP](#) port states, see [STP States](#) on page 1737.

### *MSTP Link Types*

[MSTP](#) uses the same link types as [STP](#) and RSTP, respectively.

In an MSTP environment, configure the same link types for the CIST and all MSTIs.

For more information about the link types, see [Link Types](#) on page 1750.

### *MSTP Edge Safeguard*

You can configure edge safeguard for loop prevention and detection on an [MSTP](#) edge port. For more information, see [Configuring Edge Safeguard](#) on page 1752.

#### **Note**

In MSTP, configuring edge safeguard at CIST will be inherited in all [MSTIs](#).

In MSTP, an edge port needs to be added to a CIST before adding it to an MSTI.

### *MSTP Timers*

[MSTP](#) uses the same timers as [STP](#) and RSTP. For more information, see [RSTP Timers](#) on page 1753.

### *MSTP Hop Counts*

In an [MSTP](#) environment, the hop count has the same purpose as the maxage timer for 802.1D and 802.1w environments. The CIST hop count is used within and outside a region. The [MSTI](#) hop count is used only inside of the region. In addition, if the other end is an 802.1D or 802.1w bridge, the maxage timer is used for interoperability between the protocols.

The BPDUs use hop counts to age out information and to notify neighbors of a topology change.

To configure the hop count.

```
configure stpd stpd_name max-hop-count hopcount
```

By default, the hop count of a BPDU is 20 hops. The range is 6 to 40 hops.

### *Configuring MSTP on the Switch*

To configure and enable [MSTP](#):

1. Create the MSTP region using the following command:

```
configure mstp region regionName
```

2. Create and configure the CIST, which forms the CST, using the following commands:

```
create stpd stpd_name {description stpd-description}
configure stpd stpd_name mode mstp cist
```

#### Note

You can configure the default *STPD*, S0 as the CIST.

No *VLAN* can be bound to the CIST and no ports can be added to the CIST. Therefore, the *VLAN* should be bound to the *MSTI* and the “show MSTI port” command will show the *VLAN* ports. The ports added to the *MSTI* are bound automatically to the CIST even though they are not added to it.

3. Enable the CIST using the command:

```
enable stpd {stpd_name}
```

4. Create and configure *MSTIs* using the commands:

```
create stpd stpd_name {description stpd-description}
configure stpd stpd_name mode mstp cist instance
```

5. Add *VLANs* to the *MSTIs* using one of the following commands:

- a. Manually binding ports

```
configure stpd stpd_name add vlan vlan_name ports [all | port_list]
{[dot1d | emistp | pvst-plus]}
```

```
configure vlan vlan_name add ports [all | port_list] {tagged {} |
untagged} stpd stpd_name {[dot1d | emistp | pvst-plus]}
```

- b. Automatically binding ports to an *STPD* when ports are added to a member *VLAN*

```
enable stpd stpd_name auto-bind vlan vlan_name
```

6. Enable the *MSTIs* using the command:

```
enable stpd {stpd_name}
```

For a more detailed configuration example, see [MSTP Configuration Example](#) on page 1783.

## MSTP Operation

To further illustrate how *MSTP* operates and converges, [Figure 226](#) on page 1771 displays a network with two *MSTP* regions. Each region contains three *MSTP* bridges and one *MSTI*. The overall network topology also contains one CIST root bridge (Switch A, which has the lowest bridge ID), one interconnecting 802.1w bridge (Switch D), and 10 full duplex, point-to-point segments. *VLAN* Default spans all of the bridges and segments in the network, *VLAN* engineering is local to its respective region, and *STPD* S0 is configured as the CIST on all bridges.

