- Enables *STP*.

**Note**

To assign the carrier VLAN, the StpdID must be identical to the VLAN ID of the carrier VLAN.

```
configure vlan default delete ports 2:5-2:10
create vlan engineering
configure vlan engineering tag 150
configure vlan engineering add ports 2:5-2:10 untagged
create stpd s1
configure stpd s1 default-encapsulation dot1d
enable stpd s1 auto-bind vlan engineering
configure stpd s1 tag 150
enable stpd s1
```

By default, the port encapsulation mode for user-defined STPDs is dot1d. In this example, you set it to dot1d.

## EMISTP Configuration Example

Figure 230 is an example of EMISTP.

**Figure 230: EMISTP Configuration Example**

**Note**

By default, all ports added to a user-defined *STPD* or STPD s0 are in dot1d mode, unless otherwise specified.

The following commands configure the switch located between S1 and S2:

```
create vlan red
configure red tag 100
configure red add ports 1:1-1:4 tagged
create vlan green
configure green tag 200
configure green add ports 1:1-1:2 tagged
```

```

create vlan yellow
configure yellow tag 300
configure yellow add ports 1:3-1:4 tagged
create stpd s1
configure stpd s1 add green ports all emistp
configure stpd s1 add red ports 1:1-1:2 emistp
configure stpd s1 tag 100
enable stpd s1
create stpd s2
configure stpd s2 add yellow ports all emistp
configure stpd s2 tag 300
configure stpd s2 add red ports 1:3-1:4 emistp
enable stpd s2

```

## RSTP 802.1w Configuration Example

Figure 231 on page 1782 is an example of a network with multiple STPDs that can benefit from RSTP.

For RSTP to work:

1. Create an STPD.
2. Configure the mode of operation for the STPD.
3. Create the VLANs and assign the VLAN ID and the VLAN ports.
4. Assign the carrier VLAN.
5. Add the protected VLANs to the STPD.
6. Configure the port link types.
7. Enable STP.

**Figure 231: RSTP Example**

In this example, the commands configure Switch A in STPD1 for rapid reconvergence.

Use the same commands to configure each switch and STPD in the network.

```
create stpd stpd1
configure stpd stpd1 mode dot1w
create vlan sales
create vlan personnel
create vlan marketing
configure vlan sales tag 100
configure vlan personnel tag 200
configure vlan marketing tag 300
configure vlan sales add ports 1:1,2:1 tagged
configure vlan personnel add ports 1:1,2:1 tagged
configure vlan marketing add ports 1:1,2:1 tagged
configure stpd stpd1 add vlan sales ports all
configure stpd stpd1 add vlan personnel ports all
configure stpd stpd1 add vlan marketing ports all
configure stpd stpd1 ports link-type point-to-point 1:1,2:1
configure stpd stpd1 tag 100
enable stpd stpd1
```

## MSTP Configuration Example

You must first configure a CIST before configuring any MSTIs in the region. You cannot delete or disable a CIST if any of the MSTIs are active in the system.

Figure 232 is an example with multiple *STPDs* that can benefit from *MSTP*. In this example, we have two MSTP regions that connect to each other and one external 802.1w bridge.

**Figure 232: MSTP Configuration Example**

For MSTP to work, complete the following steps on all switches in Region 1 and Region 2:

1. Remove ports from the VLAN Default that will be added to VLAN Engineering.
2. Create the VLAN Engineering.
3. Assign a VLAN ID to the VLAN Engineering.

**Note**

If you do not explicitly configure the VLAN ID in your MSTP deployment, use the `show vlan` command to see the internal VLAN ID automatically assigned by the switch.

4. Add ports to the VLAN Engineering.
5. Create the MSTP region.

**Note**

You can configure only one MSTP region on the switch at any given time.

6. Create the STPD to be used as the CIST, and configure the mode of operation for the STPD.
7. Specify the priority for the CIST.
8. Enable the CIST.
9. Create the STPD to be used as an MSTI and configure the mode of operation for the STPD.
10. Specify the priority for the MSTI.
11. Assign the VLAN Engineering to the MSTI.
12. Configure the port link type.
13. Enable the MSTI.

On the external switch (the switch that is not in a region):

1. Create an STPD that has the same name as the CIST, and configure the mode of operation for the STPD.
2. Specify the priority of the STPD.
3. Enable the STPD.

**Note**

In the following sample configurations, any lines marked (Default) represent default settings and do not need to be explicitly configured. STPD s0 already exists on the switch.

In the following example, the commands configure Switch A in Region 1 for MSTP. Use the same commands to configure each switch in Region 1:

```
create vlan engineering
configure vlan engineering tag 2
configure vlan engineering add port 2-3 tagged
configure mstp region region1
create stpd s0 (Default)
disable stpd s0 auto-bind vlan Default
configure stpd s0 mode mstp cist (Default)
configure stpd s0 priority 32768 (Default)
enable stpd s0 (Default)
```

```
create stpd s1
configure stpd s1 mode mstp msti 1
configure stpd s1 priority 32768 (Default)
enable stpd s1 auto-bind vlan engineering
configure stpd s0 ports link-type point-to-point 2-3
enable stpd s1
```

In the following example, the commands configure Switch E in Region 2 for MSTP. Use the same commands to configure each switch in Region 2:

```
create vlan finance
configure vlan finance tag 2
configure vlan finance add port 2-3 tagged
configure mstp region region2
create stpd s0 (Default)
configure stpd s0 mode mstp cist (Default)
configure stpd s0 priority 32768 (Default)
disable stpd s0 auto-bind vlan Default
enable stpd s0 (Default)
create stpd s1
configure stpd s1 mode mstp msti 1
configure stpd s1 priority 32768 (Default)
enable stpd s1 auto-bind vlan finance
configure stpd s0 ports link-type point-to-point 2-3
```

In the following example, the commands configure switch D, the external switch. Switch D becomes the CIST root bridge:

```
create stpd s0 (Default)
disable stpd s0
configure stpd s0 mode dot1w
configure stpd s0 priority 28672
enable stpd s0 auto-bind vlan Default (Default)
configure stpd s0 ports link-type point-to-point 4-5
enable stpd s0
```

# Supported Standards, Protocols, and MIBs

---

[Extreme Networks Proprietary MIBs](#) on page 1786

[MIB Support Details](#) on page 1970

This appendix provides information about the MIB support provided by the ExtremeXOS *SNMP (Simple Network Management Protocol)* agent residing on Extreme Networks devices running ExtremeXOS and Extreme Networks proprietary MIBs.

## Note

All information for supported standards and protocols can be found in the following location: <http://www.extremenetworks.com/resources>. This appendix contains only the MIB support details.

## Extreme Networks Proprietary MIBs

---

The Extreme Networks MIBs are located at <http://www.extremenetworks.com/support/policies/mibs/>.

## EXTREME ACL MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group          | Supported Variables        | Comments                                                                                           |
|----------------------|----------------------------|----------------------------------------------------------------------------------------------------|
| extremeAclStatsTable | extremeAclStatsVlanIfIndex | The IfIndex of the <i>VLAN (Virtual LAN)</i> in which this policy/rule is applied                  |
|                      | extremeAclStatsPortIfIndex | The IfIndex of the the port in which this policy/rule is applied                                   |
|                      | extremeAclDirection        | The ingress/egress direction to which this policy/rule is applied (0 for ingress and 1 for Egress) |
|                      | extremeAclStatsCounterName | Name of the counter for which the stats is requested                                               |
|                      | extremeAclStatsPktCount    | The total number of packets that matches this rule                                                 |
|                      | extremeAclStatsByteCount   | The total number of bytes that matches this rule                                                   |

## CTRON Alias MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group  | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ctAliasTable |                     | <p>The ctAliasTable contains information about the aliases known by the agent. This table is indexed using a unique and arbitrary ID and a TimeFilter to allow a management station to learn all alias entries that have been modified since time X. This table is NOT designed to do a single GET. This Table is designed for MIB Walks only. This table contains objects that map upper-layer network services and entities to the physical location of the associated port, and the MAC address of the associated end-system (node). All entries in this table are deleted when sysUpTime is reset to zero. This table allows for a time filtered view. It is useful for determining what has been modified in the Alias Table since a specified time. If a management station reads the ctAliasTable of an entity at time X, subsequent updates can be realized by performing get-next requests of this table to determine which entries have been modified since time X. Then the management station can use GET requests to retrieve only the records of interest from the Alias table. There is a delay between retrieving the Alias Reference values from this table, and a GET request to retrieve a modified row from the Alias table. The management station should be prepared for two possibilities: 1) the GET request may fail if the Alias table entry has been deleted during the delay, and 2) the entry may have been modified during the delay, so the modification time of the retrieved entry may differ from the modification time of the Delta entry. If the entry in the Alias Control table identified by ctAliasID is marked inactive by management request, and subsequently deleted to free resources, all corresponding</p> |

| Table/Group | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|             | ctAliasReference    | An integer ID assigned by the agent. The value of this object is equal to an existing ctAliasID.<br>Access = not-accessible                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|             | ctAliasInterface    | The ifIndex of the interface on which this entry was discovered. The ifIndex is an 'external value' that identifies a physical component associated with the Alias entry. This object can be used to identify the physical location of the interface in the ifTable [RFC2863]. The possibility of ifIndex value re-assignment must be accommodated by a management application whenever the value of sysUpTime is reset to zero. Since ifIndex values in different 'naming scopes' are not related to one another, the interface to physical component associations are relative to the same logical entity within the agent. For more discussion of naming scopes, see the ENTITY-MIB [RFC2037].<br>Access = read-only |
|             | ctAliasMacAddress   | The MAC address associated with this alias. The TEXTUAL-CONVENTION MacAddress is defined in SNMPv2-TC as an 802 MAC address represented in 'canonical' order as defined by IEEE 802.1a, i.e., as if it were transmitted least significant bit first."                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| ctAliasConfigurationTable |                                           | This table is used to prevent any single chatty port from monopolizing all of the available alias buffers in the system by letting an administrator tune each port.<br>Access = not-accessible                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                           | ctAliasConfigurationEntry                 | Each entry contains an enable/disable control variable and variables showing the number of maximum allowable and currently used entries.<br>Access = not-accessible                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                           | ctAliasConfigurationInterfaceTotalEntries | The total number of alias entries currently in use by this ctAliasInterface.<br>Access = read-only                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                           | ctAliasConfigurationInterfaceMaxEntries   | This object represents the maximum number of alias entries in the ctAliasTable which were created by this ctAliasInterface. When the object ctAliasConfigurationInterfaceTotalEntries equals this object, the next alias appearing on this ctAliasInterface causes the oldest entry created by this ctAliasInterface to be deleted. The sum of this object across all ctAliasInterface shall not exceed ctAliasConfigurationSystemTotalEntries. If the value of this object is increased, then oldest entry removal ceases until the maximum is reached again. If management reduces the value of this object, then, starting with the oldest, alias entries are removed until the new number of entries is reached.<br>Access = read/write |
|                           | ctAliasConfigurationInterfaceEnableState  | The enable state of the alias agent on this ctAliasInterface.<br>Access = read/write                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                           | ctAliasConfigurationNumQueueWraps         | This object represents the number of times the queue for this ctAliasConfigurationEntry has wrapped. Since circular queues are used for storing the entries, when all allocated entries are used, the oldest entries are reused, thus creating a wrap condition. A value                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Table/Group | Supported Variables                     | Comments                                                                                                                                                                                                        |
|-------------|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                         | of zero indicates the queue has not wrapped, except in the case that the counter itself has wrapped.<br>Access = read-only                                                                                      |
|             | ctAliasConfigurationProtocolEnableState | A bit field of the protocol types where a set indicates the detection of that protocol is enabled. A bit position with a cleared bit indicates detection of that protocol is not enabled.<br>Access = read-only |

| Table/Group | Supported Variables          | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | ctAliasMacAddressInterface   | The ifIndex of the interface on which this entry was discovered. The ifIndex is an 'external value' that identifies a physical component associated with the Alias entry. This object can be used to identify the physical location of the interface in the ifTable [RFC2863]. The possibility of ifIndex value re-assignment must be accommodated by a management application whenever the value of sysUpTime is reset to zero. Since ifIndex values in different 'naming scopes' are not related to one another, the interface to physical component associations are relative to the same logical entity within the agent. For more discussion of naming scopes, see the ENTITY-MIB [RFC2037]<br>Access = read-only |
|             | ctAliasMacAddressVlanID      | The VLAN ID contained in the header of the message associated with this alias. On agents which support this MIB but do not support VLANs, the value for this object MUST be (1).<br>Access = read-only                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|             | ctAliasMacAddressIsActive    | The status of this entry. A true(1) value indicates the alias is active. A false(2) value indicates an entry which has been marked inactive by network management, using the ctAliasEntryStatus object in the ctAliasControlTable. Entries which have been marked inactive may remain in the table to allow consistent mappings between network management stations until an agent needs to free resources.<br>Access = read-only                                                                                                                                                                                                                                                                                      |

|             | ctAliasProtocolAddressInterface   | <p>The ifIndex of the interface on which this entry was discovered. The ifIndex is an 'external value' that identifies a physical component associated with the Alias entry. This object can be used to identify the physical location of the interface in the ifTable [RFC2863]. The possibility of ifIndex value re-assignment must be accommodated by a management application whenever the value of sysUpTime is reset to zero. Since ifIndex values in different 'naming scopes' are not related to one another, the interface to physical component associations are relative to the same logical entity within the agent. For more discussion of naming scopes, see the ENTITY-MIB [RFC2037]</p> <p>Access = read-only</p> |
|             | ctAliasProtocolAddressVlanID      | <p>The VLAN ID contained in the header of the message associated with this alias. On agents which support this MIB but do not support VLANs, the value for this object MUST be (1).</p> <p>Access = read-only</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

Entries which have been marked inactive may remain in the table to allow consistent mappings between network management stations until an agent needs to free resources.<br>Access = read-only     |
|                        | ctAliasInterfaceAddressText | The address associated with this entry in a human readable textual format.<br>Access = read-only                                                                                                                                                                                                                                                                                                                                      |
|                        | ctAliasInterfaceTime        | The value of sysUpTime when this entry was last modified.<br>Access = read-only                                                                                                                                                                                                                                                                                                                                                       |
| ctAliasMacAddressTable |                             | The ctAliasMacAddressTable contains information about the aliases known by the agent indexed by MAC address and protocol. This table contains information that is identical to the ctAliasTable, but it is instanced by MAC address and protocol to allow management entities to search for a MAC address and protocol, or part of a MAC address and protocol, using a single <i>SNMP</i> GetNext request.<br>Access = not-accessible |
|                        | ctAliasMacAddressEntry      | Each entry contains information pertaining to the alias of a node in a table indexed by MAC address, protocol type, protocol address, and alias ID.<br>Access = not-accessible                                                                                                                                                                                                                                                        |

| Table/Group                 | Supported Variables | Comments                                                                                           |
|-----------------------------|---------------------|----------------------------------------------------------------------------------------------------|
| ctAliasBasicGroup           |                     | A collection of objects for the discovery and mapping of end systems and aliases.                  |
| ctAliasStatsGroup           |                     | A collection of objects pertaining to discovery and mapping of end systems and aliases.            |
| ctAliasControlGroup         |                     | This group has been deprecated. See ctAliasControlGroup1.                                          |
| ctAliasConfigurationGroup   |                     | A collection of objects for configuring port buffer queues.                                        |
| ctAliasMacAddressGroup      |                     | A collection of objects for the discovery and mapping of end systems and aliases.                  |
| ctAliasProtocolAddressGroup |                     | A collection of objects for the discovery and mapping of end systems and aliases.                  |
| ctAliasControlGroup1        |                     | A collection of objects which make the Aliases accessible using the TimeFilter TEXTUAL CONVENTION. |
| ctAliasGroup                |                     | An object used for removing alias entries.                                                         |
| ctAliasConfigurationGroup1  |                     | An object to indicate queue usage.                                                                 |
| ctAliasConfigurationGroup2  |                     | A collection of objects for configuring port buffer queues.                                        |
| ctAliasInterfaceGroup       |                     | A collection of objects for the discovery and mapping of end systems and aliases.                  |

## EXTREME-CFGMGMT-MIB

This MIB provides the ability to query configuration activity and to perform switch management operations. The following features are part of this MIB:

- Expose the time and date of the last configuration save operation.
- Issue a notification to NMS upon completion of a database save operation.
- Provide the ability for ExtremeXOS to report on-demand the presence of unsaved configuration changes on the system.
- Issue a notification whenever any system configuration is altered, added, or deleted.

The following tables, groups, and variables are supported in this MIB.

| Table/Group             | Supported Variables           | Comments                                                                                                                                                                                                                                          |
|-------------------------|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeLastSaveCfgTable | extremeLastSavedEntry         | This group of objects contain<br>of the last saved configuration<br>operation for the running con<br>If the value of<br>extremeLastChangeConfigTin<br>is greater than<br>extremeLastSaveConfigTime,<br>configuration has been chang<br>not saved. |
|                         | extremeLastSaveConfigSlotId   | Specifies the MSM/MM modul<br>number of a switch or the slot<br>number currently being used<br>active stack node.                                                                                                                                 |
|                         | extremeLastSaveConfigTime     | This object return the date an<br>time of the last configuration<br>operation. This data reflects th<br>command or the last setting o<br>extremeSaveConfiguration ob                                                                              |
|                         | extremeLastSaveConfigFileName | This object returns the config<br>file name of the last save oper                                                                                                                                                                                 |
|                         | extremeLastSaveConfigSource   | This object indicates the sourc<br>of the last configuration save<br>operation for the configuratio<br>file associated with this entry,<br>extremeLastSaveConfigFileNa                                                                            |

| Table/Group               | Supported Variables             | Comments                                                                                                                                                                                                                                           |
|---------------------------|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeLastChangeCfgTable | extremeLastChangeEntry          | This group of objects contain<br>of the last change configuration<br>operation for the running con<br>If the value of<br>extremeLastChangeConfigTime<br>is greater than<br>extremeLastSaveConfigTime,<br>configuration has been chang<br>not saved |
|                           | extremeLastChangeConfigSlotId   | Specifies the slot number curr<br>being used by the active stack                                                                                                                                                                                   |
|                           | extremeLastChangeConfigTime     | This object returns the date an<br>time of the last configuration<br>change operation. This data re<br>the last command or the last s<br>of the extremeSaveConfigurat<br>object.                                                                   |
|                           | extremeLastChangeConfigFileName | This object returns the config<br>file name of the last change<br>operation.                                                                                                                                                                       |
|                           | extremeLastChangeConfigSource   | This object indicates the<br>source of the last<br>configuration change operati<br>extremeLastChangeConfigFile                                                                                                                                     |
| cfgMgmtTraps              | cfgMgmtConfigSaveTrap           | This notification indicates that<br>the running configuration of t<br>managed system has updated<br>NVRAM storage of the current<br>configuration.                                                                                                 |
|                           | cfgMgmtConfigChangeTrap         | This notification contain detai<br>of the last change configurati<br>operation for the running con                                                                                                                                                 |
| cfgMgmtControl            | cfgMgmtConfigSaveTrapEnable     | This variable indicates<br>whether the system produces<br>the cfgMgmtConfigSaveTrap<br>notification. A false value prev<br>notifications from being gene<br>by this system.                                                                        |
|                           | cfgMgmtConfigChangeTrapEnable   | This variable indicates<br>whether the system produces<br>the cfgMgmtConfigChangeTra<br>notification. A false value prev<br>notifications from being gene<br>by this system.                                                                       |

## ENTERASYS-APPLICATION-SIGNATURE-MIB

| Table/Group             | Supported Variables    | Comments                                                                                                                        |
|-------------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| Application Group Table | etsysAppSignGroupTable | A table that contains the standard Application Groups for the Extreme Network deep packet inspection engine.<br>Not-accessible. |
|                         | etsysAppSignGroupEntry | An entry that ties a given application Group Name to a particular application group ID.<br>Not-accessible.                      |
|                         | etsysAppSignGroupId    | A pre-defined unique group index that points to the group to which the application belongs.<br>Not-accessible.                  |
|                         | etsysAppSignGroupName  | A pre-defined application group name.<br>Read-only.                                                                             |

| Table/Group                    | Supported Variables              | Comments                                                                                                                                                                                                                                                                                                        |
|--------------------------------|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application Display Name Table | etsysAppSignDisplayNameTable     | A table that describes attributes of a user-defined application display name. Not-accessible.                                                                                                                                                                                                                   |
|                                | etsysAppSignDisplayNameEntry     | Describes a particular entry within the etsysAppSignDisplayNameTable." Not-accessible.                                                                                                                                                                                                                          |
|                                | etsysAppSignDisplayId            | A unique ID assigned to a specific extended signature. The user can only assign an index in a range from 5,000 to 5,999. The rest of the indices are reserved for internal use. Not-accessible.                                                                                                                 |
|                                | etsysAppSignDisplayName          | A user-friendly name assigned to this extended signature. The display name and display ID <i>must</i> be unique within the scope of a single managed entity. This object <i>must not</i> be modifiable while this entry's RowStatus is active (1) or if etsysAppSignDisplayId is a reserved index. Read-create. |
|                                | etsysAppSignDisplayNameRowStatus | This object allows for the dynamic creation and deletion of entries within the etsysAppSignDisplayNameTable as well as the activation and deactivation of these entries. Read-create.                                                                                                                           |

| Table/Group                      | Supported Variables          | Comments                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application Pattern String Table | etsysAppSignPatternTable     | A table that describes attributes of a user-defined pattern string.<br>Not-accessible.                                                                                                                                                                                                                                                    |
|                                  | etsysAppSignPatternEntry     | An entry describing the matching pattern of a WebApplRule and its assigned index. For use by the Extreme Networks deep packet inspection engine.<br>Not-accessible.                                                                                                                                                                       |
|                                  | etsysAppSignPatternIndex     | A unique identifier for a pattern string. The user can only assign an index in a range from 1,000,000 to 2,000,000. The rest of the indices are reserved for internal use.<br>Not-accessible.                                                                                                                                             |
|                                  | etsysAppSignPattern          | A case-sensitive string for matching against the 'host' field of an HTTP request packet, or the 'server name' in the 'client Hello' packet of a TLS session. This is used to identify the application.<br>Read-create.                                                                                                                    |
|                                  | etsysAppSignPatternRowStatus | This object allows the dynamic creation and deletion of entries within the etsysAppSignPatternTable, as well as the activation and deactivation of these entries.<br><br>etsysAppSignPatternRowStatus <i>must not</i> be set to active (1) and createAndGo(4) if the etsysAppSignPattern object contains an empty string.<br>Read-create. |

## ENTERASYS-CONVERGENCE-END-POINT-MIB

| Table/Group                         | Supported Variables                       | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysConvEndPointGlobalConfigEnable |                                           | When set to enabled(1) this object activates the current Convergence End Point configuration. When set to disabled(2) this MIB SHALL be configurable, but MUST NOT be applied, all entries will be removed from the etsysConvEndPointConnMacTable and the etsysConvEndPointConnPortTable, and any policies that have been changed as a result of End Point detection will revert to their default states. Maintaining the value of this object across agent reboots is REQUIRED.<br>Read-write. |
| etsysConvEndPointGlobalConfigTable  |                                           | This table represents all Convergence End Point types supported by this entity, and provides a default policy profile for each Convergence End Point type.<br>Not-accessible.                                                                                                                                                                                                                                                                                                                   |
|                                     | etsysConvEndPointGlobalConfigEntry        | Defines the default policy to be applied when this type of Convergence End Point is detected or discovered.<br>Not-accessible.                                                                                                                                                                                                                                                                                                                                                                  |
|                                     | etsysConvEndPointGlobalDefaultPolicyIndex | The policy that should be applied for this type of Convergence End Point. This value is an etsysPolicyProfileIndex as defined in the ENTERASYS-POLICY-PROFILE-MIB. If no such policy index exists, then no policy will be applied when this type of Convergence End Point is detected or discovered. The value zero is not a valid etsysPolicyProfileIndex, so zero indicates that no policy should be applied. Maintaining the value of this object across system reboots is REQUIRED.         |

| Table/Group                              | Supported Variables                            | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| etsysCEPCdpPortConfigTable |                                    | A table of per port configuration for Convergence End Point detection related to the Cisco CDP protocol. Only ports that are capable of participating in Cisco CDP protocol are represented in this table.<br>Not-accessible.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                            | etsysCEPCdpPortConfigEntry         | An entry containing per port Convergence End Point data. Only interfaces that are able to detect Convergence End Points are represented in this table.<br>Not-accessible.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                            | etsysCEPCiscoCDPVoicePortVlan      | This object controls the behavior of the remote configuration of Cisco VOIP phones via Cisco CDP. Setting this object to a value of -1 will cause the device to not attempt to remotely configure a Cisco phone using CDP. Setting this object to a value of 0 will cause the device to configure the phone to send 802.1p priority tagged frames. A value of 4095 will cause the device to configure the phone to send untagged frames. A value in the range 1..4094 will cause the device to configure the phone to send 802.1Q tagged frames using that value as the <u>VLAN</u> ID encoded in the tag. This object SHOULD be maintained across device reboots.<br>Read-write. |
|                            | etsysConvEndPointGlobalConfigGroup | Objects which provide global control of the Convergence End Point features.<br>Status = deprecated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## EXTREME ENTERASYS ENTITY SENSOR MIB

The Extreme Enterasys Entity Sensor MIB's extremeEntityTempSfpSensorExtEntry contains objects for representing per transceiver sensor information that extends the information provided in the Entity Sensor MIB Extensions' entPhySensorTable of the SFP/QSFP. The following table list the objects supported.

| Table/Group                     | Description                                                                                              | Comments   |
|---------------------------------|----------------------------------------------------------------------------------------------------------|------------|
| etsysEntitySfpSensorState       | Integer indicates temperature state of sensor                                                            | Read-only  |
| etsysEntitySfpSensorHighAlarm   | Integer representing the sensor's high alarm threshold                                                   | Read-only  |
| etsysEntitySfpSensorHighWarning | Integer representing the sensor's high warning threshold                                                 | Read-only  |
| etsysEntitySfpSensorLowAlarm    | Integer representing the sensor's low alarm threshold                                                    | Read-only  |
| etsysEntitySfpSensorLowWarning  | Integer representing the sensor's low warning threshold                                                  | Read-only  |
| etsysEntitySfpSensorTrapEnable  | Indicates if notification will be sent when sensor state changes as defined by etsysEntitySfpSensorState | Read-Write |

## ENTERASYS-MAC-AUTHENTICATION-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                       | Supported Variables                               | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysMACAuthenticationSystemGroup | etsysMACAuthenticationSystemEnable                | When enabled(1), all objects in this MIB are fully active. When disabled(2), this object overrides all other object settings in this MIB without affecting their values.                                                                                                                                                                                                                                                                                                                    |
|                                   | etsysMACAuthenticationMACUserPassword             | This is the string to be used as a password credential when authenticating a MAC address when etsysMACAuthenticationMode is set to sharedSecret(1).                                                                                                                                                                                                                                                                                                                                         |
|                                   | etsysMACAuthenticationPortUserNameSignificantBits | This object represents the number of significant bits in the MAC addresses to be used starting with the left-most bit of the vendor portion of the MAC address. The significant portion of the MAC address is sent as a user-name credential when the primary attempt to authenticate the full MAC address fails. Any other failure to authenticate the full address, (i.e. authentication server timeout) causes the the next attempt to start once again with a full MAC authentication." |
|                                   | etsysMACAuthenticationMode                        | This object is used to determine the type of password credential to use when authenticating a MAC address.<br><br>password(1) - Attempt to authenticate a user with the password credential provided by etsysMACAuthenticationMACUserPassword.<br><br>radiusUsername(2) - Attempt to authenticate a user with a password credential that is the same as their radius username credential.                                                                                                   |
|                                   | etsysMACAuthenticationSystemAccountEnable         | When enabled(1), RADIUS accounting start, interim and stop frames are sent to the configured RADIUS server(s).                                                                                                                                                                                                                                                                                                                                                                              |

| Table/Group                           | Supported Variables                      | Comments                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysMACAuthenticationPortConfigGroup | etsysMACAuthenticationPortConfigTable    | A table containing configuration objects for each MAC authentication port. The configuration for each port in this table must be non-volatile.                                                                                                                                                                                                                                  |
|                                       | etsysMACAuthenticationPortConfigEntry    | Each conceptual row provides control over all of the initial values used by each authenticated MAC on this port. Subsequent changes to rows in this table, except where noted, have no effect on existing MACs authenticated on this port.                                                                                                                                      |
|                                       | etsysMACAuthenticationPort               | This is the InterfaceIndex associated with this row.                                                                                                                                                                                                                                                                                                                            |
|                                       | etsysMACAuthenticationPortInitialize     | When set to true(1), the MAC authentication logic on this port is initialized, forcibly ending all MAC authentication sessions currently in existence on this port. A set with the value false(2) has no affect and a read always returns false.                                                                                                                                |
|                                       | etsysMACAuthenticationPortReauthenticate | When set to true(1), the MAC authentication entity on this port is required to immediately verify all currently authenticated MACs on this port. This requires that each MAC address be authenticated with the authentication server through the local authentication client or some other authentication mechanism. Each supplicant remains authenticated pending the outcome. |
|                                       | etsysMACAuthenticationPortEnable         | When set to enabled(1), a platform dependent triggering mechanism initiates an authentication exchange using a MAC address for authentication credentials. When disabled(2), authentication attempts are disabled and all currently authenticated MAC sessions or those in the process of authentication on this port are terminated.                                           |
|                                       | etsysMACAuthenticationPortQuietPeriod    | Unsupported object.                                                                                                                                                                                                                                                                                                                                                             |
|                                       | etsysMACAuthenticationPortReauthPeriod   | The value, in seconds, between attempts to re-authenticate any current MAC authenticated on this port.                                                                                                                                                                                                                                                                          |
|                                       | etsysMACAuthentication                   | If enabled(1), then every                                                                                                                                                                                                                                                                                                                                                       |

| Table/Group | Supported Variables                            | Comments                                                                                                                                                                                                                                                                                                                                                                         |
|-------------|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | PortReauthEnabled                              | etsysMACAuthenticationReauthPeriod the switch attempts to validate all currently authenticated MACs on this port. When set to disabled(2) all current re-authentications in progress are allowed to complete and the requisite actions are taken. When set to disabled(2), no further re-authentications are attempted.                                                          |
|             | etsysMACAuthenticationAuthenticationsAllowed   | The maximum number of concurrent authentications supported on this port on this module. The default value of this object is platform and resource dependent.                                                                                                                                                                                                                     |
|             | etsysMACAuthenticationAuthenticationsAllocated | The maximum number of MAC authentications permitted on this port on this module. This value must be non-zero and be less than or equal to the value of etsysMACAuthenticationAuthenticationsAllowed. Setting this object to a value less than the current number of authenticated MACs on this port prevents further authentications, but has no affect on the current sessions. |
|             | etsysMACAuthenticationLastFailedAuthCause      | The string will be formatted with 'XX-XX-XX-XX-XX-XX: TIME&DATE: Textual failure reason'; where XX-XX-XX-XX-XX-XX is the MAC address and TIME&DATE is the time (hh/mm/ss) and date (mm/dd/yyyy) of the failure. It is also only best effort; as there could be multiple failures per port and the agent may query this at any random time.                                       |

| Table/Group                          | Supported Variables                     | Comments                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysMACAuthenticationMACConfigGroup | etsysMACAuthenticationMACConfigTable    | A table containing configuration objects for each MAC authenticated on a port. Each row in this table is created dynamically when a MAC authenticates on a port.                                                                                                                                                                                                                                      |
|                                      | etsysMACAuthenticationMACConfigEntry    | Each conceptual row inherits its initial information from the row in the etsysMACAuthenticationPortConfigTable corresponding to the correct port. Each row represents an authenticated MAC.                                                                                                                                                                                                           |
|                                      | etsysMACAuthenticationMACAddress        | This is the MAC address that was authenticated on this port.                                                                                                                                                                                                                                                                                                                                          |
|                                      | etsysMACAuthenticationSupplicantPort    | This is the InterfaceIndex associated with this row's authenticated MAC.                                                                                                                                                                                                                                                                                                                              |
|                                      | etsysMACAuthenticationMACInitialize     | When set to true(1), this MAC session terminates causing the corresponding row in this table and in the etsysMACAuthenticationSessionTable to be removed.<br>Setting this object to false(2) has no effect on the system. Reads of this object always return false(2).                                                                                                                                |
|                                      | etsysMACAuthenticationMACReauthenticate | When set to true(1), this MAC authentication session on this port is required to immediately verify its credentials. This requires that each MAC address be authenticated with the authentication server through the local authentication client or some other authentication mechanism.<br>Setting this object to false(2) has no effect on the system. Reads of this object always return false(2). |
|                                      | etsysMACAuthenticationMACReauthPeriod   | The value, in seconds, between attempts to re-authenticate the MAC associated with this row.                                                                                                                                                                                                                                                                                                          |
|                                      | etsysMACAuthenticationMACReauthEnabled  | If enabled(1), then every etsysMACAuthenticationReauthPeriod the switch attempts to validate all currently authenticated MACs on this port. If disabled(2), reauthentication is not attempted.                                                                                                                                                                                                        |

| Table/Group                        | Supported Variables                | Comments                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysMACAuthenticationSessionGroup | etsysMACAuthenticationSessionTable | A table containing configuration objects for each MAC authentication on a port. The successful completion of an authentication causes the creation of a new row in this table. When a MAC becomes unauthenticated because of a link-down, a management change, or system re-initialization, then the corresponding row is removed from this table. |
|                                    | etsysMACAuthenticationSessionEntry | Each conceptual row inherits its initial information from the row in the etsysMACAuthenticationPortConfigTable corresponding to the correct port. Each row represents an authenticated MAC.                                                                                                                                                        |
|                                    | etsysMACAuthenticationSessionPort  | This is the InterfaceIndex associated with the authenticated MACs session.                                                                                                                                                                                                                                                                         |
|                                    | etsysMACAuthenticationDuration     | The value, in seconds, which have elapsed since the start of this session.                                                                                                                                                                                                                                                                         |

## ENTERASYS-MIRROR-CONFIG-MIB

The following tables, groups, and variables are supported in this MIB.

**Table 163: ENTERASYS-MIRROR-CONFIG-MIB**

| Table/Group                                     | Supported Variables | Comments                                                                                                 |
|-------------------------------------------------|---------------------|----------------------------------------------------------------------------------------------------------|
| etsysMirrorSystemMaxLocalMirrors                |                     | This value represents the maximum number of local mirrors that the device supports.<br>Read-only         |
| etsysMirrorSystemMaxRemoteMirrors               |                     | This value represents the maximum number of remote mirrors that the device supports.<br>Read-only        |
| etsysMirrorSystemMaxLocalMirrorDestinationPorts |                     | This value represents the maximum number of destination ports supported for a local mirror.<br>Read-only |

**Table 163: ENTERASYS-MIRROR-CONFIG-MIB (continued)**

| Table/Group                                        | Supported Variables | Comments                                                                                                                                                                 |
|----------------------------------------------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysMirrorSystemMaxMirrorDestinationControlGroups |                     | This value represents the maximum number of rows in the etsysMirrorDestinationControlTable.<br>Read-only                                                                 |
| etsysMirrorSystemMaxMirrorFirstN                   |                     | This value represents the maximum configurable number of initial packets of a flow that can be mirrored. If this value is 0, this feature is not supported.<br>Read-only |

## ENTERASYS-MULTI-AUTH-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                          | Supported Variables                   | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Multiple Authentication System Group | etsysMultiAuthSystemSupportedTypes    | This object specifies that authentication types that the device supports. A bit will be set for each corresponding type that is supported.                                                                                                                                                                                                                                                                                                                                                                                     |
|                                      | etsysMultiAuthSystemMaxNumUsers       | The maximum number of users the can be actively authenticated or have authentications in progress at one time in the system.                                                                                                                                                                                                                                                                                                                                                                                                   |
|                                      | etsysMultiAuthSystemCurrentNumUsers   | The current number of users the are actively authenticated, have authentications in progress, or the device is keeping authentication termination information for in the system.                                                                                                                                                                                                                                                                                                                                               |
|                                      | etsysMultiAuthSystemMode              | The value strictIeee8021x(1) will cause the device to authenticate in strict adherence to IEEE Std. 802.1X-2001. In this mode no other authentication mechanisms will be active. While in this mode, changes may be made to other objects in the MIB, but they will have no effect on the operation of the device until such time as the system mode is changed to etsysMultiAuth(2). A set of this object to a value of etsysMultiAuth(2) will cause the device to authenticate using multiple authenticators simultaneously. |
|                                      | etsysMultiAuthSystemDefaultPrecedence | The precedence that authentication results will be applied to network traffic by default. This object will have a size equal to the number of enumerations specified by the EtsysMultiAuthTypes textual convention.                                                                                                                                                                                                                                                                                                            |
|                                      | etsysMultiAuthSystemAdminPrecedence   | This object allows one to modify the default precedence by which authentication results will be applied to network traffic. Sets to this object are not required to specify all of the types that the device supports. If less types are specified than are supported, then all types that were not specified                                                                                                                                                                                                                  |

| Table/Group | Supported Variables                | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                    | <p>will be given an operational precedence based on that type's default precedence relative to the last type specified. For example, if the default precedence is '030102'H and the object is set to '02'H then operational precedence would be '020301'H.</p> <p>A set to this object of a zero length octet string will clear the administrative precedence. In this case the operational precedence would be equal to the default precedence.</p>                                                                                                         |
|             | etsysMultiAuthSystemOperPrecedence | This object returns the operational precedence of authentication types as they will be applied to network traffic. The value returned by this object is the calculated result of the etsysMultiAuthSystemDefaultPrecedence and etsysMultiAuthSystemAdminPrecedence objects. This object will have a size equal to the number of enumerations specified by the EtsysMultiAuthTypes textual convention.                                                                                                                                                        |
|             | etsysMultiAuthTypePropertiesTable  | A table of properties per authentication type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|             | etsysMultiAuthTypePropertiesEntry  | An entry containing per authentication type properties.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|             | etsysMultiAuthType                 | The authentication type the entry properties pertain to.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|             | etsysMultiAuthSessionTimeout       | <p>The maximum number of seconds an authenticated session may last before termination of the session. A value of zero indicates that no session timeout will be applied. This value MAY be superseded by a session timeout value provided by the authenticating server. For example, if a session is authenticated by a RADIUS server, that server may encode a Session-Timeout Attribute in its authentication response. The operational timeout value of a given authenticated session is specified by the etsysMultiAuthSessionSessionTimeout object.</p> |
|             | etsysMultiAuthIdleTimeo            | The maximum number of                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|                                    | -etsysMultiAuthPortEntry          | An entry containing per port authentication data. Only interfaces that are able to authenticate users are represented in this table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                                    | etsysMultiAuthPortMode            | This object specifies the authorization mode to use for packets received on this interface.<br>A value of forceUnauthorized(1) indicates that the interface is always unauthenticated.<br>A value of forceAuthorized(2) indicates that users on this port will always be considered to be authenticated.<br>A value of authOptional(3) indicates that authentication is optional on this interface. Packets received from unauthenticated users on the interface will be processed using the static configuration of the interface. Users may promote the policy applied to their traffic by actively authenticating on this interface.<br>A value of authRequired(4) indicates that all packets received on the interface will be dropped until authentication succeeds. Some authentication types, such as PWA, will not be fully functional in this mode of operation. |
|                                    | etsysMultiAuthPortMaxNumUsers     | The maximum number of users that can be actively authenticated or have authentications in progress at one time on this interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                                    | etsysMultiAuthPortNumUsersAllowed | The user configured number of users that can be actively authenticated or have authentications in progress at one time on this interface. This object has a default value equal to the value of etsysMultiAuthPortMaxNumUsers for this interface. If the value set to this object is less than its current value, it will have the same effect as setting                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Table/Group | Supported Variables               | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                   | the etsysMultiAuthPortClearUsers object to a value of true(1).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|             | etsysMultiAuthPortCurrentNumUsers | The current number of users that are actively authenticated or have authentications in progress at one time on this interface. By definition this value can not exceed the value specified by etsysMultiAuthPortMaxNumUsers for the same interface.                                                                                                                                                                                                                                                                                                                                                                       |
|             | etsysMultiAuthPortClearUsers      | Setting this object to a value of true(1) will cause all users that are currently authenticated or that have authentications in progress on this interface to become unauthenticated. This will cause any such entries with matching ifIndex values in the etsysMultiAuthSessionStationTable tables to change their authorization status to authTerminated(5)<br>Setting this object to a value of false(2) has no effect. This object will always return a value of false(2).                                                                                                                                            |
|             | etsysMultiAuthPortTrapEnable      | This object allows for the enabling or disabling of each trap on a per interface basis. Setting a given bit to a value of 1 allows traps of that type to be sent for events on that interface. Setting a given bit to a value of 0 disallows traps of that type to be sent for events on that interface. The individual bits correlate to specific traps as follows:<br>BIT NOTIFICATION<br>-----<br>----- authSuccessTrap(0)<br>etsysMultiAuthSuccess<br>authFailedTrap(1)<br>etsysMultiAuthFailed<br>authTerminatedTrap(2)<br>etsysMultiAuthTerminated<br>maxNumUsersReachedTrap(3)<br>etsysMultiAuthMaxNumUsersReached |
|             | etsysMultiAuthPortTypeTable       | A table of per port, per authentication type information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|             | etsysMultiAuthPortTypeEntry       | An entry containing per port, per authentication type data. Only interfaces that are able to                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Table/Group | Supported Variables                       | Comments                                                                                                                                           |

|             |                                      | <p>not succeeding or not having completed.</p> <p>All values other than zero are valid Policy Profile Indexes that specify the policy profile the user will receive on this interface. If a given user has been authenticated by multiple authentication types on the same interface the policy that is applied to the user's packets is determined by the precedence of the agents as specified by etsysMultiAuthSystemOperPrecedence. These indexes are suitable for indexing in the ENTERASYS-POLICY-PROFILE-MIB.</p>                         |
|             | etsysMultiAuthSessionIsApplied       | <p>This object indicates whether this entry and the policy index contained within it are actively being applied to traffic matching the interface and station address of this entry. A value of true(1) indicates that this entry is being applied. A value of false(2) indicates that the entry is not being applied. Only one authentication type per interface station address ordered pair may be applied at a single time. The operational precedence of the various authentication types determines which if any type will be applied.</p> |
|             | etsysMultiAuthSessionTerminationTime | <p>The local date and time that the session was terminated. If the session is not in the authTerminated(5) state this object MUST return '00000000'H.</p>                                                                                                                                                                                                                                                                                                                                                                                        |
|             | etsysMultiAuthSessionSessionTimeout  | <p>The maximum number of seconds this session may last before automatic termination. A value of zero indicates that no session timeout will be applied. This value MAY be provided by the etsysMultiAuthSessionTimeout object or by the authenticating server.</p>                                                                                                                                                                                                                                                                               |

|                                            | etsysMultiAuthCounterEnable             | This object allows for the enabling or disabling of per-user counters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Multiple Authentication Notification Group | etsysMultiAuthSuccess NOTIFICATION-TYPE | An etsysMultiAuthSuccess trap signifies that the SNMP entity, acting in an agent role, has successfully authenticated a station on one of its interfaces. The included objects of etsysMultiAuthStationAddrType and etsysMultiAuthStationAddr uniquely identify the station that has been authenticated. The interface that the station was authenticated on is specified by the ifIndex object, and the type of authentication used is to authenticate the station is specified by the etsysMultiAuthSessionAgentType object. This trap will only be generated on interfaces that are in the authOptional(3) or authRequired(4) state. |

| Table/Group | Supported Variables                        | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | etsysMultiAuthFailed NOTIFICATION-TYPE     | An etsysMultiAuthFailed trap signifies that the SNMP entity, acting in an agent role, has identified a station that attempted and subsequently failed to authenticate on one of its interfaces. The included objects of etsysMultiAuthStationAddrType and etsysMultiAuthStationAddr uniquely identify the station that attempted to authenticate. The interface that the station attempted to authenticate on is specified by the ifIndex object, and the type of authentication attempted is specified by the etsysMultiAuthSessionAgentType object. This trap will only be generated on interfaces that are in the authOptional(3) or authRequired(4) state.          |
|             | etsysMultiAuthTerminated NOTIFICATION-TYPE | An etsysMultiAuthTerminated trap signifies that the SNMP entity, acting in an agent role, has terminated the authentication of a station on one of its interfaces. The included objects of etsysMultiAuthStationAddrType and etsysMultiAuthStationAddr uniquely identify the station for which authentication was terminated. The interface that the station was previously authenticated on is specified by the ifIndex object, and the type of authentication that the station was terminated for is specified by the etsysMultiAuthSessionAgentType object. This trap will only be generated on interfaces that are in the authOptional(3) or authRequired(4) state. |

|             | etsysMultiAuthMaxNumUsersReached<br>NOTIFICATION-TYPE       | An etsysMultiAuthMaxNumUsersReached trap signifies that the SNMP entity, acting in an agent role, has an interface where subsequent to a successful authentication, the number of current sessions on the interface equals the maximum number of sessions allowed for that interface. The interface that the maximum number of sessions has been reached is specified by the ifIndex object.   |
|             | etsysMultiAuthModuleMaxNumUsersReached<br>NOTIFICATION-TYPE | An etsysMultiAuthModuleMaxNumUsersReached trap signifies that the SNMP entity, acting in an agent role, has a module where subsequent to a successful authentication, the number of current sessions on the module equals the maximum number of sessions allowed for that module. The module that the maximum number of sessions has been reached is specified by the entPhysicalIndex object. |
|             | etsysMultiAuthSystemMaxNumUsersReached<br>NOTIFICATION-TYPE | An etsysMultiAuthSystemMaxNumUsersReached trap signifies that the SNMP entity, acting in an agent role, where subsequent to a successful authentication, has the number of current sessions on the system equals the maximum number of sessions allowed for that system, .                                                                                                                     |