**Figure 226: MSTP Topology with the CIST Root Bridge Contained within a Region**

MSTP Region 1 consists of the following:

- Three bridges named Switch A, Switch B, and Switch C
- One MSTI STPD named S1 with an MSTI ID of 1
- VLAN Engineering mapped to the MSTI STPD, S1
- Switch A as the CIST root bridge (this is the CIST root bridge for all regions)
- Switch A as the CIST regional root bridge
- Switch A as the MSTI regional root bridge
- Three boundary ports that connect to MSTP Region 2 and other 802.1D or 802.1w bridges

MSTP Region 2 consists of the following:

- Three bridges named Switch E, Switch F, and Switch G
- One MSTI STPD named S1 with an MSTI ID of 1

**Note**

The MSTI ID does not have any significance outside of its region so you can reuse IDs across regions.

- VLAN finance mapped to the MSTI STPD, S1
- Switch E as the CIST regional root bridge
- Switch F as the MSTI regional root bridge
- One master port that connects to the CIST
- Three boundary ports that connect to MSTP Region 1 and other 802.1D or 802.1w bridges

The following sequence describes how the MSTP topology convergences:

1. Determining the CIST root bridge, MSTP regions, and region boundaries.

Each bridge believes that it is the root bridge, so each bridge initially sends root bridge BPDUs throughout the network. As bridges receive BPDUs and compare vectors, the bridge with the lowest Bridge ID is elected the CIST root bridge. In our example, Switch A has the lowest Bridge ID and is the CIST root bridge.

The bridges in the MSTP regions (Switches A, B, C, E, F, and G) advertise their region information along with their bridge vectors.

Segments 1, 3, and 9 receive BPDUs from other regions and are identified as boundary ports for Region 1. Similarly, segments 2, 3, and 9 are identified as boundary ports for Region 2.

2. Controlling boundary ports.

The CIST regional root is advertised as the Bridge ID in the BPDUs exiting the region. By sending CIST BPDUs across regional boundaries, the CIST views the MSTP regions as virtual 802.1w bridges. The CIST takes control of the boundary ports and only CIST BPDUs enter or exit a region boundary.

Each MSTP region has a CIST regional root bridge that communicates to the CIST root bridge. The bridge with the lowest path cost becomes the CIST regional root bridge. The port on the CIST regional root bridge that connects to the CIST root bridge is the CIST root port.

For Region 1, Switch A has the lowest cost (0 in this example) and becomes the CIST regional root. Since the bridge is both the CIST root bridge and the CIST regional root bridge, there is no CIST root port on the bridge.

For Region 2, Switch E is the CIST regional root bridge and so a port on that bridge becomes the CIST root port.

3. Identifying MSTI regional roots.

Each MSTI in a region has an MSTI regional root bridge. MSTI regional roots are selected independently of the CIST root and CIST regional root. The MSTP BPDUs have M-records for each MSTI. Bridges belonging to an MSTI compare vectors in their M-records to elect the MSTI regional root.

4. Converging the CIST.

The CIST views every region as a virtual bridge and calculates the topology using the 802.1w algorithm. The CIST calculates the topology both inside and outside of a region.

5. Converging MSTIs.

After the CIST identifies the boundary ports, each MSTI in a domain converge their own trees using 802.1w.

At this point, all CIST and MSTIs have assigned port roles (Root, Designated, Alternate, and Backup) to their respective spanning trees. All root and designated

ports transition to the forwarding state while the remaining ports remain in the discarding state.

Propagating topology change information is similar to that described for RSTP.

For more information, see [Propagating Topology Change Information](#) on page 1757.

For a configuration example, see [MSTP Configuration Example](#) on page 1783.

## STP and Network Login

STP and network login can be enabled on the same port. This feature can be used to prevent loops while providing redundancy and security on aggregated as well as end switches.

### Note

You should be aware that an STP topology change will affect the network login clients. See [STP Rules and Restrictions](#) on page 1776 for further information.

[Figure 227](#) shows STP and network login enabled on ports 2 and 3 of Switch 2 and Switch 3 for a typical aggregation scenario.

**Figure 227: STP and Network Login Enabled**

This relieves the administrator from having to configure network login on all the edge ports. All the traffic can be monitored and resiliency is provided at the aggregation side.

The [Figure 228](#) shows a typical scenario for protecting loops and monitoring traffic on the edge side.