## ENTERASYS-POLICY-PROFILE-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group              | Supported Variables                       | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysPolicyProfile group | etsysPolicyProfileMaxEntries              | The maximum number of entries allowed in the etsysPolicyProfileTable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                          | etsysPolicyProfileNumEntries              | The current number of entries in the etsysPolicyProfileTable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                          | etsysPolicyProfileLastChange              | The sysUpTime at which the etsysPolicyProfileTable was last modified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                          | etsysPolicyProfileTableNextAvailableIndex | <p>This object indicates the numerically lowest available index within this entity, which may be used for the value of etsysPolicyProfileIndex in the creation of a new entry in the etsysPolicyProfileTable.</p> <p>An index is considered available if the index value falls within the range of 1 to 65535 and is not being used to index an existing entry in the etsysPolicyProfileTable contained within this entity.</p> <p>This value should only be considered a guideline for management creation of etsysPolicyProfileEntries, there is no requirement on management to create entries based upon this index value.</p> |
|                          | etsysPolicyProfileTable                   | A table containing policy profiles. A policy is a group of classification rules which may be applied on a per user basis, to ports or to stations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                          | etsysPolicyProfileEntry                   | Conceptually defines a particular entry within the etsysPolicyProfileTable. Entries within this table MUST be considered non-volatile and MUST be maintained across entity resets.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                          | etsysPolicyProfileIndex                   | A unique arbitrary identifier for this Policy. Since a policy will be applied to a user regardless of his or her location in the network fabric policy names SHOULD be unique within the entire network fabric. Policy IDs and policy names MUST be                                                                                                                                                                                                                                                                                                                                                                                |

| Table/Group | Supported Variables         | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|             | etsysPolicyProfileForbiddenVlans | The set of VLANs which are prohibited by this policy to egress on ports for which this policy is active. Changes to this object that cause a port to be included or excluded affect the per-port per-VLAN Registrar control for Registration Forbidden for the relevant GVRP state machine on each port for which this policy is active. A VLAN may not be added in this set if it is already a member of the set of VLANs in etsysPolicyProfileEgressVlans. This object is superseded on a per-port per-VLAN basis by any 'set' bits in the dot1qVlanStaticEgressPorts and dot1qVlanForbiddenEgressPorts. The default value of this object is a string of zeros. |
|             | etsysPolicyProfileUntaggedVlans  | The set of VLANs which should transmit egress packets as untagged on ports for which this policy is active. This object is superseded on a per-port per-VLAN basis by any 'set' bits in dot1qVlanStaticUntaggedPorts.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|             | etsysPolicyProfileOverwriteTCI   | If set, the information contained within the TCI field of inbound, tagged packets will not be used by the device after the ingress classification stage of packet relay. The net effect will be that the TCI information may be used to classify the packet, but will be overwritten (and ignored) by subsequent stages of packet relay.                                                                                                                                                                                                                                                                                                                          |
|             | etsysPolicyProfileRulePrecedence | Each octet will contain a single value representing the rule type to be matched against, defined by the PolicyClassificationRuleType textual convention. When read, will return the currently operating rule matching precedence, ordered from first consulted (in the first octet) to last consulted (in the last octet).                                                                                                                                                                                                                                                                                                                                        |

| Table/Group | Supported Variables                   | Comments                                                                                                                                                                                                                                                                                                |
|-------------|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                       | A set of a single octet of 0x00 will result in a reversion to the default precedence ordering. A set of any other values will result in the specified rule types being matched in the order specified, followed by the remaining rules, in default precedence order.                                    |
|             | etsysPolicyProfileVlanRFC3580Mappings | The set of VLANs which are currently being mapped onto this policy profile by the etsysPolicyRFC3580MapTable. This only refers to the mapping of vlan-tunnel-attributes returned from RADIUS in an RFC3580 context.                                                                                     |
|             | etsysPolicyProfileMirrorIndex         | A reference to a packet mirror destination (defined elsewhere).<br>A value of (-1) indicates no mirror is specified, but a mirror is not explicitly prohibited.<br>A value of (0) indicates that mirroring is explicitly prohibited, unless a higher precedence source (a rule) has specified a mirror. |
|             | etsysPolicyProfileAuditSyslogEnable   | Enables the sending of a syslog message if no rule bound to this profile has prohibited it.                                                                                                                                                                                                             |
|             | etsysPolicyProfileAuditTrapEnable     | Enables the sending of a SNMP NOTIFICATION if no rule bound to this profile has prohibited it.                                                                                                                                                                                                          |
|             | etsysPolicyProfileDisablePort         | Will set the ifOperStatus of the port, on which the frame which used this profile was received, to disable, if if no rule bound to this profile has prohibited it.                                                                                                                                      |
|             | etsysPolicyProfileUsageList           | When read, a set bit indicates that this profile was used to send a syslog or trap message for corresponding port. When set, the native PortList will be bit-wise AND'ed with the set PortList, allowing the agent to clear the usage indication.                                                       |
|             | etsysPolicyProfileFstIndex            | A reference to a Flow Setup Throttling (FST) class as defined by the etsysFlowLimitingClassType object.                                                                                                                                                                                                 |

| Table/Group | Supported Variables                 | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|-------------|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | etsysPortPolicyProfileSummaryOperID    | An aggregate list of all Ports currently supporting rules which assign this profileIndex through either an administrative or dynamic means. The profileId which will be assigned operationally, as frames are handled are too be reported here. |
|             | etsysPortPolicyProfileSummaryDynamicID | An aggregate list of all Ports currently supporting rules which assign this profileIndex through a dynamic means. For example the profileIndex returned via a successful 802.1X supplicant authentication.                                      |

| Table/Group                     | Supported Variables                 | Comments                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysStationPolicyProfile group | etsysStationPolicyProfileMaxEntries | The maximum number of entries allowed in the etsysStationPolicyProfileTable. If this number is exceeded, based on stations connecting to the edge device, the oldest entries will be deleted.                                                                                                                                                                                                                |
|                                 | etsysStationPolicyProfileNumEntries | The current number of entries in the etsysStationPolicyProfileTable.                                                                                                                                                                                                                                                                                                                                         |
|                                 | etsysStationPolicyProfileLastChange | sysUpTime at which the etsysStationPolicyProfileTable was last modified.                                                                                                                                                                                                                                                                                                                                     |
|                                 | etsysStationPolicyProfileTable      | This table allows for a one to one mapping between a station's identifying address and a Policy Profile.                                                                                                                                                                                                                                                                                                     |
|                                 | etsysStationPolicyProfileEntry      | Describes a particular entry within the etsysStationPolicyProfileTable. Entries within this table MUST be considered non-volatile and MUST be maintained across entity resets.                                                                                                                                                                                                                               |
|                                 | etsysStationPolicyProfileIndex      | An index value which represents a unique station entry.                                                                                                                                                                                                                                                                                                                                                      |
|                                 | etsysStationIdentifierType          | Indicates the type of station identifying address contained in etsysStationIdentifier.                                                                                                                                                                                                                                                                                                                       |
|                                 | etsysStationIdentifier              | A value which represents a unique MAC Address, IP Address, or other identifying address for a station, or other logical and authenticatable sub-entity within a station, connected to a port.                                                                                                                                                                                                                |
|                                 | etsysStationPolicyProfileOperID     | <p>This object is the current policy which is being applied to this entry's MAC Address. A value of zero(0) indicates there is no policy being applied to this MAC Address.</p> <p>The value of this object reflects either the setting from an underlying AAA service such as RADIUS, or the default setting based on the etsysPortPolicyProfileAdminID for the port on which the station is connected.</p> |

| Table/Group                    | Supported Variables               | Comments                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                |                                   | This object and the corresponding etsysPortPolicyProfileAdminID will not be the same if this object has been set by an underlying security protocol such as RADIUS.                                                                                                                                                                                                                                                         |
|                                | etsysStationPolicyProfilePortType | A textual convention that defines the specific type of port designator the corresponding entry represents.                                                                                                                                                                                                                                                                                                                  |
|                                | etsysStationPolicyProfilePortID   | A value which represents the physical port, of the type defined by this entry's etsysStationPolicyProfilePortType, on which the associated station entity is connected. This object is for convenience in cross referencing stations to ports.                                                                                                                                                                              |
| etsysInvalidPolicyPolicy group | etsysInvalidPolicyAction          | Specifies the action that the edge device should take if asked to apply an invalid or unknown policy.<br>applyDefaultPolicy(1) - Ignore the result and search for the next policy assignment rule.<br>dropPackets(2) - Block traffic.<br>forwardPackets(3) - Forward traffic, as if no policy had been assigned (via 802.1D/Q rules).<br>Although dropPackets(2) is the most secure option, it may not always be desirable. |
|                                | etsysInvalidPolicyCount           | Increments to indicate the number of times the device has detected an invalid/unknown policy.                                                                                                                                                                                                                                                                                                                               |
| etsysDevicePolicyProfile group | etsysDevicePolicyProfileDefault   | If this value is non-zero, the value indicates the etsysPolicyProfileEntry (and its associated etsysPolicyClassificationTable entries) which should be used by the device if the device is incapable of using the profile (or specific parts of the profile) explicitly applied to an inbound frame. A value of zero indicates that no default profile is currently active.                                                 |

| Table/Group                 | Supported Variables                  | Comments                                                                                                                                                                                                                                                                                                                            |
|-----------------------------|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysPolicyCapability group | etsysPolicyCapabilities              | A list of capabilities related to policies. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported.                                                                                                                  |
|                             | etsysPolicyDynaPIDRule Capabilities  | A list of rule types which are supported by this device for the purpose of dynamically assigning a profile to the network traffic described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported.      |
|                             | etsysPolicyAdminPIDRule Capabilities | A list of rule types which are supported by this device for the purpose of administratively assigning a profile to the network traffic described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported. |
|                             | etsysPolicyVlanRuleCapabilities      | A list of rule types which are supported by this device for the purpose of assigning a VlanId to the network traffic described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported.                   |
|                             | etsysPolicyCosRuleCapabilities       | A list of rule types which are supported by this device for the purpose of assigning a CoS to the network traffic described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported.                      |
|                             | etsysPolicyDropRuleCapabilities      | A list of rule types which are supported by this device for the purpose of discarding the                                                                                                                                                                                                                                           |

| Table/Group | Supported Variables                    | Comments                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                        | <p>network traffic described by the bit.</p> <p>A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported.</p>                                                                                                                                                  |
|             | etsysPolicyForwardRuleCapabilities     | <p>A list of rule types which are supported by this device for the purpose of forwarding the network traffic described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported.</p>                                                               |
|             | etsysPolicySyslogRuleCapabilities      | <p>A list of rule types which are supported by this device for the purpose of issuing syslog messages when the rule is used to identify the network traffic described by the bit.</p> <p>A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported.</p>         |
|             | etsysPolicyTrapRuleCapabilities        | <p>A list of rule types which are supported by this device for the purpose of issuing an SNMP notify (trap) messages when the rule is used to identify the network traffic described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported.</p> |
|             | etsysPolicyDisablePortRuleCapabilities | <p>A list of rule types which are supported by this device for the purpose of disabling the ingress port identified when the rule matches the network traffic described by the bit.</p> <p>A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates</p>                                                     |

| Table/Group | Supported Variables                  | Comments                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                      | the described functionality is not supported.                                                                                                                                                                                                                                                                                                                                        |
|             | etsysPolicySupportedPortList         | The list ports which support policy profile assignment (i.e. the ports which _do_ policy). This object may be useful to management entities which desire to scope action to only those ports which support policy. A port which appears in this list, must support, at minimum, the assignment of a policy profile to all traffic ingressing the port.                               |
|             | etsysPolicyEnabledTable              | This table allows for the configuration of policy profile assignment methods, per port, including the ability to disable policy profile assignment, per port. In addition, a ports capabilities, with respect to policy profile assignment are reported.                                                                                                                             |
|             | etsysPolicyEnabledTableEntry         | Describes a particular entry within the etsysPolicyEnabledTable.                                                                                                                                                                                                                                                                                                                     |
|             | etsysPolicyEnabledSupportedRuleTypes | The list of rule types which the devices supports for the purpose of assigning policy profiles to network traffic ingressing this dot1dBasePort.                                                                                                                                                                                                                                     |
|             | etsysPolicyEnabledEnabledRuleTypes   | The list of rule types from which the device will assign policy profiles to network traffic ingressing this dot1dBasePort. Rules which have a type not enumerated here must not be used to assign policy profiles, but must still be used to interrogate the rule-set bound to the determined policy profile. A set of all cleared bits will effectively disable policy in the port. |
|             | etsysPolicyEnabledEgressEnabled      | Controls the enabling and disabling the application of policy as packets egress the switching process on the dot1dBasePort specified in the indexing.                                                                                                                                                                                                                                |
|             | etsysPolicyRuleAttributeTable        | This table details each supported rule type attribute                                                                                                                                                                                                                                                                                                                                |

| Table/Group | Supported Variables                     | Comments                                                                                                                                                                                                                                                                                                                                                             |
|-------------|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                         | for rule data length in bytes, rule data length in bits, and the maximum number of rules that may use that type.                                                                                                                                                                                                                                                     |
|             | etsysPolicyRuleAttributeTableEntry      | Describes a particular entry within the etsysPolicyRuleAttributeTable.                                                                                                                                                                                                                                                                                               |
|             | etsysPolicyRuleAttributeByteLength      | This rule type's maximum length, in bytes of the etsysPolicyRuleData. Devices supporting this object MUST allow sets for this rule data of any valid length up to and including the length value represented by this object. Management entities must also expect to read back the maximum data length for each type regardless of the length the data was set with. |
|             | etsysPolicyRuleAttributeBitLength       | This rule type's maximum bit length for traffic data. This value also represents the maximum mask that may be used for rule data. The mask MUST NOT exceed the rule data size. Masks that exceed the data size shall be considered invalid and result in an SNMP set failure.                                                                                        |
|             | etsysPolicyRuleAttributeMaxCreatable    | If this value is non-zero, the value indicates the maximum number of rules of this type the agent can support.                                                                                                                                                                                                                                                       |
|             | etsysPolicyRuleTciOverwriteCapabilities | A list of rule types which are supported by this device for the purpose of overwriting the TCI in received packets described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates the described functionality is not supported.                                                      |
|             | etsysPolicyRuleMirrorCapabilities       | A list of rule types which are supported by this device for the purpose of mirroring the network traffic described by the bit. A set bit, with the value 1, indicates support for the described functionality. A clear bit, with the value 0, indicates                                                                                                              |

| Table/Group          | Supported Variables                   | Comments                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      |                                       | the described functionality is not supported.                                                                                                                                                                                                                                                                                                                                       |
|                      | etsysPolicyRuleQuarantineCapabilities | A list of rule types which are supported by this device for the purpose of quarantining the user to a specified profile id when the rule is used to identify the network traffic described by the bit. A set bit, with the value of 1, indicates support for the described functionality. A clear bit, with the value of 0, indicates the described functionality is not supported. |

| Table/Group            | Supported Variables              | Comments                                                                                                                                                                                                                                                                                                                                               |
|------------------------|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysPolicyRules group | etsysPolicyRulesMaxEntries       | The maximum number of entries allowed in the etsysPolicyRulesTable.                                                                                                                                                                                                                                                                                    |
|                        | etsysPolicyRulesNumEntries       | The current number of entries in the etsysPolicyRulesTable.                                                                                                                                                                                                                                                                                            |
|                        | etsysPolicyRulesLastChange       | The sysUpTime at which the etsysPolicyRulesTable was last modified.                                                                                                                                                                                                                                                                                    |
|                        | etsysPolicyRulesAccountingEnable | Controls the collection of rule usage statistics. If disabled, no usage statistics are gathered and no auditing messages will be sent. When enabled, rule will gather usage statistics, and auditing messages will be sent, if enabled for a given rule.                                                                                               |
|                        | etsysPolicyRulesPortDisabledList | <p>A portlist containing bits representing the dot1dBridgePorts which have been disabled via the mechanism described in the etsysPolicyRuleDisablePort leaf. A set bit indicates a disabled port.</p> <p>Ports may be enabled by performing a set with the corresponding bit cleared. Bits which are set will be ignored during the set operation.</p> |

| Table/Group          | Supported Variables         | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysPolicyRuleTable | etsysPolicyRuleTable        | A table containing rules bound to individual policies. A Rule is comprised of three components, a unique description of the network traffic, an associated list of actions, and an associated list of accounting and auditing controls and information. The unique description of the network traffic, defined by a PolicyClassificationRuleType together with a length, matching data and a relevant bits field, port type, and port number (port number zero is reserved to mean any port), and scoped by a etsysPolicyProfileIndex, is used as the table index. |
|                      | etsysPolicyRuleEntry        | Describes a particular entry within the etsysPolicyRuleTable. Entries within this table MUST be considered non-volatile and MUST be maintained across entity resets.                                                                                                                                                                                                                                                                                                                                                                                               |
|                      | etsysPolicyRuleProfileIndex | The etsysPolicyProfileIndex for which the rule is defined. A value of zero(0) has special meaning in that it scopes rules which are used to determine the Policy Profile to which the frame belongs. See the etsysPolicyRuleResult1 and etsysPolicyRuleResult2 descriptions for specifics of how the results of a rule hit differ when the etsysPolicyRuleProfileIndex is zero.                                                                                                                                                                                    |
|                      | etsysPolicyRuleType         | The type of network traffic reference by the etsysPolicyRuleData.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                      | etsysPolicyRuleData         | The data pattern to match against, as defined by the etsysPolicyRuleType, encoded in network-byte order.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                      | etsysPolicyRulePrefixBits   | The relevant number of bits defined by the etsysPolicyRuleData, to be used when matching against a frame, relevant bits are specified in                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Table/Group | Supported Variables        | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                            | longest-prefix-first style (left to right). A value of zero carries the special meaning of all bits are relevant.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|             | etsysPolicyRulePortType    | The port number on which the rule will be applied. Zero(0) is a special case, indicating that the rule should be applied to all ports.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|             | etsysPolicyRulePort        | The port number on which the rule will be applied. Zero(0) is a special case, indicating that the rule should be applied to all ports.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|             | etsysPolicyRuleRowStatus   | <p>The status of this row.</p> <p>When set to active(1) this entry's classification rule, as referenced by etsysPolicyRulesOID, becomes one of its associated policy's set of rules.</p> <p>When this entry's associated policy, as defined by etsysPolicyRuleProfileIndex, is active and assigned to a port through the etsysPortPolicyProfileTable or to a station through the etsysStationPolicyProfileTable, this classification rule will be applied to the port or station. The exact behavior of this application depends upon the classification rule.</p> <p>When this object is set to notInService(2) or notReady(3) this entry is not considered one of its associated policy's set of rules and this classification rule will not be applied.</p> |
|             | etsysPolicyRuleStorageType | <p>The storage type of this row.</p> <p>When set to volatile(1) this entry's classification rule, as referenced by etsysPolicyRulesOID, will be removed (if present) from non-volatile storage. Rows created dynamically by the device will typically report this as their default storage type.</p> <p>When set to nonVolatile(1) this entry's classification</p>                                                                                                                                                                                                                                                                                                                                                                                             |

| etsysPolicyRulePortTable | etsysPolicyRulePortTable                        | The purpose of this table is to provide an agent the ability to easily determine which rules have been used on a given bridge port. A row will only be present when the rule which the instancing describes has been used. The agent may remove a row (and clear the used status) by setting the etsysPolicyRulePortHit leaf to False.<br>PolicyClassificationRuleType together with a length, matching data and a relevant bits field, port type, and port number (port number zero is reserved to mean any port), scoped by a etsysPolicyRuleProfileIndex, and preceded by a dotIdBasePort is used as the table index. |
|                          | etsysPolicyRulePortEntry                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                          | etsysPolicyRulePortHit                          | Every row will report a value of True, indicating that the Rule described by the instancing was used on the given port. An agent may be set this leaf to False to clear remove the row and clear the Rule Use bit for the specified Rule, on the given bridgePort.                                                                                                                                                                                                                                                                                                                                                       |
|                          | etsysPolicyRuleDynamicProfileAssignmentOverride | If true, administratively assigned profile assignment rules override dynamically assigned profiles assignments for a given rule. If false, the dynamically assigned value (typically created by a successful authentication attempt) overrides the administratively configured value. The agent may optionally implement this leaf as read-only.                                                                                                                                                                                                                                                                         |
|                          | etsysPolicyRuleDefaultDynamicSyslogStatus       | If enabled(1), rules dynamically created will set etsysPolicyRuleAuditSyslogEnable to enabled. If disabled(2) a dynamically created rule will have etsysPolicyRuleAuditSyslogEnable set to disabled. The agent may optionally implement this leaf as read-only.                                                                                                                                                                                                                                                                                                                                                          |
|                          | etsysPolicyRuleDefaultDynamic                   | If enabled(1), rules                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Table/Group | Supported Variables                   | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | namicTrapStatus                       | dynamically created will set etsysPolicyRuleAuditTrapEnable to enabled. If disabled(2) a dynamically created rule will have etsysPolicyRuleAuditTrapEnable set to disabled. The agent may optionally implement this leaf as read-only.                                                                                                                                                                                                                                                   |
|             | etsysPolicyRuleStatsAutoClearOnLink   | If set to enabled(1), when operstatus up is detected on any port the agent will clear the rule usage information associated with that port. This ability is further scoped to the list of ports defined by etsysPolicyRuleStatsAutoClearPorts. This leaf is optional and will have no effect on an agent which has rule use accounting disabled or does not support rule use accounting. By default, the rule use accounting information will not be modified by operstatus transitions. |
|             | etsysPolicyRuleStatsAutoClearInterval | The interval at which the device will automatically clear rule usage statistics, in minutes. This ability is disabled (usage statistics will not be automatically cleared) if set to zero(0). This ability is further scoped to the list of ports defined by etsysPolicyRuleStatsAutoClearPorts. This leaf is optional and will have no effect on an agent which has rule use accounting disabled or does not support rule use accounting.                                               |
|             | etsysPolicyRuleStatsAutoClearPorts    | The list ports on which rule usage statistics will be cleared by one of the AutoClear actions (etsysPolicyRuleStatsAutoClearInterval, etsysPolicyRuleStatsAutoClearOnProfile, or etsysPolicyRuleStatsAutoClearOnLink). By default, no ports will be set in this list. This leaf is optional, unless the agent claims support for one of the other 'autoclear' objects, and will have no effect on an agent                                                                               |

| Table/Group | Supported Variables                       | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                           | which has rule use accounting disabled or does not support rule use accounting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|             | etsysPolicyRuleStatsAutoClearOnProfile    | If set to enabled(1), when a rule assigning a PolicyProfile (whose etsysPolicyRuleProfileIndex is zero(0)) is activated, all the rule usage bits associated with the rules bound to the PolicyProfile specified by the etsysPolicyRuleOperPid and the port specified by the etsysPolicyRulePort are cleared (if there is no port specified or no valid etsysPolicyRuleProfileIndex specified, then no action follows). This ability is further scoped to the list of ports defined by etsysPolicyRuleStatsAutoClearPorts. This leaf is optional and will have no effect on an agent which has rule use accounting disabled or does not support rule use accounting. By default, the rule use accounting information will not be modified by the creation or activation of PolicyProfile assignment rules." DEFVAL { disabled } |
|             | etsysPolicyRuleStatsDroppedNotifications  | A count of the number of times the agent has dropped notification (syslog or trap) of a etsysPolicyRuleUsageList bit transition. A management entity might use this leaf as an indication to read the etsysPolicyRuleUsageList objects for important rules. This count should be kept to the best of the device's ability, and explicitly does not cover notifications discarded by the network.                                                                                                                                                                                                                                                                                                                                                                                                                               |
|             | etsysPolicyRuleSylogMachineReadableFormat | If enabled, the device should format rule usage messages so that they might be processed by a machine (scripting backend, etc). If disabled, the messages                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Table/Group | Supported Variables                | Comments                                                                                                                                                                                                                                                                                               |
|-------------|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                    | should be formatted for human consumption.                                                                                                                                                                                                                                                             |
|             | etsysPolicyRuleSylogExtendedFormat | If enabled, the device should provide additional information in rule-hit syslog messages. This information MAY include what actions may have been initiated by the rule (if any) or data mined from the packet which matched the rule.                                                                 |
|             | etsysPolicyRuleSylogEveryTime      | If enabled, the device will syslog on every rule hit (or profile hit) which specifies SYSLOG as the action, instead of only when the associated bit in the etsysPolicyProfileUsageList or the etsysPolicyRuleUsageList is clear. It should be noted that this may cause MANY messages to be generated. |

| Table/Group                     | Supported Variables                   | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| etsysPolicyRFC3580Map group | etsysPolicyRFC3580MapResolveReponseConflict | Indicates which field to use in the application of the RADIUS response in the event that both the proprietary filter-id indicating a policy profile and the standard (RFC3580) vlan-tunnel-attribute are present. If policyProfile(1) is selected, then the filter-id will be used, if vlanTunnelAttribute(2) is selected, then the vlan-tunnel-attribute will be used (and the policy-map will be applied, if present). A value of vlanTunnelAttributeWithPolicyProfile(3) indicates that both attributes should be applied, in the following manner: the policyProfile should be enforced, with the exception of the etsysPolicyProfilePortVid (if present), the returned vlan-tunnel-attribute will be used in its place. In this case, the policy-map will be ignored (as the policyProfile was explicitly assigned). VLAN classification rules will still be applied, as defined by the assigned policyProfile. Modifications of this value will not effect the current status of any users currently authenticated. The new state will be applied to new, successful authentications. The current status of current authentication may be modified through the individual agents or through the ENTERASYS-MULTI-AUTH-MIB, if supported. |
|                             | etsysPolicyRFC3580MapLastChange             | The value of sysUpTime when the etsysPolicyRFC3580MapTable was last modified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                             | etsysPolicyRFC3580MapTableDefault           | If read as True, then the etsysPolicyRFC3580MapTable is in the default state (no mappings have been created), if False, then non-default mappings exist. If set to True, then the etsysPolicyRFC3580MapTable will be put into the default state                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|             |                                  | (no mappings will exist). A set to False is not valid and MUST fail.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|             | etsysPolicyRFC3580MapTable       | A table containing VLAN ID to policy mappings. A policy is a group of classification rules which may be applied on a per user basis, to ports or to stations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|             | etsysPolicyRFC3580MapEntry       | Conceptually defines a particular entry within the etsysPolicyRFC3580MapTable. Entries within this table MUST be considered non-volatile and MUST be maintained across entity resets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|             | etsysPolicyRFC3580MapVlanId      | The VlanIndex which will map to the policy profile specified by the etsysPolicyRFC3580MapPolicyIndex of this row. This will be used to map the VLAN returned by value from the Tunnel- Private- Group-ID RADIUS attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|             | etsysPolicyRFC3580MapPolicyIndex | The index of a Policy Profile as defined in the etsysPolicyProfileTable. A value of 0 indicates that the row is functionally non- operational (no mapping exists). Devices which support the ENTERASYS-VLAN-AUTHORIZATION-MIB, and for which the value of etsysVlanAuthorizationEnable is Enabled and the value of etsysVlanAuthorizationStatus is Enabled on the port referenced by the authorization request, should then use the VlanIndex provisioned (e.g. from the Tunnel-Private-Group-ID RADIUS attribute) as defined by RFC3580, otherwise, the device should treat the result as if no matching Policy Profile had been found (e.g. as a simple success). In the case where a Policy Profile is already being applied to the referenced station, but no mapping exists, the device MUST treat the Tunnel-Private- Group-ID as an override to the etsysPolicyProfilePortVid defined by that profile (any |

| Table/Group | Supported Variables                 | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                     | <p>matched classification rules which explicit provision a VLAN MUST still override both the etsysPolicyProfilePortVid and the Tunnel-Private-Group-ID.)</p> <p>A non-zero value of this object indicates that the VlanIndex provisioned (e.g. from the Tunnel-Private-Group-ID RADIUS attribute) should be mapped to a Policy Profile as defined in the etsysPolicyProfileTable, and that policy applied as if the Policy name had been provisioned instead (e.g. in the Filter-ID RADIUS attribute). If the mapping references a non-existent row of the etsysPolicyProfileTable, or the referenced row has a etsysPolicyProfileRowStatus value other than Active, the device MUST behave as if the mapping did not exist (apply the vlan-tunnel-attribute). The etsysPolicyRFC3580MapInvalidMapping MUST then be incremented.</p> |
|             | etsysPolicyRFC3580MapInvalidMapping | <p>Increments to indicate the number of times the device has detected an invalid/unknown EtsysPolicyRFC3580MapEntry (i.e. one that references an in-active or non-existent etsysPolicyProfile).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Table/Group                   | Supported Variables                  | Comments                                                                                                                                                                                                                                                                                                                 |
|-------------------------------|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysPolicyHttpRedirect group | etsysPolicyHttpRedirectMaxNumSockets | The maximum number of TCP port numbers the device may listen on simultaneously for HTTP redirection.                                                                                                                                                                                                                     |
|                               | etsysPolicyHttpRedirectMaxNumServer  | The number of servers that may be configured per server group in the etsysPolicyHttpRedirectServerTable.                                                                                                                                                                                                                 |
|                               | etsysPolicyHttpRedirectSocketTable   | A table containing TCP sockets the device will listen on for HTTP traffic to redirect. Entries within this table MUST be considered non-volatile and MUST be maintained across entity resets.                                                                                                                            |
|                               | etsysPolicyHttpRedirectSocketEntry   | Conceptually specifies a TCP socket the device will listen on for HTTP traffic to redirect.                                                                                                                                                                                                                              |
|                               | etsysPolicyHttpRedirectSocketIndex   | An arbitrary index from 1 to etsysPolicyHttpRedirectMaxNumSockets.                                                                                                                                                                                                                                                       |
|                               | etsysPolicyHttpRedirectListenSocket  | TCP port number (1-65535) that the device will listen on for HTTP traffic suitable for redirection. A value of 0 indicates that this entry does not specify a TCP socket to listen on.                                                                                                                                   |
|                               | etsysPolicyHttpRedirectServerTable   | A table containing HTTP redirect server group entries.                                                                                                                                                                                                                                                                   |
|                               | etsysPolicyHttpRedirectServerEntry   | Conceptually defines a HTTP redirect server group. Within each group, one or more redirect servers may be defined. HTTP redirects will be sent to different servers within a group using a round-robin algorithm. Entries within this table MUST be considered non-volatile and MUST be maintained across entity resets. |
|                               | etsysPolicyHttpRedirectGroupIndex    | The index referenced by etsysPolicyProfileHttpRedirectIndex to identify a particular HTTP redirect server group. The maximum value of this index is specified by the etsysPolicyHttpRedirectNumServerGroups object.                                                                                                      |
|                               | etsysPolicyHttpRedirectServerIndex   | The index for a particular server within the redirect group. The                                                                                                                                                                                                                                                         |

| Table/Group             | Supported Variables                 | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         |                                     | maximum value of this index is specified by the etsysPolicyHttpRedirectMaxNumServer object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                         | etsysPolicyHttpRedirectServerUri    | The absolute URI on the redirect server to redirect the user to. This object MUST specify the scheme, authority and path. The URI may optionally include a query and/or fragment portions as well.                                                                                                                                                                                                                                                                                                                                                                                         |
|                         | etsysPolicyHttpRedirectServerStatus | A value of enabled(1) causes the entry to be made ready for use in redirecting HTTP traffic. A set of enabled(1) will only succeed if the the other entries with STATUS of read-write in table have been set to appropriate non-default values.                                                                                                                                                                                                                                                                                                                                            |
| etsysPolicySystem group | etsysPolicyEnabledState             | Controls the enabling and disabling the entire Policy application.<br><br>A value of enabled(1) indicates that all objects in this MIB module are actively being applied on the device. A value of disabled(2) indicates that none of the objects in this MIB are actively being applied.<br><br>The agent may optionally implement this leaf as read-only. All other objects in this MIB module MUST remain available and configurable regardless of the current value of this object. This object MUST be considered non-volatile and its value MUST be maintained across entity resets. |

## ENTERASYS-RADIUS-ACCT-CLIENT-EXT-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group | Supported Variables                  | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MIB Objects | etsysRadiusAcctClientEnable          | This object indicates whether or not RADIUS Accounting is enabled or disabled. This parameter value is maintained across system reboots.                                                                                                                                                                                                                                                                                                                                                                                                                        |
|             | etsysRadiusAcctClientUpdateInterval  | This indicates how many seconds elapse between accounting interim updates. This parameter value is maintained across system reboots. A value of zero means no Interim Updates. If the value is less than etsysRadiusAcctClientIntervalMinimum, the etsysRadiusAcctClientIntervalMinimum value will be used for the update interval time. If RADIUS Accounting is not enabled, this object is ignored. Note that Accounting Interim Updates are not issued by the RADIUS Accounting Client, unless so requested by the RADIUS Server in an Access Accept packet. |
|             | etsysRadiusAcctClientIntervalMinimum | This indicates the minimum value in seconds between accounting interim updates supported by the managed entity. This parameter value is maintained across system reboots. If RADIUS Accounting is not enabled, this object is ignored.                                                                                                                                                                                                                                                                                                                          |
|             | etsysRadiusAcctClientServerTable     | The (conceptual) table listing the RADIUS Accounting servers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|             | etsysRadiusAcctClientServerEntry     | An entry (conceptual row) representing a RADIUS Accounting server with which the client shares a secret. If RADIUS Accounting is not enabled, this table is ignored. All created conceptual rows are non-volatile and as such must be maintained upon restart of the agent.                                                                                                                                                                                                                                                                                     |
|             | etsysRadiusAcctClientServerIndex     | A number uniquely identifying each conceptual row in the etsysRadiusAcctClientServerTable. In the event of an agent restart, the same value of etsysRadiusAcctClientServerIndex must be used to identify each conceptual row in                                                                                                                                                                                                                                                                                                                                 |

| Table/Group | Supported Variables                      | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                          | etsysRadiusAcctClientServerTable as was used prior to the restart.                                                                                                                                                                                                                                                                                                                                                                                 |
|             | etsysRadiusAcctClientServerAddressType   | The type of Internet address by which the RADIUS Accounting server is reachable.                                                                                                                                                                                                                                                                                                                                                                   |
|             | etsysRadiusAcctClientServerAddress       | The Internet address for the RADIUS Accounting server. Note that implementations must limit themselves to a single entry in this table per reachable server. The etsysRadiusAcctClientServerAddress may not be empty due to the SIZE restriction. Also the size of a DNS name is limited to 64 characters. This parameter value is maintained across system reboots.                                                                               |
|             | etsysRadiusAcctClientServerPortNumber    | The UDP port number (1-65535) the client is using to send requests to this server. The officially assigned port number for RADIUS Accounting is 1813. This parameter value is maintained across system reboots.                                                                                                                                                                                                                                    |
|             | etsysRadiusAcctClientServerSecret        | This object is the secret shared between the RADIUS Accounting server and RADIUS client. This parameter value is maintained across system reboots. While the 'official' MAX-ACCESS for this object is read-create, all security-conscious implementations will 'lie' on a read, and return a null-string, or something else that is fairly innocuous. The ability to read back passwords and secret encryption keys is generally a Bad Thing (tm). |
|             | etsysRadiusAcctClientServerSecretEntered | This indicates the existence of a shared secret.                                                                                                                                                                                                                                                                                                                                                                                                   |
|             | etsysRadiusAcctClientServerRetryTimeout  | The number of seconds to wait for a RADIUS Accounting Server to respond to a request. This parameter value is maintained across system reboots. A value of -1 indicates that the appropriate realm value should be used - etsysRadiusAcctClientMgmtRetryTimeout or etsysRadiusAcctClientNetworkRetryTimeout.                                                                                                                                       |
|             | etsysRadiusAcctClientServerRetries       | The number of times to resend an accounting packet if a RADIUS Accounting Server does                                                                                                                                                                                                                                                                                                                                                              |

|---------------------------------------|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Additional RADIUS Acct Client Scalars | etsysRadiusAcctClientMgmtEnable          | This object indicates whether or not RADIUS Accounting is enabled or disabled for management sessions. This parameter value is maintained across system reboots. The unset value (0) indicates that the value in etsysRadiusAcctClientEnable should be used.    |
|                                       | etsysRadiusAcctClientNetworkEnable       | This object indicates whether or not RADIUS Accounting is enabled or disabled for network sessions. This parameter value is maintained across system reboots. The unset value (0) indicates that the value in etsysRadiusAcctClientEnable should be used.       |
|                                       | etsysRadiusAcctClientMgmtRetryTimeout    | The number of seconds to wait for a RADIUS Accounting Server in the management realm to respond to a request. This parameter value is maintained across system reboots. This value may be overridden by the per server etsysRadiusAcctClientServerRetryTimeout. |
|                                       | etsysRadiusAcctClientNetworkRetryTimeout | The number of seconds to wait for a RADIUS Accounting Server in the network realm to respond to a request. This parameter value is maintained across system reboots. This value may be overridden by the per server etsysRadiusAcctClientServerRetryTimeout.    |

## ENTERASYS-RADIUS-AUTH-CLIENT-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                                      | Supported Variables               | Comments                                                                                                                                                                                                                                                                          |
|--------------------------------------------------|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Branches of the Enterasys RADIUS Auth Client MIB | etsysRadiusAuthClientMIBObjects   |                                                                                                                                                                                                                                                                                   |
| RADIUS Auth Client Scalars                       | etsysRadiusAuthClientRetryTimeout | The number of seconds to wait for a RADIUS Server to respond to a request. Maintaining the value of this object across agent reboots is REQUIRED.                                                                                                                                 |
|                                                  | etsysRadiusAuthClientRetries      | The number of times to resend an authentication packet if a RADIUS Server does not respond to a request. Maintaining the value of this object across agent reboots is REQUIRED.                                                                                                   |
|                                                  | etsysRadiusAuthClientEnable       | Controls and indicates the operational state of the RADIUS client functionality. Maintaining the value of this object across agent reboots is REQUIRED.                                                                                                                           |
|                                                  | etsysRadiusAuthClientAuthType     | This indicates which method is being used for authentication.<br>mac(1) - indicates MAC address authentication<br>eapol(2) - indicates EAPOL authentication<br>This list of enumeration constants is subject to change. This parameter value is maintained across system reboots. |

| Table/Group                     | Supported Variables                      | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RADIUS Auth Client Server Table | etsysRadiusAuthServerTable               | A list of RADIUS servers that this client may attempt to use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                                 | etsysRadiusAuthServerEntry               | A RADIUS server that this client may attempt to use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                                 | etsysRadiusAuthServerIndex               | A number uniquely identifying each conceptual row in the etsysRadiusAuthServerTable.<br>etsysRadiusAuthServerIndices with range between 2147483642 and 2147483647 indicate the highest priority servers stored for backwards compatibility. After consideration of these special indice values this value indicates the relative priority of the servers. Relative priority of the servers is used when using the standard authentication retransmission algorithm. Maintaining the value of etsysRadiusAuthServerIndex for all active(1) entries across agent reboots is REQUIRED. |
|                                 | etsysRadiusAuthClientServerAddressType   | This object specifies how etsysRadiusAuthClientServerAddress is encoded. Support for all possible enumerations defined by InetAddressType is NOT REQUIRED.                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                                 | etsysRadiusAuthClientServerAddress       | The encoded unicast IP address or hostname of a RADIUS server. RADIUS requests will be sent to this address. If this address is a DNS hostname, then that hostname SHOULD be resolved into an IP address each time an authentication session is initialized.                                                                                                                                                                                                                                                                                                                        |
|                                 | etsysRadiusAuthClientServerPortNumber    | The UDP port number (0-65535) the client will use to send RADIUS requests to this server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                                 | etsysRadiusAuthClientServerSecret        | This object is the secret shared between the RADIUS authentication server and the RADIUS client.<br>On a read operation this object MUST return a zero length string. Writing this object with a zero length string clears the secret.                                                                                                                                                                                                                                                                                                                                              |
|                                 | etsysRadiusAuthClientServerSecretEntered | true(1) - Indicates that etsysRadiusAuthClientServerSecret                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Table/Group | Supported Variables                  | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|             |                                      | <p>was last set with some value other than the empty string.</p> <p>false(2) - Indicates that etsysRadiusAuthClientServerSecret has never been set, or was last set to the empty string."</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|             | etsysRadiusAuthClientServerClearTime | <p>The number of seconds elapsed since the counters were last cleared.</p> <p>Writing the value zero will cause the servers counters to be cleared and the clear time will be set to zero. Writing any value other than zero will have no effect.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|             | etsysRadiusAuthClientServerStatus    | <p>The row status of this conceptual row in the table.</p> <p>active - The server is available for performing RADIUS operations. Other writable leaves in this row MUST NOT be modified while the row is in the active state.</p> <p>notInService - The entry is fully configured but is not available for performing RADIUS operations. Conceptual rows with this status MAY be deleted at the discretion of the agent, at which time it will be treated as if destroy(6) was SET to this object.</p> <p>notReady - The entry exists in the agent, but is missing information necessary in order to be available for use by the managed device (i.e., one or more required columns in the conceptual row have not been instantiated);</p> <p>createAndGo - Not possible.</p> <p>createAndWait - Creates a new instance of a conceptual row, but does not make it available for use by the managed device.</p> <p>destroy - This will remove the conceptual row from the table and make it unavailable for RADIUS client operations. This MUST also cause any persistent data related to this row to be removed from the system. Maintaining active(1) entries across agent reboots is REQUIRED.</p> |
|             | etsysRadiusAuthClientServerRealmType | This object allows a server to be restricted to providing                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|             | etsysRadiusAuthClientMgmtEnable          | Controls and indicates the operational state of the RADIUS client functionality for management sessions. Maintaining the value of this object across agent reboots is REQUIRED. The unset value (0) indicates that the value in etsysRadiusAuthClientEnable should be used.       |
|             | etsysRadiusAuthClientNetworkEnable       | Controls and indicates the operational state of the RADIUS client functionality for network sessions. Maintaining the value of this object across agent reboots is REQUIRED. The unset value (0) indicates that the value in etsysRadiusAuthClientEnable should be used.          |

## ENTERASYS-RADIUS-DYNAMIC-AUTHOR-SERVER-EXT-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group | Supported Variables                         | Comments                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MIB Objects | etsysRadiusDynAuthorServerMIBObjects        | This object indicates whether or not RADIUS Dynamic Authorization is enabled or disabled. This parameter value MUST be maintained across system reboots.                                                                                                                                                                                                                                            |
|             | etsysRadiusDynAuthorServerClientTable       | The (conceptual) table listing the RADIUS Accounting servers.                                                                                                                                                                                                                                                                                                                                       |
|             | etsysRadiusDynAuthorServerClientEntry       | An entry (conceptual row) representing a RADIUS dynamic authorization server with which the server shares a secret. If RADIUS dynamic authorization is not enabled, this table is ignored. All created conceptual rows are non-volatile and as such MUST be maintained upon restart of the agent.                                                                                                   |
|             | etsysRadiusDynAuthorServerClientIndex       | A number uniquely identifying each conceptual row in the etsysRadiusDynAuthorServerClient Table.<br><br>In the event of an agent restart, the same value of etsysRadiusDynAuthorServerClient Index MUST be used to identify each conceptual row in etsysRadiusDynAuthorServerClient Table as was used prior to the restart.                                                                         |
|             | etsysRadiusDynAuthorServerClientAddressType | The type of Internet address by which the RADIUS Dynamic Authorization Client is reachable.                                                                                                                                                                                                                                                                                                         |
|             | etsysRadiusDynAuthorServerClientAddress     | The Internet address for the RADIUS Dynamic Authorization Client. Note that implementations MUST limit themselves to a single entry in this table per reachable server.<br><br>The etsysRadiusDynAuthorServerClient Address may not be empty due to the SIZE restriction. Also the size of a DNS name is limited to 64 characters.<br><br>This parameter value is maintained across system reboots. |
|             | etsysRadiusDynAuthorServerSecret            | This object is the secret shared                                                                                                                                                                                                                                                                                                                                                                    |

| Table/Group | Supported Variables                           | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------|-----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | serverClientSecret                            | between the RADIUS Dynamic Authorization client and RADIUS server. This parameter value is maintained across system reboots. While the 'official' MAX-ACCESS for this object is read-create, all implementations MUST return an empty string on a read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|             | etsysRadiusDynAuthorServerClientSecretEntered | true(1) - Indicates that etsysRadiusDynAuthorServerClientSecret was last set with some value other than the empty string.<br>false(2) - Indicates that etsysRadiusDynAuthorServerClientSecret has never been set, or was last set to the empty string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|             | etsysRadiusDynAuthorServerClientStatus        | Lets users create and delete RADIUS Dynamic Authorization client entries on systems that support this capability.<br>Rules<br><ol style="list-style-type: none"> <li>1. When creating a RADIUS Dynamic Authorization Client, it is up to the management station to determine a suitable etsysRadiusDynAuthorServerClientIndex. To facilitate interoperability, agents SHOULD not put any restrictions on the etsysRadiusDynAuthorServerClientIndex beyond the obvious ones that it be valid and unused.</li> <li>2. Before a new row can become 'active', values must be supplied for the columnar objects etsysRadiusDynAuthorServerClientAddress, etsysRadiusDynAuthorServerClientSecret, etsysRadiusDynAuthorServerClientAddress, and etsysRadiusDynAuthorClientServerClientVirtualRouterName.</li> <li>3. The value of etsysRadiusDynAuthorServerClientStatus must be set to 'notInService' in order to modify a writable object in the same conceptual row.</li> <li>4. etsysRadiusDynAuthorServerClient entries whose status is</li> </ol> |

| Table/Group | Supported Variables                                     | Comments                                                                                                                                                                                                                                  |
|-------------|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                                         | 'notReady' or 'notInService' will not be used for Dynamic Authorization.                                                                                                                                                                  |
|             | etsysRadiusDynAuthorClientServerClientAddressType       | This object specifies how etsysRadiusDynAuthorServerClientAddressType is encoded. Support for all possible enumerations defined by InetAddressType is NOT REQUIRED.                                                                       |
|             | etsysRadiusDynAuthorClientServerClientAddress           | The encoded unicast IP address of a local system interface. RADIUS Dynamic Authorization responses will be sent from this address.                                                                                                        |
|             | etsysRadiusDynAuthorClientServerClientVirtualRouterName | The name of the local system virtual router that traffic sent to this RADIUS Dynamic Authorization server should be associated with.<br><br>Writing this object with a zero length string clears the virtual router name for this server. |

## ENTERASYS SYSLOG MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                   | Supported Variables                      | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| The Syslog Server Defaults | etsysSyslogServerDefaultUdpPort  | <p>The default UDP port number that the managed entity is using to send syslog messages. This value will be used as the default value for etsysSyslogServerUdpPort when creating rows in the etsysSyslogServerTable and either:</p> <ul style="list-style-type: none"> <li>no value is specified for etsysSyslogServerUdpPort</li> <li>etsysSyslogServerUdpPort is implemented read-only.</li> </ul> <p>If etsysSyslogServerUdpPort is implemented read-only, and this value is changed, it should affect the UDP port that is used to send syslog messages to all servers as soon as it is practical.</p> <p>This parameter value is maintained across system reboots.</p> <p>etsysSyslogServerDefaultUdpPort value is 514.</p> <p>Read-only</p> |
|                            | etsysSyslogServerDefaultFacility | <p>The default syslog facility (local0-local7) that will be encoded in syslog messages. This value will be used as the default value for etsysSyslogServerFacility when creating rows in the etsysSyslogServerTable and either:</p> <ul style="list-style-type: none"> <li>no value is specified for etsysSyslogServerFacility</li> <li>etsysSyslogServerFacility is implemented read-only.</li> </ul> <p>If etsysSyslogServerFacility is implemented read-only, and this value is changed, it should affect the syslog facility that is encoded in all syslog messages as soon as it is practical.</p>                                                                                                                                           |

| Table/Group | Supported Variables              | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |                                  | <p>This parameter value is maintained across system reboots.</p> <p>etsysSyslogServerDefaultFacility value is local0(16),</p> <p>Read-only</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|             | etsysSyslogServerDefaultSeverity | <p>The default syslog message severity level that will be used to filter all syslog messages. This value will be used as the default value for etsysSyslogServerSeverity when creating rows in the etsysSyslogServerTable and either:</p> <ul style="list-style-type: none"> <li>no value is specified for etsysSyslogServerSeverity</li> <li>etsysSyslogServerSeverity is implemented read-only.</li> </ul> <p>The higher the severity level, the less critical it is. If etsysSyslogServerSeverity is implemented read-only, and this value is changed, it should affect the syslog message severity level that will be used to filter all syslog messages as soon as it is practical.</p> <p>This parameter value is maintained across system reboots.</p> <p>etsysSyslogServerDefaultSeverity value is debug(8).</p> <p>Read-only</p> |

The mapping between Syslog MIB severity (for example, etsysSyslogServerSeverity) and ExtremeXOS severity is not one-to-one as ExtremeXOS does not support “emergency” and “alert” severity; and Syslog MIB does not support “debug-data”, “debug-verbose” and “debug-summary” severity.

The following table shows the mapping between the two:

| etsysSyslogServerSeverity  | ExtremeXOS Syslog Severity |
|----------------------------|----------------------------|
| emergency, alert, critical | critical                   |
| Error                      | error                      |

| etsysSyslogServerSeverity | ExtremeXOS Syslog Severity              |
|---------------------------|-----------------------------------------|
| Warning                   | warning                                 |
| Notice                    | notice                                  |
| Info                      | info                                    |
| debug                     | debug-data,debug-verbose, debug-summary |

## ENTERASYS-VLAN-AUTHORIZATION-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                  | Supported Variables | Comments                                                                                                                                                                                                                                                     |
|------------------------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysVlanAuthorizationEnable | All objects         | The enable/disable state for the VLAN authorization feature. When disabled, no modifications to the VLAN attributes related to packet switching should be enforced.                                                                                          |
| etsysVlanAuthorizationTable  | All objects         | Extensions to the table that contains information about every port that is associated with this transparent bridge.                                                                                                                                          |
| etsysVlanAuthorizationEntry  | All objects         | A list of extensions that support the management of proprietary features for each port of a transparent bridge. This is indexed by dotIdBasePort.                                                                                                            |
| etsysVlanAuthorizationStatus | All objects         | The enabled/disabled status for the application of VLAN authorization on this port, if disabled, the information returned in the VLAN-Tunnel-Type from the authentication will not be applied to the port (although it should be represented in this table). |

| Table/Group                       | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysVlanAuthorizationAdminEgress | All objects         | Controls the modification of the current vlan egress list (of the vlan returned in the VLAN-Tunnel-Type, and reported by etsysVlanAuthorizationVlanID) upon successful authentication in the following manner:<br>none(1) No egress manipulation will be made.<br>tagged(2) The authenticating port will be added to the current egress for the VLAN-ID returned.<br>untagged(3) The authenticating port will be added to the current untagged egress for the VLAN-ID returned.<br>dynamic(4) The authenticating port will use information returned in the authentication response to modify the current egress lists. This value is supported only if the device supports a mechanism through which the egress status may be returned through the RADIUS response. Should etsysVlanAuthorizationEnable become disabled, etsysVlanAuthorizationStatus become disabled for a port, or should etsysVlanAuthorizationVlanID become 0 or 4095, all effect on the port egress MUST be removed. |

| Table/Group                      | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etsysVlanAuthorizationOperEgress | All objects         | Reports the current state of modification to the current vlan egress list (of the vlan returned in the VLAN-Tunnel-Type) upon successful authentication, if etsysVlanAuthorizationStatus is enabled, in the following manner: none(1) No egress manipulation will be made. tagged(2) The authenticating port will be added to the current egress for the VLAN-ID returned. untagged(3) The authenticating port will be added to the current untagged egress for the VLAN-ID returned. The purpose of this leaf is to report, specifically when etsysVlanAuthorizationAdminEgress has been set to dynamic(4), the currently enforced egress modification. If the port is unauthenticated, or no VLAN-ID has been applied, this leaf should return none(1). |
| etsysVlanAuthorizationVlanID     | All objects         | The 12 bit VLAN identifier for a given port, used to override the PVID of the given port, obtained as a result of an authentication. A value of zero indicates that there is no authenticated VLAN ID for the given port. Should a port become unauthenticated this value MUST be returned to zero. A value of 4095 indicates that a the port has been authenticated, but that the VLAN returned could not be applied to the port (possibly because of resource constraints or misconfiguration). In this instance, the original PVID should still be applied. Should the feature become disabled or the session terminate, all effect on the Port VLAN ID MUST be removed.                                                                               |
| etsysVlanAuthorizationGroup      | All objects         | A collection of objects relating to VLAN Authorization.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## EXTREME-AUTOPROVISION-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                | Supported Variables | Comments                                                      |
|----------------------------|---------------------|---------------------------------------------------------------|
| extremeAutoProvisionConfig |                     | Enables or disables the Auto Provision feature on the switch. |

The following traps can be generated.

| Trap                       | Notification Objects               | Comments                                                                                                                                                                                    |
|----------------------------|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeAutoProvisionStatus |                                    | This trap reports the auto provision result (success/failed). It contains the attributes it received from the <i>DHCP (Dynamic Host Configuration Protocol)</i> server.                     |
|                            | extremeAutoProvisionResult         | Result of the Auto provision.                                                                                                                                                               |
|                            | extremeAutoProvisionIpAddress      | The IP address received from the DHCP server for this interface.                                                                                                                            |
|                            | extremeAutoProvisionGateway        | The gateway address received from the DHCP server for this interface.                                                                                                                       |
|                            | extremeAutoProvisionTFTPServer     | The IP address of the TFTP server received from the DHCP server.                                                                                                                            |
|                            | extremeAutoProvisionConfigFileName | The configuration file name received from the DHCP server which the auto-provision enabled switch will download from the TFTP server and apply. It can use either the cfg or xsf extension. |

## EXTREME-CFM-MIB

The ExtremeCFM MIB provides information about the Connectivity Fault Management (CFM) Group. This is an extension to IEEE8021- CFM-MIB.

The following tables, groups, and variables are supported in this MIB.

| Table/Group                   | Supported Variables           | Comments                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeCfmGroup               | ExtremeCfmGroupOperStatus     | This is a textual convention which, indicates the operational status of a group associated with a MEP on a port of an association in a given domain.                                                                                                                                                                               |
| extremeCfmGroupNextIndexTable |                               | This object contains an unused value for extremeCfmGroupIndex in the extremeCfmGroupTable, or a zero to indicate that none exists.                                                                                                                                                                                                 |
|                               | extremeCfmGroupNextIndexEntry | The conceptual row of extremeCfmGroupNextIndexTable.<br>Not accessible.                                                                                                                                                                                                                                                            |
|                               | extremeCfmGroupNextIndex      | Value used as the index of the Group table entries, for this Maintenance association End Point Identifier when the management entity wants to create a new row in that table.<br>Read only.                                                                                                                                        |
| extremeCfmGroupTable          |                               | Includes configuration objects and operations for the Group function, mainly used by the registered clients like <i>ERPS (Ethernet Ring Protection Switching)</i> , <i>EAPS (Extreme Automatic Protection Switching)</i> to know link detection failure through CFM. Each row in the table represents a Group for the defined MEP. |
|                               | extremeCfmGroupEntry          | This is a complex index with four indices to access any row in extremeCfmGroupTable. The first three are Maintenance Domain, MaNet, and MEP indices. The fourth index is the specific Group on the selected MEP.<br>Not accessible.                                                                                                |
|                               | extremeCfmGroupName           | The name of a CFM group. Group name must be alphanumeric.                                                                                                                                                                                                                                                                          |
|                               | extremeCfmGroupStatus         | Whether the group is operational or not. Ready only.                                                                                                                                                                                                                                                                               |

| Table/Group                      | Supported Variables           | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                  | extremeCfmMepIfIndex          | Interface index of the interface, either a bridge port, or an aggregated IEEE 802.1 link within a bridge port, to which the MEP and hence the group is attached.<br><br>Upon a restart of the system, the system, if necessary, changes the value of this variable so that it indexes the entry in the interface table with the same value of ifAlias that it indexed before the system restart. If no such entry exists, then the system sets this variable to 0.<br>Read only. |
|                                  | extremeCfmGroupRemoteMEPs     | Lists the Remote MEPs associated with a group. Not all Remote MEPs of an MA may be associated with a group. Ready only.                                                                                                                                                                                                                                                                                                                                                          |
|                                  | extremeCfmGroupClients        | Lists all the registered clients with a group. The clients are informed with link failure or recovery through group status notifications. Ready only.                                                                                                                                                                                                                                                                                                                            |
|                                  | extremeCfmGroupRowStatus      | The status of the row. All columns must have a valid value before a row can be activated.                                                                                                                                                                                                                                                                                                                                                                                        |
| extremeCfmGroupMepDbTable        |                               | Maintains information about other MEPs in that group.                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                                  | extremeCfmGroupMepDbEntry     | Complex index including Maintenance Domain, MaNet, MEP and Group indices along with RMEP ID to identify a row in this table.<br>Not accessible.                                                                                                                                                                                                                                                                                                                                  |
|                                  | extremeCfmGroupMepDbRMEPId    | Maintenance association End Point Identifier of a remote MEP whose information from the group MEP database is to be returned.<br>Not accessible.                                                                                                                                                                                                                                                                                                                                 |
|                                  | extremeCfmGroupMepDbRowStatus | The status of the row. All columns must have a valid value before a row can be activated.                                                                                                                                                                                                                                                                                                                                                                                        |
| extremeCfmGroupStatusDownUpAlarm | extremeCfmGroupStatus         | A notification (DownUpAlarm) is sent to the management entity with the OID of the group that has detected the status change.                                                                                                                                                                                                                                                                                                                                                     |

## EXTREME-CLEARFLOW-MIB

This MIB defines the following Extreme-specific CLEAR-Flow traps generated by Extreme Networks devices.

| Trap                                     | Comments                                          |
|------------------------------------------|---------------------------------------------------|
| extremeClearflowMessage                  | CLEAR-Flow message trap.                          |
| The varbinds supported in this trap are: |                                                   |
| extremeClearflowMsgId                    | User-defined message ID.                          |
| extremeClearflowMsg                      | User-defined message.                             |
| extremeClearflowPolicyName               | Policy file name.                                 |
| extremeClearflowRuleName                 | Rule name which triggered this message.           |
| extremeClearflowRuleValue                | Calculated rule value.                            |
| extremeClearflowRuleThreshold            | Rule threshold value.                             |
| extremeClearflowRuleInterval             | Rule sampling and evaluation interval.            |
| extremeClearflowVlanName                 | <u>VLAN</u> name on which this policy is applied. |
| extremeClearflowPortName                 | Port name on which this policy is applied.        |

## EXTREME-CPU-MONITOR-TOTAL-UTILIZATION-MIB

The following tables, groups, and variables are supported in this MIB:

| Table/Group                            | Supported Variables                     | Comments  |
|----------------------------------------|-----------------------------------------|-----------|
| extremeCpuMonitorTotalUtilizationTable | extremeCpuMonitorTotalUtilizationEntry  |           |
|                                        | extremeCpuMonitorTotalUtilizationSlotId | Read-only |
|                                        | extremeCpuMonitorTotalUtilizationOfSlot | Read-only |

## EXTREME-EAPS-MIB

Managed objects for EAPS MIB are defined proprietary on ExtremeXOS.

[Table 164](#) lists the existing traps supported in this MIB.

**Table 164: EAPS MIB Traps**

| Trap                               | Varbinds                                                                                                                                                                                           | Comments                                                                                   |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| extremeEapsStateChange             | extremeEapsName,<br>extremeEapsMode,<br>extremeEapsPrevState,<br>extremeEapsState,<br>extremeEapsFailedFlag,<br>extremeEapsPrimaryStatus<br>extremeEapsSecondaryStatus                             | Send on Master/Transit Nodes                                                               |

Table 165 lists the MIB entries.

**Table 165: EAPS MIB Entries**

| MIB Variable                | Description                                                                                                                                                                                                                                                                                                                         |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeEapsLastStatusChange | Time gets updated for any of the following changes... extremeEapsState, extremeEapsSharedPortState, extremeEapsSharedPortSegmentStatus, extremeEapsFailedFlag, extremeEapsPrimaryStatus, extremeEapsSecondaryStatus, extremeEapsSharedPortNbrStatus, extremeEapsSharedPortRootBlockerStatus, extremeEapsSharedPortSegmentFailedFlag |
| extremeEapsStatusTrapCount  | Indicates the number of status traps sent out since the switch booted. Status traps include extremeEapsStateChange, extremeEapsPortStatusChange, extremeEapsSharedPortStateChange, extremeEapsRootBlockerStatusChange                                                                                                               |

## EXTREME-EDP-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group             | Supported Variables | Comments                                                                                |
|-------------------------|---------------------|-----------------------------------------------------------------------------------------|
| extremeEdpTable         | All objects         | This table contains <i>EDP (Extreme Discovery Protocol)</i> information of this device. |
| extremeEdpNeighborTable | All objects         | This table contains EDP neighbor information.                                           |
| extremeEdpPortTable     | All objects         |                                                                                         |

## EXTREME-ENTITY-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group           | Supported Variable        | Comments                                                               |
|-----------------------|---------------------------|------------------------------------------------------------------------|
| extremeEntityFRUTable | entPhysicalIndex          | A table containing information about each FRU based on the Entity MIB. |
|                       | extremeEntityFRUStartTime | First recorded start time.                                             |

| Table/Group | Supported Variable           | Comments                                                                                                               |
|-------------|------------------------------|------------------------------------------------------------------------------------------------------------------------|
|             | extremeEntityFRUOdometer     | Number of time units in service.                                                                                       |
|             | extremeEntityFRUOdometerUnit | Time unit used to represent value reported by extremeEntityFRUOdometer. Depends on the underlying hardware capability. |

## EXTREME-ERPS-MIB

Managed objects for *ERPS* MIB are defined proprietary on ExtremeXOS. Groups and tables are implemented as read only.

The following tables, groups, and variables are supported in this MIB.

| Table/Group                   | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeErpsProtectedVlanTable | All objects         | Contains the grouping of set of protected VLANs.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| extremeErpsRingTable          | All objects         | Contains information for each ERPS ring present in the switch.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| extremeErpsStatsTable         | All objects         | Contains statistics information for each of the ring present in the switch.                                                                                                                                                                                                                                                                                                                                                                                                             |
| extremeErpsGlobalInfo         |                     | Contains the information of ERPS configured globally in the switch.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| extremeErpsNotification       |                     | Contains two types of traps: extremeErpsStateChangeTrap and extremeErpsFailureTrap. extremeErpsStateChangeTrap is generated on the following events: <ul style="list-style-type: none"> <li>Local SF is received for the ring.</li> <li>Local Clear SF is received for the ring.</li> <li>Remote failure is detected on this ring.</li> <li>Remote failure is cleared on this ring.</li> <li>Force Switch is issued for a ring.</li> <li>Manual Switch is issued for a ring.</li> </ul> |

## EXTREME-ESRP-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                    | Supported Variables          | Comments                                                                                               |
|--------------------------------|------------------------------|--------------------------------------------------------------------------------------------------------|
| extremeEsrpDomainTable         | All objects                  | This table contains information for domains on this device.                                            |
| extremeEsrpDomainMemberTable   | All objects                  | This table contains information for member VLANs of the ESRP domain.                                   |
| extremeEsrpDomainNeighborTable | All objects                  | This table contains neighbor router information for ESRP domains on this device.                       |
| extremeEsrpDomainAwareTable    | All objects                  | This table contains ESRP aware information for this device.                                            |
| extremeEsrpDomainStatsTable    | All objects                  | This table contains statistics on ESRP hello packets exchanged and ESRP state changes for this device. |
| extremeEsrpNotifications       | extremeEsrpDomainStateChange | Signifies ESRP state change.                                                                           |

## EXTREME-FDB-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group            | Supported Variables | Comments                                               |
|------------------------|---------------------|--------------------------------------------------------|
| extremeFdbIpFdbTable   | All objects         | Supports <i>SNMP</i> get and get next operations only. |
| extremeFdbPermFdbTable | All objects         |                                                        |

| Table/Group                  | Supported Variables       | Comments                                                                                                                                                                                        |
|------------------------------|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeFdbMacExosFdbTable    | extremeFdbMacExosFdbEntry | A table that contains information about the hardware MAC <i>FDB (forwarding database)</i> table. Supported only on switches running ExtremeXOS. Supports SNMP get and get next operations only. |
| extremeFdbMacFdbCounterTable | All objects               | Supports SNMP get and get next operations only.                                                                                                                                                 |

| Trap                   | Comments                                                                                          |
|------------------------|---------------------------------------------------------------------------------------------------|
| extremeMACTrackingAdd  | The specified MAC address was added to the FDB on the mentioned port and VLAN.                    |
| extremeMACTrackingDel  | The specified MAC address was deleted from the FDB on the mentioned port and VLAN.                |
| extremeMACTrackingMove | The specified MAC address was moved from the previous port to the new port on the specified VLAN. |

## EXTREME-MAC-AUTH-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group               | Supported Variables                | Comments                                                                                                     |
|---------------------------|------------------------------------|--------------------------------------------------------------------------------------------------------------|
| extremeMacAuthClientTable | All objects                        | This table contains client authentication based on the source MAC address of the traffic received on a port. |
| ExtremeMacAuthClientEntry |                                    | An entry in the MAC authentication table. Each entry represents a MAC authentication client                  |
|                           | extremeMacAuthClientAddress        | The MAC address of the client.                                                                               |
|                           | extremeMacAuthClientInitialize     | Remove the entry for the client from extremeMacAuthClientTable.                                              |
|                           | extremeMacAuthClientReauthenticate | Re-authenticate the client on all ports on which the client is connected.                                    |

## EXTREME MLAG MIB

The following tables, groups, and variables are supported in this MIB.

### Note

EXTREME MLAG MIB objects such as `extremeMlagLocalAddrType`, `extremeMlagLocalIP`, `extremeMlagAlternateLocalAddrType`, `extremeMlagAlternateLocalIP` are defined with a maximum access of read-create and are populated automatically based on MLAG peer info.

| Table/Group                       | Supported Variables                   | Comments                                                                                                                                                                                                                                                                         |
|-----------------------------------|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>extremeMlagPeerTable</code> |                                       | This table contains MLAG peer entries. This table contains a MLAG peer switch association structure, associates an MLAG peer structure with an MLAG peer switch IP address. Displays User configured items, MLAG peer switch state, MLAG port count and health-check statistics. |
|                                   | <code>extremeMlagPeerName</code>      | Read-create<br>The name of the MLAG Peer switch. MLAG Peer names must be alpha-numeric and must start with an alpha character.                                                                                                                                                   |

|                      | extremeMlagPeerAlternateTxHellos      | Read-only<br>Number of Health Check Hellos transmitted on the alternate health check connection                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                      | extremeMlagPeerCheckpointAuthType     | Read-create<br>Enumerates the possible types of authentication types for the MLAG checkpoint connection to the MLAG peer.<br>none(1) Do not use authentication.<br>md5(2) Use MD5 authentication.                                                                                                                                                                                                                                                                                                                                         |
|                      | extremeMlagPeerCheckpointAuthKey      | Read-create<br>The authentication key to be used for checkpoint connection to the peer. Recommended to be of size 12-24 per RFC 3562. This object will return a blank string of minimum length when queried.                                                                                                                                                                                                                                                                                                                              |
| extremeMlagPortTable |                                       | This table contains Mlag port entries<br><br>Binds a local port or LAG port to an MLAG port uniquely identified by the MLAG Id value. Once the MLAG group binding is made, any change to load sharing on MLAG ports is disallowed. Displays User configured items, MLAG peer switch state, port count and health-check statistics.<br><br><b>Note:</b> To create a row in the extremeMlagPortTable, extremeMlagPortId and extremeMlagPortPeer should be specified in the SNMP SET request in addition to extremeMlagPortLocalPortIfIndex. |

| Table/Group | Supported Variables             | Comments                                                                                                                                                                                                                                                                                                                                |
|-------------|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | extremeMlagPortLocalPortIfIndex | Read-create<br>The ifIndex of the local member port of the MLAG port. The specified port ifIndex may be a single port or the master port of a load share port but should not be a load share member port.                                                                                                                               |
|             | extremeMlagPortId               | Read-create<br>The identifier which is used to identify the MLAG port                                                                                                                                                                                                                                                                   |
|             | extremeMlagPortPeer             | Read-create<br>This object identifies the MLAG peer switch with which this port is associated                                                                                                                                                                                                                                           |
|             | extremeMlagPortLocalLinkStatus  | Read-only<br>Local MLAG Port Status, that can be Active/Disabled/Ready/Port not present. It reflects the status of entire LAG when LAG is used in conjunction with MLAG.                                                                                                                                                                |
|             | extremeMlagPortRemoteLinkStatus | Read-only<br>Remote MLAG Port Status, which can be<br>Up(1) - One or more links are active on the remote switch or<br>Down(2)- No links are active on the remote switch or<br>N/A(3) - The peer has not communicated link state for this MLAG group.<br>It reflects the status of entire LAG when LAG is used in conjunction with MLAG. |
|             | extremeMlagPortPeerState        | Read-only<br>MLAG Peer Switch State, up/down                                                                                                                                                                                                                                                                                            |
|             | extremeMlagPortLocalFailures    | Read-only<br>Gives the number of ports that are down in the local MLAG port.                                                                                                                                                                                                                                                            |
|             | extremeMlagPortRemoteFailures   | Read-only<br>Gives number of ports that are down in the remote MLAG port                                                                                                                                                                                                                                                                |
|             | extremeMlagPortRowStatus        | Read-create<br>The status of this entry.                                                                                                                                                                                                                                                                                                |

| Table/Group | Supported Variables              | Comments                                                                                                                                                                                                                                                                                                                                   |
|-------------|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | extremeMlagConvergenceControl    | Read-write<br>This object specifies if an ACL can be used on an MLAG port to achieve faster convergence. If an ACL is used, better convergence times can be achieved irrespective of the number of FDB entries present on the MLAG port. The second time can be chosen when convergence time is not an issue and ACLs are to be preserved. |
|             | extremeMlagReloadDelayInterval   | Read-write<br>Time Interval in seconds that is used to delay the enabling of MLAG ports during startup. This is used to allow convergence of protocols and for reachability of MLAG peer.                                                                                                                                                  |
|             | extremeMlagReloadDelayEnable     | Read-write<br>Setting this object to true will enable the reload delay feature. Enabling reload delay will delay enabling of MLAG ports during startup to allow convergence of protocols and for reachability of MLAG peer.                                                                                                                |
|             | extremeMlagLinkupIsolationEnable | Read-write<br>Setting this object to true will isolate MLAG ports from sending traffic to local ISC port during link-up transition until remote ISC port is configured.                                                                                                                                                                    |
|             | extremeMlagPeerUp                | This trap is sent when the MLAG peer comes up.                                                                                                                                                                                                                                                                                             |
|             | extremeMlagPeerDown              | This notification is sent when health check messages are not received from the peer MLAG switch for 3 times the configured hello interval.                                                                                                                                                                                                 |
|             | extremeMlagAltPathUp             | This notification is sent when the ISC goes down and the alternate path to MLAG peer comes up.                                                                                                                                                                                                                                             |
|             | extremeMlagAltPathDown           | This notification is sent when the alternate path to MLAG peer is down. This can happen when either alternate path or remote peer is down or the ISC link has come up.                                                                                                                                                                     |

## EXTREME-MPLS-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group              | Supported Variables                | Comments                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeMplsNotifications | extremepwUpDownNotificationEnable  | If this object is set to true (1), then it enables the emission of pwUp and pwDown notifications; otherwise these notifications are not emitted.                                                                                                                                                                                                         |
|                          | extremepwDeletedNotificationEnable | If this object is set to true (1), then it enables the emission of pwDeleted notification; otherwise this notification is not emitted.                                                                                                                                                                                                                   |
|                          | pwNotificationMaxRate              | This variable indicates the maximum number of notifications issued per second. If events occur more rapidly, the implementation may simply fail to emit these notifications during that period, or might queue them until an appropriate time. A value of 0 means no throttling is applied and events might be notified at the rate at which they occur. |
|                          | extremepwNotificationPwIndex       | This variable indicates the index of the PW that either went up, down, or was deleted as reported by the corresponding notification.                                                                                                                                                                                                                     |
|                          | extremepwNotificationPwOperStatus  | This variable is used to report the value of pwOperStatus in pwTable (RFC 5601) associated with the PW that went up or down.                                                                                                                                                                                                                             |
|                          | extremepwNotificationPeerAddrType  | Denotes the address type of the peer node.                                                                                                                                                                                                                                                                                                               |
|                          | extremepwNotificationPeerAddr      | This object contains the value of the peer node address.                                                                                                                                                                                                                                                                                                 |
|                          | extremeMplsNotifTunnelIndex        | Uniquely identifies a set of tunnel instances between a pair of ingress and egress LSRs. Contains part of the index of a TE tunnel that underwent state change. The same tunnel can also be looked up in the TE MIB.                                                                                                                                     |
|                          | extremeMplsNotifTunnelInstance     | Uniquely identifies a particular instance of a tunnel between a pair of ingress and egress LSRs.                                                                                                                                                                                                                                                         |
|                          | extremeMplsNotifTunnelIngressLSRId | Identity of the ingress LSR associated with this tunnel instance.                                                                                                                                                                                                                                                                                        |

| Table/Group | Supported Variables                         | Comments                                                                                                                                                                                                                                  |
|-------------|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | extremeMplsNotifTunnelEgressLSRIId          | Identity of the egress LSR associated with this tunnel instance.                                                                                                                                                                          |
|             | extremeMplsNotifTunnelAdminStatus           | Reports the desired operational status of this tunnel.                                                                                                                                                                                    |
|             | extremeMplsNotifTunnelOperStatus            | Reports the actual operational status of this tunnel, which is typically but not limited to, a function of the state of individual segments of this tunnel.                                                                               |
|             | extremeMplsNotifLdpEntityLdpld              | The LDP identifier. This is the primary index to identify a row in the mplsLdpEntityTable (RFC 3815).                                                                                                                                     |
|             | extremeMplsNotifLdpEntityIndex              | This index is used as a secondary index to uniquely identify a row in the mplsLdpEntityTable (RFC 3815). This object is meaningful to some, but not all, LDP implementations.                                                             |
|             | extremeMplsNotifLdpPeerLdpld                | The LDP identifier of this LDP Peer.                                                                                                                                                                                                      |
|             | extremeMplsNotifLdpSessionState             | The current state of the session, all of the states 1 to 5 are based on the state machine for session negotiation behavior.                                                                                                               |
|             | extremeMplsNotifLdpSessionDiscontinuityTime | The initial value of this object is the value of sysUpTime when the entry was created in this table. Subsequent notifications report the time when the session between a given entity and peer goes away or a new session is established. |
|             | extremeVplsNotifConfigIndex                 | Unique index for the conceptual row identifying a VPLS service in the vplsConfigTable.                                                                                                                                                    |
|             | extremeVplsNotifConfigVpnId                 | This object indicates the IEEE 802-1990 VPN ID of the associated VPLS service. This object has the same value as vplsConfigVpnId in the vplsConfigTable for an index value equal to extremeVplsNotifConfigIndex sent in the notification. |

| Table/Group | Supported Variables               | Comments                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | extremeVplsNotifConfigAdminStatus | The administrative state of the VPLS service.<br>This object has the same value as vplsConfigAdminStatus in the vplsConfigTable for an index value equal to extremeVplsNotifConfigIndex sent in the notification.                                                                                                                                                           |
|             | extremeVplsNotifStatusOperStatus  | The current operational state of this VPLS service. A value of up (1) indicates that all PWs for this VPLS are up and the attachment circuit is up.<br>A value of degraded (2) indicates that at least one PW for this VPLS is up and the attachment circuit is up.<br>A value of down (3) indicates that all PWs for this VPLS are down or the attachment circuit is down. |
|             | extremePwStatusChange             | This notification is generated when the pwOperStatus object for a pseudowire transitions from up (1) to down (2) or from down (2) to up (1).                                                                                                                                                                                                                                |
|             | extremePwDeleted                  | This notification is generated when a PW has been deleted.                                                                                                                                                                                                                                                                                                                  |
|             | extremeMplsTunnelStatusChange     | This notification is generated when the mplsTunnelOperStatus object for a TE-LSP transitions from up (1) to down (2) or from down (2) to up (1). This new state is indicated by the included value of mplsTunnelOperStatus.                                                                                                                                                 |
|             | extremeMplsLdpSessionStatusChange | This notification is generated when the value of 'mplsLdpSessionState' (RFC3815) enters or leaves the operational (5) state.                                                                                                                                                                                                                                                |

| Table/Group            | Supported Variables         | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | extremeVplsStatusChange     | <p>This notification is generated to inform recipients of the state of the VPLS.</p> <p>When all PWs in this VPLS are up or ready and the attachment circuit is up, extremeVplsNotifStatusOperStatus is set to vplsOperStatusUp (1) in the notification.</p> <p>When at least one PW in this VPLS is up or ready and the attachment circuit is up, extremeVplsNotifStatusOperStatus is set to vplsOperStatusDegraded (2) in the notification.</p> <p>When all PWs in this VPLS are down or the attachment circuit is down, extremeVplsNotifStatusOperStatus is set to vplsOperStatusDown (3) in the notification.</p> <p>Once a notification has been sent with vplsOperStatusDegraded (2), no further notification will be sent until extremeVplsNotifStatusOperStatus transitions to vplsOperStatusUp (1) or vplsOperStatusDown (3).</p> |
| extremeVplsConfigTable |                             | This table specifies information for configuring and monitoring VPLS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                        | extremeVplsConfigEntry      | A row in this table represents a VPLS in a packet network. It is indexed by extremeVplsConfigIndex, which uniquely identifies a single VPLS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| ExtremeVplsConfigEntry | extremeVplsConfigIndex      | Unique index for the conceptual row identifying a VPLS service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                        | extremeVplsConfigRedundType | <p>This variable indicates the redundancy type for this VPLS. Redundancy states can be None, <i>EAPS</i>, <i>ESRP (Extreme Standby Router Protocol)</i> and <i>STP (Spanning Tree Protocol)</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Table/Group            | Supported Variables         | Comments                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | extremeVplsConfigEAPSStatus | This variable indicates the EAPS redundancy status for this VPLS. It displays Protected if the <u>VLAN</u> is protected, else Not Protected. EAPS status displays the following values:<br>Waiting—if waiting on EAPS status.Connected—if EAPS ring status is connected to VLAN. PW is not installed in this state.Disconnected—if EAPS ring state is disconnected. PW is installed in this state.Unknown—if EAPS is not found. |
|                        | extremeVplsConfigESRPState  | This variable indicates the ESRP redundancy state for this VPLS. ESRP states can have two values: master and slave. PW is installed only when ESRP is in the master state.                                                                                                                                                                                                                                                      |
| extremeVplsStatusTable |                             | This table specifies information for configuring and monitoring VPLS.                                                                                                                                                                                                                                                                                                                                                           |
|                        | extremeVplsStatusEntry      | A row in this table represents a VPLS in a packet network. It is indexed by extremeVplsConfigIndex, which uniquely identifies a single VPLS.                                                                                                                                                                                                                                                                                    |
|                        | extremeVplsStatusIndex      | Unique index for the conceptual row identifying a VPLS service.                                                                                                                                                                                                                                                                                                                                                                 |
|                        | extremeVplsOperStatus       | This variable indicates the VPLS operation status. This is different from the VPLS PW status shown in the standard MIB. Supported values are:<br>Up—all PWs are in the Up or Ready state.Degraded—At least one PW is in the Up or Ready state.Down—None of the PWs are in Up or Ready state.                                                                                                                                    |
| extremeVplsPeerTable   |                             | This table provides information for monitoring VPLS peer entries.                                                                                                                                                                                                                                                                                                                                                               |
|                        | extremeVplsPeerEntry        | This entry contains information for all the peers belonging to a particular VPLS.                                                                                                                                                                                                                                                                                                                                               |
|                        | extremeVplsIndex            | Unique index for the conceptual row identifying a VPLS service.                                                                                                                                                                                                                                                                                                                                                                 |

| Table/Group | Supported Variables     | Comments                                                                                                                                                                                                                        |
|-------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | extremeVplsPwBindIndex  | Secondary Index for the conceptual row identifying a PW within the PwEntry which must match an entry from the PW-STD-MIB's PwTable, which represents an already-provisioned PW that is then associated with this VPLS instance. |
|             | extremePwInstalled      | Boolean true or false, indicating if PW is installed.                                                                                                                                                                           |
|             | extremePwMode           | The peer mode of this PW. It indicates its current mode and the mode of the switch it is connected to. It can have the following values: Core-to-core, Core-to-Spoke, and Spoke-to-Core.                                        |
|             | extremePwConfiguredRole | The configured role of this PW. It applies only in the case the PWMode is Core-to-core. In this case, the configured role can either be Primary or Secondary. For all the other PW modes, the configured role does not apply.   |

The following traps can be generated:

| Trap                    | Comments                                                                                                                             |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| pwStatusChange          | This notification is generated when the pwOperStatus object for a PW transitions from up (1) to down (2) or from down (2) to up (1). |
| pwDeleted               | This notification is generated when a PW has been deleted.                                                                           |
| extremeMPLSTrapsEnable  | MPLS trap status. If enabled then all the MPLS related traps are sent out.                                                           |
| extremeL2VpnTrapsEnable | L2VPN trap status. If enabled then all the L2VPN related traps are sent out.                                                         |

## EXTREME-MPLS-TE-MIB

The following tables, groups, and variables are supported in this MIB:

| Table/Group            | Supported Variables      | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeMplsTunnelTable | mplsTunnelIndex          | The mplsTunnelTable (see RFC3812) allows new MPLS tunnels to be created between an LSR and a remote endpoint, and existing tunnels to be reconfigured or removed. Note that only point-to-point tunnel segments are supported, although multipoint-to-point and point-to-multipoint connections are supported by an LSR acting as a cross-connect. Each MPLS tunnel can thus have one out-segment originating at this LSR and/or one in-segment terminating at this LSR. Extreme Networks MPLS implementation allows tunnel instances with a common endpoint to be grouped at the ingress LSR to provide redundancy. The role of each tunnel in the group must be configured and is indicated by extremeMplsTunnelRedundancyType. |
|                        | mplsTunnelInstance       | Uniquely identifies a particular instance of a tunnel between a pair of ingress and egress LSRs. It is useful to identify multiple instances of tunnels for the purposes of backup and parallel tunnels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                        | mplsTunnelIngressLSRId   | Identity of the ingress LSR associated with this tunnel instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                        | mplsTunnelEgressLSRId    | Identity of the egress LSR associated with this tunnel instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                        | mplsTunnelRedundancyType | Identifies the tunnel redundancy type associated with this tunnel instance. A value of primary (1) or secondary (2) MAY be assigned by the network administrator or by an <i>SNMP</i> manager at the time of setting up the tunnel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Table/Group | Supported Variables        | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | mplsTunnelRedundancyStatus | Indicates the actual redundancy status of this tunnel. When the status is active, the tunnel is the preferred tunnel in the group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|             | mplsTunnelTransportStatus  | Indicates the type of traffic the tunnel group can be used for sending.<br>When the status is allowAllIp (0), IP traffic destined for all IPv4 routes is allowed over any tunnel in the group marked active. When the status is allowAssignedIpOnly (1), IP traffic destined only for IPv4 static routes that have been explicitly configured to use this tunnel group is allowed. When the status is allowAllLayer 2Vpn (2), Layer 2 VPN traffic for all Layer 2 VPNs is allowed over any tunnel in the group marked active. When the status is allowAssignedLayer 2VpnOnly (3), Layer 2 VPN traffic destined only for PWs that have been explicitly configured to use this tunnel group are allowed. |

## EXTREME-OSPF-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group               | Supported Variables | Comments                                                                                                           |
|---------------------------|---------------------|--------------------------------------------------------------------------------------------------------------------|
| extremeOspfInterfaceTable | All objects         | This table contains Extreme Networks specific information about <i>OSPF (Open Shortest Path First)</i> interfaces. |

## EXTREME-PoE-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                           | Supported Variables | Comments                         |
|---------------------------------------|---------------------|----------------------------------|
| extremePethSystemAdminEnable          |                     | Objects are supported read-only. |
| extremePethSystemDisconnectPrecedence |                     |                                  |
| extremePethSystemUsageThreshold       |                     |                                  |
| extremePethSystemPowerSupplyMode      |                     |                                  |

| Table/Group                    | Supported Variables       | Comments                        |
|--------------------------------|---------------------------|---------------------------------|
| extremePethPseSlotTable        | extremePethOperatorLimit  |                                 |
|                                | extremePethPortResetPower |                                 |
| extremePethPseSlotTable        | All other objects         | Objects are supported read-only |
| extremePethPortDetectionType   |                           |                                 |
| extremePethPortMeasuredVoltage |                           |                                 |
| extremePethPortMeasuredCurrent |                           |                                 |
| extremePethPortFastPoeEnable   |                           |                                 |
| extremePethSlotPerpetualPoe    |                           |                                 |

## EXTREME-PORT-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group                | Supported Variables | Comments       |
|----------------------------|---------------------|----------------|
| extremePortLoadshareTable  | All objects         | Not supported. |
| extremePortSummitlinkTable | All objects         | Not supported. |

| Table/Group                | Supported Variables                | Comments                                                                                                                                                                                                                                                 |
|----------------------------|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremePortLoadshare2Table | extremePortLoadshare2Entry         | A table of bindings between a master port and its load-sharing slaves. Create/delete entries here to add/delete a port to/from a load-sharing group. Default is empty table. There are restrictions on what row creates will be accepted by each device. |
|                            | extremePortLoadshare2MasterIfIndex | The if Index value which identifies the port controlling a load-sharing group of ports that includes extremePortLoadshareSlaveIfIndex.                                                                                                                   |
|                            | extremePortLoadshare2SlaveIfIndex  | The if Index value which identifies the port which is a member of a load-sharing group controlled by extremePortLoadshare2MasterIfIndex.                                                                                                                 |
|                            | extremePortLoadshare2Algorithm     | This value identifies the load sharing algorithm to be used for this group of load shared ports.                                                                                                                                                         |
|                            | extremePortLoadshare2Status        | The row status variable, used according to row installation and removal conventions.                                                                                                                                                                     |
|                            | extremePortLoadshare2MinLinks      | The minimum active links that must be up in order trunk to remain up.                                                                                                                                                                                    |
| extremePortRateShapeTable  | All objects                        | Not supported                                                                                                                                                                                                                                            |

|                                    | extremePortQP3CongPkts             | The number of QoS 3 packets that got dropped due to congestion on this port.                                            |
|                                    | extremePortQP4CongPkts             | The number of QoS 4 packets that got dropped due to congestion on this port.                                            |
|                                    | extremePortQP5CongPkts             | The number of QoS 5 packets that got dropped due to congestion on this port.                                            |
|                                    | extremePortQP6CongPkts             | The number of QoS 6 packets that got dropped due to congestion on this port.                                            |
|                                    | extremePortQP7CongPkts             | The number of QoS 7 packets that got dropped due to congestion on this port.                                            |

| Table/Group            | Supported Variables        | Comments                                                                                                                                |
|------------------------|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| extremePortConfigTable |                            | Not-accessible.<br>This table lists port entries with information including auto negotiation, configured port speed, and duplex.        |
|                        | extremePortConfigEntry     | Not-accessible.<br>An individual Port Information Entry with information including auto negotiation, configured port speed, and duplex. |
|                        | extremePortAutoNegotiation | Read-write access.<br>Indicates whether the port is operating auto negotiation mode.                                                    |
|                        | extremePortAdminSpeed      | Read-write access.<br>The configured speed of the port. The current actual speed of the port can be determined from ifSpeed             |
|                        | extremePortDuplex          | Read-write access.<br>Indicates whether the port is operating in half-duplex, full-duplex, or auto negotiation mode.                    |
|                        | extremePortMedium          | Read-write access.<br>Medium-specific attributes for combination ports.                                                                 |

The following traps can be generated:

| Trap                          | Comments                                                                                                                                                                                                                                                                                              |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremePortMauChangeTrap      | This trap is sent whenever a MAU is inserted or removed. When the MAU is inserted, the value of extremePortMauStatus is 'inserted' and extremePortMauType indicates the type of the MAU inserted. If MAU is removed, the value of extremePortMauStatus is empty and the type of the MAU will be NONE. |
| extremeRateLimitExceededAlarm | This notification indicates the first time a poll of a rate-limited port has a non-zero counter.                                                                                                                                                                                                      |

## Pseudowire LSP Sharing MIB

By implementing the tables in PW LSP sharing MIB, the *SNMP* manager is able to observe the transmit packet counters over each LSP that is configured for used by the

PW, and aggregated transmit and receive packet counters over PW itself. It consist three tables:

- extremePwPerfTable
- extremePwLspOutboundMappingTable
- extremePwLspPerfTable

There are no standard MIB tables and scalars objects that can be used for Pseudo Wire LSP Sharing. MIB table and object defined here are Extreme Networks proprietary. These three table are implemented in code/ l3protocol/ mpls/src/extrememplsMIB.my.

A new SNMP MIB object is introduced for PW LSP Load Sharing: extremePwObjects  
OBJECT IDENTIFIER ::= { extremeMplsMIB 5 }

#### *extremePwPerfTable*

This table contains the aggregated transmit and receive packet counters for in-service PWs.

| MIB Object         | Description                                 | Variable Type | Support Status |
|--------------------|---------------------------------------------|---------------|----------------|
| pwPerfInPackets    | Receive packet counter per PW               | Read          | Supported      |
| pwPerfInBytes      | Receive packet counter in bytes per PW      | Read          | Supported      |
| pwPerfOutPackets   | Transmit packet counters per PW             | Read          | Supported      |
| pwPerfOutBytes     | Transmit packet counter in bytes per PW     | Read          | Supported      |
| pwPerfInHCPackets  | Receive high capacity packet counter per PW | Read          | Supported      |
| pwPerfInHCBytes    | Receive packet counter in bytes per PW      | Read          | Supported      |
| pwPerfOutHCPackets | Transmit packet counters per PW             | Read          | Supported      |
| pwPerfOutHCBytes   | Transmit packet counter in bytes per PW     | Read          | Supported      |

#### *extremePwLspOutboundMappingTable*

This table provides the mapping between PWs and LSPs by providing an LSP index. LSP indexes are assigned uniquely for each PW. Entries in this table indicate that an

LSP is being used by an in-service PW. An SNMP notification will be sent when an entry is added or deleted.

| MIB Object                   | Description                                                                                                                                                                 | Variable Type | Support Status |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|----------------|
| lspIndex                     | LSP index per LSP used by the PW. It is only unique per PW peer.                                                                                                            | Index         | Supported      |
| pwLspOutboundLsrXcIndex      | Corresponding entry in the <i>MPLS (Multiprotocol Label Switching)-LSR-STD-MIB</i>                                                                                          | Read          | Supported      |
| pwLspOutboundTunnelIndex     | Corresponding RSVP-TE tunnel index based on LSP index used by the PW                                                                                                        | Read          | Supported      |
| pwLspOutboundTunnelInstance  | Corresponding RSVP-TE tunnel instance based on LSP index used by the PW                                                                                                     | Read          | Supported      |
| pwLspOutboundTunnelLclLSR    | Corresponding RSVP-TE tunnel ingress LSR ID based on LSP index used by the PW                                                                                               | Read          | Supported      |
| pwLspOutboundTunnelPeerLSR   | Corresponding RSVP-TE tunnel egress LSR ID based on LSP index used by the PW                                                                                                | Read          | Supported      |
| pwLspOutboundTunnelTypeInUse | LSP Type used by the PW. mplsTe value (MIB definition is 1) is being used for RSVP-TE LSPs, and mplsNonTe value (MIB definition is 2) is being used for Static or LDP LSPs. | Read          | Supported      |

*extremePwLspPerfTable*

This table contains the transmit packet and byte counters for traffic sent over a specific PW using a specific LSP.

| MIB Object            | Description                                                           | Variable Type | Support Status |
|-----------------------|-----------------------------------------------------------------------|---------------|----------------|
| pwLspPerfOutPackets   | Receive packet counter per LSP used by the PW.                        | Index         | Supported      |
| pwLspPerfOutBytes     | Receive packet counter in bytes per LSP used by the PW.               | Read          | Supported      |
| pwLspPerfOutHCPackets | Receive high capacity packet counter per LSP used by the PW.          | Read          | Supported      |
| pwLspPerfOutHCBytes   | Receive high capacity packet counter in bytes per LSP used by the PW. | Read          | Supported      |

## EXTREME-QOS-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group            | Supported Variables       | Comments                                                                                                                                                                       |
|------------------------|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeQosProfileTable | extremeQosProfileIndex    | An index that uniquely identifies an entry in the <i>QoS</i> table.                                                                                                            |
|                        | extremeQosProfileName     | A unique QoS profile name.                                                                                                                                                     |
|                        | extremeQosProfileMinBw    | The minimum percentage of bandwidth that this queue requires. The switch is required to provide the minimum amount of bandwidth to the queue. The lowest possible value is 0%. |
|                        | extremeQosProfileMaxBw    | The maximum percentage of bandwidth that this queue is permitted to use.                                                                                                       |
|                        | extremeQosProfilePriority | The level of priority at which this queue will be serviced by the switch.                                                                                                      |

| Table/Group            | Supported Variables        | Comments                                                                                                                                                                                                                                                           |
|------------------------|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | extremeQosProfileRowStatus | The status of the extremeQosProfile entry. This object can be set to:<br>active (1)createAndGo (4)createAndWait(5)destroy (6)<br>The following values may be read:<br>active<br>(1)notInService(2)notReady (3)                                                     |
| extremeQosProfileTable | extremeQosProfileIndex     | The ExtremeXOS software does not support global QoS profile settings in CLI; it supports per port settings only. Walks of this table display the default values with which the ports are initialized.                                                              |
|                        | extremeQosProfileName      | A unique ingress QoS profile name.                                                                                                                                                                                                                                 |
|                        | extremeQosProfileMinBwType | The type of the current minimum bandwidth setting. A value of 1 signifies that the minimum bandwidth value is a percentage of the configurable port bandwidth. A value of 2 or 3 signifies a guaranteed minimum available bandwidth in Kbps or Mbps, respectively. |
|                        | extremeQosProfileMinBw     | The guaranteed minimum bandwidth for this queue, expressed as either a percentage or a specific bandwidth value, as specified by the value of extremeQosProfileMinBwType.                                                                                          |
|                        | extremeQosProfileMaxBwType | The type of the current maximum bandwidth setting. A value of 1 signifies that the maximum bandwidth value is a percentage of the configurable port bandwidth. A value of 2 or 3 signifies a maximum allowed bandwidth in Kbps or Mbps, respectively.              |

| Table/Group            | Supported Variables       | Comments                                                                                                                                                                                                                                                                                       |
|------------------------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | extremeQosProfileMaxBw    | The maximum allowed input bandwidth for this queue, expressed as either a percentage or a specific bandwidth value, as specified by the value of extremeQosProfileMaxBwType.                                                                                                                   |
|                        | extremeQosProfileRED      | The random early drop threshold. When the input queue fill ratio exceeds this percentage, frames start to drop randomly with a linear increasing drop probability as the queue fill count approaches the maximum queue size. A value of 100 indicates that this feature is currently disabled. |
|                        | extremeQosProfileMaxBuf   | The percentage of the total ingress queue size to use. Lower values can be used to reduce the maximum latency through this queue, but with potentially greater loss with bursty traffic.                                                                                                       |
| extremePerPortQosTable | extremePerPortQosIndex    | The value of this variable is the same as the value of extremeQosProfileIndex of the QoS profile which is overridden (for the port specified by ifIndex) by the definition in this table.                                                                                                      |
|                        | extremePerPortQosMinBw    | The minimum percentage of bandwidth that this queue on the specified port requires. The switch is required to provide the minimum amount of bandwidth to the queue. The lowest possible value is 0%.                                                                                           |
|                        | extremePerPortQosMaxBw    | The maximum percentage of bandwidth that this queue on the specified port is permitted to use.                                                                                                                                                                                                 |
|                        | extremePerPortQosPriority | The level of priority at which this queue will be serviced by the switch.                                                                                                                                                                                                                      |

| Table/Group                   | Supported Variables                     | Comments                                                                                                                                                                                                                                                                                               |
|-------------------------------|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               | extremePerPortQosRowStatus              | The status of the extremePerPortQos entry. This object can be set to active (1) and createAndGo (4). The following value may be read: active (1). Note that a destroy (6) is not supported. A row will only be deleted from this table when the QoS profile indicated in that row is changed globally. |
| extremeQosByVlanMapping Table | extremeVlanIfIndex                      | Shows mapping of <u>VLAN</u> to queues for untagged packets. For tagged packets, the vpri field determines which queue the packet should be using.                                                                                                                                                     |
|                               | extremeQosByVlanMappingQoSProfile Index | Value of extremeQosProfileIndex that uniquely identifies a QoS profile entry in an extremeQosProfileTable. This indicates the QoS to be given to traffic for this VLAN in the absence of any other more specific configuration information for this traffic.                                           |

## EXTREME-PVLAN-MIB

Two MIB tables allow for GET/SET operations to view and configure ExtremeXOS PVLAN objects. The first is a PVLAN name table with PVLAN name as the index, and the second is the PVLAN subscriber table with PVLAN name, member VLAN type, and Subscriber VlanIfIndex as the index. Functionality includes supporting the current set of PVLAN CLI configuration options.

*PVLAN Table (extremePvlanTable)*

| extremePvlanName (index) | extremePvlanVrName | extremePvlanNetworkVlanIfIndex |
|--------------------------|--------------------|--------------------------------|
| DisplayString            | DisplayString      | InterfaceIndexOrZero           |
| p1                       | VR-Default14       | 14                             |
| foo                      | VR-Cust1           | 0                              |

PVLAN Subscriber Table (*extremePvlanSubscriberTable*)

| extremePvlanName<br>(index) | extremePvlanSubscriberVlanIfIndex<br>(index) | extremePvlanSubscriberType | extremePvlanSubscriberLoopBackPortIfIndex |
|-----------------------------|----------------------------------------------|----------------------------|-------------------------------------------|
| DisplayString               | InterfaceIndex                               | Integer                    | InterfaceIndexOrZero                      |
| foo                         | 9                                            | PVLAN_ISOLATED(2)          | 0                                         |
| foo                         | 12                                           | PVLAN_ISOLATED(2)          | 1002                                      |
| p1                          | 1                                            | PVLAN_ISOLATED(2)          | 0                                         |
| p1                          | 6                                            | PVLAN_NON_ISOLATED(1)      | 1004                                      |
| p1                          | 8                                            | PVLAN_ISOLATED(2)          | 1010                                      |
| p1                          | 10                                           | PVLAN_NON_ISOLATED(1)      | 0                                         |

RowStatus is defined as: active(1), createAndGo(4), destroy(6)

## EXTREME-SNMPv3-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group               | Supported Variables               | Comments                                                                                                                                                                                                                                                                                                                                      |
|---------------------------|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeTargetAddrExtTable | extremeTargetAddrExtIgnoreMPModel | The value of the snmpTargetParamsMPModel object in the snmpTargetParamsTable is ignored while determining the version of the trap/notification to be sent. When a trap-receiver is created through the CLI command 'configure snmp add trapreceiver ....', the value of this object is set to TRUE for the corresponding entry in this table. |
|                           | extremeTargetAddrExtStandardMode  | When this object is set to TRUE, the management target is treated as a 'standard mode' one, in that any Extreme Networks specific extra varbinds present in a standards-based trap/notification is not sent to this management target. Only the varbinds defined in the standard are sent.                                                    |

| Table/Group                  | Supported Variables           | Comments                                                                                                                                                                          |
|------------------------------|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              | extremeTargetAddrExtTrapSrcIp | This object contains the source IP address from which traps have to be sent out. If this object is assigned an IP address that does not belong to the switch, an error is thrown. |
|                              | extremeTargetAddrExtVrName    | This object contains the VR name through which the <i>SNMP</i> Traps are being sent out.                                                                                          |
| extremeUsmAesCfb192 Protocol |                               | Supported from ExtremeXOS 12.3                                                                                                                                                    |
| extremeUsmAesCfb256 Protocol |                               | Supported from ExtremeXOS 12.3                                                                                                                                                    |

## EXTREME-STP-EXTENSIONS-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group             | Supported Variables             | Comments                                                                                                                              |
|-------------------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| extremeStpDomainTable   | All objects                     | This table contains <i>STP</i> information per STP domain.                                                                            |
|                         | extremeStpDomainStpdDescription | The description associated with this STP domain.                                                                                      |
| extremeStpPortTable     | All objects                     | This table contains port-specific information per STP domain.                                                                         |
| extremeStpVlanPortTable | All objects                     | This table contains information of the ports belonging to a STP domain on a per <i>VLAN</i> basis.                                    |
| extremeStpNotifications | extremeStpEdgePortLoopDetected  | This is a trap that would be sent when a loop has been detected on the network login edge safeguard port (the port will be disabled). |

## EXTREME-STPNOTIFICATIONS-MIB

This MIB defines the following Extreme-specific *STP* Notifications trap generated by Extreme Networks devices.

| Trap                           | Comments                                                                                         |
|--------------------------------|--------------------------------------------------------------------------------------------------|
| extremeStpEdgePortLoopDetected | A loop has been detected on the network login edge safeguard port and the port will be disabled. |