**Figure 228: Traffic Monitoring on the Edge Side**

In huge networks, it is not easy to control or prevent end users from connecting devices other than workstations to the edge ports. This feature helps prevent the network loops that occur when end users connect a switch or hub to the existing edge port in order to increase the number of end user ports.

## STP and ONEPolicy

STP can be configured on ONEPolicy-enabled ports to prevent loop at the edge. In this configuration, it is recommended to modify the port blocking mechanism to *spanning-tree-group* by running the command **configure forwarding L2-protocol blocking-type spanning-tree-group**. To revert to the default blocking mechanism, use the command **configure forwarding L2-protocol blocking-type ingress-filtering**.

The blocking type configuration can be verified with the command **show forwarding configuration**.

## STP and MLAG

You can configure MSTP and RSTP on peers and access switches, which can prevent loops in networks containing MLAG topology. This allows third-party switches to be connected to MLAG topology (as access switches) and an MSTP or RSTP domain can span ExtremeXOS and third-party switches.

In typical MLAG deployments (see [Figure 229](#)), connections can exist between access switches, which can cause data loops. By configuring MSTP/RSTP on all the nodes, loops can be effectively prevented.

You should configure the MSTP/RSTP domain in the MLAG peers with a higher priority than the access switches, which blocks the redundant link between access switches. The LAG links in blue form one set of MLAG links and the corresponding ports at MLAG peers are associated with one MLAG index. The LAG links in red form another set of

MLAG links, and the corresponding ports at MLAG peers are associated with another MLAG index.

**Figure 229: MLAG and MSTP/RSTP**

MSTP/RSTP is supported in simple and two-tier MLAG topologies.

For the purpose of synchronization of protocol information, a master is elected for each MLAG index between MLAG peers, based on switch MAC address of peers and MLAG index. By choosing MLAG index with odd or even number, it is possible to change mastership between MLAG peers. Only the master node will transmit BPDUs and process BPDUs. Port roles and states are computed by the master node for the given MLAG index and applied on the local MLAG port. These details are check pointed to the backup node and are applied on its MLAG port.

## Recommendations for Configuring MSTP/RSTP with MLAG

You should configure in such a way that one of the MLAG peers become root bridge (see [Bridge Priority](#) on page 1721), and also configure MLAG peers with backup root option (see [Backup Root](#) on page 1728). The former avoids less powerful access switches from becoming the root bridge; the latter facilitates faster convergence as the other MLAG peer becomes root bridge quicker. Loop protect feature (see [Loop Protect](#) on page 1725) should not be enabled on LAG ports (which are part of the MLAG topology) on access switches. This is because a multi-source condition is triggered when one of the two MLAG peers goes down. The loop protect feature prevents the port from going to the forwarding state, if configured. However, enabling this feature on MLAG ports is acceptable.

Since both MLAG peers should act like single switch, the ISC link should not be blocked, regardless of MSTP/RSTP role. Keeping this in mind, the port cost of the ISC port is

chosen internally to be the lowest possible value (see [Default Port Path Cost](#) on page 1720). This helps in selecting the ISC link as the active link if there are any parallel links to the ISC. MLAG links do not have special preference over redundant connections that are in parallel to the MLAG link. The standard MST/RSTP algorithm disables both MLAG links if it has higher root path cost than the redundant link. This allows the lower cost link to be chosen as active link. If you configure MSTP over MLAG, both MLAG peers and access switches should be in the same MSTP region. This makes MLAG and ISC ports internal ports.