## EXTREME-SYSTEM-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group | Supported Variables            | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | extremeSaveConfiguration       | When this object is set, the device copies the contents of the configuration database to a buffer and saves it to the persistent store specified by the value of the object. The save is performed asynchronously, and the <i>SNMP</i> agent continues to respond to both gets and sets while the save is taking place. A network management application may use the extremeSaveStatus object to determine when the asynchronous save operation has completed. |
|             | extremeSaveStatus              | This object returns the status of a save operation invoked by setting the extremeSaveConfiguration object. A network management application can read this object to determine that a save operation has completed.                                                                                                                                                                                                                                             |
|             | extremeCurrentConfigInUse      | Shows which NVRAM configuration store was used at last boot.                                                                                                                                                                                                                                                                                                                                                                                                   |
|             | extremeConfigToUseOnReboot     | Controls which NVRAM configuration store will be used on next reboot.                                                                                                                                                                                                                                                                                                                                                                                          |
|             | extremeOverTemperatureAlarm    | Alarm status of overtemperature sensor in device enclosure.                                                                                                                                                                                                                                                                                                                                                                                                    |
|             | extremePrimaryPowerOperational | Not supported. Always returns True.                                                                                                                                                                                                                                                                                                                                                                                                                            |
|             | extremePowerStatus             | Not supported. Always returns presentOK.                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Table/Group | Supported Variables            | Comments                                                                                                    |
|-------------|--------------------------------|-------------------------------------------------------------------------------------------------------------|
|             | extremePowerAlarm              | Not supported. Always returns False.                                                                        |
|             | extremeRedundantPowerStatus    |                                                                                                             |
|             | extremeRedundantPowerAlarm     | Not supported. Always returns presentOK.                                                                    |
|             | extremeInputPowerVoltage       | Contains the input voltage of the latest power-supply to power-on in a system with multiple power-supplies. |
|             | extremePrimarySoftwareRev      | This value indicates the revision number of the software image on the primary partition.                    |
|             | extremeSecondarySoftwareRev    | This value indicates the revision number of the software image on the secondary partition.                  |
|             | ExtremedImageToUseOnReboot     | This value indicates the partition where the software image is located and to be used on the next boot.     |
|             | extremeSystemID                | This represents the system ID of a switch.                                                                  |
|             | extremeSystemBoardID           | Not supported.                                                                                              |
|             | extremeSystemLeftBoardID       |                                                                                                             |
|             | extremeSystemRightBoardID      |                                                                                                             |
|             | extremeRmonEnable              |                                                                                                             |
|             | extremeBootROMVersion          | Returns information for the current MSM only.                                                               |
|             | extremeDot1dTpFdbTableEnable   | Not supported.                                                                                              |
|             | extremeHealthCheckErrorType    |                                                                                                             |
|             | extremeHealthCheckAction       |                                                                                                             |
|             | extremeHealthCheckMaxRetries   |                                                                                                             |
|             | extremeCpuUtilRisingThreshold  |                                                                                                             |
|             | extremeCpuTaskUtilPair         |                                                                                                             |
|             | extremeCpuAggregateUtilization |                                                                                                             |
|             | extremeCpuUtilRisingThreshold  |                                                                                                             |

| extremePowerSupplyEntPhysicalIndex | extremePowerSupplyEntPhysicalIndex | The entity index for this psu entity in the entityPhysicalTable of the entity MIB.                                                              |
| extremePowerSupplyNumber           | extremePowerSupplyNumber           | Power supply number.                                                                                                                            |
| extremePowerSupplySerialNumber     | extremePowerSupplySerialNumber     | The serial number of the power supply unit.                                                                                                     |
| extremePowerSupplySource           | extremePowerSupplySource           | The power supply unit input source.                                                                                                             |
| extremePowerSupplyTable            | extremePowerSupplyStatus           | Status of the power supply.                                                                                                                     |
|                                    | extremePowerSupplyInputVoltage     | Input voltage of the power supply.                                                                                                              |
|                                    | extremePowerSupplyFan1Speed        | The speed of Fan-1 in the power supply unit.                                                                                                    |
|                                    | extremePowerSupplyFan2Speed        | The speed of Fan-2 in the power supply unit.                                                                                                    |
|                                    | extremePowerSupplyInputPowerUsage  | Input power usage for the given psu slot. The value 0 in this field indicates the power usage is not supported or that there is a read failure. |

| Table/Group                        | Supported Variables                             | Comments                                                                                                                                                                                          |
|------------------------------------|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                    | extremePowerMonSupplyNumOutput                  | Number of output sensors in the power supply unit.                                                                                                                                                |
|                                    | extremePowerSupplyInputPowerUsageUnitMultiplier | The magnitude of watts for the usage value in extremePowerSupplyInputPowerUsage.                                                                                                                  |
|                                    | extremePowerSupplyTotalPowerAvailable           | Total power available.                                                                                                                                                                            |
|                                    | extremePowerSupplyOutputVoltage                 | Output voltage.                                                                                                                                                                                   |
|                                    | extremePowerSupplyOutputCurrent                 | Output current.                                                                                                                                                                                   |
| extremePowerSupplyOutputPowerTable | extremePowerSupplyIndex                         | Power supply unit slot index.                                                                                                                                                                     |
|                                    | extremePowerSupplyOutputSensorIdx               | Power supply Sensor index.                                                                                                                                                                        |
|                                    | extremePowerSupplyOutputVoltage                 | Output voltage per sensor for the current PSU slot number. A zero (0) in this field indicates that the PSU does not support output voltage reading or else there is an output voltage read error. |
|                                    | extremePowerSupplyOutputCurrent                 | Output current per sensor for the current PSU slot number. A zero (0) in this field indicates that the PSU does not support output current reading or else there is an output current read error. |
|                                    | extremePowerSupplyOutputUnitMultiplier          | The magnitude of volts and amps for the usage value in extremePowerSupplyOutputVoltage and extremePowerSupplyOutputCurrent.                                                                       |
| extremePowerSupplyUsageTable       | extremeSlotIndex                                | Slot number in the stack- based system.                                                                                                                                                           |

| Table/Group                    | Supported Variables                      | Comments                                                                                                                                                                              |
|--------------------------------|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                | extremePowerSupplyUsageValue             | Power usage of the particular slot in the stack. The power usage is measured in milliwatts.                                                                                           |
|                                | extremePowerSupplyUnitMultiplier         | The magnitude of watts for the usage value in extremePowerSupplyUsageValue.                                                                                                           |
| extremeSystemPowerUsage        | extremeSystemPowerUsageValue             | The current power usage of the system. In stack mode, this variable tells the total power usage of the entire system.                                                                 |
|                                | extremeSystemPowerUsageUnitMultiplier    | The magnitude of watts for the usage value in extremeSystemPowerUsageValue.                                                                                                           |
| extremeSystemPowerMonitorTable | extremeSystemPowerMonitorIndex1          | Reserved. Can be used for future expansion. Currently set to zero.                                                                                                                    |
|                                | extremeSystemPowerMonitorPollInterval    | Configure how often input power is measured. It is configured in seconds with a default value of 60 seconds. If zero (0) is configured, then the input power measurement is disabled. |
|                                | extremeSystemPowerMonitorReportChanges   | Configure report-changes. Has none or log or trap or log-and-trap, with a default of none.                                                                                            |
|                                | extremeSystemPowerMonitorChangeThreshold | Configure the input power change threshold to initiate report-changes action. By default 2 watts is configured. This field is configured in watts.                                    |

| Table/Group                         | Supported Variables                                                                      | Comments                                                                                                                                                                             |
|-------------------------------------|------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeSystemPowerUsageNotification | sysUpTime, sysDescr, extremeSystemPowerUsageValue, extremeSystemPowerUsageUnitMultiplier | Whenever the power usage is increased/decreased by the configured threshold value, then the power usage trap is generated if the trap is enabled.                                    |
| extremeImageTable                   | extremeImageNumber                                                                       | This table contains image information for all images installed on the device. extremeImageNumber values are not compatible with EW releases. Current image has value 3 instead of 0. |
|                                     | extremeMajorVersion                                                                      | This is the first number within the software image version number which consists of 4 numbers separated by a period.                                                                 |
|                                     | extremeMinorVersion                                                                      | This is the second number within the software image version number.                                                                                                                  |
|                                     | extremeBuildNumber                                                                       | This is the fourth number within the software image version number.                                                                                                                  |
|                                     | extremeTechnologyReleaseNumber                                                           | The technology release version. This value is zero for all but TR releases.                                                                                                          |
|                                     | extremeSustainingReleaseNumber                                                           | The sustaining release number for the ExtremeXOS version.                                                                                                                            |
|                                     | extremeBranchRevisionNumber                                                              | This is the branch from where the software image was built.                                                                                                                          |
|                                     | extremeImageType                                                                         | This is the software image type (for example, ExtremeXOS core, ExtremeXOS module, ExtremeXOS firmware).                                                                              |

| Table/Group                       | Supported Variables       | Comments                                                                                                                                                                                      |
|-----------------------------------|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   | extremeImageDescription   | Description of image contains image version, including major version, submajor version, minor version, build version, build branch, build-master login, and build date.                       |
|                                   | extremePatchVersion       | The ExtremeXOS release patch version. This is the third number within the software image version number.                                                                                      |
| extremeImageFeatureTable          | extremeImageFeatureEntry  | A table containing information about the software features.                                                                                                                                   |
|                                   | extremeImageFeatureNumber | A unique integer identifying the particular software image. This indicates the partition on which the image is loaded:<br>0—Current partition1<br>—Primary partition2—<br>Secondary partition |
|                                   | extremeImageSshCapability | Indicates whether image has SSH capability:<br>1=nossh—shown by default when the SSH license is not enabled.2=ssh—shown when the SSH license is enabled.                                      |
|                                   | extremeImageUAACapability | Not supported.                                                                                                                                                                                |
| extremeCpuMonitorInterval         |                           | This value determines how frequent CPU usage will be monitored.                                                                                                                               |
| extremeCpuMonitorTotalUtilization |                           | This value indicates the total CPU utilization.                                                                                                                                               |
| extremeCpuMonitorTable            |                           | This value indicates the total CPU utilization.                                                                                                                                               |
|                                   | extremeCpuMonitorSlotId   | This value indicates the slot ID where the CPU is being monitored.                                                                                                                            |

| Table/Group                  | Supported Variables                     | Comments                                                                 |
|------------------------------|-----------------------------------------|--------------------------------------------------------------------------|
|                              | extremeCpuMonitorProcessName            | This value indicates the process name for the process being monitored.   |
|                              | extremeCpuMonitorProcessId              | This value indicates the process ID.                                     |
|                              | extremeCpuMonitorProcessState           | This value indicates the current state of the process.                   |
|                              | extremeCpuMonitorUtilization5secs       | This value indicates the CPU utilization in the past 5 seconds.          |
|                              | extremeCpuMonitorUtilization10secs      | This value indicates the CPU utilization in the past 10 seconds.         |
|                              | extremeCpuMonitorUtilization30secs      | This value indicates the CPU utilization in the past 30 seconds.         |
|                              | extremeCpuMonitorUtilization1min        | This value indicates the CPU utilization in the past 1 minute.           |
|                              | extremeCpuMonitorUtilization5mins       | This value indicates the CPU utilization in the past 5 minutes.          |
|                              | extremeCpuMonitorUtilization30mins      | This value indicates the CPU utilization in the past 30 minutes.         |
|                              | extremeCpuMonitorUtilization1hour       | This value indicates the CPU utilization in the past 1 hour.             |
|                              | extremeCpuMonitorUserTime               | This value indicates the CPU usage under User Mode.                      |
|                              | extremeCpuMonitorSystemTime             | This value indicates the CPU usage under system mode.                    |
| extremeCpuMonitorSystemTable |                                         | This table contains CPU monitoring information for all system processes. |
|                              | extremeCpuMonitorSystemSlotId           | This value indicates the slot ID where the CPU is being monitored.       |
|                              | extremeCpuMonitorSystemUtilization5secs | This value indicates the CPU utilization in the past 5 seconds.          |

| Table/Group                      | Supported Variables                      | Comments                                                                                    |
|----------------------------------|------------------------------------------|---------------------------------------------------------------------------------------------|
|                                  | extremeCpuMonitorSystemUtilization10secs | This value indicates the CPU utilization in the past 10 seconds.                            |
|                                  | extremeCpuMonitorSystemUtilization30secs | This value indicates the CPU utilization in the past 30 seconds.                            |
|                                  | extremeCpuMonitorSystemUtilization1min   | This value indicates the CPU utilization in the past 1 minute.                              |
|                                  | extremeCpuMonitorSystemUtilization5mins  | This value indicates the CPU utilization in the past 5 minutes.                             |
|                                  | extremeCpuMonitorSystemUtilization30mins | This value indicates the CPU utilization in the past 30 minutes.                            |
|                                  | extremeCpuMonitorSystemUtilization1hour  | This value indicates the CPU utilization in the past 1 hour.                                |
|                                  | extremeCpuMonitorSystemMax Utilization   | This value indicates the maximum CPU utilization so far.                                    |
| extremeMemoryMonitorSystem Table |                                          | This table contains system-level memory monitor information.                                |
|                                  | extremeMemoryMonitorSystemSlotId         | This value indicates the slot ID where the memory is being monitored.                       |
|                                  | extremeMemoryMonitorSystemTotal          | This value indicates the total memory installed on the switch.                              |
|                                  | extremeMemoryMonitorSystemFree           | This value indicates the amount of memory that is free.                                     |
|                                  | extremeMemoryMonitorSystemUsage          | This value indicates the amount of memory consumed for kernel code.                         |
|                                  | extremeMemoryMonitorUserUsage            | This value indicates the amount of memory consumed by user processes as well as the kernel. |
| extremeMemoryMonitorTable        |                                          | This table contains memory monitor information for each user process.                       |

| Table/Group | Supported Variables                     | Comments                                                                       |
|-------------|-----------------------------------------|--------------------------------------------------------------------------------|
|             | extremeMemoryMonitorSlotId              | This value indicates the slot ID where the memory is being monitored.          |
|             | extremeMemoryMonitorProcessName         | This value indicates the name of the process being monitored.                  |
|             | extremeMemoryMonitorUsage               | This value indicates the amount of memory being consumed by this user process. |
|             | extremeMemoryMonitorLimit               | Not supported.                                                                 |
|             | extremeMemoryMonitorZone                |                                                                                |
|             | extremeMemoryMonitorGreenZoneCount      |                                                                                |
|             | extremeMemoryMonitorYellowZoneCount     |                                                                                |
|             | extremeMemoryMonitorOrangeZoneCount     |                                                                                |
|             | extremeMemoryMonitorRedZoneCount        |                                                                                |
|             | extremeMemoryMonitorGreenZoneThreshold  |                                                                                |
|             | extremeMemoryMonitorYellowZoneThreshold |                                                                                |
|             | extremeMemoryMonitorOrangeZoneThreshold |                                                                                |
|             | extremeMemoryMonitorRedZoneThreshold    |                                                                                |

## EXTREME-TRAP-MIB

This MIB defines the following Extreme-specific SNMPv1 traps generated by Extreme Networks devices.

| Trap             | Comments                                                                                                                                                                                                                               |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeOverheat  | The on-board temperature sensor has reported an overheat condition. The system shuts down until the unit has sufficiently cooled such that operation can begin again. A cold start trap is issued when the unit has come back on line. |
| extremeFanfailed | One or more of the cooling fans inside the device has failed. A fanOK trap will be sent once the fan has attained normal operation.                                                                                                    |

| Trap                       | Comments                                                                                                                                                |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeFanOK               | A fan has transitioned out of a failure state and is now operating correctly.                                                                           |
| extremeInvalidLoginAttempt | A user attempted to log into the console or by telnet but was refused access due to an incorrect username or password.                                  |
| extremePowerSupplyGood     | One or more previously bad sources of power to this agent has come back to life without causing an agent restart.                                       |
| extremePowerSupplyFail     | One or more sources of power to this agent has failed. Presumably a redundant power-supply has taken over.                                              |
| extremeEdpNeighborAdded    | This node discovers a new neighbor through <i>EDP</i> .                                                                                                 |
| extremeEdpNeighborRemoved  | No EDP updates are received from this neighbor within the configured timeout period and this neighbor entry is aged out by the device.                  |
| extremeModuleStateChanged  | Signifies that the value of the extremeSlotModuleState for the specified extremeSlotNumber has changed. Traps are reported only for significant states. |

## EXTREME-V2TRAP-MIB

This MIB defines the following Extreme-specific SNMPv2c traps generated by Extreme Networks devices.

| Trap                               | Comments                                                                                                                                                                                                 |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeHealthCheckFailed           | CPU HealthCheck has failed.                                                                                                                                                                              |
| extremeBgpM2PrefixReachedThreshold | This notification is generated when the number of prefixes received over this peer session reaches the threshold limit.                                                                                  |
| extremeBgpM2PrefixMaxExceeded      | This notification is generated when the number of prefixes received over this peer session reaches the maximum configured limit.                                                                         |
| extremeEapsStateChange             | Send on master/transit nodes.                                                                                                                                                                            |
| extremeEapsFailTimerExpFlagSet     | This notification is generated when the <i>EAPS</i> domain fail timer expires for the first time, while its state is not in Fail state.                                                                  |
| extremeEapsFailTimerExpFlagClear   | This notification is generated when the EAPS domain fail timer expired flag is cleared.                                                                                                                  |
| extremeEapsLinkDownRingComplete    | If a transit is in link-down state, and it receives a Health-Check-Pdu from the master indicating the ring is complete, there is some problem with the transit switch that has issued this trap message. |
| extremeEapsLastStatusChangeEvent   | Sent on master/transit nodes. Provides a general indication of a status change using a 10 second timer.                                                                                                  |

| Trap                               | Comments                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeEapsPortStatusChange        | Sent on master/transit nodes.                                                                                                                                                                                                                                                                                                                                                        |
| extremeEapsConfigChange            | Sent on master/transit nodes. This trap has a granularity of 30 seconds.                                                                                                                                                                                                                                                                                                             |
| extremeEapsSharedPortStateChange   | Sent on controller/partner nodes.                                                                                                                                                                                                                                                                                                                                                    |
| extremeEapsRootBlockerStatusChange |                                                                                                                                                                                                                                                                                                                                                                                      |
| extremeOverheatNormal              | An overheat (return to) normal notification indicates that the on-board temperature sensor has reported a temperature that has returned to within the normal operating range from having been in an overheat (or overcold) condition. The temperature of the unit has sufficiently cooled to be below the maximum (or warmed to be above the minimum) of the normal operating range. |

## EXTREME-VLAN-MIB

The following tables, groups, and variables are supported in this MIB.

### Note

SNMP Set operations are not allowed for "Mgmt" and "Default" VLANs.

| Table/Group         | Supported Variables              | Comments                                                                                                                                                                                                                                                      |
|---------------------|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeVirtualGroup | extremeNextAvailableVirtualIndex |                                                                                                                                                                                                                                                               |
| extremeVlanIfTable  | extremeVlanIfIndex               | While creating a new row in the extremeVlanIfTable, the value of the object extremeVlanIfDescr must be specified.<br>For all tables in this MIB that contain objects with RowStatus semantics, the only values supported are: {active, createAndGo, destroy}. |
|                     | extremeVlanIfDescr               | This is a description of the VLAN interface.                                                                                                                                                                                                                  |
|                     | extremeVlanIfType                | The VLAN interface type.                                                                                                                                                                                                                                      |
|                     | extremeVlanIfGlobalIdentifier    | Not supported.                                                                                                                                                                                                                                                |

| Table/Group                         | Supported Variables               | Comments                                                                                                                                                                                                                                                                                                                |
|-------------------------------------|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                     | extremeVlanIfStatus               | The status column for this VLAN interface.<br>This object can be set to:<br>active (1); createAndGo (4);<br>createAndWait (5); destroy (6).<br>The following values may be<br>read: active (1); notInService (2);<br>notReady (3).                                                                                      |
|                                     | extremeVlanIfIgnoreStpF<br>lag    | Not supported.                                                                                                                                                                                                                                                                                                          |
|                                     | extremeVlanIfIgnoreBpd<br>uFlag   | Not supported.                                                                                                                                                                                                                                                                                                          |
|                                     | extremeVlanIfLoopback<br>ModeFlag | Setting this object to true<br>causes loopback mode to be<br>enabled on this VLAN.                                                                                                                                                                                                                                      |
|                                     | extremeVlanIfVlanId               | The VLAN ID of this VLAN.                                                                                                                                                                                                                                                                                               |

| extremeVMFTPServerTable | extremeVMFTPServerEntry   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                         | extremeVMFTPServerType    | The type of the FTP server. The backup server is contacted if the primary fails to respond.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                         | extremeVMFTPAddrType      | The IP type of IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                         | extremeVMFTPServer        | The IP address of the FTP server used for transferring various management files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                         | extremeVMFTPSynchInterval | The time in minutes between automatic synchronization attempts. A value of 0 indicates that automatic synchronizations are not performed. Note that each switch does not perform a synchronization at exactly the time configured, but varies the synchronization interval between 3/4 and 5/4 of the configured interval. This avoids the situation where all switches in a network attempt a synchronization at exactly the same moment. Automatic synchronization is disabled by default, and requests to enable them are rejected until the FTP server information (IPv4 or IPv6 address, username, and password) is configured. |
|                         | extremeVMFTPRowStatus     | There can only be two entries in this table, one each for primary and secondary FTP servers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Table/Group      | Supported Variables      | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                  | extremeVMFTPPathName     | The FTP server directory name for the policies to be synchronized. A value of '/pub' is used by default.                                                                                                                                                                                                                                                                                                                                           |
|                  | extremeVMFTPUsername     | A valid username on the FTP server.                                                                                                                                                                                                                                                                                                                                                                                                                |
|                  | extremeVMFTPPassword     | The password associated with the FTP user. This object returns a zero length string when queried.                                                                                                                                                                                                                                                                                                                                                  |
| extremeVMGeneral | extremeVMFTPPolicyDir    | The server directory name for the policies to be synchronized. A value of '/' is used by default.                                                                                                                                                                                                                                                                                                                                                  |
|                  | extremeVMLastSynch       | The timestamp of the most recent synchronization attempt.                                                                                                                                                                                                                                                                                                                                                                                          |
|                  | extremeVMLastSynchStatus | The result of the most recent synchronization attempt:success (1)—indicates that the synchronization completed successfullyaccessDenied (2)—The username and password were not accepted by the serverserverTimeout (3)—Could not establish a file transfer session with the configured serverserverNotConfigured (4)—The server configuration is not complete.                                                                                     |
|                  | extremeVMSynchAdminState | Triggers a synchronization cycle on demand. A synchronization automatically downloads new or updated policies as well as delete policies to match those on the server:<br>idle (1) is returned whenever this object is read.synchronizeNow (2) triggers an immediate synchronization, and is reflected in extremeVMSynchOperState. Attempts to set this variable to synchronizeNow (2) are rejected if a synchronization is currently in progress. |
|                  | extremeVMSynchOperState  | Indicates if a synchronization is in progress, either on-demand or automatic.                                                                                                                                                                                                                                                                                                                                                                      |

| Table/Group              | Supported Variables                  | Comments                                                                                                                                                                                                                       |
|--------------------------|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | extremeVMTrackingEnabled             | The virtual machine (VM) tracking feature is disabled by default and can be enabled using this object.                                                                                                                         |
|                          | extremeVMPortConfigTable             | Configures the VM features on each port.                                                                                                                                                                                       |
| extremeVMPortConfigEntry |                                      | An entry in the table for VM features on each port.                                                                                                                                                                            |
|                          | extremeVMPortConfigIfIndex           | The value of ifIndex of a physical port capable of supporting the VM tracking features.                                                                                                                                        |
|                          | extremeVMPortConfigVMTrackingEnabled | Enables the VM tracking feature on a port. The VM tracking feature is disabled by default.                                                                                                                                     |
| extremeVMVPPTable        |                                      | This table contains port policies contained within this switch. Port policies come in two variants: network and local. Network policies are downloaded from the FTP server; local policies reside only within a single switch. |
| extremeVMVPPEntry        |                                      | An entry in the table of VM policy information of this device. This table is populated with two sets of policies, those downloaded from the policy server and those defined locally on this switch.                            |
|                          | extremeVMVPPType                     | The type of the port policy. Network port policies are obtained from a central policy store. Local policies are specific to this particular switch.                                                                            |
|                          | extremeVMVPPName                     | The name of the port VPP. VPP names must be alpha-numeric and must start with an alpha character.                                                                                                                              |
|                          | extremeVMVPPControl                  | Performs the requested operation on this policy. synchronizeNow (1) downloads a copy of the policy from the FTP server. (Network policies only). This object returns noOperation (2) if read.                                  |
|                          | extremeVMVPPRowStatus                | Only local VPPs can be created or deleted.                                                                                                                                                                                     |

| Table/Group           | Supported Variables            | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeVMMappingTable |                                | This table contains the mapping of port policies to VM MAC addresses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                       | extremeVMMappingEntry          | An entry in the table of VM information of this device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                       | extremeVMMappingType           | The type of mapping for this entry. A local mapping exists only on this specific switch. A network mapping is one obtained through a download of a mapping file.                                                                                                                                                                                                                                                                                                                                                                                       |
|                       | extremeVMMappingMAC            | The MAC address associated with the VM. Note that a VM can have multiple MAC addresses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                       | extremeVMMappingIngressVPPName | The ingress policy associated with the VM/MAC address. Note that this may refer to a policy without a corresponding entry in the extremeVMVPPTable if a network policy mapping refers to a non-existent policy. This indicates an error in the policy mapping file that is consulted if network authentication fails.<br>When creating an entry in this table, this name must refer to an existing, valid, local policy. The creation of a mapping to a network policy is not permitted. Those mappings must be created at the central policy server.  |
|                       | extremeVMMappingEgressVPPName  | The egress policy associated with the VM/MAC address. Note that this might refer to a policy without a corresponding entry in the extremeVMVPPTable if a network policy mapping refers to a non-existent policy. This indicates an error in the policy mapping file that is consulted if network authentication fails.<br>When creating an entry in this table, this name must refer to an existing, valid, local policy. The creation of a mapping to a network policy is not permitted. Those mappings must be created at the central policy server. |

| Table/Group              | Supported Variables           | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | extremeVMMappingStatus        | Indicates the virtual port profile mapping status:<br>vppValid (1)—A VPP mapped to this VM MAC address does not have any policies associated with it (or) all the policies associated with this VPP can be applied (policy validation is success). Policy validation will happen only when this VM MAC is detected.vppMissing (2)—This value is applicable only for network VM if the specified VPP name was missing.vppInvalid (3)—One of the policies mapped to VPP cannot be applied (policy validation failed) because the policy file contains one or more errors that prevent it from being applied.vppNotMapped (4)—The VM does not have any VPP mapped. |
|                          | extremeVMMappingRowStatus     | Only local policies can be created or deleted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                          |                               | The virtual port profile associated with the VM MAC address. When creating an entry in this table, this name must refer to an existing, valid, local profile. The creation of a mapping to a network profile is not permitted. Those mappings must be created at the central policy server.                                                                                                                                                                                                                                                                                                                                                                     |
| extremeVMVPP2PolicyTable |                               | This table contains the mapping of a VPP to individual policies.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| extremeVMVPP2PolicyEntry |                               | An individual mapping of VPP to policy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                          | extremeVMVPP2PolicyVPPName    | The name of the VPP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                          | extremeVMVPP2PolicyOrder      | The order in which this policy is executed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                          | extremeVMVPP2PolicyRowStatus  | The row status for this mapping.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Table/Group            | Supported Variables             | Comments                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extremeVMDetected      | extremeVMDetectedNumber         | The number of VMs detected on this switch.                                                                                                                                                                                                                                                                                                                                                              |
| extremeVMDetectedTable |                                 | This table contains the currently detected VMs on this switch.                                                                                                                                                                                                                                                                                                                                          |
| extremeVMDetectedEntry |                                 | An entry in the table of VM information of this device.                                                                                                                                                                                                                                                                                                                                                 |
|                        | extremeVMDetectedMAC            | The MAC address associated with the VM. Note that a VM can have multiple MAC addresses.                                                                                                                                                                                                                                                                                                                 |
|                        | extremeVMDetectedVMName         | The name of the VM. Note that a VM authenticated locally might not have a name.                                                                                                                                                                                                                                                                                                                         |
|                        | extremeVMDetectedIngressVPPName | The name of the policy applied (or attempted to apply) to this VM.                                                                                                                                                                                                                                                                                                                                      |
|                        | extremeVMDetectedEgressVPPName  | The name of the policy applied (or attempted to apply) to this VM.                                                                                                                                                                                                                                                                                                                                      |
|                        | extremeVMDetectedIfIndex        | The value of ifIndex on which this VM was detected.                                                                                                                                                                                                                                                                                                                                                     |
|                        | extremeVMDetectedAdminStatus    | The administrative status of the VM authentication. Setting this variable to authenticating (1) will force the re-authentication of the VM. This variable always returns idle (2) when read.                                                                                                                                                                                                            |
|                        | extremeVMDetectedOperStatus     | The authentication status of the VM:<br>authenticating (1)—an authentication is currently in progress<br>authenticatedNetwork (2)—the VM has been authenticated by a network source<br>authenticatedLocally (3)—the VM has been authenticated by the local database<br>denied (4)—the VM was explicitly denied<br>entrynotAuthenticated (5)—the authentication process timed out or was never attempted |

| Table/Group              | Supported Variables             | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | extremeVMDetectedResultIngress  | Indicates the result of a VM entry into the network. Only the two values below will be returned at any point of time:<br>policyApplied (1)—All the ingress policies in the VPP were successfully applied to the port.<br>policyNotApplied (2) - One of the ingress policies in the VPP was not applied to the port. If this value is returned then refer to the extremeVMDetectedIngErrPolicies object for list of failed ingress policies. |
|                          | extremeVMDetectedResultEgress   | Indicates the result of a VM entry into the network. Only the two values below will be returned at any point of time:<br>policyApplied (1) - All the egress policies in the VPP were successfully applied to the port.<br>policyNotApplied (2) - One of the egress policies in the VPP was not applied to the port. If this value is returned then refer to the extremeVMDetectedEgrErrPolicies object for list of failed egress policies.  |
|                          | extremeVMDetectedIngErrPolicies | Displays the list of failed ingress policies.                                                                                                                                                                                                                                                                                                                                                                                               |
|                          | extremeVMDetectedEgrErrPolicies | Displays the list of failed egress policies.                                                                                                                                                                                                                                                                                                                                                                                                |
|                          | extremeVMDetectedVPPName        | The name of the VPP applied (or attempted to apply) to this VM.                                                                                                                                                                                                                                                                                                                                                                             |
|                          | extremeVMDetectedVPPResult      | Indicates the result of a VPP associated with a VM MAC:<br>vppMapped (1)—indicates that the named VPP was mapped.<br>vppNotMapped (2)—indicates that the no VPP was mapped.<br>vppInvalid (3)—indicates that the VPP mapped was invalid.<br>vppMissing (4)—indicates that the VPP mapped was missing                                                                                                                                        |
| extremeVMVPPDetail Table |                                 | This table contains the mapping of a VPP to individual policies.                                                                                                                                                                                                                                                                                                                                                                            |

| Table/Group             | Supported Variables          | Comments                                              |
|-------------------------|------------------------------|-------------------------------------------------------|
| extremeVMVPPDetailEntry |                              | A set of mappings from a VPP to one or more policies. |
|                         | extremeVMVPPDetailVPPName    | The name of the VPP.                                  |
|                         | extremeVMVPPDetailDirection  | The direction in which the policy is applied.         |
|                         | extremeVMVPPDetailType       | The type of policy.                                   |
|                         | extremeVMVPPDetailOrder      | The order in which this policy is executed.           |
|                         | extremeVMVPPDetailPolicyName | The name of the local policy                          |
|                         | extremeVMVPPDetailRowStatus  | The row status for this mapping.                      |
| extremeVMVPPSyncType    |                              | Indicates the type of policy                          |

The following traps can be generated.

| Trap                        | Notification Objects    | Comments                                                                                                   |
|-----------------------------|-------------------------|------------------------------------------------------------------------------------------------------------|
| extremeVMNotificationPrefix | extremeVMVPPSyncFailed  | A synchronization attempt failed.                                                                          |
|                             | extremeVMVPPInvalid     | A VPP definition is invalid, indicating it cannot be applied to a port.                                    |
|                             | extremeVMMapped         | This notification is generated whenever a MAC address is manually mapped to a local policy.                |
|                             | extremeVMUnMapped       | This notification is generated whenever a MAC address is manually unmapped to a local policy.              |
|                             | extremeVMDetectResult   | This notification is generated after a VM is detected on a port and reflects the result of that operation. |
|                             | extremeVMUnDetectResult | This notification is generated after a VM is undetected (removed) from a port.                             |

## MIB Support Details

The following sections describe the MIB support provided by the ExtremeXOS *SNMP* agent residing on Extreme Networks devices running ExtremeXOS:

Where applicable, these sections note how the implementation differs from the standards, or from the private MIBs.

**Note**

Only entries for the default VR are supported.

ExtremeXOS software supports only the following “Row status” in the MIBs:

- Create and Go
- Active
- Destroy

The standard MIBs are described in the following sections.

## ETMONSERVICEABILITYTRAP

The following tables, groups, and variables are supported in this MIB.

| Table/Group                   | Supported Variables | Comments                                                                                                                                                                                                                 |
|-------------------------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| etmonServiceabilityTrapPrefix | noMoreMemory        | Status = current.<br>"Memory full, No more memory. System memory is depleted."                                                                                                                                           |
|                               | asyncQGrowing       | Status = current.<br>"async queue is growing. Logged messages in switch will provide more information related to growing async queue. MIB have limitation to provide all the information related to growing sync queue." |

## IEEE 802.1AB (LLDP-MIB)

All tables and variables of this MIB are supported.

## IEEE 802.1AB (LLDP-EXT-DOT1-MIB)

All tables and variables of this MIB are supported.

## IEEE 802.1AB (LLDP-EXT-DOT3-MIB)

All tables and variables of this MIB are supported.

## IEEE 802.1AG (CFM MIB)

This MIB contains objects for the 802.1ag protocol.

The following tables, groups, and variables are supported in this MIB.

| Table/Group               | Supported Variables        | Comments                                                                                                                                                                                                           |
|---------------------------|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dotlagCfmMdTable          | dotlagCfmMdIndex           | The index to the Maintenance Domain (MD) table.                                                                                                                                                                    |
|                           | dotlagCfmMdFormat          | Supported as read only. The type (and thereby format) of the MD name.                                                                                                                                              |
|                           | dotlagCfmMdName            | Supported as read only. The MD name.                                                                                                                                                                               |
|                           | dotlagCfmMdMdLevel         | Supported as read only. The MD Level.                                                                                                                                                                              |
|                           | dotlagCfmMdMhfCreation     | Enumerated value indicating whether the management entity can create MHFs (MIP Half Function) for this MD. Supported as read only. Configuration in CLI is not supported. The defMHFdefault (2) value is returned. |
|                           | dotlagCfmMdMhfIdPermission | Supported as read only. Configuration in CLI is not supported. The sendIdChassisManage (4) value is returned.                                                                                                      |
|                           | dotlagCfmMdMaNextIndex     | Value to be used as the index of the Maintenance Association (MA) table entries.                                                                                                                                   |
|                           | dotlagCfmMdRowStatus       | The status of the row. The writable columns in a row cannot be changed if the row is active. All columns must have a valid value before a row can be activated.                                                    |
| dotlagCfmMdTableNextIndex | dotlagCfmMdTableNextIndex  | An unused value for dotlagCfmMdIndex that is used as the MD index for the next newly created domain.                                                                                                               |
| dotlagCfmMaNetTable       | dotlagCfmMdIndex           | MD index.                                                                                                                                                                                                          |
|                           | dotlagCfmMaIndex           | Index of the MA table. dotlagCfmMdMaNextIndex needs to be inspected to find an available index for row-creation.                                                                                                   |

| Table/Group       | Supported Variables       | Comments                                                                                                                                                                                             |
|-------------------|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | dotlagCfmMaNetFormat      | Supported as read only. The type of the MA name.                                                                                                                                                     |
|                   | dotlagCfmMaNetName        | Supported as read only. MA name.                                                                                                                                                                     |
|                   | dotlagCfmMaNetCcmInterval | Supported as read only. Transmission interval between CCMs to be used by all MEPs in the MA.                                                                                                         |
|                   | dotlagCfmMaNetRowStatus   | The status of the row. The writable columns in a row cannot be changed if the row is active. All columns must have a valid value before a row can be activated.                                      |
| dotlagCfmMepTable | dotlagCfmMdIndex          | MD Index.                                                                                                                                                                                            |
|                   | dotlagCfmMaIndex          | MA Index.                                                                                                                                                                                            |
|                   | dotlagCfmMepIdentifier    | A small integer, unique over a given MA identifying a specific MA end point.                                                                                                                         |
|                   | dotlagCfmMepIfIndex       | Supported as read only. Interface index of the interface bridge port.                                                                                                                                |
|                   | dotlagCfmMepDirection     | Supported as read only. The direction in which the MEP faces on the bridge port.                                                                                                                     |
|                   | dotlagCfmMepPrimaryVid    | Supported as read only. VID of the MEP.                                                                                                                                                              |
|                   | dotlagCfmMepActive        | Supported as read only. Administrative state of the MEP.                                                                                                                                             |
|                   | dotlagCfmMepFngState      | Current state of the MEP Fault Notification Generator State Machine. Can have any one of the following values:fngReset (1)fngDefect (2)fngReportDefect (3)fngDefectReported (4)fngDefectClearing (5) |
|                   | dotlagCfmMepCciEnabled    | Supported as read only. If set to true, the MEP will generate CCM.                                                                                                                                   |

| Table/Group | Supported Variables         | Comments                                                                                                                                                                                                |
|-------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | dotlagCfmMepCcmLtmPriority  | Supported as read only. The priority value for CCMs and LTMs transmitted by the MEP. Configuration in CLI is not supported. Default value 0 is returned.                                                |
|             | dotlagCfmMepMacAddress      | MAC address of the MEP. In Extreme Networks switches, the MAC is returned.                                                                                                                              |
|             | dotlagCfmMepLowPrDef        | Supported as read only. An integer value specifying the lowest priority defect that is allowed to generate a Fault Alarm. Configuration in CLI is not supported. Default VLAN macRemErrXon is returned. |
|             | dotlagCfmMepFngAlarmTime    | Supported as read only. The time that defects must be present before a Fault Alarm is issued. Configuration in CLI is not supported. Default value 2.5 seconds is returned.                             |
|             | dotlagCfmMepFngResetTime    | Supported as read only. The time that defects must be absent before resetting a Fault Alarm. Configuration in CLI is not supported. Default value 10 seconds is returned.                               |
|             | dotlagCfmMepHighestPrDefect | The highest priority defect that has been present. Possible values are:none (0)defRDICCM (1)defMACstatus (2)defRemoteCCM (3)defErrorCCM (4)defXconCCM (5)                                               |
|             | dotlagCfmMepDefects         | Error condition to be sent. The conditions can be any one of the following:bDefRDICCM (0)bDefMACstatus (1)bDefRemoteCCM (2)bDefErrorCCM (3)bDefXconCCM (4)                                              |

| Table/Group | Supported Variables                   | Comments                                                                                                                           |
|-------------|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
|             | dotlagCfmMepErrorCcmLastFailure       | The last-received CCM that triggered a DefErrorCCM fault.                                                                          |
|             | dotlagCfmMepXconCcmLastFailure        | The last-received CCM that triggered a DefXconCCM fault.                                                                           |
|             | dotlagCfmMepCcmSequenceErrors         | The total number of out-of-sequence CCMs received from all remote MEPs.                                                            |
|             | dotlagCfmMepCciSentCcms               | The total number of Continuity Check messages transmitted.                                                                         |
|             | dotlagCfmMepNextLbmTransId            | Next sequence number/transaction identifier to be sent in a Loopback message.                                                      |
|             | dotlagCfmMepLbrIn                     | The total number of valid, in-order Loopback Replies received.                                                                     |
|             | dotlagCfmMepLbrInOutOfOrder           | The total number of valid, out-of-order Loopback Replies received.                                                                 |
|             | dotlagCfmMepLbrBadMsdu                | The total number of LBRs received whose mac_service_data_unit did not match (except for the OpCode) that of the corresponding LBM. |
|             | dotlagCfmMepLtmNextSeqNumber          | Next transaction identifier/sequence number to be sent in a Linktrace message.                                                     |
|             | dotlagCfmMepUnexpLtrIn                | The total number of unexpected LTRs received.                                                                                      |
|             | dotlagCfmMepLbrOut                    | The total number of Loopback Replies transmitted.                                                                                  |
|             | dotlagCfmMepTransmitLbmStatus         | Supported as read only. A Boolean flag set to true by the bridge port to indicate that another LBM may be transmitted.             |
|             | dotlagCfmMepTransmitLbmDestMacAddress | Supported as read only. The target MAC address field to be transmitted.                                                            |

| Table/Group | Supported Variables                     | Comments                                                                                                                                                         |
|-------------|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | dotlagCfmMepTransmitLbmDestMepId        | Supported as read only. To transmit the LBM, destMEPID need not be given.                                                                                        |
|             | dotlagCfmMepTransmitLbmDestinationMepId | Supported as read only. This always returns FALSE.                                                                                                               |
|             | dotlagCfmMepTransmitLbmMessages         | Supported as read only. The number of Loopback messages to be transmitted.                                                                                       |
|             | dotlagCfmMepTransmitLbmDataTlv          | Supported as read only. An arbitrary amount of data to be included in the Data TLV if the Data TLV is selected to be sent. This returns 0.                       |
|             | dotlagCfmMepTransmitLbmVlanPriority     | Priority. A three-bit value to be used in the VLAN tag, if present in the transmitted frame. Configuration in CLI is not supported. Default value 0 is returned. |
|             | dotlagCfmMepTransmitLbmVlanDropEnable   | Not supported. Returns FALSE.                                                                                                                                    |
|             | dotlagCfmMepTransmitLbmResultOK         | Indicates the result of the operation linked with MEP active state.                                                                                              |
|             | dotlagCfmMepTransmitLbmSequenceNumber   | The Loopback Transaction Identifier of the first LBM (to be) sent. The value returned is undefined if dotlagCfmMepTransmitLbmResultOK is false.                  |
|             | dotlagCfmMepTransmitLtmStatus           | Supported as read only. A Boolean flag set to true by the bridge port to indicate that another LTM may be transmitted.                                           |
|             | dotlagCfmMepTransmitLtmFlags            | Supported as read only. The flags field for LTMs transmitted by the MEP. Currently, useFDBOnly (0) is supported.                                                 |
|             | dotlagCfmMepTransmitLtmTargetMacAddress | Supported as read only. The target MAC address field to be transmitted.                                                                                          |

| Table/Group         | Supported Variables                     | Comments                                                                                                                                                        |
|---------------------|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | dotlagCfmMepTransmitLtmTargetMepId      | Not supported. To transmit the LTM destMEPID need not be given. Value 0 is returned.                                                                            |
|                     | dotlagCfmMepTransmitLtmTargetIsMepId    | Not supported. This always returns FALSE.                                                                                                                       |
|                     | dotlagCfmMepTransmitLtmTtl              | Supported as read only. The LTM TTL field.                                                                                                                      |
|                     | dotlagCfmMepTransmitLtmResult           | Supported as read only. Indicates the result of the operation. Linked with MEP active state.                                                                    |
|                     | dotlagCfmMepTransmitLtmSeqNumber        | The LTM transaction identifier.                                                                                                                                 |
|                     | dotlagCfmMepTransmitLtmEgressIdentifier | Supported as read only. Identifies the MEP Linktrace Initiator that is originating or the Linktrace Responder that is forwarding this LTM.                      |
|                     | dotlagCfmMepRowStatus                   | The status of the row. The writable columns in a row cannot be changed if the row is active. All columns must have a valid value before a row can be activated. |
| dotlagCfmMepDbTable | dotlagCfmMdIndex                        | MD Index.                                                                                                                                                       |
|                     | dotlagCfmMaIndex                        | MA Index.                                                                                                                                                       |
|                     | dotlagCfmMepIdentifier                  | MA end point identifier.                                                                                                                                        |
|                     | dotlagCfmMepDbRMepIdentifier            | Maintenance association end point identifier of a remote MEP whose information from the MEP database is to be returned.                                         |
|                     | dotlagCfmMepDbRMepState                 | The operational state of the remote MEP IFF state machines. The state can be any one of the following: rMepIdle (1) rMepStart (2) rMepFailed (3) rMepOk (4)     |

| Table/Group       | Supported Variables              | Comments                                                                                                                                                                                                                                                            |
|-------------------|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | dotlagCfmMepDbRMepFailedOkTime   | The time (SysUpTime) at which the IFF remote MEP state machine last entered either the RMEP_FAILED or RMEP_OK state.                                                                                                                                                |
|                   | dotlagCfmMepDbMacAddress         | The MAC address of the remote MEP.                                                                                                                                                                                                                                  |
|                   | dotlagCfmMepDbRdi                | State of the RDI bit in the last received CCM.                                                                                                                                                                                                                      |
|                   | dotlagCfmMepDbPortStatusTlv      | An enumerated value of the Port status TLV received in the last CCM from the remote MEP or the default value. The value is one of the following: psNoPortStateTlv (0) psBlocked (1) psUp (2)                                                                        |
|                   | dotlagCfmMepDbInterfaceStatusTlv | An enumerated value of the Interface status TLV received in the last CCM from the remote MEP. The value can be one of the following: isNoInterfaceStatusTlv (0) isUp (1) isDown (2) isTesting (3) isUnknown (4) isDormant (5) isNotPresent (6) isLowerLayerDown (7) |
|                   | dotlagCfmMepDbChassisIdSubtype   | networkAddress (5) is returned if senderIDTLV is received.                                                                                                                                                                                                          |
|                   | dotlagCfmMepDbChassisId          | The first octet contains the IANA Address Family Numbers enumeration value for the specific address type, and octets 2 through N contain the network address value in network byte order.                                                                           |
|                   | dotlagCfmMepDbManAddressDomain   | Not supported. Value zero is returned.                                                                                                                                                                                                                              |
|                   | dotlagCfmMepDbManAddress         | Not supported. Value zero is returned.                                                                                                                                                                                                                              |
| dotlagCfmLtrTable | dotlagCfmMdIndex                 | MD Index.                                                                                                                                                                                                                                                           |

|                   | dotlagCfmMepIdentifier           | MA end point identifier.                                                                                                                                                                                                                                            |

| Table/Group | Supported Variables              | Comments                                                                                                                                                                                  |
|-------------|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | dotlagCfmLtrSeqNumber            | Transaction identifier/sequence number returned by a previous transmit linktrace message command.                                                                                         |
|             | dotlagCfmLtrReceiveOrder         | An index to distinguish among multiple LTRs with the same LTR Transaction Identifier field value.                                                                                         |
|             | dotlagCfmLtrTtl                  | TTL field value for a returned LTR.                                                                                                                                                       |
|             | dotlagCfmLtrForwarded            | Indicates if a LTM was forwarded by the responding MP.                                                                                                                                    |
|             | dotlagCfmLtrTerminalMep          | Not supported. Value FALSE is returned.                                                                                                                                                   |
|             | dotlagCfmLtrLastEgressIdentifier | An octet field holding the Last Egress Identifier returned in the LTR Egress Identifier TLV of the LTR.                                                                                   |
|             | dotlagCfmLtrNextEgressIdentifier | An octet field holding the Next Egress Identifier returned in the LTR Egress Identifier TLV of the LTR.                                                                                   |
|             | dotlagCfmLtrRelay                | Value returned in the Relay Action field.                                                                                                                                                 |
|             | dotlagCfmLtrChassisIdSubtype     | networkAddress (5) is returned if senderIDTLV is received.                                                                                                                                |
|             | dotlagCfmLtrChassisId            | The first octet contains the IANA Address Family Numbers enumeration value for the specific address type, and octets 2 through N contain the network address value in network byte order. |
|             | dotlagCfmLtrManAddressDomain     | Not supported. Value zero is returned.                                                                                                                                                    |
|             | dotlagCfmLtrManAddress           | Not supported. Value zero is returned.                                                                                                                                                    |
|             | dotlagCfmLtrIngress              | The value returned in the Ingress Action Field of the LTM.                                                                                                                                |

| Table/Group         | Supported Variables                 | Comments                                                                                                                                                                                                  |
|---------------------|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | dotlagCfmLtrIngressMac              | MAC address returned in the ingress MAC address field.                                                                                                                                                    |
|                     | dotlagCfmLtrIngressPortIdSubtype    | interfaceName (5) is returned if present.                                                                                                                                                                 |
|                     | dotlagCfmLtrIngressPortId           | interfaceName (5), then the octet string identifies a particular instance of the ifName object. If the particular ifName object does not contain any values, another port identifier type should be used. |
|                     | dotlagCfmLtrEgress                  | The value returned in the Egress Action Field of the LTM.                                                                                                                                                 |
|                     | dotlagCfmLtrEgressMac               | MAC address returned in the egress MAC address field.                                                                                                                                                     |
|                     | dotlagCfmLtrEgressPortIdSubtype     | interfaceName (5) is returned if present.                                                                                                                                                                 |
|                     | dotlagCfmLtrEgressPortId            | interfaceName (5), then the octet string identifies a particular instance of the ifName object. If the particular ifName object does not contain any values, another port identifier type should be used. |
|                     | dotlagCfmLtrOrganizationSpecificTlv | All organization specific TLVs returned in the LTR.                                                                                                                                                       |
| dotlagCfmStackTable | dotlagCfmStackIfIndex               | Index object. This object represents the bridge port or aggregated port on which MEPs or MHFs might be configured.                                                                                        |
|                     | dotlagCfmStackVlanIdOrNone          | Index object. VLAN ID to which the MP is attached.                                                                                                                                                        |
|                     | dotlagCfmStackMdLevel               | Index object. MD Level of the Maintenance Point.                                                                                                                                                          |
|                     | dotlagCfmStackDirection             | Index object. Direction in which the MP faces on the bridge port.                                                                                                                                         |
|                     | dotlagCfmStackMdIndex               | The index of the MD in the dotlagCfmMdTable to which the MP is associated.                                                                                                                                |

| Table/Group             | Supported Variables          | Comments                                                                                               |
|-------------------------|------------------------------|--------------------------------------------------------------------------------------------------------|
|                         | dotlagCfmStackMaIndex        | The index of the MA in the dotlagCfmMaNetTable and dotlagCfmMaCompTable to which the MP is associated. |
|                         | dotlagCfmStackMepId          | If an MEP is configured, the MEP ID.                                                                   |
|                         | dotlagCfmStackMacAddress     | MAC address of the MP.                                                                                 |
| dotlagCfmMaMepListTable | dotlagCfmMdIndex             | MD Index.                                                                                              |
|                         | dotlagCfmMaIndex             | MA Index.                                                                                              |
|                         | dotlagCfmMaMepListIdentifier | MEP identifier.                                                                                        |
|                         | dotlagCfmMaMepListRowStatus  |                                                                                                        |

| Table/Group                        | Supported Variables         | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## IEEE8021-PAE-MIB

This MIB contains objects for the 802.1X protocol draft D10 of the 802.1X standard.

The following tables, groups, and variables are supported in this MIB.

| Table/Group                | Supported Variables | Comments                                                                                                                             |
|----------------------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| dot1xPaeSystemAuthControl  |                     |                                                                                                                                      |
| dot1xPaePortTable          | All objects         |                                                                                                                                      |
| dot1xAuthConfigTable       | Not supported       | In lieu of these tables, Extreme Networks supports the per-station based versions which are present in the IEEE8021X-EXTENSIONS-MIB. |
| dot1xAuthStatsTable        | Not supported       |                                                                                                                                      |
| dot1xAuthDiagTable         | Not supported       | This table has been deprecated in the drafts subsequent to the 2001 version of the 802.1X standard.                                  |
| dot1xAuthSessionStatsTable | Not supported       |                                                                                                                                      |
| dot1xSuppConfigTable       | None                | These tables are not applicable to the switch since they are for a supplicant.                                                       |
| dot1xSuppStatsTable        | None                |                                                                                                                                      |

## IEEE8021X-EXTENSIONS-MIB

The following tables, groups, and variables are supported in this MIB.

| Table/Group           | Supported Variables | Comments |
|-----------------------|---------------------|----------|
| dot1xAuthStationTable | All objects         |          |
| dot1xAuthConfigTable  | All objects         |          |
| dot1xAuthStatsTable   | All objects         |          |

## ISIS-MIB (draft-ietf-isis-wg-mib-10.txt)

The following tables, groups, and variables are supported in this MIB.

| Table/Group  | Supported Variables | Comments |
|--------------|---------------------|----------|
| IsisSysTable | isisSysInstance     |          |
|              | isisSysVersion      |          |
|              | isisSysType         |          |
|              | isisSysID           |          |

| Table/Group          | Supported Variables          | Comments                                                                      |
|----------------------|------------------------------|-------------------------------------------------------------------------------|
|                      | isisSysMaxPathSplits         | Unsupported object. Always returns MIB default value if one exists for a GET. |
|                      | isisSysMaxLSPGenInt          | Unsupported object. Always returns MIB default value if one exists for a GET. |
|                      | isisSysMaxAreaAddresses      | Unsupported object. Always returns MIB default value if one exists for a GET. |
|                      | isisSysPollIESHelloRate      | Unsupported object. Always returns MIB default value if one exists for a GET. |
|                      | isisSysWaitTime              | Unsupported object. Always returns MIB default value if one exists for a GET. |
|                      | isisSysAdminState            |                                                                               |
|                      | isisSysLogAdjacencyChanges   | Unsupported object. Always returns MIB default value if one exists for a GET. |
|                      | isisSysNextCircIndex         |                                                                               |
|                      | isisSysL2toL1Leaking         | Unsupported object. Always returns MIB default value if one exists for a GET. |
|                      | isisSysMaxAge                |                                                                               |
|                      | isisSysReceiveLSPBufferSize  | Unsupported object. Always returns MIB default value if one exists for a GET. |
|                      | isisSysExistState            | Only state destroy (6) is supported.                                          |
| isisSysLevelTable    | isisSysLevelIndex            |                                                                               |
|                      | isisSysLevelOrigLSPBuffSize  | Unsupported object. Always returns MIB default value if one exists for a GET. |
|                      | isisSysLevelMinLSPGenInt     | Supported<br>isisSysLevelMinLSPGenInt range is 1 - 120 (MIB is 1 - 65535).    |
|                      | isisSysLevelOverloadState    |                                                                               |
|                      | isisSysLevelSetOverload      |                                                                               |
|                      | isisSysLevelSetOverloadUntil |                                                                               |
|                      | isisSysLevelMetricStyle      |                                                                               |
|                      | isisSysLevelSPFConsiders     |                                                                               |
| isisManAreaAddrTable | isisManAreaAddr              |                                                                               |
|                      | isisManAreaAddrExistState    |                                                                               |

| Table/Group          | Supported Variables       | Comments                                                                       |
|----------------------|---------------------------|--------------------------------------------------------------------------------|
| isisAreaAddrTable    | isisAreaAddr              | isisAreaAddrTable only displays the contents of the isisManAreaAddrTable.      |
| isisSysProtSuppTable | isisSysProtSuppProtocol   |                                                                                |
|                      | isisSysProtSuppExistState | Supported as read-only.                                                        |
| isisSummAddrTable    | isisSummAddressType       |                                                                                |
|                      | isisSummAddress           |                                                                                |
|                      | isisSummAddrPrefixLen     |                                                                                |
|                      | isisSummAddrExistState    |                                                                                |
|                      | isisSummAddrMetric        | Supported as read-only.                                                        |
|                      | isisSummAddrFullMetric    | Supported as read-only.                                                        |
| isisCircTable        | isisCircIndex             |                                                                                |
|                      | isisCircIfIndex           | Supported as read-only.                                                        |
|                      | isisCircIfSubIndex        | Supported as read-only.                                                        |
|                      | isisCircAdminState        | Setting isisCircAdminState to off (2) deletes the entry.                       |
|                      | isisCircExistState        | Only state destroy (6) is supported.                                           |
|                      | isisCircType              | Only broadcast (1) and ptToPt (2) are supported for isisCircType.              |
|                      | isisCircExtDomain         | Unsupported object. Always returns MIB default value if one exists for a GET.  |
|                      | isisCircLevel             |                                                                                |
|                      | isisCircPassiveCircuit    | Unsupported object. Always returns MIB default value if one exists for a GET.  |
|                      | isisCircMeshGroupEnabled  |                                                                                |
|                      | isisCircMeshGroup         |                                                                                |
|                      | isisCircSmallHellos       |                                                                                |
|                      | isisCircLastUpTime        |                                                                                |
|                      | isisCirc3WayEnabled       | Supported as read-only.                                                        |
| isisCircLevelTable   | isisCircLevelIndex        |                                                                                |
|                      | isisCircLevelMetric       | Supported isisCircLevelMetric range is 1 - 63 (MIB is 0 - 63).                 |
|                      | isisCircLevelWideMetric   | Supported isisCircLevelMetricWide range is 1 - 16777214 (MIB is 0 - 16777214). |
|                      | isisCircLevelISPriority   |                                                                                |

| Table/Group            | Supported Variables             | Comments                                                                                                                                                                                  |
|------------------------|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | isisCircLevelIDOctet            | Supported as read-only.                                                                                                                                                                   |
|                        | isisCircLevelID                 |                                                                                                                                                                                           |
|                        | isisCircLevelDesIS              |                                                                                                                                                                                           |
|                        | isisCircLevelHelloMultiplier    | Default isisCircLevelHelloMultiplier is 3 (MIB is 10).                                                                                                                                    |
|                        | isisCircLevelHelloTimer         | Default isisCircLevelHelloTimer is 10000 ms (MIB is 3000 ms). Supported range is 1000 - 600000 ms (MIB is 10 - 600000 ms). Fractions of a second are rounded to the nearest whole second. |
|                        | isisCircLevelDRHelloTimer       | Supported as read-only. isisCircLevelDRHelloTimer object is computed as 1/3 of isisCircLevelHelloTimer.                                                                                   |
|                        | isisCircLevelLSPThrottle        | Default isisCircLevelLSPThrottle is 33 ms (MIB is 30 ms).                                                                                                                                 |
|                        | isisCircLevelMinLSPRetransInt   |                                                                                                                                                                                           |

## OSPFv3-MIB (draft-ietf-ospf-ospfv3-mib-10)

All tables and variables of this MIB are supported.

### Note

*SNMP*SET requests for *OSPFv3 (Open Shortest Path First version 3)* MIB objects are not supported.

## PIM-MIB (draft-ietf-pim-mib-v2-01.txt)

This MIB is superset of RFC 2934.

| Table/Group       | Supported Variables           | Comments                                  |
|-------------------|-------------------------------|-------------------------------------------|
| pimInterfaceTable | pimInterfaceIndex             |                                           |
|                   | pimInterfaceAddress           |                                           |
|                   | pimInterfaceNetMask           |                                           |
|                   | pimInterfaceMode              |                                           |
|                   | pimInterfaceDR                |                                           |
|                   | pimInterfaceHelloInterval     |                                           |
|                   | pimInterfaceStatus            |                                           |
|                   | pimInterfaceJoinPruneInterval |                                           |
|                   | pimInterfaceCBSPRPreference   |                                           |
|                   | pimInterfaceTrigHelloInterval | Not supported.                            |
|                   | pimInterfaceHelloHoldtime     | These objects are supported as read only. |
|                   | pimInterfaceLanPruneDelay     |                                           |
|                   | pimInterfacePropagationDelay  |                                           |
|                   | pimInterfaceOverrideInterval  |                                           |
|                   | pimInterfaceGenerationID      |                                           |
|                   | pimInterfaceJoinPruneHoldtime |                                           |

| Table/Group             | Supported Variables            | Comments                                               |
|-------------------------|--------------------------------|--------------------------------------------------------|
|                         | pimInterfaceGraftRetryInterval |                                                        |
|                         | pimInterfaceMaxGraftRetries    |                                                        |
|                         | pimInterfaceSRTTLThreshold     |                                                        |
|                         | pimInterfaceLanDelayEnabled    |                                                        |
|                         | pimInterfaceSRCapable          |                                                        |
|                         | pimInterfaceDRPriority         | This object is supported as read only.                 |
| pimNeighborTable        | pimNeighborAddress             |                                                        |
|                         | pimNeighborIfIndex             |                                                        |
|                         | pimNeighborUpTime              |                                                        |
|                         | pimNeighborExpiryTime          |                                                        |
|                         | pimNeighborMode                | Feature unsupported, only default value is returned.   |
|                         | pimNeighborLanPruneDelay       | Feature unsupported, only default value is returned.   |
|                         | pimNeighborOverrideInterval    |                                                        |
|                         | pimNeighborTBit                | Feature unsupported so only default value is returned. |
|                         | pimNeighborSRCapable           | Feature unsupported so only default value is returned. |
|                         | pimNeighborDRPresent           | Feature unsupported so only default value is returned. |

## SNMPv3 MIBs

The ExtremeXOS *SNMP* stack fully supports the SNMPv3 protocol and therefore implements the MIBs in the SNMPv3 RFCs.

Specifically, the MIBs in following RFCs are fully supported:

- RFC 2576—Coexistence between Version 1, Version 2, and Version 3 of the Internet-standard Network Management Framework
- RFC 3410—Introduction and Applicability Statements for Internet-Standard Management Framework
- RFC 3411—An Architecture for Describing Simple Network Management Protocol (SNMP) Management Frameworks
- RFC 3412—Message Processing and Dispatching for the Simple Network Management Protocol (SNMP)
- RFC 3413—Simple Network Management Protocol (SNMP) Applications.
- RFC 3414—User-based Security Model (USM) for version 3 of the Simple Network Management Protocol (SNMPv3)
- RFC 3415—View-based Access Control Model (VACM) for the Simple Network Management Protocol (SNMP)
- RFC 3826—The Advanced Encryption Standard (AES) Cipher Algorithm in the SNMP User-based Security Model

## RFC 1213 (MIB-II)

The following tables, groups, and variables are supported in this MIB.

| Table/Group          | Supported Variables | Comments                                                                                                                                                                         |
|----------------------|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System group scalars | All objects         | The sysServices object always returns the value 79.<br><br><b>Note:</b> The allowed character set is A-Z, a-z, 0-9, +, -, @, ., ;, (, /, " for sysName, sysLocation, sysContact. |
| Interfaces group     |                     | Supported as per RFC 2233.                                                                                                                                                       |
| IP Group scalars     | All objects         |                                                                                                                                                                                  |

| ipNetToMediaTable | All objects         | <p>context support is available for the ipNetToMediaTable in MIB-2. In order to retrieve entries in various VRs for ipNetToMediaTable in MIB-2, VRs can be mentioned as contexts. For example, to get the entries in <u>VR-Mgmt</u>, the following net-snmp query needs to be used:</p> <pre>snmpwalk -v3 -n "VR-Mgmt" -u &lt;v3username&gt; -a md5 -a &lt;v3user-authentication password&gt; &lt;deviceIpAddress/Hostname&gt; ipNetToMediaTable</pre> <p>Here -n has the context value of "VR-Mgmt". If no context is specified in the <u>SNMP</u> query, then only the entries in the <u>VR-Default</u> are shown.</p> |
| ICMP group        | All objects         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## RFC 1215

This MIB defines an SMI for SNMPv1 traps, and some traps themselves.

Of these, the following are supported.

| Traps                 | Comments                                                                                                                                                                                              |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| coldStart             |                                                                                                                                                                                                       |
| warmStart             |                                                                                                                                                                                                       |
| authenticationFailure | The authentication failure trap will have additional extreme proprietary varbinds (extremeAuthFailSrcAddr, extremeAuthFailSrcAddressType, extremeAuthFailSrcAddress, extremeAuthFailSrcAddressVrName) |

## RFC 1493 (BRIDGE-MIB) and draft-ietf-bridge-rstpmib-03.txt

The BRIDGE-MIB has been augmented with draft-ietf-bridge-rstpmib-03.txt for 802.1w support.

Objects below that are defined in the latter are marked as such.

## RFC 4363 (P-BRIDGE-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group                  | Supported Variables                    | Comments                                                                                                                                                                                                                                                       |
|------------------------------|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dot1dPortCapabilitiesTable   | dot1dDeviceCapabilities.               | A table that contains capabilities information about every port that is associated with this bridge.<br>Read-only.                                                                                                                                             |
| dot1dDeviceCapabilities      | Bit 0 (dot1dExtendedFilteringServices) | Denotes the multicast address filtering capability by GMRP. ExtremeXOS does not support this, and returns 0 always.                                                                                                                                            |
|                              | Bit 1 (dot1dTrafficClasses)            | Denotes switch capability on user priority mapping for multiple traffic classes. ExtremeXOS supports this, and always returns 1.                                                                                                                               |
|                              | Bit 2 (dot1qStaticEntryIndividualPort) | Denotes switch capability on Static unicast/multicast address support for all/particular port. ExtremeXOS does not support this, and returns 0 always.                                                                                                         |
|                              | Bit 3 (dot1qIVLCapable)                | Denotes switch capability on Independent VLAN Learning (IVL). ExtremeXOS supports this, and always returns 1.                                                                                                                                                  |
|                              | Bit 4 (dot1qSVLCapable)                | Denotes switch capability on Shared VLAN Learning (SVL). ExtremeXOS does not support this, and returns 0 always.                                                                                                                                               |
|                              | Bit 5 (dot1qHybridCapable)             | Denotes switch capability to support both IVL and SVL. ExtremeXOS does not support this, and returns 0 always.                                                                                                                                                 |
|                              | Bit 6 (dot1qConfigurablePvidTagging)   | Denotes whether the switch supports the ability to override the default PVID setting and its egress status (VLAN-Tagged or Untagged) on each port. ExtremeXOS supports this, and always returns 1.                                                             |
|                              | Bit 7 (dot1dLocalVlanCapable)          | Denotes whether the switch supports multiple local vlans. ExtremeXOS supports this, and always returns 1.                                                                                                                                                      |
| dot1dPortDefaultUserPriority |                                        | The default ingress User Priority for this port. This only has effect on media, such as Ethernet, that do not support native User Priority. The value of this object MUST be retained across reinitializations of the management system.<br>Read-write access. |

## RFC 4363 (Q-BRIDGE-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group                                    | Supported Variables    | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|----------------------------------------|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dot1qPortVlanTable<br>Read-only access | dot1qPvid                        | The PVID, the VLAN-ID assigned to untagged frames or Priority-Tagged frames received on this port. Read-Write access.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                                        | dot1qPortAcceptableFrameTypes    | When admitAll (1), untagged frames or Priority-Tagged frames received on this port will be accepted and assigned to a VID based on the PVID and VID Set for this port. This control does not affect VLAN-independent Bridge Protocol Data Unit (BPDU) frames, such as GVRP and Spanning Tree Protocol ( <i>STP</i> ). It does affect VLAN- dependent BPDU frames, such as GMRP. ExtremeXOS does not support on setting of this object with admitOnlyVlanTagged (2).<br>Read-write access.                                                                                                                                                                                                            |
|                                        | dot1qPortIngressFiltering        | When this is true (1), the device discards incoming frames for VLANs that do not include this Port in its Member set. When false (2), the port accepts all incoming frames. This control does not affect VLAN-independent BPDU frames, such as GVRP and STP. It does affect VLAN-dependent BPDU frames such as GMRP. The value of this object MUST be retained across reinitializations of the management system.<br><br><b>Note:</b> Note: Ingress filtering cannot be disabled on this object.<br>Read-Write access.                                                                                                                                                                               |
|                                        | dot1qPortGvrpStatus              | The state of GVRP operation on this port. The value enabled (1) indicates that GVRP is enabled on this port, as long as dot1qGvrpStatus is also enabled for this device. When disabled (2) but dot1qGvrpStatus is still enabled for the device, GVRP is disabled on this port: any GVRP packets received is silently discarded, and no GVRP registrations is propagated from other ports. This object affects all GVRP Applicant and Registrar state machines on this port. A transition from disabled (2) to enabled (1) causes a reset of all GVRP state machines on this port. The value of this object MUST be retained across reinitializations of the management system.<br>Read-write access. |
|                                        | dot1qPortGvrpFailedRegistrations | The total number of failed GVRP registrations, for any reason, on this port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## RFC 1724 (RIPv2-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group     | Supported Variables    | Comments |
|-----------------|------------------------|----------|
| rip2Globals     | rip2GlobalRouteChanges |          |
|                 | rip2GlobalQueries      |          |
| rip2IfStatTable | All objects            |          |
| rip2IfConfTable | All objects            |          |
| rip2PeerTable   | Not supported          |          |

## RFC 1850 (OSPF-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group            | Supported Variables | Comments |
|------------------------|---------------------|----------|
| ospfGeneralGroup       | All objects         |          |
| ospfAreaTable          | All objects         |          |
| ospfStubAreaTable      | All objects         |          |
| ospfLsdbTable          | All objects         |          |
| ospfAreaRangeTable     | All objects         |          |
| ospfHostTable          | All objects         |          |
| ospfIfTable            | All objects         |          |
| ospfIfMetricTable      | All objects         |          |
| ospfVirtIfTable        | All objects         |          |
| ospfNbrTable           | All objects         |          |
| ospfVirtNbrTable       | All objects         |          |
| ospfExtLsdbTable       | All objects         |          |
| ospfAreaAggregateTable | All objects         |          |
| ospfTrap               | All traps           |          |

## RFC 2021 (RMON2-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group | Supported Variables | Comments |
|-------------|---------------------|----------|
|             | probeCapabilities   |          |
|             | probeSoftwareRev    |          |
|             | probeHardwareRev    |          |

| Table/Group   | Supported Variables | Comments |
|---------------|---------------------|----------|
|               | probeDateTime       |          |
|               | probeResetControl   |          |
| trapDestTable | All objects         |          |

## RFC 2233 (IF-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group | Supported Variables        | Comments                                                                                                                  |
|-------------|----------------------------|---------------------------------------------------------------------------------------------------------------------------|
|             | IfNumber                   |                                                                                                                           |
| ifTable     | ifIndex                    | The ifIndex for ports is calculated as ((slot * 1000) + port). For VLANs, the ifIndex starts from 1000001.                |
|             | ifDescr                    |                                                                                                                           |
|             | ifType                     | Only the following values are supported: {other, ethernetCsmacd, softwareLoopback, propVirtual}                           |
|             | ifMtu                      |                                                                                                                           |
|             | ifSpeed                    |                                                                                                                           |
|             | ifPhysAddress              |                                                                                                                           |
|             | ifAdminStatus              | The testing state is not supported.                                                                                       |
|             | ifOperStatus               |                                                                                                                           |
|             | ifLastChange               |                                                                                                                           |
|             | ifInOctets                 | Updated every time queries this counter.                                                                                  |
|             | ifInUcastPkts              | Updated every time SNMP queries this counter.                                                                             |
|             | IfInNUcastPkts(deprecated) | Though deprecated, this object returns a value if the system keeps a count. Updated every time SNMP queries this counter. |
|             | ifInDiscards               | No count is kept of this object, so it always returns 0.                                                                  |

## RFC 2613 (SMON)

The following tables, groups, and variables are supported in this MIB.

| Table/Group               | Supported Variables            | Comments                                                                                                                                                               |
|---------------------------|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| smonVlanStatsControlTable | smonVlanStatsControlIndex      | A unique arbitrary index for this smonVlanStatsControlEntry.                                                                                                           |
|                           | smonVlanStatsControlDataSource | The source of data for this set of <u>VLAN</u> statistics. This object MAY NOT be modified if the associated smonVlanStatsControlStatus object is equal to active (1). |
|                           | smonVlanStatsControlCreateTime | The value of sysUpTime when this control entry was last activated. This object allows a management station to detect deletion and recreation cycles between polls.     |

| Table/Group          | Supported Variables                 | Comments                                                                                                                                                                                                                                                        |
|----------------------|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | smonVlanStatsControlOwner           | Administratively assigned named of the owner of this entry. It usually defines the entity that created this entry and is therefore using the resources assigned to it, though there is no enforcement mechanism, nor assurance that rows created are ever used. |
|                      | smonVlanStatsControlStatus          | The status of this row. An entry MAY NOT exist in the active state unless all objects in the entry have an appropriate value. If this object is not equal to active (1), all associated entries in the smonVlanIdStatsTable SHALL be deleted.                   |
| smonVlanIdStatsTable | smonVlanIdStatsId                   | The unique identifier of the VLAN monitored for this specific statistics collection. Tagged packets match the VID for the range between 1 and 4094                                                                                                              |
|                      | smonVlanIdStatsTotalPkts            | The total number of packets counted on this VLAN.                                                                                                                                                                                                               |
|                      | smonVlanIdStatsTotalOverflowPkts    | The number of times the associated smonVlanIdStatsTotalPkts counter has overflowed.                                                                                                                                                                             |
|                      | smonVlanIdStatsTotalHCPkts          | The total number of packets counted on this VLAN.                                                                                                                                                                                                               |
|                      | smonVlanIdStatsTotalOctets          | The total number of octets counted on this VLAN.                                                                                                                                                                                                                |
|                      | smonVlanIdStatsTotalOverflowOctets  | The number of times the associated smonVlanIdStatsTotalOctets counter has overflowed.                                                                                                                                                                           |
|                      | smonVlanIdStatsTotalHCOctets        | The total number of octets counted on this VLAN.                                                                                                                                                                                                                |
|                      | smonVlanIdStatsNUcastOverflowOctets | The number of times the associated smonVlanIdStatsNUcastOctets counter has overflowed.                                                                                                                                                                          |
|                      | smonVlanIdStatsCreateTime           | The value of sysUpTime when this entry was last activated. This object allows a management station to detect deletion and recreation cycles between polls.                                                                                                      |

| Table/Group         | Supported Variables    | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dataSourceDapsTable | dataSourceCapsObject   | Defines an object that can be a SMON data source or a source or a destination for a port copy operation.                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                     | dataSourceCopyCaps     | PortCopy function capabilities of the specified dataSource. Note that these are static capabilities, which SHOULD NOT be adjusted because of current resources or configuration.                                                                                                                                                                                                                                                                                                                                            |
|                     | dataSourceCapsIfIndex  | This object contains the ifIndex value of the ifEntry associated with this smonDataSource. The agent MUST create 'propVirtual' ifEntries for each dataSourceCapsEntry of type VLAN or entPhysicalEntry.                                                                                                                                                                                                                                                                                                                     |
| portCopyConfigTable | portCopySource         | The ifIndex of the source which has all packets redirected to the destination as defined by portCopyDest.                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                     | portCopyDest           | Defines the ifIndex destination for the copy operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                     | portCopyDestDropEvents | The total number of events in which port copy packets were dropped by the switch at the destination port due to lack of resources. Note that this number is not necessarily the number of packets dropped; it is just the number of times this condition has been detected. A single dropped event counter is maintained for each portCopyDest. Thus all instances associated with a given portCopyDest will have the same portCopyDestDropEvents value. The value for this field is "0" (zero) due to hardware limitation. |

| Table/Group | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | portCopyDirection   | <p>This object affects the way traffic is copied from a switch source port, for the indicated port copy operation. If this object has the value copyRxOnly (1), then only traffic received on the indicated source port will be copied to the indicated destination port. If this object has the value copyTxOnly (2), then only traffic transmitted out the indicated source port will be copied to the indicated destination port. If this object has the value copyBoth (3), then all traffic received or transmitted on the indicated source port will be copied to the indicated destination port.</p> <p>The creation and deletion of instances of this object is controlled by the portCopyRowStatus object. Note that there is no guarantee that changes in the value of this object performed while the associated portCopyRowStatus object is equal to active will not cause traffic discontinuities in the packet.</p> |
|             | portCopyStatus      | <p>Defines the status of the port copy entry. In order to configure a source to destination portCopy relationship, both source and destination interfaces MUST be present as an ifEntry in the ifTable and their respective ifAdminStatus and ifOperStatus values must be equal to up (1). If the value of any of those two objects changes after the portCopyEntry is activated, portCopyStatus transitions to notReady (3).</p> <p>The capability of an interface to be source or destination of a port copy operation is described by the copySourcePort (0) and copyDestPort (1) bits in dataSourceCopyCaps. Those bits should be appropriately set by the agent, in order to allow for a portCopyEntry to be created.</p>                                                                                                                                                                                                    |

*Other Unsupported Tables and Nodes in EtherLike MIB:*

dot3ControlTable, dot3PauseTable, dot3Tests – all nodes under this, dot3Errors, etherConformance, etherGroups, etherCompliance, dot3Compliance. RFC 1657 (Definitions of Managed Objects for the Fourth Version of the BGP-4 using SMIv2).

All tables and variables of this MIB are supported with read-only access.

## RFC 2668 (MAU-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group       | Supported Variables | Comments                                                       |
|-------------------|---------------------|----------------------------------------------------------------|
| ifMauTable        | All objects         |                                                                |
| ifJackTable       | All objects         |                                                                |
| ifMauAutoNegTable | All objects         | Setting auto-negotiation through <i>SNMP</i> is not supported. |

The following new Extreme proprietary MAU types have been added to the ifMauType textual convention:

```

extremeMauType1000BaseWDMHD OBJECT IDENTIFIER

 ::= { extremeMauType 7 }

 "Gigabit WDM, half duplex"

extremeMauType1000BaseWDMFD OBJECT IDENTIFIER

 ::= { extremeMauType 8 }

 "Gigabit WDM, full duplex"

extremeMauType1000BaseLX70HD OBJECT IDENTIFIER

 ::= { extremeMauType 9 }

 "Gigabit LX70, half duplex"

extremeMauType1000BaseLX70FD OBJECT IDENTIFIER

 ::= { extremeMauType 10 }

 "Gigabit LX70, full duplex"

extremeMauType1000BaseZXHD OBJECT IDENTIFIER

 ::= { extremeMauType 11 }

 "Gigabit ZX, half duplex"

extremeMauType1000BaseZXFD OBJECT IDENTIFIER

 ::= { extremeMauType 12 }

 "Gigabit ZX, full duplex"

```

```

extremeMauType1000BaseLX100HD OBJECT IDENTIFIER
 ::= { extremeMauType 13 }
 "Gigabit LX100, half duplex"
extremeMauType1000BaseLX100FD OBJECT IDENTIFIER
 ::= { extremeMauType 14 }
 "Gigabit LX100, full duplex"
extremeMauType10GBaseCX4 OBJECT IDENTIFIER
 ::= { extremeMauType 15 }
 "10 Gigabit CX4"
extremeMauType10GBaseZR OBJECT IDENTIFIER
 ::= { extremeMauType 16 }
 "10 Gigabit ZR"
extremeMauType10GBaseDWDM OBJECT IDENTIFIER
 ::= { extremeMauType 17 }
 "10 Gigabit DWDM"
extremeMauType10GBaseCX OBJECT IDENTIFIER
 ::= { extremeMauType 18 }
 "10 Gigabit CX - SFP+ twin coax cable"
extremeMauType10GBaseT OBJECT IDENTIFIER
 ::= { extremeMauType 19 }
 "10 Gigabit BaseT"
extremeMauType40G OBJECT IDENTIFIER
 ::= { extremeMauType 20 }
 "40 Gigabit interface"

```

Corresponding MAU Type List Bits values have been added:

```

extreme_ifMauTypeListBits_b1000baseWDMHD -- 64
extreme_ifMauTypeListBits_b1000baseWDMFD -- 65
extreme_ifMauTypeListBits_b1000baseLX70HD -- 66
extreme_ifMauTypeListBits_b1000baseLX70FD -- 67
extreme_ifMauTypeListBits_b1000baseZXHD -- 68
extreme_ifMauTypeListBits_b1000baseZXFD -- 69

```

The following standards-based additions have been made as a 'Work in Progress', as per draft-ietf-hubmib-mau-mib-v3-02.txt:

A new enumeration 'fiberLC(14)' for the JackType textual convention.

New MAU types:

```
dot3MauType10GigBaseX OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "X PCS/PMA (per 802.3 section 48), unknown PMD."
 ::= { dot3MauType 31 }

dot3MauType10GigBaseLX4 OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "X fiber over WWDM optics (per 802.3 section 53)"
 ::= { dot3MauType 32 }

dot3MauType10GigBaseR OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "R PCS/PMA (per 802.3 section 49), unknown PMD."
 ::= { dot3MauType 33 }

dot3MauType10GigBaseER OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "R fiber over 1550 nm optics (per 802.3 section 52)"
 ::= { dot3MauType 34 }

dot3MauType10GigBaseLR OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "R fiber over 1310 nm optics (per 802.3 section 52)"
 ::= { dot3MauType 35 }

dot3MauType10GigBaseSR OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "R fiber over 850 nm optics (per 802.3 section 52)"
 ::= { dot3MauType 36 }

dot3MauType10GigBaseW OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "W PCS/PMA (per 802.3 section 49 and 50), unknown PMD."
 ::= { dot3MauType 37 }
```

```

dot3MauType10GigBaseEW OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "W fiber over 1550 nm optics (per 802.3 section 52)"
 ::= { dot3MauType 38 }

dot3MauType10GigBaseLW OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "W fiber over 1310 nm optics (per 802.3 section 52)"
 ::= { dot3MauType 39 }

dot3MauType10GigBaseSW OBJECT-IDENTITY
 STATUS current
 DESCRIPTION "W fiber over 850 nm optics (per 802.3 section 52)"
 ::= { dot3MauType 40 }

```

Corresponding new Mau Type List bit values:

|                 |               |
|-----------------|---------------|
| b10GbaseX(31)   | – 10GBASE-X   |
| b10GbaseLX4(32) | – 10GBASE-LX4 |
| b10GbaseR(33)   | – 10GBASE-R   |
| b10GbaseER(34)  | – 10GBASE-ER  |
| b10GbaseLR(35)  | – 10GBASE-LR  |
| b10GbaseSR(36)  | – 10GBASE-SR  |
| b10GbaseW(37)   | – 10GBASE-W   |
| b10GbaseEW(38)  | – 10GBASE-EW  |
| b10GbaseLW(39)  | – 10GBASE-LW  |
| b10GbaseSW(40)  | – 10GBASE-SW  |

## RFC 2787 (VRRP-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group    | Supported Variables      | Comments |
|----------------|--------------------------|----------|
| vrrpOperations | vrrpNodeVersion          |          |
|                | vrrpNotificationCntl     |          |
| vrrpStatistics | vrrpRouterChecksumErrors |          |

| Table/Group          | Supported Variables     | Comments                                                                                                                                                                                                          |
|----------------------|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | vrrpRouterVersionErrors |                                                                                                                                                                                                                   |
|                      | vrrpRouterVrldErrors    |                                                                                                                                                                                                                   |
| vrrpOperTable        | All objects             | Creation of a new row or modifying an existing row requires vrrpOperAdminState to be set to down; otherwise any kind of set will fail on this table.<br>vrrpOperAuthType does not support ipAuthenticationHeader. |
| vrrpAssolpAddrTable  | All objects             |                                                                                                                                                                                                                   |
| vrrpRouterStatsTable | All objects             |                                                                                                                                                                                                                   |
| vrrpNotifications    | vrrpTrapNewMaster       |                                                                                                                                                                                                                   |
|                      | vrrpTrapAuthFailure     |                                                                                                                                                                                                                   |

## RFC-3433 (Entity Sensor MIB)

The Entity Sensor MIB contains a single entitySensorValueGroup that contains objects for representing values and status of the SFP/QSFP.

| Table/Group            | Supported Variables         | Comments                                                                                |
|------------------------|-----------------------------|-----------------------------------------------------------------------------------------|
| entitySensorValueGroup | entPhySensorType            | An integer that defines the type of data units for the sensor.<br>Read-only.            |
|                        | enetPhySensorScale          | An integer representing the data scaling factor for the sensor.<br>Read-only.           |
|                        | entPhySensorPrecision       | An integer representing the number of decimal places of sensor precision.<br>Read-only. |
|                        | entPhySensorValue           | An integer representing the sensor value.<br>Read-only.                                 |
|                        | entPhyOperStatus            | Operational status of the sensor.                                                       |
|                        | entPhySensorUnitsDisplay    | Text description of data units used in entPhySensorValue.<br>Read-only.                 |
|                        | entPhySensorValueTimeStamp  | Value of sysUpTime at the time the status and value was last obtained.<br>Read-only.    |
|                        | entPhySensorValueUpdateRate | Frequency that the agent updates the associated entPhySensorValue.<br>Read-only.        |

*entPhySensorType*

The entPhySensorType object is an integer that defines the sensor as one of the following types:Value

| Value | Sensor Type |
|-------|-------------|
| 1     | Other       |
| 2     | Unknown     |
| 3     | voltsAC     |
| 4     | voltsDC     |
| 5     | Amperes     |
| 6     | Watts       |
| 7     | Hertz       |
| 8     | Celsius     |
| 9     | percentRH   |
| 10    | Rpm         |
| 11    | Cmm         |
| 12    | thruthvalue |

The following sensor types are used for the digital diagnostic monitoring data.

| Sensor          | Sensor Type |
|-----------------|-------------|
| Temperature     | Celsius     |
| VCC             | voltsDC     |
| Tx Bias Current | Amperes     |
| Rx Power        | Watts       |
| Tx Power        | Watts       |

Power measurements may be represented as decibels (dB). If this is the case, the sensor type is defined as “other” and the units of measurement are determined using entPhySensorUnitsDisplay.

*entPhySensorScale*

The entPhySensorScale object is an integer that defines the scale of the sensor as one of the following.

| Value | Sensor Scale |
|-------|--------------|
| 1     | Yocto        |
| 2     | Zepto        |
| 3     | Atto         |
| 4     | femto        |

| Value | Sensor Scale |
|-------|--------------|
| 5     | Pico         |
| 6     | nano         |
| 7     | micro        |
| 8     | milli        |
| 9     | units        |
| 10    | Kilo         |
| 11    | mega         |
| 12    | giga         |
| 13    | tera         |
| 14    | Exa          |
| 15    | peta         |
| 16    | zetta        |
| 17    | yotta        |

#### *entPhySensorPrecision*

This object defines the sensor precision range.

A value in the range 1 to 9, represents the number of decimal places in the fractional part of an associated entPhySensorValue fixed-point number. A value in the range -8 to -1, represents the number of accurate digits in the associated entPhySensorValue fixed-point number. The value zero indicates the associated entPhySensorValue object is not a fixed-point number.

#### *entPhySensorValue*

The entPhySensorValue object is the value of the sensor.

#### *entPhySensorOperStatus*

The entPhySensorOperStatus object is an integer that defines the operating status of the sensor as one of the following.

| Value | Sensor Status  |
|-------|----------------|
| 1     | Ok             |
| 2     | Unavailable    |
| 3     | Nonoperational |

Ports without a populated transceiver or one that is unreachable due to i2c bus errors, etc. are designated “nonoperational”. Ports populated with a transceiver that does not support digital diagnostic monitoring are designated “unavailable.”

*entPhySensorUnitsDisplay*

The entPhySensorUnitsDisplay object is a textual description of the data units that should be used in the display of entPhySensorValue.

*entPhySensorValueTimeStamp*

The entPhySensorValueTimeStamp object is the value of sysUpTime at the time the status and/or value of this sensor were last obtained.

*entPhySensorValueUpdateRate*

The entPhySensorValueUpdateRate object is an indication of the frequency that the agent updates the associated entPhySensorValue object, represented in milliseconds.

## RFC 3621 (PoE-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group       | Supported Variables               | Comments                             |
|-------------------|-----------------------------------|--------------------------------------|
| pethPsePortTable  | All objects                       | Objects in this table are read-only. |
| pethMainPseTable  | All objects                       | Objects in this table are read-only. |
| pethNotifications | pethPsePortOnOffNotification      |                                      |
|                   | pethMainPowerUsageOnNotification  |                                      |
|                   | pethMainPowerUsageOffNotification |                                      |

## RFC 4022 (TCP-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group        | Supported Variables  | Comments                                                                                                                                                                                                                                                           |
|--------------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tcpConnectionTable | tcpConnectionState   | The state of this TCP connection.                                                                                                                                                                                                                                  |
|                    | tcpConnectionProcess | The system's process ID for the process associated with this connection, or zero if there is no such process. This value is expected to be the same as HOST-RESOURCES-MIB::hrSWRunIndex or SYSAPPL-MIB::sysAppElmtRunIndex for some row in the appropriate tables. |

| Table/Group      | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tcpListenerTable | All objects         | <p>A table containing information about TCP listeners. A listening application can be represented in three possible ways:</p> <ol style="list-style-type: none"> <li>1. An application that is willing to accept both IPv4 and IPv6 datagrams is represented by a <code>tcpListenerLocalAddressType</code> of unknown (0) and a <code>tcpListenerLocalAddress</code> of "" (a zero-length octet-string).</li> <li>2. An application that is willing to accept only IPv4 or IPv6 datagrams is represented by a <code>tcpListenerLocalAddressType</code> of the appropriate address type and a <code>tcpListenerLocalAddress</code> of 0.0.0.0 or ::, respectively.</li> <li>3. An application that is listening for data destined only to a specific IP address, but from any remote system, is represented by a <code>tcpListenerLocalAddressType</code> of an appropriate address type, with <code>tcpListenerLocalAddress</code> as the specific local address.</li> </ol> <p><b>Note:</b> The address type in this table represents the address type used for the communication, irrespective of the higher-layer abstraction. For example, an application using IPv6 'sockets' to communicate via IPv4 between <code>::ffff:10.0.0.1</code> and <code>::ffff:10.0.0.2</code> would use <code>InetAddressType ipv4(1)</code>.</p> |
| tcpBaseGroup     | All objects         | The group of counters common to TCP entities.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Table/Group | Supported Variables | Comments                                                                                                                                                                                                                                                                                                           |
|-------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tcpHCGroup  | tcpHCInSegs         | The total number of segments received, including those received in error. This count includes segments received on currently established connections. This object is the 64-bit equivalent of tcpInSegs. Discontinuities in the value of this counter are indicated via discontinuities in the value of sysUpTime. |
|             | tcpHCOutSegs        | The total number of segments sent, including those on current connections but excluding those containing only retransmitted octets. This object is the 64-bit equivalent of tcpOutSegs. Discontinuities in the value of this counter are indicated via discontinuities in the value of sysUpTime.                  |

## RFC 4087 (TUNNEL-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group   | Supported Variables    | Comments                                                                                                                                                                                                                                  |
|---------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| tunnellfTable | tunnellfAddressType    | The type of address in the corresponding tunnellfLocalIpAddress and tunnellfRemoteIpAddress objects.                                                                                                                                      |
|               | tunnellfEncapsLimit    | The maximum number of additional encapsulations permitted for packets undergoing encapsulation at this node. A value of -1 indicates that no limit is present (except as a result of the packet size).                                    |
|               | tunnellfLocalIpAddress | The address of the local endpoint of the tunnel (i.e., the source address used in the outer IP header). If the address is unknown, the value is 0.0.0.0 for IPv4 or :: for IPv6. The type of this object is given by tunnellfAddressType. |

| Table/Group           | Supported Variables          | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | tunnellfRemotelnetAddress    | The address of the remote endpoint of the tunnel (i.e., the destination address used in the outer IP header). If the address is unknown or the tunnel is not a point-to-point link (e.g., if it is a 6to4 tunnel), the value is 0.0.0.0 for tunnels over IPv4 or :: for tunnels over IPv6. The type of this object is given by tunnelfAddressType.                                                                                                                                                                                                                                                                                                                                                      |
| tunnellnetConfigTable | tunnellnetConfigAddressType  | The address type over which the tunnel encapsulates packets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                       | tunnellnetConfigEncapsMethod | The encapsulation method used by the tunnel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                       | tunnellnetConfigEntry        | An entry (conceptual row) containing the information on a particular configured tunnel. Note that there is a 128 subid maximum for object OIDs. Implementers need to be aware that if the total number of octets in tunnellnetConfigLocalAddress and tunnellnetConfigRemoteAddress exceeds 110 then OIDs of column instances in this table will have more than 128 sub-identifiers and cannot be accessed using SNMPv2c or SNMPv3. In practice this is not expected to be a problem since IPv4 and IPv6 addresses will not cause the limit to be reached, but if other types are supported by an agent, care must be taken to ensure that the sum of the lengths do not cause the limit to be exceeded. |

| Table/Group | Supported Variables            | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | tunnellNetConfigID             | An identifier used to distinguish between multiple tunnels of the same encapsulation method, with the same endpoints. If the encapsulation protocol only allows one tunnel per set of endpoint addresses (such as for GRE or IP-in-IP), the value of this object is: For encapsulation methods (such as L2F), which allow multiple parallel tunnels, the manager is responsible for choosing any ID which does not conflict with an existing row, such as choosing a random number. |
|             | tunnellNetConfigIfIndex        | If the value of tunnellNetConfigStatus for this row is active, then this object contains the value of ifIndex corresponding to the tunnel interface. A value of 0 is not legal in the active state, and means that the interface index has not yet been assigned.                                                                                                                                                                                                                   |
|             | tunnellNetConfigLocalAddresses | The address of the local endpoint of the tunnel, or 0.0.0.0 (for IPv4) or :: (for IPv6) if the device is free to choose any of its addresses at tunnel establishment time.                                                                                                                                                                                                                                                                                                          |
|             | tunnellNetConfigRemoteAddress  | The address of the remote endpoint of the tunnel.                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Table/Group | Supported Variables    | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | tunnellnetConfigStatus | <p>Read-create. The status of this row, by which new entries may be created, or old entries deleted from this table. The agent need not support setting this object to createAndWait or notInService since there are no other writable objects in this table, and writable objects in rows of corresponding tables such as the tunnelfTable may be modified while this row is active. To create a row in this table for an encapsulation method which does not support multiple parallel tunnels with the same endpoints, the management station should simply use a tunnellnetConfigID of 1, and set tunnellnetConfigStatus to createAndGo. For encapsulation methods such as L2F which allow multiple parallel tunnels, the management station may select a pseudo-random number to use as the tunnellnetConfigID and set tunnellnetConfigStatus to createAndGo. In event that this ID is already in use and an inconsistentValue is returned in response to the set operation, the management station should simply select a new pseudo-random number and retry the operation. Creating a row in this table will cause an interface index to be assigned by the agent in an implementation-dependent manner, and corresponding rows will be instantiated in the ifTable and the tunnelfTable. The status of this row will become active as soon as the agent assigns the interface index, regardless of whether the interface is operationally up. Deleting a row in this table will likewise delete the corresponding row in the ifTable and in the tunnelfTable.</p> |

| Table/Group        | Supported Variables         | Comments                                                                                                        |
|--------------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------|
|                    | tunnelInetConfigStorageType | Read-create. The storage type of this row. If the row is permanent (4), no objects in the row need be writable. |
| tunnelMIBInetGroup | All objects                 | A collection of objects to support basic management of IPv4 and IPv6 Tunnels.                                   |

## RFC 4113 (UDP-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group      | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                        |
|------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| udpBaseGroup     | All objects         | The group of objects providing for counters of UDP statistics.                                                                                                                                                                                                                                                                                                  |
| udpEndpointGroup | All objects         | The group of objects providing for the IP version independent management of UDP 'endpoints'.                                                                                                                                                                                                                                                                    |
| udpEndpointTable | udpEndpointEntry    | Information about a particular current UDP endpoint.<br>Implementers need to be aware that if the total number of elements (octets or sub-identifiers) in udpEndpointLocalAddress and udpEndpointRemoteAddress exceeds 111, then OIDs of column instances in this table will have more than 128 sub-identifiers and cannot be accessed using SNMPv2c or SNMPv3. |
|                  | udpEndpointInstance | The instance of this tuple. This object is used to distinguish among multiple processes 'connected' to the same UDP endpoint. For example, on a system implementing the BSD sockets interface, this would be used to support the SO_REUSEADDR and SO_REUSEPORT socket options.                                                                                  |

| Table/Group | Supported Variables         | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | udpEndpointLocalAddress     | <p>The local IP address for this UDP endpoint. The value of this object can be represented in three possible ways, depending on the characteristics of the listening application:</p> <ol style="list-style-type: none"> <li>1. For an application that is willing to accept both IPv4 and IPv6 datagrams, the value of this object must be "h" (a zero-length octet-string), with the value of the corresponding instance of the udpEndpointLocalAddressType object being unknown(0).</li> <li>2. For an application that is willing to accept only IPv4 or only IPv6 datagrams, the value of this object must be 0.0.0.0 or ::, respectively, while the corresponding instance of the udpEndpointLocalAddressType object represents the appropriate address type.</li> <li>3. For an application that is listening for data destined only to a specific IP address, the value of this object is the specific IP address for which this node is receiving packets, with the corresponding instance of the udpEndpointLocalAddressType object representing the appropriate address type.</li> </ol> <p>As this object is used in the index for the udpEndpointTable, implementors of this table should be careful not to create entries that would result in OIDs with more than 128 subidentifiers; else the information cannot be accessed using SNMPv1, SNMPv2c, or SNMPv3.</p> |
|             | udpEndpointLocalAddressType | The address type of udpEndpointLocalAddress. Only IPv4, IPv4z, IPv6, and IPv6z addresses are expected, or unknown(0) if datagrams for all local IP addresses are accepted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|             | udpEndpointLocalPort        | The local port number for this UDP endpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|             | udpEndpointProcess          | The system's process ID for the process associated with this endpoint, or zero if there is no such process. This value is expected to be the same as HOST-RESOURCES-MIB::hrSWRunIndex or SYSAPPL-MIB::sysAppElmtRunIndex for some row in the appropriate tables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|-------------|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | udpEndpointRemoteAddress     | The remote IP address for this UDP endpoint. If datagrams from any remote system are to be accepted, this value is "" (a zero-length octet-string). Otherwise, it has the type described by udpEndpointRemoteAddressType and is the address of the remote system from which datagrams are to be accepted (or to which all datagrams will be sent). As this object is used in the index for the udpEndpointTable, implementors of this table should be careful not to create entries that would result in OIDs with more than 128 subidentifiers; else the information cannot be accessed using SNMPv2c or SNMPv3. |
|             | udpEndpointRemoteAddressType | The address type of udpEndpointRemoteAddress. Only IPv4, IPv4z, IPv6, and IPv6z addresses are expected, or unknown(0) if datagrams for all remote IP addresses are accepted. Also, note that some combinations of udpEndpointLocalAdressType and udpEndpointRemoteAddressType are not supported. In particular, if the value of this object is not unknown(0), it is expected to always refer to the same IP version as udpEndpointLocalAddressType.                                                                                                                                                              |
|             | udpEndpointRemotePort        | The remote port number for this UDP endpoint. If datagrams from any remote system are to be accepted, this value is zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## RFC-4133 (ENTITY MIB)

For RFC-4133, the entityPhysicalGroup contains a single table, entityPhysicalTable, to identify physical system components. The following table lists the objects that are supported.

| Table/Group               | Description                                                                                       | Comments       |
|---------------------------|---------------------------------------------------------------------------------------------------|----------------|
| entPhysicalIndex          | The arbitrarily assigned index for the table                                                      | Not-accessible |
| entPhysicalDescr          | Text description of the sensor.                                                                   | Read-only      |
| entPhysicalVendorType     | Specified OID used to identify enterprise-wide type/version/model.                                | Read-only      |
| entPhysicalContainedIn    | The entPhysicalIndex of the parent device. For SFP sensors, this is the corresponding port index. | Read-only      |
| entPhysicalClass          | Integer that defines the general device type. SFP sensors are of class "sensor (8)".              | Read-only      |
| entPhysicalParentRelPos   | Relative position of the parent device.                                                           | Read-only      |
| entPhysicalModuleInfoName | Text String of the model information stored in the SFP/QSFP.                                      | Read-only      |
| entPhysicalSerialNum      | Text String of the serial number information stored in the SFP/QSFP.                              | Read-only      |
| entPhysicalMfgName        | Manufacture Name of the SFP/QSFP, "Extreme Networks".                                             | Read-only      |

## RFC 4292 (IP-FORWARD-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group           | Supported Variables | Comments                                                                                                                                                                                                                                              |
|-----------------------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| inetCidrRouteTable    | All objects         |                                                                                                                                                                                                                                                       |
| inetCidrRouteDiscards |                     | The number of valid route entries discarded from the inetCidrRouteTable. Discarded route entries do not appear in the inetCidrRouteTable. One possible reason for discarding an entry would be to free up buffer space for other route table entries. |
| inetCidrRouteNumber   |                     | The number of current inetCidrRouteTable entries that are not invalid.                                                                                                                                                                                |

## RFC 4293 (IP-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group        | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ipAddressTable     | All objects         | <p>This table contains addressing information relevant to the entity's interfaces. This table does not contain multicast address information. Tables for such information should be contained in multicast specific MIBs, such as RFC 3019. While this table is writable, the user will note that several objects, such as ipAddressOrigin, are not. The intention in allowing a user to write to this table is to allow them to add or remove any entry that isn't permanent. The user should be allowed to modify objects and entries when that would not cause inconsistencies within the table. Allowing write access to objects, such as ipAddressOrigin, could allow a user to insert an entry and then label it incorrectly.</p> <p><b>Note:</b> When including IPv6 link-local addresses in this table, the entry must use an InetAddressType of 'ipv6z' in order to differentiate between the possible interfaces.</p> |
| ipSystemStatsTable | All objects         | <p>The number of valid route entries discarded from the inetCidrRouteTable. Discarded route entries do not appear in the inetCidrRouteTable. One possible reason for discarding an entry would be to free-up buffer space for other route table entries.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Table/Group             | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ipAddressPrefixTable    | All objects         | This table allows the user to determine the source of an IP address or set of IP addresses, and allows other tables to share the information via pointer rather than by copying. For example, when the node configures both a unicast and anycast address for a prefix, the ipAddressPrefix objects for those addresses will point to a single row in this table. This table primarily provides support for IPv6 prefixes, and several of the objects are less meaningful for IPv4. The table continues to allow IPv4 addresses to allow future flexibility. In order to promote a common configuration, this document includes suggestions for default values for IPv4 prefixes. Each of these values may be overridden if an object is meaningful to the node. All prefixes used by this entity should be included in this table independent of how the entity learned the prefix. (This table isn't limited to prefixes learned from router advertisements. |
| ipv6ScopeZoneIndexTable | All objects         | The table used to describe IPv6 unicast and multicast scope zones. For those objects that have names rather than numbers, the names were chosen to coincide with the names used in the IPv6 address architecture document.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ipDefaultRouterTable    | All objects         | The table used to describe the default routers known to this                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ipv6RouterAdvertTable   | All objects         | The table containing information used to construct router advertisements.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## RFC 5601 (PW-STD-MIB)

The following tables, groups, and variables are supported in this MIB.

All tables and variables of this MIB are supported as read only. The comments here are abbreviated versions of the description in the RFC documentation.

| Table/Group | Supported Variables | Comments                                                                                                                                                                                                                                                                      |
|-------------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pwTable     | pwIndex             | A unique index for the conceptual row identifying a PW within this table.                                                                                                                                                                                                     |
|             | pwPeerAddr          | This object contains the value of the peer node address of the PW/PE maintenance protocol entity. This object should contain a value of all zeroes if not applicable (pwPeerAddrType is 'unknown').                                                                           |
|             | pwID                | Pseudowire identifier. If the pwOwner object is pwldFecSignaling or l2tpControlProtocol, then this object is signaled in the outgoing PW ID field within the Virtual Circuit FEC Element. For other values of pwOwner, this object is not signaled and it can be set to zero. |
|             | pwLocalCapabAdvert  | If a maintenance protocol is used, it indicates the capabilities the local node will advertise to the peer.                                                                                                                                                                   |
|             | pwRemoteGroupID     | This object is obtained from the Group ID field as received through the maintenance protocol used for PW setup. Value of zero is reported if not used. Value of 0xFFFFFFFF is used if the object is yet to be defined by the PW maintenance protocol.                         |
|             | pwOutboundLabel     | The PW label used in the outbound direction (i.e., toward the PSN). It might be set manually if pwOwner is 'manual'; otherwise, it is set automatically.                                                                                                                      |
|             | pwInboundLabel      | The PW label used in the inbound direction (i.e., packets received from the PSN). It may be set manually if pwOwner is 'manual'; otherwise, it is set automatically.                                                                                                          |
|             | pwCreateTime        | The value of sysUpTime at the time this PW was created.                                                                                                                                                                                                                       |
|             | pwUpTime            | Specifies the time since last change of pwOperStatus to Up (1).                                                                                                                                                                                                               |
|             | pwLastChange        | The value of sysUpTime at the time the PW entered its current operational state. If the current state was entered prior to the last re-initialization of the local network management subsystem, then this object contains a zero value.                                      |
|             | pwAdminStatus       | The desired operational status of this PW. This object can be set at any time.                                                                                                                                                                                                |

| Table/Group         | Supported Variables | Comments                                                                                                                                                                                                  |
|---------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | pwOperStatus        | This object indicates the operational status of the PW; it does not reflect the status of the Customer Edge (CE) bound interface.                                                                         |
|                     | pwLocalStatus       | Indicates the status of the PW in the local node.                                                                                                                                                         |
|                     | pwRemoteStatus      | Indicates the status of the PW as was advertised by the remote.                                                                                                                                           |
|                     | pwRowStatus         | For creating, modifying, and deleting this row. This object can be changed at any time.                                                                                                                   |
|                     | pwOamEnable         | This variable indicates if OAM is enabled for this PW. It can be changed at any time.                                                                                                                     |
| pwIndexMappingTable | All objects         | This table enables the reverse mapping of the unique Pwid parameters [peer IP, PW type, and PW ID] and the pwIndex. The table is not applicable for PWs created manually or by using the generalized FEC. |

## RFC 5602 (PW-MPLS-STD-MIB)

The following tables, groups, and variables are supported in this MIB.