## STP Rules and Restrictions

---

This section summarizes the rules and restrictions for configuring *STP* are:

- The carrier *VLAN* must span all ports of the *STPD*. (This is not applicable to *MSTP*.)
- The StpdID must be the VLAN ID of the carrier VLAN; the carrier VLAN cannot be partitioned. (This is not applicable to MSTP.)
- A default VLAN cannot be partitioned. If a VLAN traverses multiple STPDs, the VLAN must be tagged.
- An STPD can carry, at most, one VLAN running in PVST+ mode, and its STPD ID must be identical with that VLAN ID. In addition, the PVST+ VLAN cannot be partitioned.
- The default VLAN of a PVST+ port must be identical to the native VLAN on the PVST+ device connected to that port.
- If an STPD contains both PVST+ and non-PVST+ ports, that STPD must be enabled. If that STPD is disabled, the BPDUs are flooded in the format of the incoming STP port, which may be incompatible with those of the connected devices.
- The 802.1D ports must be untagged and the EMISTP/PVST+ ports must be tagged in the carrier VLAN.
- STP and network login operate on the same port as follows:
  - STP (802.1D), RSTP (802.1w), and MSTP (802.1s) support both network login and STP on the same port.
  - At least one VLAN on the intended port should be configured both for STP and network login.
  - STP and Network Login operate together in both Network Login ISP mode and campus mode starting with Extreme 22.2.
  - When STP blocks a port, network login does not process authentication requests. All network traffic, except STP BPDUs, is blocked.
  - When STP places a port in forwarding state, all network traffic is allowed and network login starts processing authentication requests.
- STP cannot be configured on the following ports:
  - *FDB* flush does not occur on STP- and NetLogin-enabled ports during the topology changes.
  - A mirroring target port.
  - A software-controlled redundant port.
- When you are using the older method of enabling STP instead of using EAPsv2 to block the super loop in a shared-port environment, you can continue to do so. In all other scenarios, it is not recommended to use both STP and EAPS on the same port.

- MSTP and 802.1D STPDs cannot share a physical port.
- Only one MSTP region can be configured on a switch.
- In an MSTP environment, a VLAN can belong to one of the MSTIs.
- A VLAN can belong to only one MSTP domain.
- MSTP is not interoperable with PVST+.
- No VLAN can be bound to the CIST.
- Starting with ExtremeXOS 22.2, under the following two conditions, these attributes are preserved with autobind being used to bind the STPD domain to the VLAN: STP enable, Cost, Priority, LinkType, Edge-Sage-Guard, BPDU Restrict, Restrict Role, ActiveRole, LoopProtect, LoopProtect-Partner, AutoEdge, Restricted TCN:
  - With sharing and STP configurations established, disabling sharing no longer removes the STP port configuration for the configured master port and it preserves certain configuration attributes and restores them when the port is recreated.
  - Configured port's STP properties are preserved when the port is moved from one VLAN to another, provided the new port gets associated with same STP domain.
- MLAG is not supported with STP (802.1D).

## Configuring STP on the Switch

### Note

If you are transitioning from EOS to ExtremeXOS, please note that ExtremeXOS blocks on a more granular (*VLAN*) level, instead of at the port level as EOS does.

To configure basic *STP*:

1. Create one or more *STPDs* using the command:

```
create stpd stpd_name {description stpd-description}
```

2. Add one or more VLANs to the STPD using the command:

```
configure stpd stpd_name add vlan vlan_name | vlan_list ports [all | port_list] {[dot1d | emistp | pvst-plus]}
```

3. Define the carrier VLAN using the command:

```
configure stpd stpd_name tag stpd_tag
```

### Note

The carrier VLAN's ID must be identical to the StpdID.

4. Enable STP for one or more STPDs using the command:

```
enable stpd {stpd_name}
```

5. After you have created the STPD, you can optionally configure STP parameters for the STPD.

### Note

You should not configure any STP parameters unless you have considerable knowledge and experience with STP. The default STP parameters are adequate for most networks.

The following parameters can be configured on each STPD:

- Hello time (In an *MSTP* environment, configure this only on the CIST.)
- Forward delay
- Max age (In an MSTP environment, configure this only on the CIST.)
- Max hop count (MSTP only)
- Bridge priority
- Domain description
- StpdID (STP, RSTP, EMISTP, and PVST+ only)
- *MSTI*/ID (MSTP only)

The following parameters can be configured on each port:

- Path cost
- Port priority
- Port mode

**Note**

When using more than one STP domain over the same set of ports, it is recommended to turn off the L2-fast-convergence feature (`configure forwarding l2-protocol fast-convergence off`) as this feature causes unnecessary flooding during topology changes.