All tables and variables of this MIB are supported as read only. The comments here are abbreviated versions of the description in the RFC documentation.

| Table/Group | Supported Variables       | Comments                                                                                         |
|-------------|---------------------------|--------------------------------------------------------------------------------------------------|
| pwMplsTable | pwIndex                   | This table controls MPLS-specific parameters when the PW is going to be carried over MPLS PSN.   |
|             | pwMplsMplsType            | This object is set by the operator to indicate the outer tunnel types, if existing.              |
|             | pwMplsTtl                 | This object is set by the operator to indicate the PW TTL value to be used on the PW shim label. |
|             | pwMplsLocalLdpID          | The LDP identifier of the LDP entity that creates this PW in the local node.                     |
|             | pwMplsLocalLdpEntityIndex | The local node LDP Entity Index of the LDP entity creating this PW.                              |

| Table/Group         | Supported Variables | Comments                                                                                                                                                                                                                                                       |
|---------------------|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                     | pwMplsPeerLdpID     | The peer LDP identifier of the LDP session. This object should return the value zero if LDP is not used or if the value is not yet known.                                                                                                                      |
| pwMplsOutboundTable | All objects         | This table reports and configures the current outbound MPLS tunnels (i.e., toward the PSN) or the physical interface in the case of a PW label only that carries the PW traffic. It also reports the current outer tunnel and LSP that forward the PW traffic. |

## RFC 5603 (PW-ENET-STD-MIB)

The following tables, groups, and variables are supported in this MIB.

All tables and variables of this MIB are supported as read only. The comments here are abbreviated versions of the description in the RFC documentation.

| Table/Group | Supported Variables | Comments                                                                                                                                                                                                                                 |
|-------------|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pwEnetTable | pwIndex             | This table contains the index to the Ethernet tables associated with this Ethernet PW, the <u>VLAN</u> configuration, and the VLAN mode.                                                                                                 |
|             | pwEnetPwInstance    | If multiple rows are mapped to the same PW, this index is used to uniquely identify the individual row.                                                                                                                                  |
|             | pwEnetPwVlan        | This object defines the (service-delimiting) VLAN field value on the PW.                                                                                                                                                                 |
|             | pwEnetVlanMode      | This object indicates the mode of VLAN handling between the port or the virtual port associated with the PW and the PW encapsulation.                                                                                                    |
|             | pwEnetPortVlan      | This object defines if the mapping between the original port (physical port or VPLS virtual port) to the PW is VLAN based or not.                                                                                                        |
|             | pwEnetPortIfIndex   | This object is used to specify the ifIndex of the Ethernet port associated with this PW for point-to-point Ethernet service, or the ifIndex of the virtual interface of the VPLS instance associated with the PW if the service is VPLS. |
|             | pwEnetRowStatus     | This object enables creating, deleting, and modifying this row.                                                                                                                                                                          |

## RFC 5643

A subset of the traps in RFC 5643 are supported.

## RFC 6933 (ENTITY-MIB)

The following tables, groups, and variables are supported in this MIB.

| Table/Group         | Supported Variables    | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| entityPhysicalTable | entPhysicalIndex       | The index for this entry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                     | entPhysicalDescr       | A textual description of physical entity. This object should contain a string that identifies the manufacturer's name for the physical entity and should be set to a distinct value for each version or model of the physical entity.                                                                                                                                                                                                                                                                                                                        |
|                     | entPhysicalVendorType  | An indication of the vendor-specific hardware type of the physical entity. Note that this is different from the definition of MIB-II's sysObjectID. An agent should set this object to an enterprise-specific registration identifier value indicating the specific equipment type in detail. The associated instance of entPhysicalClass is used to indicate the general type of hardware device. If no vendor-specific registration identifier exists for this physical entity, or the value is unknown by this agent, then the value { 0 0 } is returned. |
|                     | entPhysicalContainedIn | The value of entPhysicalIndex for the physical entity that 'contains' this physical entity. A value of zero indicates this physical entity is not contained in any other physical entity. Note that the set of 'containment' relationships define a strict hierarchy; that is, recursion is not allowed. In the event that a physical entity is contained by more than one physical entity (e.g., double-wide modules), this object should identify the containing entity with the lowest value of entPhysicalIndex.                                         |

| Table/Group | Supported Variables     | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | entPhysicalClass        | An indication of the general hardware type of the physical entity. An agent should set this object to the standard enumeration value that most accurately indicates the general class of the physical entity, or the primary class if there is more than one entity. If no appropriate standard registration identifier exists for this physical entity, then the value 'other(1)' is returned. If the value is unknown by this agent, then the value 'unknown(2)' is returned.                                                                                                                                                                                                                                                       |
|             | entPhysicalParentRelPos | An indication of the relative position of this 'child' component among all its 'sibling' components. Sibling components are defined as entPhysicalEntries that share the same instance values of each of the entPhysicalContainedIn and entPhysicalClass objects.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|             | entPhysicalName         | The textual name of the physical entity. The value of this object should be the name of the component as assigned by the local device and should be suitable for use in commands entered at the device's 'console'. This might be a text name (e.g., 'console') or a simple component number (e.g., port or module number, such as '1'), depending on the physical component naming syntax of the device. If there is no local name, or if this object is otherwise not applicable, then this object contains a zero-length string. Note that the value of entPhysicalName for two physical entities will be the same in the event that the console interface does not distinguish between them, e.g., slot-1 and the card in slot-1. |

| Table/Group | Supported Variables    | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | entPhysicalHardwareRev | The vendor-specific hardware revision string for the physical entity. The preferred value is the hardware revision identifier actually printed on the component itself (if present). Note that if revision information is stored internally in a non-printable (e.g., binary) format, then the agent must convert such information to a printable format in an implementation-specific manner. If no specific hardware revision string is associated with the physical component, or if this information is unknown to the agent, then this object will contain a zero-length string. |
|             | entPhysicalFirmwareRev | The vendor-specific firmware revision string for the physical entity. Note that if revision information is stored internally in a non-printable (e.g., binary) format, then the agent must convert such information to a printable format in an implementation-specific manner. If no specific firmware programs are associated with the physical component, or if this information is unknown to the agent, then this object will contain a zero-length string.                                                                                                                      |
|             | entPhysicalSoftwareRev | The vendor-specific software revision string for the physical entity. Note that if revision information is stored internally in a non-printable (e.g., binary) format, then the agent must convert such information to a printable format in an implementation-specific manner. If no specific software programs are associated with the physical component, or if this information is unknown to the agent, then this object will contain a zero-length string.                                                                                                                      |

| Table/Group | Supported Variables  | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | entPhysicalSerialNum | <p>The vendor-specific serial number string for the physical entity. The preferred value is the serial number string actually printed on the component itself (if present). On the first instantiation of a physical entity, the value of entPhysicalSerialNum associated with that entity is set to the correct vendor-assigned serial number, if this information is available to the agent. If a serial number is unknown or non-existent, the entPhysicalSerialNum will be set to a zero-length string instead. Note that implementations that can correctly identify the serial numbers of all installed physical entities do not need to provide write access to the entPhysicalSerialNum object. Agents that cannot provide non-volatile storage for the entPhysicalSerialNum strings are not required to implement write access for this object. Not every physical component will have a serial number, or even need one. Physical entities for which the associated value of the entPhysicalIsFRU object is equal to 'false(2)' (e.g., the repeater ports within a repeater module) do not need their own unique serial numbers. An agent does not have to provide write access for such entities and may return a zero-length string. If write access is implemented for an instance of entPhysicalSerialNum and a value is written into the instance, the agent must retain the supplied value in the entPhysicalSerialNum instance (associated with the same physical entity) for as long as that entity remains instantiated. This includes instantiations across all re-initializations/reboots of the network management system, including those resulting in a change of the physical entity's entPhysicalIndex value.</p> |

| Table/Group | Supported Variables  | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | entPhysicalMfgName   | The name of the manufacturer of this physical component. The preferred value is the manufacturer name string actually printed on the component itself (if present). Note that comparisons between instances of the entPhysicalModelName, entPhysicalFirmwareRev, entPhysicalSoftwareRev, and the entPhysicalSerialNum objects are only meaningful amongst entPhysicalEntries with the same value of entPhysicalMfgName. If the manufacturer name string associated with the physical component is unknown to the agent, then this object will contain a zero-length string. |
|             | entPhysicalModelName | The vendor-specific model name identifier string associated with this physical component. The preferred value is the customer-visible part number, which may be printed on the component itself. If the model name string associated with the physical component is unknown to the agent, then this object will contain a zero-length string.                                                                                                                                                                                                                               |
|             | entPhysicalAlias     | Not supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|             | entPhysicalAssetID   | Not supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|             | entPhysicalIsFRU     | This object indicates whether or not this physical entity is considered a 'field replaceable unit' by the vendor. If this object contains the value 'true(1)', then this entPhysicalEntry identifies a field replaceable unit. For all entPhysicalEntries that represent components permanently contained within a field replaceable unit, the value 'false(2)' should be returned for this object.                                                                                                                                                                         |
|             | entPhysicalMfgDate   | This object contains the date of manufacturing of the managed entity. If the manufacturing date is unknown or not supported, the object is not instantiated. The special value '0000000000000000'H may also be returned in this case.                                                                                                                                                                                                                                                                                                                                       |

| Table/Group | Supported Variables       | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | entPhysicalUris           | <p>This object contains identification information about the physical entity. The object contains URIs; therefore, the syntax of this object must conform to RFC 3986. Multiple URIs may be present and are separated by white space characters. Leading and trailing white space characters are ignored. If no URI identification information is known about the physical entity, the object is not instantiated. A zero-length octet string may also be returned in this case.</p> <p><b>Note:</b> This object has read-write permission, but is implemented with read-only mode. Write operation is not supported.</p> |
|             | entPhysicalUUID           | <p>This object contains identification information about the physical entity. The object contains a Universally Unique Identifier, the syntax of this object must conform to RFC 4122, Section 4.1. A zero-length octet string is returned if no UUID information is known.</p>                                                                                                                                                                                                                                                                                                                                           |
|             | entAliasMappingIdentifier | <p>The value of this object identifies a particular conceptual row associated with the indicated entPhysicalIndex and entLogicalIndex pair. Because only physical ports are modeled in this table, only entries that represent interfaces or ports are allowed. If an ifEntry exists on behalf of a particular physical port, then this object should identify the associated ifEntry. For repeater ports, the appropriate row in the 'rprrPortGroupTable' should be identified instead.</p>                                                                                                                              |
|             | entPhysicalChildIndex     | <p>The value of entPhysicalIndex for the contained physical entity.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Table/Group   | Supported Variables | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | entConfigChange     | An entConfigChange notification is generated when the value of entLastChangeTime changes. It can be utilized by an NMS to trigger logical/physical entity table maintenance polls. An agent should not generate more than one entConfigChange 'notification-event' in a given time interval (five seconds is the suggested default). A 'notification-event' is the transmission of a single trap or inform PDU to a list of notification destinations. If additional configuration changes occur within the throttling period, then notification-events for these changes should be suppressed by the agent until the current throttling period expires. At the end of a throttling period, one notification-event should be generated if any configuration changes occurred since the start of the throttling period. In such a case, another throttling period is started right away. An NMS should periodically check the value of entLastChangeTime to detect any missed entConfigChange notification-events. |
| entityGeneral | entLastChangeTime   | The value of sysUpTime at the time a conceptual row is created, modified, or deleted in any of these tables: <ul style="list-style-type: none"> <li>• entPhysicalTable</li> <li>• entLogicalTable</li> <li>• entLPMappingTable</li> <li>• entAliasMappingTable</li> <li>• entPhysicalContainsTable</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### VPLS-MIB (draft-ietf-l2vpn-vpls-mib-02.txt)

The following tables, groups, and variables are supported in this MIB.

All tables and variables of this MIB are supported as read only. The comments here are abbreviated versions of the description in the RFC documentation.

| Table/Group     | Supported Variables   | Comments                                                                                                                                                              |
|-----------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| vplsConfigTable | vplsConfigIndex       | Unique index for the conceptual row identifying a VPLS service.                                                                                                       |
|                 | vplsConfigName        | A textual name of the VPLS. If there is no local name, or this object is otherwise not applicable, then this object MUST contain a zero-length octet string.          |
|                 | vplsConfigAdminStatus | The desired administrative state of the VPLS service.                                                                                                                 |
|                 | vplsConfigRowStatus   | For creating, modifying, and deleting this row.                                                                                                                       |
|                 | vplsConfigMtu         | The value of this object specifies the MTU of this vpls instance.                                                                                                     |
|                 | vplsConfigVpnId       | This object indicates the IEEE 802-1990 VPN ID of the associated VPLS service.                                                                                        |
| vplsStatusTable | All objects           | This table provides information for monitoring VPLS.                                                                                                                  |
| vplsPwBindTable | vplsConfigIndex       | This table provides an association between a VPLS service and the corresponding PWs. A service can have more than one PW association. PWs are defined in the pwTable. |
|                 | vplsPwBindIndex       |                                                                                                                                                                       |
|                 | vplsPwBindType        | The value of this object indicates whether the PW binding is of type mesh or spoke.                                                                                   |
|                 | vplsPwBindRowStatus   | For creating, modifying, and deleting this row.                                                                                                                       |

If you encounter problems when using the switch, this appendix may be helpful. Visit the Extreme Networks Support portal at <https://extremeportal.force.com/> if you have a problem not listed here or in the release notes,.

## Troubleshooting Checklists

---

This section provides simple troubleshooting checklists for Layer 1, Layer 2, and Layer 3. The commands and recommendations described are applicable to both IPv4 and IPv6 environments unless otherwise specified. If more detailed information about a topic is available, you are referred to the applicable section in this appendix.

### Layer 1

When troubleshooting Layer 1 issues, verify:

- The installation of cables and connectors.
- The behavior of LED status lights. For additional information about LEDs, see [LEDs](#).
- That the port is enabled, the link status is active, and speed and duplex parameters match the port settings at the other end of the cable.
  - a. To display the configuration of one or more ports, use the [show ports configuration](#) command.

- That the packets are being received and transmitted.
  - a. To display the number of packets being received and transmitted, use the `show ports {port_list | stack-ports stacking-port-list} statistics {no-refresh}` command.
- That there are no packet errors.
  - a. To display packet error statistics, use the following commands:  
`show ports {port_list | stack-ports stacking-port-list} rxerrors {no-refresh}`—Displays receive error statistics  
  
`show ports {port_list | stack-ports stacking-port-list} txerrors {no-refresh}`—Displays transmit error statistics  
  
`show ports {mgmt | port_list |tag tag} collisions {no-refresh}`—Displays collision statistics

## Layer 2

Layer 2 is the second, or data link, layer of the OSI model, or the MAC layer. This layer is responsible for transmitting frames across the physical link by reading the hardware, or MAC, source and destination addresses.

## Layer 3

Layer 3 is the third layer of the OSI model. Also known as the network layer, Layer 3 is responsible for routing packets to different LANs by reading the network address.

## LEDs

---

### Power LED does not light:

Check that the power cable is firmly connected to the device and to the supply outlet.

### On powering-up, the MGMT LED lights yellow:

The device has failed its Power On Self Test (POST) and you should contact your supplier for advice.

### A link is connected, but the Status LED does not light:

Check that:

- All connections are secure.
- Cables are free from damage.
- The devices at both ends of the link are powered-up.
- Both ends of the Gigabit link are set to the same autonegotiation state.

The Gigabit link must be enabled or disabled on both sides. If the two sides are different, typically the side with autonegotiation disabled will have the link LED lit, and the side with autonegotiation enabled will not be lit. The default configuration

for a Gigabit port is autonegotiation enabled. Verify by entering the following command:

```
show ports configuration
```

## Predictive Failure LED on the AC power supply blinks amber:

Check the current status of the power supply. If the speed of both fans is above 2000 RPM, the AC power supply unit (PSU) is operating normally and no failure is imminent. To check and view the health of the installed PSU, use the following command:

```
show power {ps_num} {detail}
```

## Switch does not power up:

All products manufactured by Extreme Networks use digital power supplies with surge protection. In the event of a power surge, the protection circuits shut down the power supply.

To reset the power, unplug the switch for 1 minute, plug it back in, and attempt to power-up the switch. If this does not work, try using a different power source (different power strip/outlet) and power cord.

## Using the Command Line Interface

---

This section describes helpful information for using and understanding the command line interface (CLI).

## General Tips and Recommendations

*The initial welcome prompt does not appear:*

Check that:

- Your terminal or terminal emulator is correctly configured
- Your terminal or terminal emulator has the correct settings:
  - 115200 baud for all ExtremeSwitching Universal switches
  - 8 data bits
  - 1 stop bit
  - no parity
  - XON/OFF flow control enabled

For console port access, you might need to press [Return] several times before the welcome prompt appears.

*The SNMP Network Manager cannot access the device:*

Check that:

- The SNMP (Simple Network Management Protocol) access is enabled for the system.
- The device IP address, subnet mask, and default router are correctly configured, and that the device has been reset.
- The device IP address is correctly recorded by the SNMP Network Manager (refer to the user documentation for the Network Manager).
- The community strings configured for the system and Network Manager are the same.
- The SNMPv3 USM, Auth, and VACM configured for the system and Network Manager are the same.

*The Telnet workstation cannot access the device:*

Check that:

- The device IP address, subnet mask, and default router are correctly configured, and that the device has been reset.
- You entered the IP address of the switch correctly when invoking the Telnet facility.
- Telnet access is enabled for the switch.

If you attempt to log in and the maximum number of Telnet sessions are being used, you should receive an error message indicating so.

*Traps are not received by the SNMP Network Manager:*

Check that the SNMP Network Manager's IP address and community string are correctly configured, and that the IP address of the Trap Receiver is configured properly on the system.

*The SNMP Network Manager or Telnet workstation can no longer access the device:*

Check that:

- Telnet access or SNMP access is enabled for the system.
- The port through which you are trying to access the device has not been disabled. If it is enabled, check the connections and network cabling at the port.
- The port through which you are trying to access the device is in a correctly configured VLAN (Virtual LAN).
- The community strings configured for the device and the Network Manager are the same.

Try accessing the device through a different port. If you can now access the device, a problem with the original port is indicated. Re-examine the connections and cabling.

A network problem might be preventing you from accessing the device over the network. Try accessing the device through the console port.

*Permanent entries remain in the FDB:*

If you have made a permanent entry in the FDB (forwarding database) that requires you to specify the VLAN to which the entry belongs and then deleted the VLAN, the

FDB entry remains. Although this does not harm the system, if you want to removed the entry, you must manually delete it from the FDB.

#### *Default and static routes:*

If you have defined static or default routes, those routes remain in the configuration independent of whether the VLAN and VLAN IP address that used them remains. You should manually delete the routes if no VLAN IP address is capable of using them.

#### *You forget your password and cannot log in:*

If you are not an administrator, another user having administrator access level can log in, delete your user name, and create a new user name for you, with a new password.

Alternatively, another user having administrator access level can log in and initialize the device. This will return all configuration information (including passwords) to the initial values.

In the case where no one knows a password for an administrator level user, contact your supplier.

## The ExtremeSwitching switch displays only the "(pending-AAA) login" prompt

It is possible that the switch has not yet been fully initialized in the SummitStack. Wait for the Authentication Service (AAA) on the master node is now available for login. message to appear and then log in normally.

It is also possible that the stack has no master-capable node. In this case, AAA authentication will not be possible. This can occur when a stack has been deliberately dismantled and stacking was not unconfigured beforehand.

In either case, you may log in to the node using the failsafe account. If you have forgotten this account, and the stack has no master-capable node or has been dismantled, see [Rescuing a Stack that has No Primary-Capable Node](#) on page 209.

#### **The "(Pending-AAA) login:" prompt on other switches.**

This login prompt is discussed in [Logging in to the Switch](#) on page 29.

## Node Prompt—SummitStack Only

*You do not know which Node you are connected to:*

If you use a console connection to access and configure the switch, you should connect to the console port of the master node.

The word "Slot" followed by a hyphen and a single decimal digit slot number will be inserted into the prompt in stacking mode. A sample of this prompt is:

```
* Slot-6 Stack.21 #
```

The sample indicates a changed configuration (\*), the stackable is in stacking mode and is currently using the slot number 6 in the active topology ("Slot-6"), the system

name is the default of "Stack", the command about to be executed is the 21st command, and the user is logged in as the administrator on the Master node (#).

There will be no specific prompt that indicates the node role. Run show switch command to discover the identities of the Master and Backup nodes. A successful login on a Standby node will show the ">" character instead of the "#" character at the end of the prompt.

## Command Prompt

*You do not know if the switch configuration has been saved:*

If an asterisk (\*) precedes the command prompt, a new change to the switch configuration has not been saved. To save the configuration, use the [save configuration](#) command. After you save the configuration, the asterisk (\*) no longer precedes the command prompt.

*You do not know if you are logged in as an administrator or a user:*

Observe the console prompt. If you are logged in as an administrator, the prompt ends with the hash symbol (#). If you are logged in as a user, the prompt ends with a greater than sign (>).

The following is sample output from an administrator-level account:

```
BD-10808.1 #
```

The following is sample output from a user-level account:

```
BD-10808.1 >
```

## Port Configuration

*No link light on 10/100 Base port:*

If patching from a switch to another switch, ensure that you are using a category 5 (CAT5) crossover cable. This is a CAT5 cable that has pins 1 and 2 on one end connected to pins 3 and 6 on the other end.

*Excessive RX CRC errors:*

When a device that has autonegotiation disabled is connected to an Extreme Networks switch with autonegotiation enabled, the Extreme Networks switch links at the correct speed, but in half-duplex mode. The Extreme Networks switch 10/100 physical interface uses a method called parallel detection to bring up the link. Because the other network device is not participating in autonegotiation (and does not advertise its capabilities), parallel detection on the Extreme Networks switch is able only to sense 10 Mbps versus 100 Mbps speed and not the duplex mode. Therefore, the switch establishes the link in half-duplex mode using the correct speed.

The only way to establish a full-duplex link is either to force it at both sides, or run autonegotiation on both sides (using full-duplex as an advertised capability, which is the default setting on the Extreme Networks switch).

**Note**

A mismatch of duplex mode between the Extreme switch and another network device causes poor network performance. Viewing statistics using the `show ports rxerrors` command on the Extreme Networks switch may display a constant increment of CRC errors. This is characteristic of a duplex mismatch between devices. This is NOT a problem with the Extreme Networks switch.

Always verify that the Extreme Networks switch and the network device match in configuration for speed and duplex.

***No link light on Gigabit fiber port:***

Check that:

- The transmit fiber goes to the receive fiber side of the other device and vice-versa. All Gigabit fiber cables are of the crossover type.
- The Gigabit ports are set to Auto Off (using the command `configure ports port_list {medium [copper | fiber]} auto off speed speed duplex [half | full]`) if you are connecting the Extreme Networks switch to devices that do not support autonegotiation.

By default, the Extreme Networks switch has autonegotiation set to On for Gigabit ports and set to Off for 10 Gigabit ports.

- You are using multimode fiber (MMF) when using a 1000BASE-SX small form-factor pluggable (SFP), and single-mode fiber (SMF) when using a 1000BASE-LX SFP. 1000BASE-SX technology does not work with SMF. The 1000BASE-LX technology works with MMF but requires the use of a mode conditioning patchcord (MCP).

## Software License Error Messages

***You do not have the required software license:***

If you attempt to execute a command and you do not have the required license, the switch returns the following message:

```
Error: This command cannot be executed at the current license level.
```

***You have reached the limits defined by the current software license level:***

If you attempt to execute a command and you have reached the limits defined by the current license level the switch returns the following message:

```
Error: You have reached the maximum limit for this feature at this license level.
```

For more information about licensing requirements, see the [Switch Engine v33.3.1 Licensing Guide](#) document.

## VLANs

You cannot add a port to a VLAN:

If you attempt to add a port to a and get an error message similar to:

```
localhost:7 # configure vlan marketing add ports 1:1,1:2
Error: Protocol conflict when adding untagged port 1:1. Either add this port as tagged or
assign another protocol to this VLAN.
```

You already have a VLAN using untagged traffic on a port. Only one VLAN using untagged traffic can be configured on a single physical port.

You verify the VLAN configuration using the following command:

`show vlan`

The solution for this error using this example is to remove ports 1 and 2 from the VLAN currently using untagged traffic on those ports.

If this were the "default" VLAN, the command would be:

```
localhost:23 # configure vlan default delete ports 1:1,1:2
```

You can now re-enter the previous command without error:

```
localhost:26 # configure vlan marketing add ports 1:1,1:2
```

*VLAN names:*

There are restrictions on VLAN names. They cannot contain whitespaces and cannot start with a numeric value.

*VLANs, IP addresses, and default routes:*

The system can have an IP address for each configured VLAN. You must configure an IP address associated with a VLAN if you intend to manage (Telnet, , ping) through that VLAN or route IP traffic.

You can also configure multiple default routes for the system. The system first tries the default route with the lowest cost metric.

## STP

*You have connected an endstation directly to the switch and the endstation fails to boot correctly:*

The switch has the enabled, and the endstation is booting before the STP initialization process is complete. Specify that STP has been disabled for that , or turn off STP for the switch ports of the endstation and devices to which it is attempting to connect; then, reboot the endstation.

Spanning Tree Domain names:

There are restrictions on names. They cannot contain whitespaces and cannot start with a numeric value.

*You cannot add ports within a VLAN to the specified STPD:*

Check to ensure that you are adding ports that already exist in the carrier VLAN.

If you see an error similar to the following:

```
Error: Cannot add VLAN default port 3:5 to STP domain.
```

You might be attempting to add:

- Another 802.1D mode STP port to a physical port that already contains an 802.1D mode STP port (only one 802.1D encapsulation STP port can be configured on a particular STP port).
- A carrier VLAN port to a different STP domain than the carrier VLAN belongs.
- A VLAN and/or port for which the carrier VLAN does not yet belong.

#### Note

This restriction is only enforced in an active STPD and when you enable STP to make sure you have a legal STP configuration.

*Only one carrier VLAN can exist in an STPD:*

Only one carrier VLAN can exist in a given STPD although some of the ports on the carrier VLAN can be outside the control of any STPD at the same time.

The StpdID must be identical to the VLANid of the carrier VLAN in that STPD.

*The switch keeps aging out endstation entries in the switch FDB:*

If the switch continues to age out endstation entries in the switch :

- Reduce the number of topology changes by disabling STP on those systems that do not use redundant paths.
- Specify that the endstation entries are static or permanent.

## ESRP

*ESRP names:*

There are restrictions on Extreme Standby Router Protocol (ESRP) names. They cannot contain whitespaces and cannot start with a numeric value.

*You cannot enable an ESRP domain:*

Before you enable a specific ESRP domain, it must have a domain ID. A domain ID is either a user-configured number or the 802.1Q tag (VLANid) of the tagged master VLAN. The domain ID must be identical on all switches participating in ESRP for that particular domain. If you do not have a domain ID, you cannot enable ESRP on that domain.

Note the following on the interaction of tagging, ESRP, and ESRP domain IDs:

- If you have an untagged Master VLAN, you must specify an ESRP domain ID.

- If you have a tagged master VLAN, ESRP uses the 802.1Q tag (VLANid) of the master VLAN for the ESRP domain ID. If you do not use the VLANid as the domain ID, you must specify a different domain ID.

*You cannot delete the master VLAN from the ESRP domain:*

If you attempt to remove the master VLAN before disabling the ESRP domain, you see an error message similar to the following:

```
ERROR: Failed to delete master vlan for domain "esrp1" ; ESRP is enabled!
```

If this happens:

- Disable the ESRP domain using the `disable esrp` command.
- Remove the master VLAN from the ESRP domain using the `configure esrp delete master` command.

## VRRP

*You cannot define VRRP virtual router parameters:*

Before configuring any parameters for VRRP, you must first create the VRRP instance on the switch.

If you define VRRP parameters before creating the VRRP, you may see an error similar to the following:

```
Error: VRRP VR for vlan vrrp1, vrid 1 does not exist.
Please create the VRRP VR before assigning parameters.
Configuration failed on backup MSM, command execution aborted!
```

If this happens:

- Create a VRRP instance using the `create vrrp vlan vrid` command.
- Configure the VRRP instance's parameters.

## Using ELRP to Perform Loop Tests

The Extreme Loop Recovery Protocol (ELRP) is used to detect network loops in a Layer 2 network. A switch running ELRP transmits multicast packets with a special MAC destination address out of some or all of the ports belonging to a VLAN. All of the other switches in the network treat this packet as a regular, multicast packet and flood it to all of the ports belonging to the VLAN. When the packets transmitted by a switch are received back by that switch, this indicates a loop in the Layer 2 network.

### Note

The ELRP source MAC address is changed from "00:e0:2b:00:00:01" to "0e:Switch-MAC".

After a loop is detected through ELRP, different actions can be taken such as blocking certain ports to prevent loop or logging a message to system log. The action taken is largely dependent on the protocol using ELRP to detect loops in the network.

You can use ELRP on a “standalone” basis or with other protocols such as [ESRP](#) (*Extreme Standby Router Protocol*), as described in [Using ELRP with ESRP](#). Protocols such as [EAPS](#) (*Extreme Automatic Protection Switching*) require that a network have a ring topology to operate. In this case you can use ELRP to ensure that the network has a ring topology.

The “standalone” ELRP commands determine whether or not a network has an Layer 2 loop.

## About Standalone ELRP

Standalone ELRP gives you the ability to send ELRP packets, either periodically or on an ad hoc “one-shot” basis on a specified subset of [VLAN](#) ports. If any of these transmitted packets is received back then standalone ELRP can perform a configured action such as sending a log message to the system log file, sending a trap to the [SNMP](#) manager, and disabling the port where the looped packet arrived.

ELRP uses QP8 to send/receive control packets over the network to detect loops, so it is advisable to not use QP8 in for user traffic in the network.

Standalone ELRP allows you to:

- Configure ELRP packet transmission on specified VLANs.
- Specify some or all the ports of the VLAN for packet transmission. Each VLAN must be configured individually for ELRP.

### Note

Reception of packets is not limited to any specific ports of the VLAN and cannot be configured.

- Save and restore standalone ELRP configuration across reboots.
- Request non-periodic or periodic transmission of ELRP packets on specified ports of a VLAN.

### Note

Starting with ExtremeXOS 22.2, ELRP works on both static and dynamic VLANs.

### Non-periodic ELRP Requests

You can specify the number of times ELRP packets must be transmitted and the interval between consecutive transmissions. A message is printed to the console and logged into the system log file indicating detection of network loop when ELRP packets are received back or no packets are received within the specified duration.

### Periodic ELRP Requests

You can configure the interval between consecutive transmissions. If ELRP packets are received back, a message is printed to the system log file and/or a trap is sent to the [SNMP](#) manager indicating detection of a network loop.

You have the option to configure the switch to automatically disable the port where the looped packet arrived as well as the length of time (in seconds) that the port should remain disabled. When this hold time expires, the port is automatically enabled.

Should a loop occur on multiple ports, only the first port in the VLAN on which the PDU is received is disabled. The second port is ignored for 1 or 2 seconds and then if another PDU is received, that port is disabled until the loop is gone. This prevents shutting down all ports in the VLAN.

### *ELRP Egress Port Disable*

When a loop is detected via ELRP, an option to disable the port where the packet egressed was added to suppress the loop in ExtremeXOS 16.1. All existing functionalities supported on disabling the port where the packet ingressed are supported on this enhancement as well. A log message or SNMP trap will be generated based on the configuration. The user must specify a holdtime or keep the port disabled until a user enables it.

ELRP egress blocking enhancement adds the following value:

- More efficient bandwidth utilization.
- Better loop protection in environment. If an edge device is dual-homed to an MLAG pair and this edge device loses its LAG (Link Aggregation Group) configuration, ELRP will be able to prevent the loop by disabling egress port.

**Figure 233: ELRP Egress Port Disable (1)**

**Figure 234: ELRP Egress Port Disable (2)**

#### *Exclude Port List*

When you have configured the switch to automatically disable the port where the looped packet arrived, there may be certain ports that you do not want disabled. You can then create a list of ports that are excluded from this automatic disabling and that remain enabled. This list can also contain *EAPS* ring ports. When this option is selected, the actual EAPS ring ports do not have to be explicitly listed. You can also specify that *VXLAN (Virtual Extensible LAN)* remote end points are to be excluded from getting disabled when a loop is detected.

You can configure any port on the switch into the exclude port list. The list can also be edited to add or delete any port on the switch. Then when ELRP detects a loop and the disable feature is enabled, it checks to see if the port from which the PDU arrived is on the user defined exclude port list or is part of a trunk port that is defined on the list. When the port is on the list, ELRP logs the event and does not disable the port. When the port is not on the list, ELRP disables the port.

#### **Limitations**

The following are limitations to this feature:

- A specified port is added to the list regardless of its corresponding *VLAN*.
- Only ports on the local switch can be added.
- A loop detected on an excluded port may persist indefinitely until user action is taken.
- ISC links should not be blocked, therefore they should be added to the excluded port list.

#### *ELRP with Dynamic VLANs*

ELRP supports dynamically created VLANs created by:

- *NetLogin*
- *Extreme Network Virtualization (XNV)*
- Multiple Registration Protocol (MVRP)

- Fabric Attach (starting with version 32.2)
- ONEPolicy (starting with version 32.2)

ELRP on NetLogin-enabled ports is supported.

#### *ELRP with Virtual Extensible LAN (VXLAN)*

Starting with ExtremeXOS 22.4, ELRP is supported on Virtual Extensible LAN (VXLAN).

VXLAN is an encapsulation mechanism. A VXLAN header is added to an L2 (ELRP PDU) frame and encapsulated in a UDP/IP packet. Transit nodes see only an ordinary IP packet. For more information about VXLAN, see [VXLAN](#) on page 2236.

ELRP detects loops across VXLAN tunnels. If a loop is detected across the tunnel and the disable-port option is configured (see [Configuring Periodic Requests](#) on page 2054), ELRP takes down the VXLAN remote endpoint.

If the VXLAN remote endpoint has been disabled using the permanent option, you can use the following command to re-enable the remote endpoint:

```
enable virtual-network remote-endpoint vxlan [ipaddress ipaddress {vr vr_name} | all]
```

To manually disable a remote endpoint, use the following command:

```
disable virtual-network remote-endpoint vxlan [ipaddress ipaddress {vr vr_name} | all]
```

To see if a remote endpoint is enabled or disabled, use the following command:

```
show virtual-network {vn_name} remote-endpoint vxlan {vni vni}
{ipaddress ipaddress {vr vr_name}}
```

#### *Hardware-Assisted ELRP*

Hardware-assisted ELRP allows ELRP to detect loops faster and to support more ELRP clients.

##### **Supported Platforms**

All ExtremeSwitching Universal switches.

##### **Limitations**

For hardware-assisted ELRP:

- Only front panel ports can be configured as the loopback port.
- Only disabling ingress port is supported after a loop is detected.
- MLAG ports are not supported.
- Software ELRP and hardware-assisted ELRP cannot operate simultaneously.
- Only standalone clients are supported.
- Not supported on dynamic VLANs.

- Maximum loop detection interval is determined by each platform's hardware capability. For most platforms, an ELRP packet is 70 bytes.
- Non-periodic requests are not supported.
- Extended Edge Switching is not supported.

## Configuring Standalone ELRP

The ELRP client (standalone ELRP) must be enabled globally in order for it to work on any VLAN.

- Globally enable the ELRP client for static VLANs:

```
enable elrp-client {software | hardware-assist}
```

The ELRP client can be disabled globally so that none of the ELRP VLAN configurations take effect.

- Globally disable the ELRP client for static VLANs:

```
disable elrp-client
```

- Globally enable or disable ELRP for dynamic VLANs:

```
configure elrp-client dynamic-vlans {mvrp | netlogin | vm-tracking |
policy | fabric-attach | all} [on | off]
```

- Globally enable or disable inter-VLAN loop detection:

```
configure elrp-client inter-vlan-loop-detection [on | off]
```

- Configure or unconfigure a front panel port as the designated loopback port for hardware-assisted ELRP:

```
configure elrp-client hardware-assist loopback-port [port | none]
```

### Note

Do not configure a trunk port as the loopback port. In a stack, make sure the loopback port is not on the master slot.

## Configuring Non-periodic Requests

- To start one-time, non-periodic ELRP packet transmission on specified ports of a VLAN using a particular count and interval, use one of the following commands:

```
configure elrp-client one-shot {vlan [vlan_name | all] ports [ports |
all | none] {remote-endpoints vxlan all} {interval interval {seconds |
milliseconds}} {retry count} {log | print | print-and-log}}
```

```
run elrp {vlan} vlan_name {ports [ports | all | none]} {remote-endpoints
vxlan all} {interval interval {seconds | milliseconds}} {retry count}
```

These commands start one-time, non-periodic ELRP packet transmission on the specified ports of the VLAN using the specified count and interval. If any of these transmitted packets is returned, indicating loopback detection, the ELRP client performs the configured actions of logging a message in the system log file and/or printing a log message to the console. There is no need to trap to the SNMP manager for non-periodic requests.

### Configuring Periodic Requests

- To start periodic ELRP packet transmission on specified ports of a [VLAN](#) using a particular interval, use the following command:

```
configure elrp-client periodic {vlan} vlan_name ports [ports | all
| none] {remote-endpoints vxlan all} {interval interval {seconds |
milliseconds}} {log | log-and-trap | trap} {disable-port {egress |
ingress} {duration {seconds} | permanent}}
```

This command starts periodic ELRP packet transmission on the specified ports of the VLAN using a specified interval. If any of these transmitted packets is returned, indicating loopback detection, the ELRP client performs the configured action of logging a message in the system log file and/or sending a trap to the [SNMP](#) manager.

When the option of disabling a port is configured, you choose the duration in seconds as a hold time, or you disable the port permanently. When ELRP disables the port, the operation is not persistent. When the switch is rebooted, the port is enabled when the switch comes up.

#### Note

ELRP detects loops on a per VLAN basis. When you select the disable-port option keep in mind that the entire port is disabled. In the case of [VXLAN](#), the remote tunnel endpoint's (RTEP) state is taken down for all VXLAN virtual networks. This may affect connectivity for other VLANs configured on that port that did not have any data loop problems. ELRP also does not distinguish between uplink ports and host ports. When the **disable port** option is selected and ELRP detects a loop, any and all ports where the loop was detected will be disabled, including uplink ports.

- To disable a pending one-shot or periodic ELRP request for a specified VLAN or all dynamic VLANs, use the following command:

```
unconfigure elrp-client {vlan_name | dynamic-vlans}
```

### Configuring Exclude Port List

- To configure an ELRP exclude port list, use the following command:

```
configure elrp-client disable-ports [exclude | include] [ports |
eaps-ring-ports | remote-endpoints vxlan | inter-vlan-loop]
```

- To unconfigure an ELRP exclude port list, use the following command:

```
unconfigure elrp-client disable-ports
```

## Displaying Standalone ELRP Information

- To display summary ELRP status information, use the following command:  
`show elrp`
- To display information about ELRP disabled ports, use the following command:  
`show elrp disabled-ports`

- To display information ELRP configuration on dynamic VLANs, use the following command:

```
show elrp dynamic-vlans {vm-tracking | netlogin | mvrp | policy |
fabric-attach | all}
```

## Example: ELRP on Protocol-Based VLANs

For ELRP to detect loops on a protocol-based VLAN (other than the protocol any), you need to add the ethertype 0x00bb to the protocol.

1. Create VLANs:

```
create vlan v1
create vlan v2
```

2. Configure protocol filters:

```
configure vlan v1 protocol IP
configure vlan v2 protocol decnet
```

3. Add ports to the VLANs:

```
configure vlan v1 add ports 1
configure vlan v2 add ports 2
```

4. Enable ELRP on the created VLANs:

```
enable elrp-client
configure elrp-client periodic v1 ports all interval 5 seconds log
configure elrp-client periodic v2 ports all interval 5 seconds log
```

5. Add the ethertype to the protocol:

```
configure protocol IP add snap 0x00bb
configure protocol decnet add snap 0x00bb
```

VLANs v1 and v2 can now detect the loop on their respective broadcast domains.

## Using Simple Loop Prevention Protocol (SLPP) Guard

Simple Loop Prevention Protocol (SLPP) is an application that detects loops in an or Split Multi-link Trunking (SMLT) network on VOSS/BOSS switches.

SLPP Guard is a complementary feature for ExtremeXOS switches that helps prevent loops in networks by administratively disabling an edge port if a switch receives an SLPP PDU from an SMLT network. SLPP Guard detects and discards SLPP control PDUs on a per port basis. SLPP Guard identifies SLPP PDUs using the Ethernet type field of the packet, which is configurable. When an SLPP PDU is received on a port that has SLPP Guard activated on it, it is immediately disabled. After a configurable timeout value expires (associated with each port), the port is automatically re-enabled.

### Note

When SLPP Guard disables a port, the disabled status is not persistent. If the switch reboots, the port is enabled when the switch comes back up.

### Note

If you use the CLI to enable or disable a port that has been disabled by SLPP Guard, the port is enabled or disabled as applicable and the recovery timer is stopped for that port.

When a new user is authenticated by netlogin, the *enable* attribute of SLPP Guard is given to netlogin. Netlogin processes this attribute and sends the *enable* attribute message to the SLPP Guard module. If all users are unauthenticated by netlogin, a disable message for the port is sent to SLPP Guard. At the time of re-authentication, if the FA-Service-Request = SLPPGUARD is removed from the RADIUS server, then netlogin sends an SLPP Guard *disable* message.

**Note**

If you modify the RADIUS attributes in between authentication, then a port restart or clear all netlogin clients is required in order for the service attributes to change on the port.

The status is enabled and the entry in the **save configuration** command is sent to `enable slpp guard port port_list` for the following scenarios:

- If the status of SLPP Guard is enabled by the CLI.
- If the status of SLPP Guard is enabled by both the Vendor Specific Attribute (VSA) and by the CLI.
- If after enabling SLPP Guard by the CLI, the status is then disabled from the VSA.

The status is enabled and the saved configuration contains default values for the following scenarios:

- If the status of SLPP Guard is enabled by the VSA.
- If after enabling SLPP Guard by the VSA, the status is then disabled from the CLI.

The most common use case is with an IP phone with two ports: one for a switch and one for a computer (see [Figure 235](#)). If you plug both IP phone ports onto the edge switch, a loop is created. To avoid a loop in the SMLT network, on the ExtremeXOS edge switch, enable SLPP Guard on the ports that are connected to the IP phone.

**Figure 235: SLPP Use Case**

## Supported Platforms

All ExtremeSwitching switches.

## Limitations

- SNMP for SLPP Guard is not supported.
- The SLPP Guard active state per port is limited by the number of available ACL filters.

## Configuring Simple Loop Prevention Protocol (SLPP) Guard

For Simple Loop Prevention Protocol (SLPP) Guard to operate, SLPP must have already been configured in the core of the network.

The following information explains how to configure SLPP Guard on ExtremeXOS switches.

1. Enable SLPP on the desired ports using the following command:

```
enable slpp guard ports [port_list | all]
```

**Note**

To view the SLPP status of ports, use the `show slpp guard {ports port_list} {disabled-ports}` command.

2. (Optional) Set the recovery timeout period using the following command:

```
configure slpp guard [ports [port_list | all] recovery-timeout
[seconds | none]
```

After the configured timeout value set by this command expires (associated with each port), the port is automatically re-enabled.

3. (Optional) Configure the Ethertype for SLPP Guard using the following command:

```
configure slpp guard ethertype hex
```

This command configures the Ethertype that the SLPP Guard feature uses to identify SLPP PDUs.

If you need to disable SLPP Guard on a port, use the following command:

```
disable slpp guard ports [port_list | all]
```

To view SLPP Guard status for selected ports or all SLPP Guard-disabled ports, use the following command:

```
show slpp guard {ports port_list} {disabled-ports}
```

## Debug Mode

---

The EMS provides a standard way to filter and store messages generated by the switch. With EMS, you must enable debug mode to display debug information. You must have administrator privileges to use these commands. If you do not have administrator privileges, the switch rejects the commands.

- Enable or disable debug mode for EMS:

```
enable log debug-mode
```

After debug mode has been enabled, you can configure EMS to capture specific debug information from the switch. Details of EMS can be found in [Status Monitoring and Statistics](#).

## Saving Debug Information

---

You can save switch data and statistics to a network TFTP server, an internal memory card that comes pre-installed in the switch or a removable USB 2.0 storage device on all Universal platforms.

With assistance from [Extreme Networks Technical Support](#) personnel, you can configure the switch to capture troubleshooting information, such as a core dump file, to these locations.

The switch only generates core dump files in the following situations:

- If an ExtremeXOS process fails.
- When forced under the guidance of Extreme Networks Technical Support.

The core dump file contains a snapshot of the process when the error occurred.

#### Note

Use the commands described in this section only under the guidance of Extreme Networks Technical Support personnel to troubleshoot the switch. Before you can enable and save process core dump information to removable storage devices, you must install a compact flash card or USB 2.0 storage device. .

## Enabling the Send Debug Information Switch

This allows information to be sent to the internal memory card or a removable storage device.

- Enable the switch to save process core dump information.

```
configure debug core-dumps [off | directory_path]
```

A removable storage device is a USB 2.0 storage device on a ExtremeSwitching series switch.

Core dump files have a .gz file extension. The filename format is: core.<process-name.pid>.gz where process-name indicates the name of the process that failed and pid is the numerical identifier of that process.

If you configure the switch to write core dump files to the internal memory card and attempt to download a new software image, you might have insufficient space to complete the image download.

If this occurs, you must decide whether to continue the software download or move or delete the core dump files from the internal memory. For example, if your switch supports a removable storage device with space available, transfer the files to the storage device. On switches that do not have a removable storage device, transfer the files from the internal memory card to a TFTP server. This frees up space on the internal memory card while keeping the core dump files.

## Copy Debug Information to Removable Storage Devices

- Save and copy debug information to the specified USB 2.0 storage device.

```
save debug tracefiles directory_path
```

After the switch writes a core dump file or other debug information to the storage device, and before you can view the contents on the device, you must ensure it is

safe to remove the device from the switch. Use the `eject usb-device` command to prepare the device for removal. After you run the `eject usb-device` command, you can manually remove the storage device from the switch and read the data on the device.

To access and read the data on a removable storage device, use a PC with the appropriate hardware, such as a compact flash reader/writer and follow the manufacturer's instructions to access the compact flash card and read the data.

## Copying Debug Information to a TFTP Server

**SummitStack only**—To get debug information from a node in the SummitStack that is not a master node, you must configure an alternate IP address on the node and have its management port connected. You may then use the `tftp` command to upload specific files. The upload debug command functions only on the master node.

1. Save and copy debug information to the specified TFTP server.

```
upload debug [ipaddress | hostname] {{vr} vrname} {block-size
block_size}
```

Progress messages are displayed that indicate the file being copied and when the copying is finished.

Depending on your platform, the switch displays a message similar to the following:

```
The following files on have been uploaded:
Tarball Name: TechPubsLab_C_09271428.tgz
./primary.cfg
```

You can also use this command in conjunction with the `show tech` command.

Prior to uploading debug information files, the switch prompts you with the following message to run the `show tech-support` command with the `logto file` option:

```
Do you want to run show tech logto file first? (y/n)
```

2. Enter `y` to run the `show tech-support` command before uploading debug information.

If you enter `y`, the `show_tech.log.tgz` file is included during the upload. Enter `n` to upload debug information without running the `show tech` command.

After you upload the debug information, you should see a compressed TAR file on the TFTP server, which contains the debug information.

The TAR file naming convention is

```
<SysName>_<{<slot#>|A|B}I|C>_<Current Time>.tgz
- Current Time = mmddhhmm (month(01-12), date(01-31), hour(0-24), minute(00-59)).
```

## Managing Debug Files

For the purposes of this section, it is assumed that you have configured the switch to send core dump information under the guidance of [Extreme Networks Technical Support](#).

Managing the debug files might include any of the following tasks: renaming or copying a core dump file, displaying a comprehensive list of files including core dump files, transferring core dump files, and deleting a core dump file. You can manage the debug files using the same commands that you use to manage other switch files.

### Note

Filenames are case-sensitive. For information on filename restrictions, refer to the specific command in the [Switch Engine v33.3.1 Command References](#).

## Evaluation Precedence for ACLs

The ACLs on a port are evaluated in the following order:

- Persistent dynamic ACLs
- Host-integrity permit ACLs
- MAC source address deny ACLs
- Source IP lockdown source IP permit ACLs
- Source IP lockdown deny all ACLs
- ARP validation CPU ACLs
- ACLs created using the CLI
- DoS Protect-installed ACLs
- MAC-in-MAC installed ACLs
- ACLs applied with a policy file (see [ACLs](#) on page 325 for precedence among these ACLs)

## TOP Command

The `top` command is a UNIX-based command that displays real-time CPU utilization information by process.

The output contains a list of the most CPU-intensive tasks and can be sorted by CPU usage, memory usage, and run time. For more detailed information about the `top` command, refer to your UNIX documentation.

## TFTP Server Requirements

We recommend using a TFTP server that supports blocksize negotiation (as described in RFC 2348, TFTP Blocksize Option), to enable faster file downloads and larger file downloads.

## System Odometer

Each field replaceable component contains a system odometer counter in EEPROM.

The `show odometers` command displays an approximate days of service duration for an individual component since the component was manufactured.

## Monitored Components

The odometer monitors the following components:

- Switch
- XGN-2xn card

## Recorded Statistics

### *Description*

The following odometer statistics are collected by the switch:

- Service Days—The amount of days that the component has been running
- First Recorded Start Date—The date that the component was powered-up and began running

Depending on the software version running on your switch, additional or different odometer information may appear.

The following is sample output from an ExtremeSwitching series switch:

```
show odometers
Service First Recorded
Field Replaceable Units Days Start Date

Switch : SummitX4 7 Dec-08-2004
XGM-2xn-1 :
```

## Temperature Operating Range

On ExtremeSwitching series switches, if a switch runs outside the expected range, the switch logs an error message, generates a trap, and one of the following actions occurs:

- On a SummitStack slots, the reset/none option from `configure sys-recovery-level [all | none]` command determines the action that occurs.
- For all switches, only a warning is logged and the switch continues to run with the system state as "overheat." If the temperature increases further into overheat condition, after the operating temperature exceed a further higher temperature, the hardware resets the switch.

## Understanding the Error Reading Diagnostics Message

For more detailed information about error messages and their meanings, see the [Switch Engine and ExtremeXOS v33.3.x EMS Messages Catalog](#).

If you have never run diagnostics on the switch or stack ports and use the `show diagnostics` command, the switch displays a message similar to the following:

```
Result: FAIL
Test date run is invalid. Please run Diagnostics.
Error reading diagnostics information.
```

This message is normal and expected if you have never run diagnostics on the switch. After running diagnostics, you see information about the executed test using the `show diagnostics` command.

## Proactive Tech Support

Proactive tech support functionality allows you to collect system information when support is required. System information is pushed into a cloud-hosted collector where the Extreme TAC can use it to identify problems to provide solutions. Proactive Tech Support provides the following functionality:

- Proactive tech support is implemented as a loadable application, called techSupport.xmod. The XMOD is bundled with ExtremeXOS image packages, but can also be upgraded independently at any time without restarting the switch.
- Proactive tech support allows the switch to proactively collect switch status and send the status report to up to four cloud-hosted collectors.
- Proactive tech support allows both automatic and manual status report.
- Proactive tech support allows each collector to have different report data set, report frequency, or report mode. A default collector is configured automatically to minimize the configuration required to enable the feature.

## Limitations

- Proactive tech support uses SSL to secure the switch information transmission on the Internet. If the feature is not enabled, the switch information is transmitted as clear text.
- XMOD applications can be dynamically upgraded without restarting the switch. But the upgraded XMOD version needs to match the installed ExtremeXOS version.

## Locating a Collector

The switch attempts to locate a data collector using the DNS hostname, or the IP address of a collector. You specify the DNS hostname or IP address of a collector when you add a collector. When a DNS hostname is configured for a collector, the switch attempts to resolve the IP address for the configured DNS hostname before it attempts to connect to the collector. If the process of resolving IP address for a collector fails, the connection process stops and logs an error message.

When you start the feature a default collector is automatically configured a public IP address of a Splunk server hosted in Extreme's internal network. When you enable the feature, the switch automatically attempts to locate the default collector and send switch status information to the collector. You can configure up to four collectors on the switch. If you want to collect switch status information in your own collector (beside the default collector), you can use the `configure tech-support add collector`

command to configure an additional collector. The switch will send independent status reports to each collector based on each collector's configuration.

By default, the primary IP address on the Mgmt *VLAN* interface is used for the discovery process of a collector. If an IP address is not found on the Mgmt VLAN, an error message is displayed. Optionally, you can specify a source IP address to connect to a collector. The connection between the switch and a collector is established and maintained with TCP.

## Configuring Proactive Tech Support

The examination and reporting of switch status is implemented as a loadable application, called techSupport.xmod. You can dynamically upgrade the XMOD applications without restarting the switch by issuing `download image ip_address app.xmod, run update, and then restart process techSupport` commands.

### *Safe Default Startup*

By default proactive tech support services are disabled. You can opt-out of this service either by answering "Yes", "Y", or pressing the ENTER key to answer the question that is posed when accessing the switch for the first time. You can also use the `disable tech-support collector` command. Here is the system output prompt for the tech support feature:

The switch will proactively attempt to send basic configuration and operational switch information for the purpose of assisting Extreme Networks resolve customer reported issues. Uploaded data is encrypted if the `ssh.xmod` is installed. Otherwise, a reduced switch data set is sent in clear text that contains no customer specific information.

Would you like to disable the automatic switch reporting service? [Y/n]:

## Technical Support Bundles for Troubleshooting

To troubleshoot issues, you can use debug bundles, which are JSON files with predefined modules to common problems that can be executed when an issue occurs. You can search for a bundle that best matches your issue, and then execute that relevant bundle that matches your problem.

To use tech support bundles:

1. View the available bundles using the following command:

```
show tech-support help
```

List of Bundles: L2-VPN, AAA, GTP, MLAG, optics, VLAN, MPLS, L2 multicast, Netlogin, L3 IPv4, VRRP, LAG, L2, EAPS, policy, STP, ACL, OSPF, link issues, Extended Edge Switching (VPEX).

2. Copy `debug_bundle.json` to a TFTP server. Transfer by TFTP the file to your switch using the following command:

```
tftp get [ip-address | host-name] { vr vr_name } { block-size
block_size } remote-file local-file {force-overwrite}
```

Example:

```
tftp get 10.120.89.96 debug_bundle.json
```

The debug\_bundle.json file is located at: [https://github.com/extremenetworks/ExtremeScripting/blob/master/EXOS/Debug\\_Bundle/debug\\_bundle.json](https://github.com/extremenetworks/ExtremeScripting/blob/master/EXOS/Debug_Bundle/debug_bundle.json)

3. Run a debug bundle using the following command:

```
show tech-support {all | area | {{bundle bundle_name} {monitor
num_iterations} {interval seconds}} {detail} {logto [file]}
```

# Universal Port

[Supplicant Configuration Parameters](#) on page 2082

[Universal Port Configuration Overview](#) on page 2082

[Using Universal Port in an LDAP or Active Directory Environment](#) on page 2084

[Configuring Universal Port Profiles and Triggers](#) on page 2085

[Managing Profiles and Triggers](#) on page 2087

[Sample Universal Port Configurations](#) on page 2090

Universal Port is a flexible framework that enables automatic switch configuration in response to special events such as:

- User login and logoff
- Device connection to or disconnection from a port
- Time of day
- EMS event messages

## Note

The Universal Port feature is supported only on the platforms listed for this feature in the license tables in the [Switch Engine v33.3.1 Licensing Guide](#) document.

The primary component of the Universal Port feature is the profile, which is a special form of command script that runs when triggered by the events mentioned above.

Profiles execute commands and use variables as do the scripts described in [Using CLI Scripting](#) on page 2113. The primary difference is that a profile can be executed manually or automatically in response to switch events.

## Note

The term *profile* is distinct from the term *policy* because a policy is only one particular application of a profile.

Universal Port works with the following ExtremeXOS components and third-party products:

- [ExtremeXOS Network Login](#)
- [ExtremeXOS LLDP](#)
- [ExtremeXOS CLI Scripting](#)
- [Status Monitoring and Statistics](#)
- [RADIUS Servers](#)
- Active directory services such as LDAP and Microsoft Active Directory

The following are some examples of how you can use Universal Port on a network:

- Automatically provision a VoIP phone and the attached switch port with appropriate *PoE (Power over Ethernet)* budget and *QoS (Quality of Service)* settings when the phone connects.
- Create security policies that can follow a user as the user roams around a campus. For example, an engineer can walk from Building 1 to Building 5, plug his PC into the network and be authenticated with the appropriate access rights and ACLs.
- Support separate authentication for VoIP phones and workstations on the same port.
- Create profile templates with variables so that you can re-use templates with different address ranges and parameters.
- Apply different security policies for different locations (for example, a restricted area).
- Disable wireless access after business hours.

**Note**

Special scripts can be run when the switch boots. For more information, see [Using Autoconfigure and Autoexecute Files](#) on page 1653.

## Profile Types

---

The ExtremeXOS software supports two types of profiles: [static](#) and [dynamic](#).

### Static Profiles

Static profiles are so named because they are not triggered by dynamic system events. To trigger a static profile, you must enter a command at the switch prompt or run a script that contains the command to start a static profile. The following guidelines apply to static profiles:

- Static profiles are not limited to individual ports and can include system-wide configuration changes.
- Static profiles are not assigned to a port and are not specific to a device or a user.
- Changes made by static profiles are persistent. They are saved in the switch configuration and are preserved during system reboots.

Static profiles are typically used to establish default switch settings. Using scripts and variables, you can create static profiles that serve as templates for initializing switches

or reconfiguring switches to manually respond to network or business events. These templates can simplify complex configuration tasks such as Netlogin.

## Dynamic Profiles

Dynamic profiles are so named because they are dynamically triggered by the following types of events:

- Device discovery and disconnect
- User- or standards-based authentication and logoff
- Time of day
- Switch events reported by the EMS

Dynamic profiles are event- or action-driven and do not require an administrator to start the profile.

Without dynamic profile support, IT personnel must be available when devices are added, moved, or changed so they can configure both the network port and the new device. These tasks typically take a long time, do not support mobility, and are often prone to human error.

When dynamic profiles are configured properly and a device connects to an edge port, a triggering event triggers a profile that runs a script to configure the port appropriately. The script can use system run-time variables and information gathered from tools such as Netlogin and [\*LLDP \(Link Layer Discovery Protocol\)\*](#) to customize the port configuration for the current network environment. For example, the profile can customize the port configuration based on the user ID or MAC address. Dynamic profiles allow you to automate the network response to a variety of network events.

Dynamic profiles create temporary states. For example, if a power outage causes the switch to restart, all ports return to the default configuration. When a triggering event such as a specific device connection occurs again, the profile is applied again. When the device is no longer connected, the disconnect event can trigger another profile to unconfigure the port.

The temporary state configured by a dynamic profile is configured by prepending the `configure cli mode non-persistent` command to the script. The temporary nature of profile configuration is critical for network security. Imagine a situation where a dynamic security profile is used. If the information granting access to specific network resources is saved in the configuration, the switch is restarted, and a user loses network connectivity on a secure port, the secure port still provides network access after the switch restarts. Anybody else can access network resources simply by connecting to that secure port.

Although the switch configuration returns to the default values after a restart, there is no automatic configuration rollback for dynamic profiles. For example, if a profile grants secure access to network resources at user login, the configuration is not automatically rolled back when the user logs off. To roll back the configuration at user log off, you must create another profile that responds to user log off events.

To support configuration rollback, the scripting feature allows you to save information used in dynamic profiles in variables. When a profile is activated and you want the option to roll back to the previous default setting, some information must be saved, such as the default *VLAN (Virtual LAN)* setting or the default configuration of a port. Essentially anything modified from the previous setting can be preserved for future use by the profile that rolls back the configuration.

There can be multiple profiles on a switch, but only one profile runs at a time. Data from a trigger event is used to select the appropriate profile, and that data can also be used to make decision points within a profile. A typical example is the use of a *RADIUS (Remote Authentication Dial In User Service)* server to specify a particular profile and then apply port-based policies to the user based on the user's location.

There is no profile hierarchy and no software validation to detect if a new profile conflicts with older profile. If two profiles conflict, the same profile might produce different results, depending on the events leading up to the profile trigger. When you create profiles, you must be familiar with all profiles on the switch and avoid creating profiles that conflict with each other.

## Dynamic Profile Trigger Types

---

The following sections describe the types of dynamic profile trigger types: [device](#), [user authentication](#), [time](#), and [event-management system](#).

### Device Triggers

Device triggers launch a profile when a device connects to or disconnects from a port.

The two types of device triggers are labeled device-detect and device-undetected in the software. Profiles that respond to these triggers are called device-detect profiles or device-undetected profiles.

Typically, a device-detect profile is used to configure a port for the device that has just connected.

Likewise, a device-undetected profile is used to return the port to a default configuration after a device disconnects. A variety of different devices can be connected to a port. When devices connect to the network, Universal Port helps provide the right configuration at the port.

Device triggers respond to the discovery protocols IEEE 802.1ab *LLDP* and ANSI/TIA-1057 LLDP-MED for Voice-over-IP (VoIP) phone extensions. A device-detect trigger occurs when an LLDP packet reaches a port that is assigned to a device-detect profile. A device-undetected trigger occurs when periodically transmitted LLDP packets are not received anymore. LLDP age-out occurs when a device has disconnected or an age-out time has been reached. LLDP must be enabled on ports that are configured for device-detect or device-undetected profiles. LLDP is described in [LLDP](#).

The combination of device triggers and LLDP enables the custom configuration of devices that connect to switch ports. For example, VoIP phones can send and receive information in addition to normal device identification information. The information

sent through LLDP can be used to identify the maximum power draw of the device. The switch can then set the maximum allocated power for that port.

If the switch does not have enough *PoE* left, the switch can take action to lower the PoE loading and try again. The switch can also transmit additional VoIP files and call server configuration information to the phone so the phone can register itself and receive necessary software and configuration information.

There can only be one device-detect profile and one device-undetected profile per port. To distinguish between different connecting devices, you can use if-then-else statements in a profile along with detailed information provided through LLDP.

## User Authentication Triggers

User authentication triggers launch a profile when a user or an identified device logs in or out of the network using [Network Login](#) on page 1191.

The network login feature does not permit any access beyond the port until the user or device is authenticated.

The two types of user authentication triggers are labeled user-authenticate and user-unauthenticated in the software. Profiles that respond to these triggers are called user-authenticate profiles or user-unauthenticated profiles. Typically, a user-authenticate profile is used to configure a port for a user and device that has just connected. Likewise, a user-unauthenticated profile is used to return the port to a default configuration after a user or device disconnects. Successful network login triggers the user-authenticate profile, and either an explicit logout, a session time out, or a disconnect triggers the user-unauthenticated profile.

### Note

VoIP phones are also capable of being authenticated before being allowed on the network. The phone begins 802.1X authentication based on a personal username and password. This authentication step is available and supported by the latest firmware from vendors such as Avaya and Mitel.

Network login requires a *RADIUS* server for user or device authentication.

The RADIUS server provides the following features:

- Centralized database for network authentication
- Further centralization when connected to an LDAP or Active Directory database
- Dynamic switch configuration through Vendor Specific Attributes (VSAs)

VSAs are values that are passed from the RADIUS server to the switch after successful authentication. VSAs can be used by the switch to configure connection attributes such as security policy, *VLAN*, and location. For more information on RADIUS and VSAs, see [Security](#) on page 1573.

The following sections introduce each of the network login event types that can trigger profiles:

- [802.1X Network Login](#)

- [MAC-Based Network Login](#)
- [Web-Based Network Login](#)

#### *802.1X Network Login*

Network login 802.1X requires 802.1X client software on the device to be authenticated.

At login, the user supplies a user name and password, which the switch passes to the RADIUS server for authentication. When the user passes authentication, the RADIUS server notifies the switch, and the user-authenticate profile is triggered.

One advantage of 802.1X network login is that it can uniquely identify a user. A disadvantage is that not all devices support 802.1X authentication. For more information, see [Network Login](#) on page 1191.

#### *MAC-Based Network Login*

MAC-based network login requires no additional software, and it does not require any interaction with the user.

When network login detects a device with a MAC address that is configured on the switch, the switch passes the MAC address and an optional password to the RADIUS server for authentication. When the device passes authentication, the RADIUS server notifies the switch, and the user-authenticate profile is triggered.

One advantage of MAC-based network login is that it requires no special software. A disadvantage is that security is based on the MAC address of the client, so the network is more vulnerable to spoofing attacks. For more information, see [Network Login](#) on page 1191.

#### **Note**

MAC-based authentication can also be used to identify devices. For example, an entire MAC address or some bits of the MAC address can identify a device and trigger switch port auto-configuration similar to the [LLDP](#)-based device detect event. The difference between MAC-based authentication and LLDP authentication is that MAC-based authentication does not provide information on the connected device. The advantage of MAC-based authentication is that it enables non-LLDP devices to trigger profiles.

#### **Note**

UPM VSA is supported in ONEPolicy in [NetLogin](#) mode.

#### *Web-Based Network Login*

Web-based network login requires a [DHCP \(Dynamic Host Configuration Protocol\)](#) server and may require a DNS server.

At login, the user supplies a user name and password through a web browser client, which the switch passes to the RADIUS server for authentication. When the user passes authentication, the RADIUS server notifies the switch, and the user-authenticate profile is triggered.

Some advantages of web-based network login are that it can uniquely identify a user and it uses commonly available web client software. Some disadvantages are a lower level of security and the IP configuration requirement. For more information, see [Network Login](#) on page 1191.

## Time Triggers

Time triggers launch a profile at a specific time of day or after a specified period of time.

For example, you can use time triggers to launch profiles at the following times:

- 6:00 p.m. every day
- One-time after 15 minutes
- One hour intervals

A profile that uses a time trigger is called a time-of-day profile. You might use a time trigger to launch a profile to disable guest [VLAN](#) access, shut down a wireless service, or power down a port after business hours. Time triggers enable profiles to perform timed backups for configurations, policies, statistics, and so forth. Anything that needs to happen on a regular basis or at a specific time can be incorporated into a time-of-day profile. Time-of-day profiles are not limited to non-persistent-capable CLI commands and can use any command in the ExtremeXOS CLI.

Unlike the device-detect and user-authenticate triggers, time triggers do not have an equivalent function to the device-undetected or user-unauthenticated triggers. If you need the ability to unconfigure changes made in a time-of-day profile, just create another time-of-day profile to make those changes.

## Event Management System Triggers

EMS-event triggers launch a profile when the EMS produces a message that conforms to a predefined definition that is configured on the switch. The ExtremeXOS EMS feature is described in [CLEAR-Flow](#).

Profiles that respond to EMS-event triggers are called EMS-event profiles. Typically, an EMS-event profile is used to change the switch configuration in response to a switch or network event.

The EMS events that trigger Universal Port profiles are defined in EMS filters and can be specified in more detail with additional CLI commands.

You can create EMS filters that specify events as follows:

- Component.subcomponent
- Component.condition
- Component.subcomponent.condition

You can use the `show log components` command to display all the components and subcomponents for which you can filter events. If you specify a filter to take action on a component or subcomponent, any event related to that component triggers the profile. You can use the `show log events all` command to display all the conditions or

events for which you can filter events. If you decide that you want to configure a profile to take action on an *ACL (Access Control List)* policy change, you can add a filter for the `ACL.Policy.Change` event.

You can further define an event that triggers a Universal Port profile by specifying an event severity level and text that must be present in an event message.

When a specified event occurs, event information is passed to the Universal Port profile in the form of variables, which can be used to modify the switch configuration.

EMS-triggered profiles allow you to configure responses for any EMS event listed in the `show log components` and `show log events all` commands. However, you must be careful to select the correct event and corresponding response for each profile. For example, if you attempt to create a Universal Port log target for a specific event (`component.subcomponent.condition`) and you accidentally specify a component (`component`), the profile is applied to all events related to that component. Using EMS-triggered profiles is similar to switch programming. They provide more control and therefore more opportunity for misconfiguration.

Unlike the device-detect and user-authenticate triggers, EMS-event triggers do not have an equivalent function to the device-undetected or user-unauthenticated triggers.

If you need the ability to unconfigure changes made in an EMS-event profile, just create another static or dynamic profile to make those changes.

---

## How Device-detect Profiles Work

Device-detect profiles enable dynamic port configuration without the use of a *RADIUS* server. Device-detect profiles and device-undetected profiles are triggered as described earlier in [Device Triggers](#) on page 2069.

When a device connects to a port that has a device-detect profile configured, the switch runs the specified profile and stops. Only one device detect profile can be configured for a port, so the same profile runs each time a device is detected on the port. Only one device-undetected profile can be configured for a port, so the same profile is run each time the switch detects that all previously-connected devices are no longer connected.

---

## How User Authentication Profiles Work

User-authentication profiles can be assigned to user groups or individual users. Typically, a company creates profiles for groups such as software engineering, hardware engineering, marketing, sales, technical support, operations, and executive. These kinds of categories make profile management more streamlined and simple.

The authentication process starts when a switch receives an authentication request through Network Login. The authentication request can be for a specific user or a MAC address. A user name and password might be entered directly or by means of other security instruments, such as a smart card. A MAC address would be provided by *LLDP*, which would need to be operating on the ingress port. Netogin enforces authentication before granting access to the network. All packets sent by a client on the port do not

go beyond the port into the network until the user is authenticated through a *RADIUS* server.

Starting with ExtremeXOS 30.4, the authentication VLAN information from ONEPolicy is passed to Netlogin, so that UPM scripts can make use of this information. Note that dynamic VLANs are not fully supported, because a dynamic VLAN can be created prior to the client being authenticated. In such cases, the VLAN appears as "<not found> xxx" where "xxx" is the VLAN number, rather than the VLAN name, which usually appears. UPM VLAN processing also does not function, because the VLAN has not yet been created.

The switch authenticates the user through a RADIUS server, which acts as a centralized authorization point for all network devices. The RADIUS server can contain the authentication database, or it can serve as a proxy for a directory service database, such as LDAP or Active Directory. The switch also supports optional backup authentication through the local switch database when a RADIUS server is unavailable.

The RADIUS server responds to the switch and either accepts or denies user authentication. When user authentication is accepted, the RADIUS server can also send Vendor Specific Attributes (VSAs) in the response. The VSAs can specify configuration data for the user such as the Universal Port profile to run for login, a *VLAN* name, a user location, and a Universal Port profile to run for logout. Extreme Networks has defined vendor specific attributes that specify configuration settings and can include variables to be processed by the Universal Port profile. If profile information is not provided by the RADIUS server, the user-authenticate profile is used.

Profiles are stored and processed on the switch. When a user name or MAC address is authenticated, the switch places the appropriate port in forwarding mode and runs either a profile specified by the RADIUS server, or the profile defined for the authentication event. The profile configures the switch resources for the user and stops running until it is activated again.

When a user or MAC address is no longer active on the network, due to logoff, disconnect, or inactivity, user unauthentication begins.

To complete unauthentication, the switch stops forwarding on the appropriate port and does one of the following:

1. Runs an unauthenticate profile specified by the RADIUS server during authentication.
2. Runs an unauthenticate profile configured on the switch and assigned to the affected port.
3. Runs the authenticate profile initially used to authenticate the user .

The preferred unauthenticate profile is one specified by the RADIUS server during authentication. If no unauthenticate profiles are specified, the switch runs the authenticate profile used to authenticate the user or device.

---

## Profile Configuration Guidelines

You can configure both static and dynamic profiles using the CLI.

## Obtaining Profiles

You can write your own profiles.

You can obtain profiles from the Extreme Networks website, another Extreme Networks user or partner, or Extreme Networks professional services.

Sample profiles are listed in [Sample Universal Port Configurations](#) on page 2090.

The Universal Port Handset Provisioning Module is a collection of profiles and documentation that is available with other samples on the Extreme Networks website.

## Profile Rules

All profiles have the following restrictions:

- Maximum 5000 characters in a profile.
- Maximum 128 profiles on a switch.
- Profiles are stored as part of the switch configuration file.
- Copy and paste is the only method to transfer profile data using the CLI.
- Unless explicitly preceded with the command `configure cli mode persistent`, all non-persistent-capable commands operate in non-persistent mode when operating in dynamic profiles.
- Unless explicitly preceded with the command `configure cli mode non-persistent`, all non-persistent-capable commands operate in persistent mode when operating in static profiles.

### Note

There is no profile hierarchy, which means users must verify there are no conflicting rules in static and dynamic profiles. This is a normal requirement for ACLs, and is standard when using policy files or dynamic ACLs.

When the switch is configured to allow non-persistent-capable commands to operate in non-persistent mode, the switch configuration related to the non-persistent commands is not saved to the configuration file. This behavior enables the ports to return to their initial state when a reboot or power cycle occurs. You can view the configuration changes made by non-persistent commands through the application's show commands, but the changes do not appear in `show configuration {module-name} {detail}`.

## Multiple Profiles on the Same Port

Multiple Universal Port profiles can be created on a switch, but only one profile per event can be applied per port. Different profiles on the same port apply to different events—different authentication events for different devices or users.

You can configure multiple user profiles on a port or a group of ports. For instance, you might create user-authentication profiles for different groups of users, such as Engineering, Marketing, and Sales.

You can also configure a device-triggered profile on a port that supports one or more user profiles. However, you can configure only one device-triggered profile on a port.

## Supported Configuration Commands and Functions

Static and dynamic profiles support the full ExtremeXOS command set. They also support the built-in functions described in [Using CLI Scripting](#) on page 2113.

Commands that are executed in persistent mode become part of the saved switch configuration that persists when the switch is rebooted. Commands that are executed in non-persistent mode configure temporary changes that are not saved in the switch configuration and do not persist when the switch is rebooted.

However, a subset of these commands operates by default in non-persistent mode when executed in a dynamic profile.

Most commands operate only in persistent mode. The subset of commands that operate in non-persistent mode are called non-persistent-capable commands. The Universal Port feature uses the non-persistent-capable commands to configure temporary changes that could create security issues if the switch were rebooted or reset. The use of non-persistent-capable commands in scripts and Universal Port profiles allows you to make temporary configuration changes without affecting the default configuration the next time the switch is started.

The following table shows the non-persistent capable CLI commands.

### *Non-Persistent-Capable Configuration Commands*

#### ACL Commands

```
configure access-list add dynamic_rule [[[first | last] {priority
p_number} {zone zone}] | [[before | after] rule] | [priority p_number
{zone zone}]] [any | vlan vlanname | ports portlist] {ingress |
egress}
```

```
configure access-list delete ruleName [any | vlan vlanname | ports
portlist | all] {ingress | egress}
```

#### LLDP Commands

```
configure lldp ports portlist [advertise | dont advertise | no-advertise
| dcbx] {all-tlvs | management-address | port-description | system-
capabilities | system-description | system-name | vendor-specific}
```

#### Port Commands

```
disable port [port_list | all]
```

```
disable jumbo-frame ports [all | port_list]
```

```
enable port [port_list | all]
```

```
enable jumbo-frame ports [all | port_list]
```

## Power over Ethernet Commands

```
configure inline-power label string ports port_list

configure inline-power operator-limit milliwatts ports [all | port_list]

configure inline-power priority [critical | high | low] ports port_list

disable inline-power

disable inline-power ports [all | port_list]

disable inline-power slot slot

enable inline-power

enable inline-power ports [all | port_list]

enable inline-power slot slot

unconfigure inline-power priority ports [all | port_list]
```

## VLAN Commands

```
configure {vlan} vlan_name add ports [port_list | all] {tagged |
untagged} {{stpd} stpd_name} {dot1d | emistp | pvst-plus}}

configure ip-mtu mtu vlan vlan_name
```

## QOS/Rate-limiting Commands

```
configure ports port_list {qosprofile} qosprofile
```

## Show Commands

All show commands can be executed in non-persistent mode.

By default, all commands operate in persistent mode with the following exceptions:

- In Universal Port dynamic profiles, the non-persistent-capable commands operate in non-persistent mode unless preceded by the `configure cli mode persistent` command in the profile.
- In the CLI, CLI scripts, and static profiles, the non-persistent-capable commands operate in non-persistent mode only when preceded by the `configure cli mode non-persistent` command.

You can use the `configure cli mode persistent` command and the `configure cli mode non-persistent` command to change the mode of operation for non-persistent-capable commands multiple times within a script, profile, or configuration session.

## Universal Port Variables

Universal Port uses CLI Scripting variables to make system and trigger event information available to profiles. For more information, see [Using CLI Scripting](#) on page 2113.

Variables allow you to create profiles and scripts that respond to the state of the switch as defined in the variables. When a profile is triggered, the system passes variables to the profile. You can also create and use variables of your own. User-defined variables are limited to the current context unless explicitly saved.

### Note

You must enable CLI scripting before using variables or executing a script.

If you save variables (as described in [Saving, Retrieving, and Deleting Session Variables](#) on page 2124), certain data from one profile can be reused in another profile for another event. For example, between login and logout events, the data necessary for the rollback of a port configuration can be shared.

The following sections describe the variables that are available to profiles:

- [Common Variables](#)
- [User Profile Variables](#)
- [Device Detect Profile Variables](#)
- [Event Profile Variables](#)

### Common Variables

[Table 166](#) shows the variables that are always available for use by any script. These variables are set up for use before a script or profile is executed.

**Table 166: Common Variables**

| Variable Syntax    | Definition                                                                                                         |
|--------------------|--------------------------------------------------------------------------------------------------------------------|
| \$STATUS           | Status of last command execution.                                                                                  |
| \$CLI.USER         | Username for the user who is executing this CLI.                                                                   |
| \$CLI.SESSION_ID   | An identifier for a session. This identifier is available for the roll-back event when a device or user times out. |
| \$CLI.SESSION_TYPE | Type of session of the user.                                                                                       |
| \$EVENT.NAME       | This is the event that triggered this profile.                                                                     |
| \$EVENT.TIME       | Time this event occurred. The time is in seconds since epoch.                                                      |
| \$EVENT.TIMER_TYPE | Type of timer, which is periodic or non_periodic.                                                                  |
| \$EVENT.TIMER_NAME | Name of the timer that the Universal Port is invoking.                                                             |

**Table 166: Common Variables (continued)**

| Variable Syntax         | Definition                                                                                 |
|-------------------------|--------------------------------------------------------------------------------------------|
| \$EVENT.TIMER_LATE_SECS | Time difference between when the timer fired and when the actual shell was run in seconds. |
| \$EVENT.PROFILE         | Name of the profile that is being run currently.                                           |

*User Profile Variables*

Table 167 shows the variables available to user profiles.

**Table 167: User Profile Variables**

| Variable Syntax        | Definition                                                                                                                                                                                                                                                                                                                                       |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| \$EVENT.USERNAME       | Name of user authenticated. This is a string with the MAC address for MAC-based user-login.                                                                                                                                                                                                                                                      |
| \$EVENT.NUMUSERS       | Number of authenticated supplicants on this port after this event occurred.<br><br><b>Note:</b> For user-authenticated events, the initial value of this variable is 0. For user unauthenticated events, the initial value is 1.                                                                                                                 |
| \$EVENT.USER_MAC       | MAC address of the user.                                                                                                                                                                                                                                                                                                                         |
| \$EVENT.USER_PORT      | Port associated with this event.                                                                                                                                                                                                                                                                                                                 |
| \$EVENT.USER_VLAN      | <u>VLAN</u> associated with this event or user.<br><br><b>Note:</b> If the VLAN is assigned dynamically, and the name is not available at the time of authentication, “\$EVENT.USER_VLAN” is returned as “<Not Found> xxx” where xxx is the VLAN number. This is not translated by UPM VLAN processing and appears for diagnostic purposes only. |
| \$EVENT.USER_ALL_VLANS | When a user is authenticated to multiple VLANs, this variable includes all VLANs for which the user is authenticated.                                                                                                                                                                                                                            |
| \$EVENT.USER_IP        | IP address of the user if applicable. Otherwise, this variable is blank.                                                                                                                                                                                                                                                                         |

*Device Detect Profile Variables*

Table 168 shows the variables available to device detect profiles.

**Table 168: Device Profile Variables**

| Variable Syntax                  | Definition                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| \$EVENT.DEVICE                   | Device identification string.<br>Possible values for EVENT.DEVICE are:<br>AVAYA_PHONE, GEN_TEL_PHONE, ROUTER, BRIDGE,<br>REPEATER, WLAN_ACCESS_PT, DOCSIS_CABLE_SER,<br>STATION_ONLY and OTHER.<br>These strings correspond to the devices that the <i>LLDP</i> application recognizes and reports to the Universal Port management application. |
| \$EVENT.DEVICE_IP                | The IP address of the device (if available). Blank if not available.                                                                                                                                                                                                                                                                             |
| \$EVENT.DEVICE_MAC               | The MAC address of the device (if available). Blank if not available.                                                                                                                                                                                                                                                                            |
| \$EVENT.DEVICE_POWER             | The power of the device in milliwatts (if available). Blank if not available.                                                                                                                                                                                                                                                                    |
| \$EVENT.DEVICE_MANUFACTURER_NAME | The manufacturer of the device.                                                                                                                                                                                                                                                                                                                  |
| \$EVENT.DEVICE_MODEL_NAME        | Model name of the device.                                                                                                                                                                                                                                                                                                                        |
| \$EVENT.USER_PORT                | Port associated with the event.                                                                                                                                                                                                                                                                                                                  |

*Event Profile Variables*

Table 169 shows the variables available to event profiles.

**Table 169: Event Profile Variables**

| Variable Syntax                    | Definition                                                                                                     |
|------------------------------------|----------------------------------------------------------------------------------------------------------------|
| \$EVENT.NAME                       | The event message.                                                                                             |
| \$EVENT.LOG_DATE                   | The event date.                                                                                                |
| \$EVENT.LOG_TIME                   | The event time.                                                                                                |
| \$EVENT.LOG_COMPONENT_SUBCOMPONENT | The component and subcomponent affected by the event as it appears in the show log components command display. |
| \$EVENT.LOG_EVENT                  | The event condition as it appears in the show log events command display.                                      |
| \$EVENT.LOG_FILTER_NAME            | The EMS filter that triggered the profile.                                                                     |
| \$EVENT.LOG_SEVERITY               | The event severity level defined in EMS.                                                                       |

**Table 169: Event Profile Variables (continued)**

| Variable Syntax                            | Definition                                                 |
|--------------------------------------------|------------------------------------------------------------|
| \$EVENT.LOG_MESSAGE                        | The event message with arguments listed in the format %1%. |
| \$EVENT.LOG_PARAM_0 to \$EVENT.LOG_PARAM_9 | Event arguments 0 to 9.                                    |

## Collecting Information from Supplicants

A supplicant is a device such as a VoIP phone or workstation that connects to the switch port and requests network services.

As described in [LLDP](#), LLDP is a protocol that can be used to collect information about device capabilities from attached devices or supplicants.

To use Universal Port with LLDP, you must enable LLDP on the port.

### Note

Avaya and Extreme Networks have developed a series of extensions for submission to the standards consortium for inclusion in a later version of the LLDP-MED standard:

- Avaya Power conservation mode
- Avaya file server
- Avaya call server

The following is an example of information provided through LLDP about an IP phone:

```

LLDP Port 1 detected 1 neighbor
Neighbor: (5.1)192.168.10.168/00:04:0D:E9:AF:6B, age 7 seconds
- Chassis ID type: Network address (5); Address type: IPv4 (1)
Chassis ID : 192.168.10.168
- Port ID type: MAC address (3)
Port ID : 00:04:0D:E9:AF:6B
- Time To Live: 120 seconds
- System Name: "AVAE9AF6B"
- System Capabilities : "Bridge, Telephone"
Enabled Capabilities: "Bridge, Telephone"
- Management Address Subtype: IPv4 (1)
Management Address : 192.168.10.168
Interface Number Subtype : System Port Number (3)
Interface Number : 1
Object ID String : "1.3.6.1.4.1.6889.1.69.1.13"
- IEEE802.3 MAC/PHY Configuration/Status
Auto-negotiation : Supported, Enabled (0x03)
Operational MAU Type : 100BaseTXFD (16)
- MED Capabilities: "MED Capabilities, Network Policy, Inventory"
MED Device Type : Endpoint Class III (3)
- MED Network Policy
Application Type : Voice (1)
Policy Flags : Known Policy, Tagged (0x1)
VLAN ID : 0
L2 Priority : 6
DSCP Value : 46

```

```
- MED Hardware Revision: "4625D01A"
- MED Firmware Revision: "b25d01a2_7.bin"
- MED Software Revision: "a25d01a2_7.bin"
- MED Serial Number: "061622014487"
- MED Manufacturer Name: "Avaya"
- MED Model Name: "4625"
- Avaya/Extreme Conservation Level Support
Current Conservation Level: 0
Typical Power Value : 7.4 Watts
Maximum Power Value : 9.8 Watts
Conservation Power Level : 1=7.4W
- Avaya/Extreme Call Server(s): 192.168.10.204
- Avaya/Extreme IP Phone Address: 192.168.10.168 255.255.255.0
Default Gateway Address : 192.168.10.254
- Avaya/Extreme CNA Server: 0.0.0.0
- Avaya/Extreme File Server(s): 192.168.10.194
- Avaya/Extreme IEEE 802.1q Framing: Tagged
```

**Note**

LLDP is tightly integrated with IEEE 802.1X authentication at edge ports. When used together, LLDP information from authenticated end point devices is trustable for automated configuration purposes. This tight integration between 802.1X and LLDP protects the network from automation attacks.

## Supplicant Configuration Parameters

---

As described in [LLDP](#), LLDP is a protocol that can be used to configure attached devices or supplicants. The following LLDP parameters are configurable on the switch ports when device-detect profiles execute are:

- [VLAN](#) Name
- Port VLAN ID
- Power Conservation Mode
- Avaya File Server
- Avaya Call server
- 802.1Q Framing

## Universal Port Configuration Overview

---

Because Universal Port operates with multiple ExtremeXOS software features and can operate with multiple third-party products, Universal Port configuration can require more than just the creation of profiles and triggers.

No single overview procedure can cover all the possible Universal Port configurations. The following sections provide overviews of the common types of Universal Port configurations.

## Device-Detect Configurations

A Universal Port device-detect configuration requires only a switch and supplicants. If [PoE](#) devices will connect to the switch, the switch should support PoE. Supplicants should support [LLDP](#) in the applicable software or firmware.

### Note

To support supplicant configuration, you might consider adding a [DHCP](#) server to your network.

Use the following procedure to configure Universal Port for device detection:

1. Create a device-detect profile as described in [Creating and Configuring New Profiles](#).
2. Create a device-undetect profile as described in [Creating and Configuring New Profiles](#).
3. Assign the device-detect profile to the edge ports as described in [Configuring a Device Event Trigger](#).
4. Assign the device-undetect profile to the edge ports as described in [Configuring a Device Event Trigger](#).
5. Verify that correct profiles are assigned to correct ports using the following command:  

```
show upm event event-type
```
6. Enable LLDP message advertisements on the ports that are configured for device-detect profiles as described in [LLDP](#).
7. Test profile operation as described in [Verifying a Universal Port Profile](#) on page 2089.

## User-Authentication Configurations

A Universal Port user-authenticate configuration requires specific components:

- An Extreme Networks switch, which might need to include [PoE](#) support.
- [RADIUS](#) server for user authentication and VSA transmission.
- Supplicants that support the authentication method you select. [LLDP](#) support is recommended, but is optional when MAC address authentication is used.

### Note

To support supplicant configuration, you might consider adding a [DHCP](#) server to your network. For VoIP applications, you can use a TFTP server and a call server to provide for additional supplicant configuration.

Use the following procedure to configure Universal Port for user login:

1. Configure the RADIUS server as described in [Security](#) on page 1573. The configuration should include the following:
  - User ID and password for RADIUS clients.
  - Extreme Networks custom VSAs.
  - Addition of the edge switch as a RADIUS client.
2. Create a user-authenticate profile as described in [Creating and Configuring New Profiles](#).

3. Create a user-unauthenticate profile as described in [Creating and Configuring New Profiles](#).
4. Assign the user-authenticate profile to the edge ports as described in [Configuring a User Login or Logout Event Trigger](#).
5. Assign the user-unauthenticate profile to the edge ports as described in [Configuring a User Login or Logout Event Trigger](#).
6. Configure network login on the edge switch as described in [Network Login](#).
7. Configure the edge switch as a RADIUS client as described in [Security](#).
8. Verify that correct profiles are assigned to correct ports by entering the following command:  

```
show upm event event-type
```
9. Enable LLDP message advertisements on the ports that are configured for device-detect profiles as described in [LLDP Overview](#).
10. Test profile operation as described in [Verifying a Universal Port Profile](#) on page 2089.

## Time-of-Day Configurations

To configure Universal Port to use a time-of-day profile, use the following procedure:

1. Create a profile as described in [Creating and Configuring New Profiles](#).
2. Create and configure a timer as described in [Configuring a Universal Port Timer](#).
3. Create the timer trigger and attach it to the profile as described in [Configuring a Timer Trigger](#).

## EMS-Event Configurations

To configure Universal Port to use an EMS-event profile, use the following procedure:

1. Create the EMS-Event profile as described in [Creating and Configuring New Profiles](#).
2. Create and configure an event filter to identify the trigger event as described in [Creating an EMS Event Filter](#).
3. Create the event trigger and attach it to the profile and filter as described in [Configuring an EMS Event Trigger](#).
4. Enable the event trigger as described in [Enabling and Disabling an EMS Event Trigger](#) on page 2087.

## Using Universal Port in an LDAP or Active Directory Environment

The *RADIUS* server can operate in proxy mode with information stored in a central directory service such as LDAP or Active Directory.

This proxy mode is configured between the RADIUS server and the central directory service. Once configured, supplicants can be authenticated from the central directory service.

For more information, see the following:

- [Setting Up Open LDAP](#) on page 1583.
- RADIUS server product documentation

- Product documentation for your central directory service

## Configuring Universal Port Profiles and Triggers

---

You can configure both static and dynamic profiles using the CLI.

### Note

In the CLI, “upm” is used as an abbreviation for the Universal Port feature.

## Creating and Configuring New Profiles

When you create and configure a new profile, you are basically writing a script within a profile that can be triggered by system events. For more information on the rules, commands, and variables that apply to profiles, see [Profile Configuration Guidelines](#) on page 2074.

1. Create and configure a new profile using the following command:  
`configure upm profile profile-name maximum execution-time seconds`
2. After you enter the command, the switch prompts you to add command statements to the profile as shown in the following example:

```
switch # create upm profile detect-voip
Start typing the profile and end with a . as the first and the only character on a
line.
Use - edit upm profile <name> - for block mode capability
create log message Starting_Script_DETECT-voip
set var callServer 192.168.10.204
set var fileServer 192.168.10.194
set var voiceVlan voice
set var CleanupProfile CleanPort
set var sendTraps false
#
.
switch #
```

The example above creates a log entry and sets some variables, but it is not complete. This example shows that after you enter the `create upm profile` command, you can enter system commands. When you have finished entering commands, you can exit the profile creation mode by typing the period character ( `.` ) at the start of a line and pressing **[Enter]**.

## Editing an Existing Profile

- Edit an existing profile.  
`edit upm profile profile-name`

## Configuring a Device Event Trigger

There are two types of device event triggers, which are named as follows in the CLI: `device-detect` and `device-undetected`. When you configure a device event trigger, you assign one of the two device event trigger types to a profile and specify the ports to which the triggered profile applies.

To configure a device event trigger, use the following command:

```
configure upm event upm-event profile profile-name ports port_list
```

Replace *upm-event* with one of the device event trigger types: device-detect or device-undetected.

## Configuring a User Login or Logout Event Trigger

There are two types of user event triggers, which are named as follows in the CLI: user-authenticate and user-unauthenticated. When you configure a user event trigger, you assign one of the two user event trigger types to a profile and specify the ports to which the triggered profile applies.

To configure a user event trigger, use the following command:

```
configure upm event upm-event profile profile-name ports port_list
```

Replace *upm-event* with one of the device event trigger types: user-authenticate or user-unauthenticated.

## Configuring a Universal Port Timer

To configure a Universal Port timer, you must complete two steps:

1. Create the timer by using the following command:

```
create upm timer timer-name
```

2. Configure the timer by using the following commands:

```
configure upm timer timer-name after time-in-secs {every seconds}
```

```
configure upm timer timer-name at month day year hour min secs {every seconds}
```

## Configuring a Timer Trigger

When you configure a timer trigger, you assign a configured timer to a profile. When the configured time arrives, the switch executes the profile.

To configure a timer trigger, use the following command:

```
configure upm timer timerName profile profileName
```

Replace *timerName* with the timer name and *profileName* with the profile name.

## Creating an EMS Event Filter

An EMS event filter identifies an event that can be used to trigger a profile. To create an EMS event filter, use the following procedure:

1. Create a log filter to identify the event by using the following command:

```
create log filter name {copy filter name}
```

2. Configure the log filter using the following commands:

```
configure log filter name [add | delete] {exclude} events [event-
condition | [all | event-component] {severity severity {only}}]
configure log filter name [add | delete] {exclude} events [event-
condition | [all | event-component] {severity severity {only}}] [match
| strict-match] type value
```

## Configuring an EMS Event Trigger

When you configure an EMS event trigger, you identify an EMS filter that defines the event and a profile that runs when the event occurs. To configure an EMS event-triggered profile, use the following procedure:

1. Create a log target to receive the event notification by using the following command:

```
create log target upm {upm_profile_name}
```

2. Configure the log target to specify a filter and any additional parameters that define the event by using the following commands:

```
configure log target upm {upm_profile_name} filter filter-name
{severity [[severity] {only}}]
configure log target upm {upm_profile_name} match {any | regex}
```

## Enabling and Disabling an EMS Event Trigger

When you configure an EMS event trigger, it is disabled.

To enable an EMS event trigger or disable a previously enabled trigger, use the following commands:

```
enable log target upm {upm_profile_name}
disable log target upm {upm_profile_name}
```

## Unconfiguring a Timer

To unconfigure a timer, use the following command:

```
unconfigure upm timer timerName profile profileName
```

## Managing Profiles and Triggers

Use the following actions to manage profiles and triggers.

## Manually Executing a Static or Dynamic Profile

Profiles can be run from the CLI by configuring the system to run as it would when the trigger events happen. This facility is provided to allow you to test how the system

behaves when the actual events happen. The actual configuration is applied to the switch when the profile is run.

**Note**

Variables are not validated for correct syntax.

To manually execute a profile, use the following command:

```
run upm profile profile-name {event event-name} {variables variable-string}
```

Example:

```
run upm profile afterhours
```

If the variables keyword is not present, but an event variable is specified, you are prompted for various environment variables appropriate for the event, including the VSA string for user authentication.

## Displaying a Profile

To display a profile, use the following command:

```
show upm profile name
```

## Displaying Timers

Display a list of timers and associated timer information.

```
show upm timers
```

## Displaying Universal Port Events

Display events for trigger types. You can display a list of events that relate to one of the following trigger types:

- device-detect
- device-undetected
- user-authenticate
- user-unauthenticated

To display a list of Universal Port events for one of the above triggers, use the following command:

```
show upm event event-type
```

Replace *event-type* with one of the trigger types listed above.

## Displaying Profile History

To display a list of triggered events and associate event data, enter one of the following commands:

```
show upm history {profile profile-name | event upm-event | status [pass
| fail] | timer timer-name | detail}
```

```
show upm history exec-id number
```

## Verifying a Universal Port Profile

To verify a Universal Port profile configuration, trigger the profile and verify that it works properly. Trigger the profile based on the trigger type as follows:

- Device triggers—plug in the device
- Authentication triggers—authenticate a device or user
- Timer triggers—temporarily configure the timer for an approaching time
- EMS event triggers—reproduce the event to which the trigger responds

You can use the commands described earlier in this section to view information about the profile and how it behaves.

Because Universal Port works with multiple switch features, you might want to enter commands to examine the configuration of those features.

The following commands are an example of some of the commands that can provide additional information about profile operation.

Run:

```
show lldp
show lldp neighbors
show log
show netlogin
```

## Handling Profile Execution Errors

To conserve resources, the switch stores only the last execution log for the profile that resulted in an error.

The status column displays the status of the last command executed in a profile. If the last command was successful, the status shows “pass”; otherwise, the status shows “failed”. If you wish to terminate the execution of a profile on encountering the first error, you must include the line “configure cli scripting mode abort-on-error” in the beginning of the profile. Otherwise, the profile executes all the commands even if an error was encountered and displays the status of the last command executed.

- To see a tabular display showing the complete history of the last 100 profiles, use the following command:

```
show upm history {profile profile-name | event upm-event | status
[pass | fail] | timer timer-name | detail}
```

Use the detail keyword to display the actual executions that happened when the profile was run.

- To display a specific execution that was run, use the following command:

```
show upm history exec-id number
```

Select the exec-id number from the list in the tabular display.

## Disabling and Enabling a Profile

Universal Port profiles are automatically enabled when they are created.

To disable a profile or enable a previously disabled profile, use the following commands:

```
disable upm profile profile-name
```

```
enable upm profile profile-name
```

## Deleting a Profile

To delete a profile, use the following command:

```
delete upm profile profile-name
```

## Deleting a Timer

To delete a timer, use the following command:

```
delete upm timer timer-name
```

## Deleting an EMS Event Trigger

To delete an EMS event trigger, use the following command:

```
delete log target upm {upm_profile_name}
```

## Sample Universal Port Configurations

---

The following sections provide example configurations for a switch, profile, and policy file.

## Sample MAC Tracking Profile

The example in this section shows how to create a profile that takes action based on the MAC tracking feature. When the MAC tracking feature detects a MAC move in a VLAN, the MAC tracking feature generates an EMS log, which then triggers a profile.

### Note

You can also use the Identity Management feature to configure ports in response to MAC device detection events. For more information, see [Identity Management](#).

## Switch Configuration

The general switch configuration is as follows:

```
#Vlan config
create vlan v1
configure v1 add ports 1:17-1:18
configure vlan v1 ipadd 192.168.10.1/24
#mac tracking config
create fdb mac-tracking entry 00:01:02:03:04:01
create fdb mac-tracking entry 00:01:02:03:04:02
create fdb mac-tracking entry 00:01:02:03:04:03
create fdb mac-tracking entry 00:01:02:03:04:04
create fdb mac-tracking entry 00:01:02:03:04:05
#Log filter configuration
create log filter macMoveFilter
configure log filter "macMoveFilter" add events "FDB.MACTracking.MACMove"
#Meter configuration for ingress /egress rate limit
create meter m1
configure meter m1 peak-rate 250 mbps
create meter m2
configure meter m2 peak-rate 500 mbps
```

## MAC Tracking EMS Log Message

The MAC tracking feature produces the following EMS log message and message parameters:

```
The MAC address %0% on VLAN '%1%' has moved from port %2% to port %3%"
EVENT.LOG_PARAM_1 "vlan name"
EVENT.LOG_PARAM_2 "source port"
EVENT.LOG_PARAM_3 "moved port"
```

## Profile Configuration

The profile is configured as follows:

```
create upm profile macMove ;# editor
enable cli scripting
create access-list dac11 "source-address 192.168.10.0/24 " "permit ;count dac11"
create access-list dac12 "source-address 192.168.11.0/24 " "permit ;count dac12"
create access-list dac13 "source-address 192.168.15.0/24 " "deny ;count dac13"
create access-list dac14 "source-address 192.168.16.0/24 " "deny ;count dac14"
create access-list dac15 "source-address 192.168.17.0/24 " "deny ;count dac15"
configure access-list add dac11 first ports $(EVENT.LOG_PARAM_3)
configure access-list add dac12 first ports $(EVENT.LOG_PARAM_3)
```

```

configure access-list add dacl3 first ports $(EVENT.LOG_PARAM_3)
configure access-list add dacl4 first ports $(EVENT.LOG_PARAM_3)
configure access-list add dacl5 first ports $(EVENT.LOG_PARAM_3)
conf access-list ingress_limit vlan vl
conf access-list ingress_limit ports $(EVENT.LOG_PARAM_3)
conf access-list egress_limit any ;# enter . for SAVE/EXIT
log target configuration
create log target upm "macMove"
configure log target upm "macMove" filter "macMoveFilter"
enable log target upm "macMove"

```

### Policy File Configuration

This example uses the following two policy files:

```

Ingress rate limit (ingress_limit.pol)
=====
entry ingress {
if {
ethernet-source-address 00:AA:00:00:00:01;
ethernet-destination-address 00:BB:00:00:00:01;
} then {
Meter m1;
count c1;
}
}
Egress QoS (egress_limit.pol)
=====
entry egress {
if {
ethernet-source-address 00:BB:00:00:00:01;
ethernet-destination-address 00:AA:00:00:00:01;
} then {
qosprofile qp2;
count c2;
}
}

```

### Console Logs

The following show commands display the switch configuration:

```

* (debug) BD-12804.7 # show log con fil

## Universal Port Handset Provisioning Module Profiles

The Universal Port Handset Provisioning Module provides the following profiles:

- [Device-Triggered Generic Profile](#) on page 2095
- [Authentication-Triggered Avaya Profile](#) on page 2097

*Device-Triggered Generic Profile*

This is a template for configuring network parameters for VoIP phone support without 802.1X authentication. The profile is triggered after an LLDP packet is detected on the port.