**Note**

The device supports the RFC 1493 Bridge MIB, RSTP-03, and Extreme Networks STP MIB. Parameters of the s0 default STPD support RFC 1493 and RSTP-03. Parameters of any other STPD support the Extreme Networks STP MIB.

If an STPD contains at least one port not in 802.1D (dot1D) mode, the STPD must be configured with an StpdID.

The following section provides more detailed STP configuration examples, including 802.1D, EMISTP, RSTP, and MSTP.

## STP FDB Flush Criteria

When there are more than 1000 VLANs and more than 70 ports participating in *STP*, the number of messages exchanged between STP/*FDB*/HAL modules can consume a lot of system memory when trying to flush the FDB during a STP topology change. To help avoid this high consumption, you can set the flush type from the default of vlan-and-port to port-based.

To set the flush type, enter the command:

```
configure stpd flush-method [vlan-and-port | port-only]
```

## Displaying STP Settings

---

- To display *STPD* settings, use the command:

```
show stpd {stpd_name | detail}
```

To display more detailed information for one or more STPDs, specify the detail option.

This command displays the following information:

- STPD name
- STPD state
- STPD mode of operation
- Domain description
- Rapid Root Failover
- Tag
- Ports
- Active VLANs
- Bridge priority
- Bridge ID
- Designated root
- STPD configuration information

If you have *MSTP* configured on the switch, this command displays additional information:

- MSTP Region
- Format Identifier
- Revision Level
- Common and Internal Spanning Tree (CIST)
- Total number of MST Instances (*MSTI*)

- To display the state of a port that participates in *STP*, use the command:

```
show {stpd} stpd_name ports {[detail | port_list {detail}]}
```

To display more detailed information for one or more ports in the specified STPD, including participating VLANs, specify the detail option.

This command displays the following information:

- STPD port configuration
- STPD port mode of operation
- STPD path cost
- STPD priority
- STPD state (root bridge, etc.)
- Port role (root designated, alternate, etc.)
- STPD port state (forwarding, blocking, etc.)
- Configured port link type
- Operational port link type

- Edge port settings (inconsistent behavior, edge safeguard setting)
- MSTP port role (internal or boundary)

If you have MSTP configured and specify the detail option, this command displays additional information:

- MSTP internal path cost
- MSTP timers
- STPD VLAN Settings
- If you have a VLAN that spans multiple STPDs, use the `show {vlan} vlan_name stpd` command to display the STP configuration of the ports assigned to that specific VLAN.

The command displays the following:

- STPD port configuration
- STPD port mode of operation
- STPD path cost
- STPD priority
- STPD state (root bridge, etc.)
- Port role (root designated, alternate, etc.)
- STPD port state (forwarding, blocking, etc.)
- Configured port link type
- Operational port link type

## STP Configuration Examples

### Note

If you are transitioning from EOS to ExtremeXOS, please note that ExtremeXOS blocks on a more granular (VLAN) level, instead of at the port level as EOS does.

## Basic 802.1D Configuration Example

The following example:

- Removes ports from the VLAN Default that will be added to VLAN Engineering.
- Creates the VLAN Engineering.
- Assigns a VLAN ID to the VLAN Engineering.

### Note

If you do not explicitly configure the VLAN ID in your 802.1D deployment, use the `show vlan` command to see the internal VLAN ID automatically assigned by the switch.

- Adds ports to the VLAN Engineering.
- Creates an STPD named Backbone\_st.
- Configures the default encapsulation mode of dot1d for all ports added to STPD Backbone\_st.

- Enables autobind to automatically add or remove ports from the STPD.
- Assigns the Engineering VLAN to the STPD.
- Assigns the carrier VLAN.