```
#*****
Last Updated: April 11, 2007
Tested Phones: Avaya 4610, 4620, 4625
Requirements: LLDP capable devices
#*****
@MetaDataStart
@ScriptDescription "This is a template for configuring network parameters for VoIP
phones support LLDP but without authentication. The module is triggered through the
detection of an LLDP packet on the port. The following network side configuration is
done: enable SNMP traps, QoS assignment, adjust POE reservation values based on device
requirements, add the voiceVlan to the port as tagged. "
@VariableFieldLabel "Voice VLAN name"
set var voicevlan voiceavaya
@VariableFieldLabel "Send trap when LLDP event happens (true or false)"
set var sendTraps false
@VariableFieldLabel "Set QoS Profile (true or false)"
set var setQuality false
@MetaDataEnd
#
if (!$match($EVENT.NAME,DEVICE-DETECT)) then

create log message End_LLDP_Generic_Module_Config

```

### Authentication-Triggered Generic Profile

This profile has been created for phones that support an authentication protocol and assumes that the phone does not support [LLDP](#) and is provisioned using [DHCP](#) options.

This is a template for configuring network parameters for 802.1X authenticated devices. The module is triggered through successful authentication or unauthentication of the device.

```

Last Updated: April 11, 2007
Tested Phones: Avaya 4610, 4620, 4625
Requirements: 802.1X capable devices, netlogin configured and enabled on deployment
ports

@MetaDataStart
@ScriptDescription "This is a template for configuring network parameters for 802.1X
authenticated devices. The module is triggered through successful authentication of the
device. The following network side configuration is done: QoS assignment and enables DOS
protection. When used with IP phones, phone provisioning is done through DHCP options."

### Authentication-Triggered Avaya Profile

This script has been created for Avaya phones that support both 802.1X authentication and LLDP. Instead of using DHCP options, the phone is provisioned using LLDP parameters developed jointly by Extreme Networks and Avaya.

```

#*****
Last Updated: April 11, 2007
Tested Phones: SW4610, SW4620
Requirements: 802.1X authentication server, VSA 203 and VSA 212 from authentication
server. QP7 defined on the switch
#*****
@MetaDataStart
@ScriptDescription "This is a template for configuring LLDP capable Avaya phones using
the authentication trigger. This module will provision the phone with the following
parameters: call server, file server, dot1q, dscp, power. Additionally the following
network side configuration is done: enable SNMP traps and QoS assignment"

## Sample Static Profiles

The following configuration creates a profile and runs it statically:

```

* BD-10808.4 # Create upm profile p1
Enable port 1:1
.
* BD-10808.4 #run upm profile p1
* BD-10808.4 # show upm history exec 8006
UPM Profile: p1
Event: User Request , Time run: 2006-10-18 11:56:15
Execution Identifier: 8006 Execution Status: Pass
Execution Information:
1 # enable cli scripting
2 # set var EVENT.NAME USER-REQUEST
3 # set var EVENT.TIME 1161172575
4 # set var EVENT.PROFILE p1
5 # enable port 1:1

```

This profile creates and configures *EAPS (Extreme Automatic Protection Switching)* on the edge switch for connecting to the aggregation switch, creates specific *VLANs* and assigns tags, configures network login, and configures the *RADIUS* client component on the switch.

```

Last Updated: May 11, 2007
Tested Devices: SummitX EXOS 12.0
Description: This profile configures the switch with an EAPS ring, creates specified
vlans, configure network login, RADIUS.

```

```

## Sample Configuration with Device-Triggered Profiles

The following example demonstrates how to configure Universal Port for device detection:

```
Create and configure the VLAN for the VoIP network.
#
switch 1 # create vlan voice
switch 2 # configure voice ipaddress 192.168.0.1/24
Create the universal port profile for device-detect on the switch.
#
switch 3 # create upm profile detect-voip
Start typing the profile and end with a . as the first and the only character on a line.
Use - edit upm profile <name> - for block mode capability
create log message Starting_Script_DETECT-voip
set var callServer 192.168.10.204
set var fileServer 192.168.10.194
set var voiceVlan voice
set var CleanupProfile CleanPort
set var sendTraps false
#
create log message Starting_DETECT-VOIP_Port_${EVENT.USER_PORT}
#*****
adds the detected port to the device "unauthenticated" profile port list
#*****
create log message Updating_UnDetect_Port_List_Port_${EVENT.USER_PORT}
configure upm event Device-Undetect profile CleanupProfile ports ${EVENT.USER_PORT}
#*****
adds the detected port to the proper VoIP vlan
#*****
configure $voiceVlan add port ${EVENT.USER_PORT} tag
#*****
Configure the LLDP options that the phone needs

#
Enable LLDP message advertisements on the ports assigned to universal ports.
#
* switch 10 # enable lldp ports 1-10

```

## Sample Configuration with User-Triggered Profiles

This example demonstrates how to configure a [RADIUS](#) server and Universal Port for user login. The first part of the example shows the RADIUS server configuration. For more information on RADIUS server configuration, see [Security](#) on page 1573.

```

Configure the RADIUS server for the userID and password pair.
For FreeRADIUS, edit the users file located at /etc/raddb/users as shown in the
following lines.
#
#Sample entry of using an individual MAC addresses
00040D50CCC3 Auth-Type := EAP, User-Password == "00040D50CCC3"
Extreme-Security-Profile = "phone LOGOFF-PROFILE=clearport;",
Extreme-Netlogin-VLAN = voice
#Sample entry of using wildcard MAC addresses (OUI Method)
00040D000000 Auth-Type := EAP, User-Password == "1234"
Extreme-Security-Profile = "phone LOGOFF-PROFILE=clearport;",
Extreme-Netlogin-VLAN = voice
#Sample entry of using numeric UserID and password
10284 Auth-Type := EAP, User-Password == "1234"
Extreme-Security-Profile = "voip LOGOFF-PROFILE=voip",
Extreme-Netlogin-Vlan = voice
#Sample entry of using a text UserID and password
Sales Auth-Type := EAP, User-Password == "Money"
Extreme-Security-Profile = "Sales-qos LOGOFF-PROFILE=Sales-qos",
Extreme-Netlogin-Vlan = v-sales
Define the Extreme custom VSAs on RADIUS.
For FreeRADIUS, edit the dictionary file located at //etc/raddb/dictionary to
include the following details:
VENDOR Extreme 1916

```

```

ATTRIBUTE Extreme-CLI-Authorization 201 integer Extreme
ATTRIBUTE Extreme-Shell-Command 202 string Extreme
ATTRIBUTE Extreme-Netlogin-Vlan 203 string Extreme
ATTRIBUTE Extreme-Netlogin-Url 204 string Extreme
ATTRIBUTE Extreme-Netlogin-Url-Desc 205 string Extreme
ATTRIBUTE Extreme-Netlogin-Only 206 integer Extreme
ATTRIBUTE Extreme-User-Location 208 string Extreme
ATTRIBUTE Extreme-Netlogin-Vlan-Tag 209 integer Extreme
ATTRIBUTE Extreme-Netlogin-Extended-Vlan 211 string Extreme
ATTRIBUTE Extreme-Security-Profile 212 string Extreme
ATTRIBUTE Extreme-CLI-Profile 213 string Extreme

VALUE Extreme-CLI-Authorization Disabled 0
VALUE Extreme-CLI-Authorization Enabled 1
VALUE Extreme-Netlogin-Only Disabled 0
VALUE Extreme-Netlogin-Only Enabled 1
End of Dictionary
Add the switch as an authorized client of the RADIUS server.
For FreeRADIUS, edit the file located at //etc/raddb/clients.conf to include the
switches as details:
#
client 192.168.10.4 {
secret = purple
shortname = SummitX
End of clients.conf

```

The rest of this example demonstrates the configuration that takes place at the ExtremeXOS switch:

```

Create the universal port profile for user-authenticate:
* switch 1 # create upm profile phone
Start typing the profile and end with a . as the first and the only character on a line.
Use - edit upm profile <name> - for block mode capability
create log message Starting_Script_Phone
set var callServer 192.168.10.204
set var fileServer 192.168.10.194
set var voiceVlan voice
set var CleanupProfile CleanPort
set var sendTraps false
#
create log message Starting_AUTH-VOIP_Port_${EVENT.USER_PORT}

adds the detected port to the device "unauthenticated" profile port list

create log message Updating_Unauthenticated_Port_List_Port_${EVENT.USER_PORT}

Configure the LLDP options that the phone needs

configure lldp port ${EVENT.USER_PORT} advertise vendor-specific avaya-extreme call-server
${callServer}
configure lldp port ${EVENT.USER_PORT} advertise vendor-specific avaya-extreme file-server
${fileServer}
configure lldp port ${EVENT.USER_PORT} advertise vendor-specific avaya-extreme dot1q-
framing tagged
configure lldp port ${EVENT.USER_PORT} advertise vendor-specific med capabilities
If port is PoE capable, uncomment the following lines
#create log message UPM_Script_A-Phone_Finished_Port_${EVENT.USER_PORT}
.
switch 2 #
#
Create the universal port profile for user-unauthenticate on the switch:
#
switch 1 # create upm profile clearport

```

```

Start typing the profile and end with a . as the first and the only character on a line.
Use - edit upm profile <name> - for block mode capability
create log message STARTING_Script_CLEARPORT_on_$EVENT.USER_PORT
unconfigure lldp port $EVENT.USER_PORT
create log message LLDP_Info_Cleared_on_$EVENT.USER_PORT
unconfigure inline-power operator-limit ports $EVENT.USER_PORT
create log message POE_Settings_Cleared_on_$EVENT.USER_PORT
create log message FINISHED_Script_CLEARPORT_on_$EVENT.USER_PORT
.
* switch 2 #
Configure RADIUS on the edge switch.
#
* switch 4 # config radius primary server 192.168.11.144 client-ip 192.168.10.4 vr "VR-Default"
* switch 5 # config radius primary shared-secret purple
Configure Network Login on the edge switch.
#
For Network Login 802.1X, use the following command:
* switch 7 # create vlan nvlan
* switch 8 # config netlogin vlan nvlan
* switch 9 # enable netlogin dot1x
* switch 10 # enable netlogin ports 11-20 mode mac-based-vlans
* switch 11 # enable radius netlogin
#
For Network Login MAC-based or OUI method, use the following command:
* switch 7 # create vlan nvlan
* switch 8 # config netlogin vlan nvlan
* switch 9 # enable netlogin mac
* switch 10 # config netlogin add mac-list 00:04:0D:00:00:00 24 1234
* switch 11 # enable radius netlogin
Assign the user-authenticate profile to the edge port.
#
* switch 12 # configure upm event user-authenticate profile "phone" ports 11-20
* switch 13 #
Assign the user-unauthenticated profile to the edge port.
#
* switch 14 # configure upm event user-unauthenticated profile "clearport" ports 11-20
* switch 15 #
Check that the correct profiles are assigned to the correct ports.
#
* switch 16 # show upm profile
=====
UPM Profile Events Flags Ports
=====
phone User-Authenticated e 11-20
clearport User-Unauthenticated e 11-20
=====
Number of UPM Profiles: 5
Number of UPM Events in Queue for execution: 0
Flags: d - disabled, e - enabled
Event name: log-message(Log filter name) - Truncated to 20 chars
Enable LLDP message advertisements on the ports.
#
* switch 17 # enable lldp ports 11-20

```

## Sample Timer-Triggered Profile

The following profile and timer configuration disables POE on ports 1 to 20 everyday at 6:00 p.m.:

```

* switch 1 # create upm profile eveningpoe
Start typing the profile and end with a . as the first and the only character on a line.

```

```

Use - edit upm profile <name> - for block mode capability
create log message Starting_Evening
disable inline-power ports 1-20
.
*switch 2
*switch 3 # create upm timer night
*switch 4 # config upm timer night profile eveningpoe
*switch 5 # config upm timer night at 7 7 2007 19 00 00 every 86400

```

## Sample Profile with QoS Support

The example below can be used with an ExtremeSwitching series switch that supports QoS profiles qp1 and qp8.

When the user or phone logs in with a particular MAC address, the script configures the QoS profile configured by the user in the RADIUS server for the USER-AUTHENTICATED event. In this example, the user sets the QoS profile to be qp8.

You must configure network login, the RADIUS server, and Universal Port on the switch as part of the user log-in authentication process. For more information on configuring the RADIUS users file, see [Security](#) on page 1573.

The following example is an entry in the RADIUS users file for the MAC address of the phone:

```

00040D9D12A9 Auth-Type := local, User-Password == "test"
Extreme-security-profile = "p1 QOS=\"QP8\";LOGOFF-PROFILE=p2;VLAN=\"voice- test\";"

```

Below is the Universal Port profile configuration for this example:

```

Create upm profile p1
set var z1 $uppercase($EVENT.USER_MAC)
set var z2 $uppercase(00:04:0d:9d:12:a9)
#show var z1
#show var z2
if ($match($EVENT.NAME, USER-AUTHENTICATED) == 0) then
 if ($match($z1, $z2) == 0) then
 configure port $EVENT.USER_PORT qosprofile $QOS
 endif
endif
.

```

## Sample Event Profile

If not configured properly, the STP (Spanning Tree Protocol) can create loops in a network.

Should these loops develop, they can cause network degradation and eventually crash the network by duplicating too many Ethernet frames. By leveraging Universal Port and the Extreme Loop Recovery Protocol (ELRP) as shown in example below, it is not

only possible to detect and isolate the egress port, but it is also possible to disable the egress port to break loops.

### Note

This example illustrates how to create an event profile that reconfigures the switch after an event. After this example was created, ELRP was updated with the capability to disable a port without the help of an event profile. For more information, see [Using ELRP to Perform Loop Tests](#) on page 2048.

When a loop is detected on ports where ELRP is enabled and configured, ELRP logs a message using the following format:

```
01/17/2008 08:08:04.46 <Warn:ELRP.Report.Message> [CLI:ksu:1] LOOP DETECTED : 436309
transmitted, 64 received, ingress slot:port (1) egress slot:port (24)
```

To view more information on format of this command, enter the show log events command as shown in the following example:

```
* BD8810-Rack2.6 # show log events "ELRP.Report.Message" details
Comp SubComp Condition Severity Parameters

ELRP Report Message Warning 8 total
0 - string
1 - string
2 - number (32-bit
unsigned int)
3 - string
4 - number (32-bit
unsigned int)
5 - number (unsigned int)
6 - string
7 - string
"[%0%:%1%:%2%] %3% : %4% transmitted, %5% received, ingress slot:port (%6%) egress
slot:port (%7%)"
```

In the example log statement, the VLANksu, the ports is all, and the interval is "1."

If a loop is detected, we want to disable the egress port on which the ELRP control packets went out. In this example, we enable ELRP on all ports of a VLAN as follows:

```
configure elrp-client periodic vlan ports all interval 1 seconds
```

We want the profile to disable egress ports 1 and 24 (which have been configured for loop). If we enable ELRP on only one port, then the port alone would be disabled.

We observe that parameter 7 is the one we have to disable from the above log message and the details for that event.

### Configuring Universal Port Example

The following procedure configures Universal Port to disable the egress port identified by parameter 7:

1. Create the profile and add the command to disable the egress port as follows:

```
create upm profile disable_port_elrp
disable port $EVENT.LOG_PARAM_7
```

2. Verify that the profile is created and enabled by entering the following command:

```
show upm profile
```

3. Create the EMS configuration by entering the following commands:

```
create log target upm disable_port_elrp
create log filter f1
configure log filter f1 add event ELRP.Report.Message match string "LOOP"
enable log target upm "disable_port_elrp"
configure log target upm "disable_port_elrp" filter f1
```

4. At this point, connect the ports 1 and 24 to form a loop.

Two log messages will be logged when the loop is detected on ports 1 and 24 and ELRP is enabled both. This triggers the disable\_port\_elrp profile twice, and ports 1 and 24 should be disabled.

5. View the log.

```
> show log
01/17/2008 08:08:05.49 <Info:vlan.dbg.info> Port 24 link down
01/17/2008 08:08:05.22 <Noti:UPM.Msg.upmMsgExshLaunch> Launched profile
disable_port_elrp for the event log-message
01/17/2008 08:08:04.69 <Info:vlan.dbg.info> Port 1 link down
01/17/2008 08:08:04.46 <Noti:UPM.Msg.upmMsgExshLaunch> Launched profile
disable_port_elrp for the event log-message
01/17/2008 08:08:04.46 <Warn:ELRP.Report.Message> [CLI:ksu:1] LOOP DETECTED : 436309
transmitted, 64 received, ingress slot:port (1) egress slot:port (24)
01/17/2008 08:08:04.46 <Warn:ELRP.Report.Message> [CLI:ksu:1] LOOP DETECTED : 436309
transmitted, 63 received, ingress slot:port (24) egress slot:port (1)
01/17/2008 08:08:03.50 <Info:vlan.dbg.info> Port 24 link up at 1 Gbps speed and full-
duplex
```

6. To view the profile execution history, enter the show upm history command.

If you want to see the more details, enter the show upm history details command to see all the profiles or display information on a specific event by entering the exec-id.

7. To view the configuration, use the show config upm and show config ems commands.

## Sample Configuration for Generic VoIP LLDP

## Sample Configuration for a Video Camera

This template adds an ACL to an edge port when a video camera connects.

The profile configures and applies an ACL onto a switch port when a user authenticates. This ACL blocks a particular IP address from accessing the video camera and assigns the user to QoS profile 7.

```

# Using CLI Scripting

---

[Setting Up Scripts](#) on page 2113

[Displaying CLI Scripting Information](#) on page 2126

[CLI Scripting Examples](#) on page 2128

CLI-based scripting allows you to create a list of commands that you can execute manually with a single command or automatically when a special event occurs.

## Note

The CLI is limited for 4000 Series devices. See the *4000 Series User Guide* for this version of Switch Engine for detailed information on the available commands.

CLI-based scripting supports variables and functions, so that you can write scripts that operate unmodified on multiple switches and in different environments. It allows you to significantly automate switch management.

## Note

Special scripts can be used to configure the switch when it boots. For more information, see [Using Autoconfigure and Autoexecute Files](#) on page 1653.

## Setting Up Scripts

---

### Enabling and Disabling CLI Scripting

The **permanent** option enables CLI scripting for new sessions only and makes the configuration change part of the permanent switch configuration so that the scripting configuration remains the same when the switch reboots. When the command is used without the permanent option, it enables CLI scripting for the current session only. If

you do not include the permanent option, CLI scripting is disabled the next time the switch boots.

- To support scripting, including the testing of script-related commands, enable scripting using the following command. CLI scripting is disabled by default.

```
enable cli scripting {permanent}
```

**Note**

CLI scripting cannot be enabled when CLI space auto completion is enabled with the `enable cli space-completion` command.

- To disable scripting, use the following command:

```
disable cli scripting {permanent}
```

## Creating Scripts

There are two ways to create scripts. The method you choose depends on how you want to execute the script.

If you want to create a script file to configure a switch or a switch feature, and you plan to execute that script manually, you can create a script file.

If you want to create a script that is activated automatically when a device or user connects to or disconnects from a switch port, you should create the script with the Universal Port feature. The following sections provide more information on these options.

### *Creating a Script File*

A script file is an ASCII text file that you can create with any ASCII text editor program. The text file can contain CLI commands and can use the scripting options described in the following sections:

- [Using Script Variables](#) on page 2118
- [Using Special Characters in Scripts](#) on page 2120
- [Using Operators](#) on page 2121
- [Using Control Structures in Scripts](#) on page 2122
- [Using Built-In Functions](#) on page 2123

You can move an ASCII script file to the switch using the same techniques described for managing ASCII configuration files in [Software Upgrade and Boot Options](#) on page 1632.

### *Creating Scripts for Use with the Universal Port Feature*

The Universal Port feature allows you to create dynamic profiles that are activated by a trigger event, such as a user or device connection to a switch port.

These dynamic profiles contain script commands and cause dynamic changes to the switch configuration to enforce a policy. The universal port profiles support all the scripting options listed in [Creating Scripts for Use with the Universal Port Feature](#) on

page 2114 for creating script files. For more information on entering script commands in a universal port profile, see [Universal Port](#) on page 2066.

## ExtremeXOS Shell RC Script

The ExtremeXOS Shell (EXSH) will run an RC script after a successful login. This script must be named `exshrc.xsf` and placed in the default configuration directory (`/usr/local/cfg`). This script is not user-account-specific and runs when any user logs in.

This RC script follows the ExtremeXOS scripting rules and is primarily meant for shell-specific configuration, but is capable of running any ExtremeXOS commands.

The following are some examples of commands that could be placed in this file:

```
alias ps "show process"
disable clipaging
configure cli columns 256 lines 200
```

## Python Scripting

Introduced in ExtremeXOS 15.6, Python scripting provides the ability to customize your switch and add functionality quickly by downloading and running scripts without the need for engineering expertise. Python scripting is extended using the synonymous `load script` and `run script` commands.

### Note

To use Python scripting, FIPS mode must be off (`configure security fips-mode [on | off]`) and you need to ensure that Python support is enabled (`configure security python [on | off]`).

## Expect Functionality

It may be necessary to interact with ExtremeXOS using Expect scripting functionality. The Python community offers a `pexpect.py` module that can provide this capability. ExtremeXOS uses `pexpect.py` version 3.2. For documentation, see <https://pypi.python.org/pypi/pexpect/>

The `pexpect.py` provides interfaces to run interactive shell commands and to process the results through `expect` like functions. The challenge with `exsh.clicmd()` is that it is a synchronous call and not a separate process. The `exshexpect.py` module was developed to provide a wrapper for `pexpect.py` that interfaces to `exsh.clicmd()`.

Below is an example of using `pexpect` together with the `exshexpect` module.

```
import pexpect
```

```
import exshexpect
```

Create a prompt for expect that will not match any command output.

```
exosPrompt = '::--:--::'
```

Create an expect object. Pass in the prompt and the back end function to call:

```
p = exshexpect.exshspawn(exosPrompt, exsh.clicmd)
```

Use `sendline` to send commands to the backend function (in this case `exsh.clicmd`) :

```
p.sendline('show fan') <-
idx = p.expect([exosPrompt, pexpect.EOF, pexpect.TIMEOUT])
print 'idx=',idx
print 'before->',p.before
print 'after->',p.after
```

Special case for passing in a command with an additional argument described in `exsh.clicmd()`:

```
p.send('enable debug-mode\nC211-6BB4-E6F5-B579\n')
```

In the line above, use `send()` and include 'newline' terminations for the command and the additional parameter.

This is the same as calling:

```
exsh.clicmd('enable debug-mode', True, args='C211-6BB4-E6F5-B579')
```

but using `expect` to process any response.

```
idx = p.expect([exosPrompt, pexpect.EOF, pexpect.TIMEOUT])
```

### Creating Sockets Using Python Scripts

Creating a socket in a Python script defaults to the management interface. You can change the VR when the socket is create by using the following example:

Example: Binding the socket to VR-Default (258) for an UDP socket:

```
import IN
from socket import *
udp_sock = socket(AF_INET, SOCK_DGRAM)
udp_sock.setsockopt(SOL_SOCKET, IN.SO_BINDTODEVICE, "vrf_258")

.
.
.
your program here
.
.
.

udp_sock.close()
```

#### Note

Do not use `os.system('echo 2 > /proc/self/ns_id')` to do this because `os.system()` spawns a subprocess. The subprocess will switch to vr-default, and then exit. The calling process will still be using the same VR as before.

Using `VRF_258` maps the socket to VR-Default.

In cases where the socket needs to be mapped to a user VR, include the following API in the script to get the VR name in kernel.

Example: API to find the VRF\_name for a given user VR.

```
import exsh
def vrfNameFromvrName(vrName):
 lst = exsh.cliCmd("debug cli show namespace vrId | begin namespaceEntry", True)
 lines = lst.split('\n')
 # ignore first two lines
 lines.pop(0)
 lines.pop(0)
 vrfName = None
 for line in lines:
 if line == "":
 break
 name, id, peer = line.split()
 if name == vrName:
 vrfName = "vrf_" + str(256 + (int(id)))
 break
 return vrfName
```

## Python Scripting Examples

### Example 1

This is a single line script that illustrates the `exsh.cliCmd()` called from a Python script.

```
print exsh.cliCmd('show switch', True)
```

In this example, the second parameter passed to `exsh.cliCmd()` is `True`. This returns the CLI display output that would have normally been sent to the user. In this case, the line prints the output anyway, which is shown below.

```
SysName: X670V-48x
SysLocation:
SysContact: support@extremenetworks.com, +1 888 257 3000

```

## Example 2

In this example, we create a number of *VLAN (Virtual LAN)s* in the form of *prefix tag* and add tagged port lists to each VLAN. There are a number of methods for collecting user input and validating the data type. This example uses a simple `while True:` loop until the input is the correct type. A more robust example would also apply range checking etc... to the vlan tag(s). E.g. Create vlans with tags from 1000 to 1099 The prefix is 'dave', so each vlan name will have a name like 'dave1000', 'dave1001' etc... The user provided port list will be added to each vlan name as tagged ports.

```
import sys
while True:
 prefix = raw_input('enter vlan name prefix:')
 if len(prefix):
 break

while True:
 reply = raw_input('beginning vlan tag:')
 if reply.isdigit():
 minTag = int(reply)
 break

while True:
 reply = raw_input('ending vlan tag:')
 if reply.isdigit():
 maxTag = int(reply)
 break

if minTag > maxTag:
 print 'Beginning vlan id cannot be greater than ending vlan id'
 sys.exit(-1)

while True:
 portlist = raw_input('port list:')
 if len(portlist):
 break

print 'Creating vlans from ',prefix+str(minTag),'to',prefix+str(maxTag)

for vlanId in range(minTag,maxTag + 1):
 vlanName = prefix + '{0:>04d}'.format(vlanId)
 cmd = 'create vlan '+vlanName + ' tag ' + str(vlanId)
 print exsh.cli(cmd, True)
 cmd = 'config vlan ' + vlanName + ' add port ' + portlist + ' tag'
 print exsh.cli(cmd, True)
```

### Note

UPM variables can be used with Python scripting. They must be passed as arguments of the script.

## Using Script Variables

Variable names must be followed by white space or otherwise enclosed in parentheses.

For example: create vlan v(\$X)e where X is the variable. The variable created will persist through the session and will not get reset after disable/enable cli scripting.

Table 170 shows the predefined system variables that are always available for use by any script. Predefined variables are automatically set up for use before a script or profile is executed.

#### Note

You must enable CLI scripting before using these variables or executing a script.

**Table 170: Predefined System Variables**

| Variable Syntax               | Definition                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Values -100 to 100 are reserved and automatically set by the software, but you can override the value with the command <code>return statusCode</code> . Common values are:<br>0—Successful command completion-53—Variable not found-57—WHILE depth exceeded<br>78—Script timeout                                                                                                                                                               |
| \$CLI.USER                    | User who is executing this CLI.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| \$CLI.SESSION_TYPE            | User session type.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| \$CLI.SCRIPT_TIME – REMAINING | When a script timeout value is configured with the <code>configure cli script timeout timeout</code> command, the system creates this variable, which returns the following values (in seconds):<br>If no script is running, this variable returns the configured timeout value.<br>If a script is aborted due to timeout, this variable returns the value 0.<br>If a script finishes execution (before the timeout value is reached), this variable returns the remaining time. |
| \$CLI.SCRIPT_TIMEOUT          | When a script timeout value is configured with the <code>configure cli script timeout timeout</code> command, the system creates this variable, which returns the current timeout value. If no script is running, this variable returns the configured timeout value.                                                                                                                                                                                                            |

Table 171 shows the system variables that you must define before use.

**Table 171: System Variables that Must Be Created**

| Variable Syntax | Definition                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| \$CLI.OUT       | Output of last show command. The maximum size of this variable is 1 MB. This output can be used for operations such as match and regexp. For more information on these operations, see <a href="#">Using Built-In Functions</a> on page 2123.<br>You must define this variable before it is used. To define this variable, enter either of the following statements:<br><pre>set var CLI.OUT " "</pre> <pre>set var CLI.OUT 0</pre> We recommend that you delete this variable after each use. |

## Creating Variables

You can create your own variables and change their values. When using variables, the following guidelines apply:

- Variable names are case insensitive and are limited to 32 characters.
- The variable name must be unique.
- A variable can be referenced as \$X or \$(X).
- If a variable already exists, it is overwritten. No error message is displayed.
- The variable expression can be a constant value, another variable, or a combination of the above with operators and functions. Operators are described in , and functions are described in .
- Only the `set var` command supports expression evaluation.
- If the variable name X contains special characters such as +-/\*, then the variable needs to be enclosed in parentheses. For example: `set var z ($(x) + 100)`.
- When you use a variable with a TCL special character in the \$TCL function, the variable must be enclosed in braces. For example: `set var x $TCL(string length $ {CLI.USER})`.
- For more information on TCL functions, see [Using Built-In Functions](#) on page 2123.

### Note

ExtremeXOS does not consider the dot/period character as a de-limiter. This is different from standard TCL behavior, where dot/period is considered as a de-limiter.

- To create a variable and set a value for it, or to change a variable value, use the following command:

```
set var varname _expression
```

The following examples show various ways to define or change variables:

```
set var x 100
```

```
set var x ($(x) + 2)
```

```
set var y ($x - 100)
```

- To display all variables or a specified variables, use the following command:

```
show var {varname}
```

## Using Special Characters in Scripts

The dollar sign (\$) character and quote (") characters have special purposes in scripts.

The (\$) indicates a variable, and the (") surrounds text strings. To use these characters as regular characters, precede the special character with a backslash character (\). For example:

```
set var variablename \$<varname>
set var CLI.USER "Robert \"Bob\" Smith"
```

Scripts also support quote characters within quotes.

## Using Operators

Operators allow you to manipulate variables and evaluate strings.

Some operators can be used in all numeric expressions, while others are restricted to integer or string expressions. [Table 172](#) lists the operators supported and provides comments on when they can be used. The valid operators are listed in decreasing order of precedence.

**Table 172: Operators**

| Operator | Action                        | Comments                                                                                                                                                                                                                   |
|----------|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -        | Unary minus                   | None of these operands can be applied to string operands, and the bit-wise NOT operand can be applied only to integers.                                                                                                    |
| +        | Unary plus                    |                                                                                                                                                                                                                            |
| ~        | Bit-wise NOT                  |                                                                                                                                                                                                                            |
| !        | Logical NOT                   |                                                                                                                                                                                                                            |
| *        | Multiply                      | None of these operands can be applied to string operands, and the remainder operand can be applied only to integers. The remainder always has the same sign as the divisor and an absolute value smaller than the divisor. |
| /        | Divide                        |                                                                                                                                                                                                                            |
| %        | Remainder                     |                                                                                                                                                                                                                            |
| +        | Add                           | These operands are valid for any numeric operations.                                                                                                                                                                       |
| -        | Subtract                      |                                                                                                                                                                                                                            |
| <<       | Left shift                    | These operands are valid for integer operands only. A right shift always propagates the sign bit.                                                                                                                          |
| >>       | Right shift                   |                                                                                                                                                                                                                            |
| <        | Boolean less                  | Each operator produces 1 if the condition is true, 0 otherwise. These operators can be applied to strings as well as numeric operands, in which case string comparison is used.                                            |
| >        | Boolean greater               |                                                                                                                                                                                                                            |
| <=       | Boolean less than or equal    |                                                                                                                                                                                                                            |
| >=       | Boolean greater than or equal |                                                                                                                                                                                                                            |
| ==       | Boolean equal                 | Each operator produces a zero or one result. These operators are valid for all operand types.                                                                                                                              |
| !=       | Boolean not equal             |                                                                                                                                                                                                                            |
| &        | Bit-wise AND                  | This operator is valid for integer operands only.                                                                                                                                                                          |
| ^        | Bit-wise exclusive OR         | This operator is valid for integer operands only.                                                                                                                                                                          |
|          | Bit-wise OR                   | This operator is valid for integer operands only.                                                                                                                                                                          |
| &&       | Logical AND                   | This operator produces a result of 1 if both operands are non-zero. Otherwise, it produces a result of 0. This operator is valid for numeric operands only (integers or floating-point).                                   |

**Table 172: Operators (continued)**

| Operator | Action                                          | Comments                                                                                                                                                                             |
|----------|-------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          | Logical OR                                      | This operator produces a result of 0 if both operands are zero. Otherwise, it produces a result of 1. This operator is valid for numeric operands only (integers or floating-point). |
| x?y:z    | If-then-else (as in the C programming language) | If x evaluates to non-zero, then the result is the value of y. Otherwise the result is the value of z. The x operand must have a numeric value.                                      |

## Using Control Structures in Scripts

The CLI supports the control structures described in the following sections.

### *Conditional Execution*

```
IF (<expression>) THEN
<statements>
ELSE
<statements>
ENDIF
```

The expression must be enclosed in parentheses.

### *Loop While Condition is TRUE*

```
WHILE (<expression>) DO
 <statements>
ENDWHILE
```

The expression must be enclosed in parentheses.

Nesting is supported up to five levels. The Ctrl-C key combination can be used to break out of any While loop(s).

The operators mentioned in [Using Operators](#) on page 2121 can be used in an expression in the set var command or in an IF or WHILE condition.

If there is incorrect nesting of an IF condition or WHILE loop, an error message appears. If a user tries to type more than five WHILE loops or five IF conditions, an error message appears. Breaking out of any number of WHILE loops always clears the WHILE condition.

Comments can be inserted by using the number sign (#).

## Using Built-In Functions

Built in functions allow you to manipulate and evaluate the variables inside your script and the script output. [Table 173](#) shows the built-in functions. [Table 174](#) on page 2123 shows the built-in Tool Command Language (TCL) functions.

### Note

ExtremeXOS uses TCL version 8.5.14.

**Table 173: Built-In Functions**

| Syntax                      | Function                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| \$MATCH(string 1, string 2) | Compares the two strings string 1 and string 2. Returns 0 if string1 matches string2.<br>It returns -1,0, or 1, depending on whether string1 is less than, equal to, or greater than string2.                                                                                                                                            |
| \$READ(prompt)              | Displays a prompt for user input and accepts input until the user presses <b>[Enter]</b> or the session times out. Replace prompt with the prompt to display to the user.                                                                                                                                                                |
| \$TCL(function args)        | Calls a TCL built-in function (see <a href="#">Table 174</a> on page 2123). Note that the software does not support the simultaneous operation of multiple TCL functions. For more information on TCL functions, go to <a href="http://www.tcl.tk/man/tcl8.3/TclCmd/contents.htm">http://www.tcl.tk/man/tcl8.3/TclCmd/contents.htm</a> . |
| \$UPPERCASE(string)         | Returns the string uppercased.                                                                                                                                                                                                                                                                                                           |
| \$VAREXISTS(variable name)  | Returns zero if the specified variable does not exist. Returns non-zero if the specified variable does exist.                                                                                                                                                                                                                            |

**Table 174: Supported TCL Functions**

| Function | Function Type   | Description                                        |
|----------|-----------------|----------------------------------------------------|
| after    | System related  | Execute a command after a time delay.              |
| binary   | String handling | Insert and extract fields from binary strings.     |
| clock    | System related  | Obtain and manipulate time.                        |
| concat   | List handling   | Join lists together.                               |
| expr     | Math            | Evaluate an expression.                            |
| join     | List handling   | Create a string by joining list elements together. |
| lindex   | List handling   | Retrieve an element from a list.                   |
| linsert  | List handling   | Insert elements into a list.                       |
| list     | List handling   | Create a list.                                     |
| llength  | List handling   | Count the number of elements in a list.            |
| lrange   | List handling   | Return one or more adjacent elements from a list.  |

**Table 174: Supported TCL Functions (continued)**

| Function  | Function Type   | Description                                                         |
|-----------|-----------------|---------------------------------------------------------------------|
| lreplace  | List handling   | Replace elements in a list with new elements.                       |
| lsearch   | List handling   | See if a list contains a particular element.                        |
| lsort     | List handling   | Sort the elements of a list.                                        |
| regexp    | String handling | Match a regular expression against a string.                        |
| regsub    | String handling | Perform substitutions based on regular expression pattern matching. |
| re_syntax | String handling | Syntax of TCL regular expressions.                                  |
| split     | List handling   | Split a string into a proper TCL list.                              |
| string    | String handling | Manipulate strings.                                                 |

For examples of scripts that use TCL functions, see [CLI Scripting Examples](#) on page 2128.

## Control Script Configuration Persistence

When a script runs, the commands within the script can make persistent changes to the switch configuration, which are saved across reboots, or it can make non-persistent changes. Non-persistent configuration changes remain part of the switch configuration only until the switch reboots.

The default setting for scripts is non-persistent. To change the script configuration persistence setting, use the following command:

```
configure cli mode [persistent | non-persistent]
```

## Saving, Retrieving, and Deleting Session Variables

Session variables are the set of variables that are active for a particular session. For example, if a device is detected on a universal port and this triggers a profile (and the script commands within it), the variable values that were active when the profile started are replaced with the variable values defined in the profile. The first session is the device-undetected session, and the second session is the device-detected session. Each session has its own set of variables and values.

The software allows you to save session variables before replacing them. In the example above, this allows you to retrieve the earlier values when the port returns to the device-undetected state. Up to five variables can be saved or retrieved at a time. These variables are saved to system memory using a key, which is an ID for the saved variables. You are responsible for generating unique keys. When you want to retrieve the variables, you use the key to identify the variables to be retrieved.

- To save up to five session variables, use the following command:  
`save var key key [var1 var2 ...]`

- To retrieve saved session variables, use the following command:

```
load var key key [var1 var2 ...]
```

- To delete saved session variables, use the following command:

```
sdelete var key key
```

The variables saved by the save var command are saved using the specified key and are retrievable and restored in the context that this profile was applied. They are available to rollback events like user-unauthenticate and device-undetected.

**Note**

For SummitStack, session variables are saved on the master ExtremeSwitching switch. To repopulate session variables after a failover event, manually execute the appropriate script.

## Nesting Scripts

The ExtremeXOS software supports three levels of nested scripts. An error appears if you attempt to start a fourth-level script. The following example demonstrates nested scripts:

```
Load script x1
Script x1 contents:
Cmd 1
Cmd 2
Load script x2
Cmd 3
Cmd 4
Script x2 contents:
Cmd 1
Cmd 2
Load script x3
```

In the above example, Cmd x is a generic representation for any script command. Script x1 is the first level script and launches the second level script Script x2. Script x2 launches the third level script Script x3. If Script x3 contained a command to launch another script, the script would not launch the software would generate an error.

## Executing Scripts

You can execute scripts by loading a script file or through the Universal Port feature.

### *Execute a Script File*

Transfer the script file to the switch and use the `load script filename {arg1} {arg2} ... {arg9}` command.

### *Executing a Universal Port Script*

Universal port scripts are called profiles and are executed based on several types of trigger events, including device detection and undetection and user authentication and unauthentication.

For information on how to create profiles and configure the triggers, see [Universal Port](#) on page 2066.

## Configuring Error Handling

The default error handling behavior is to ignore errors. You can change options within the scripts.

To control script error handling, use the following command:

```
configure cli mode scripting [abort-on-error | ignore-error]
```

## Aborting a Script

There are three ways to abort a script:

- Press **[Ctrl] + C** while the script is executing.
- Configure the switch to abort a script when an error occurs by using the following command:  

```
configure cli mode scripting [abort-on-error | ignore-error]
```
- Abort a script and store a status code in the \$STATUS variable by using the following command:  

```
return statusCode
```

## Displaying CLI Scripting Information

You can use the information in the following sections to display CLI scripting information.

## Viewing CLI Scripting Status

The `show switch management` command displays whether or not CLI scripting is enabled, whether or not the configuration is persistent, and the CLI scripting error mode as shown in the following example:

```
show switch management
CLI idle timeout : Enabled (20 minutes)
CLI max number of login attempts : 3
CLI max number of sessions : 8
CLI paging : Enabled
CLI space-completion : Disabled (this session only)
CLI configuration logging : Disabled (without expansion)
CLI journal size : 100
CLI password prompting only : Disabled
CLI display moved-keywords : Hidden
CLI moved-keywords hidden release: 31.5
CLI RADIUS cmd authorize tokens : 2
CLI scripting : Disabled (this session only)
CLI scripting error mode : Ignore-Error (this session only)
CLI script search path : ".:usr/local/cfg" (this session only)
CLI persistent mode : Persistent (this session only)
CLI prompting : Enabled (this session only)
CLI screen size : 24 Lines 80 Columns (this session only)
CLI refresh : Enabled
CLI history expansion : Disabled
```

```

Image integrity checking : Off
Current system port notation : slot:port
Configured system port notation : slot:port
Telnet access : Enabled (tcp port 23 vr all)
 : Access Profile : not set
SSH access : Disabled (Key invalid, tcp port 22 vr all)
 : Secure-Mode : Off
 : Access Profile : not set
SSH2 idle time : 60 minutes
SSH2 rekey interval : 4096 MB and no time limit
Web access : Enabled (tcp port 80)
 : Access Profile : not set
Total Read Only Communities : 0
Total Read Write Communities : 0

SNMP access : Disabled
 : Access Profile : not set
SNMP Notifications : Enabled
SNMP Notification Receivers : None
SNMP stats: InPkts 0 OutPkts 0 Errors 0 AuthErrors 0
 Gets 0 GetNexts 0 Sets 0 Drops 0
SNMP traps: Sent 0 AuthTraps Enabled
SNMP inform: Sent 0 Retries 0 Failed 0
(pacman debug) Slot-1 switch_model-EXOS.2 #

```

## Viewing CLI Scripting Variables

The `show var` command displays the currently defined variables and their values as shown in the following example:

```
Switch.4 # show var
```

```
Count : 3
```

| variableName     | variableValue |
|------------------|---------------|
| CLI.SESSION_TYPE | serial        |
| CLI.USER         | admin         |
| STATUS           | 0             |

## Controlling CLI Script Output

When the `load script` command is entered, the software disables CLI scripting output until the script is complete, and then CLI scripting output is enabled.

When the CLI scripting output is disabled, the only script output displayed is the `show var {varname}` command and its output. When the CLI scripting output is enabled, all script commands and responses are displayed.

Use the `enable cli scripting output` and `disable cli scripting output` commands to control what a script displays when you are troubleshooting.

## CLI Scripting Examples

The following script creates 100 VLANs with IP Addresses from 10.1.1.1/16 to 10.100.1.1/16:

```
enable cli scripting
Set var count 1
while ($count < 101) do
Create vlan v$count
configure vlan v$count ipaddress 10.$(count).1.1/16
set var count ($count + 1)
endwhile
show vlan
```

The following script introduces a 60-second delay when executed:

```
set var temp $TCL(after [expr 60 *1000])
```

The following script displays the date and time:

```
set var CLI.OUT " "
show switch
set var date $TCL(lrange ${CLI.OUT} 27 29)
set var year $TCL(lrange ${CLI.OUT} 31 31)
set var date $TCL(linsert $date 3 $year)
set var time $TCL(lrange ${CLI.OUT} 30 30)
show var date
show var time
```

The following script sorts the *FDB (forwarding database)* table in descending order:

```
set var CLI.OUT " "
show fdb
set var x1 $TCL(split ${CLI.OUT} "\n")
set var x2 $TCL(lsort -decreasing $x1)
set var output $TCL(join $x2 "\n")
show var output
```

The following script extracts the MAC address given the age of an FDB entry:

```
set var CLI.OUT " "
show fdb
set var input $TCL(split ${CLI.OUT} "\n")
set var y1 $TCL(lsearch -glob $input *age*)
set var y2 $TCL(lindex $input $y1)
set var y3 $TCL(split $y2 " ")
set var y4 $TCL(lindex $y3 0)
show var y4
```

# Virtual Routers

---

[Overview of Virtual Routers](#) on page 2129

[Managing Virtual Routers](#) on page 2137

[Virtual Router Configuration Example](#) on page 2143

This section provides information about Virtual Routers. It discusses how ExtremeXOS software supports Virtual Routers and VRFs, and provides specific information about how to configure and manage those virtual routers.

## Overview of Virtual Routers

---

The ExtremeXOS software supports virtual routers (VRs). This capability allows a single physical switch to be split into multiple VRs. This feature separates the traffic forwarded by a VR from the traffic on a different VR.

Each VR maintains a separate logical forwarding table, which allows the VRs to have overlapping IP addressing. Because each VR maintains its own separate routing information, packets arriving on one VR are never switched to another.

### Note

VRs should not be connected together through a Layer 2 domain. Since there is a single MAC address per switch in the ExtremeXOS software, this same MAC address is used for all VRs. If two VRs on the same switch are connected through a Layer 2 domain, the intermediate Layer 2 switches learn the same MAC address of the switch on different ports, and may send traffic into the wrong VR.

Ports on the switch can either be used exclusively by one VR, or can be shared among two or more VRs. One reason to configure a port for the exclusive use of a single VR is to be sure that only packets from that VR egress from that port. One reason to configure a port to be shared by multiple VRs is to pass traffic from multiple VRs across a shared link.

Each VLAN (*Virtual LAN*) can belong to only one VR.

Because a single physical switch supports multiple VRs, some commands in the ExtremeXOS software require you to specify to which VR the command applies. For example, when you use the ping command, you must specify from which VR the ping packets are generated. Many commands that deal with switch management use the

management VR by default. See the [Switch Engine v33.3.1 Command References](#) for information on the defaults for individual commands.

**Note**

The term VR is also used with the [VRRP \(Virtual Router Redundancy Protocol\)](#). VRRP uses the term to refer to a single that spans more than one physical router, which allows multiple switches to provide redundant routing services to users. For more information about VRRP, see [VRRP Overview](#) on page 2207.

## Types of Virtual Routers

This section describes the types of Virtual Routers:

- [System Virtual Routers](#) on page 2130
- [User Virtual Routers](#) on page 2131
- [VRFs](#) on page 2132
- [Local-Only Virtual Routers](#) on page 2133
- [Direct Route Leaking Between Virtual Routers](#) on page 2134

### System Virtual Routers

The system VRs are the three VRs created at boot-up time. These system VRs cannot be deleted or renamed. They are named [VR-Mgmt](#), [VR-Control](#), and [VR-Default](#). The following describes each system VR:

- **VR-Mgmt** enables remote management stations to access the switch through Telnet, SSH, and [SNMP \(Simple Network Management Protocol\)](#) sessions; it also owns the management port. No other ports can be added to VR-Mgmt, and the management port cannot be removed from it.

The Mgmt [VLAN](#) is created in VR-Mgmt during ExtremeXOS system boot-up. No other VLAN can be created in this VR, and the Mgmt VLAN cannot be deleted from it.

No routing protocol is running on or can be added to VR-Mgmt.

VR-Mgmt is called VR-0 in ExtremeXOS releases before 11.0.

- **VR-Control** is used for internal communications between all the subsystems in the switch. It has no external visible ports, and you cannot assign any port to it.

VR-Control has no VLAN interface, and no VLAN can be created for it.

No routing protocol is running on or can be added to VR-Control.

VR-Control is called VR-1 in ExtremeXOS releases before 11.0.

- **VR-Default** is the default VR created by the ExtremeXOS system. By default, all data ports in the switch are assigned to VR-Default. Any data port can be added to and deleted from VR-Default.

Users can create and delete VLANs in VR-Default. The Default VLAN is created in VR-Default during the ExtremeXOS system boot-up. The Default VLAN cannot be deleted from VR-Default.

One instance of each routing protocol is spawned for VR-Default during the ExtremeXOS system boot-up, and these routing instances cannot be deleted.

VR-Default is called VR-2 in ExtremeXOS releases before 11.0.

### User Virtual Routers

User VRs are the VRs created by users in addition to the system VRs, and each user VR supports Layer 3 routing and forwarding.

The routing tables for each VR are separate from the tables for other VRs, so user VRs can support overlapping address space.

#### Note

User VRs are supported only on the platforms listed for the VR feature in the [Switch Engine v33.3.1 Licensing Guide](#) document. When a SummitStack contains switches that do not support user VRs, the ports on those devices cannot be added to a user VR.

When a new user VR is created, by default, no ports are assigned, no [VLAN](#) interface is created, and no support for any routing protocols is added. User VRs support all switch routing protocols. When you add a protocol to a user VR, the user VR starts a process for that protocol. The ExtremeXOS software supports up to 63 user VRs, each of which supports protocols for that VR and all child [Virtual Routers and Forwarding instances \(VRFs\)](#).

#### Note

When using SNMPv2c for user created , "read community" in the [SNMP](#) tool should be set as "vr\_name@community\_name" where vr-name is user created virtual router name . Similarly for SNMPv3, "Context name" in SNMP tool should be set as "vr\_name@community\_name" where vr-name is user created virtual router name .

### IPv4 Multicast Source Discovery Protocol on User Virtual Routers

Version 33.2.1 adds support for configuring and operating IPv4 Multicast Source Discovery Protocol (MSDP) over user-created Virtual Routers (VR). This includes the following functionality:

- Ability to configure IPv4 MSDP on IPv4 PIM-SM networks on user-defined VRs.
- MSDP peering on user VRs.
- Peer authentication using TCP MD5.
- Peer-based SA policing/filtering.
- MSDP Mesh Group support.
- MSDP Cache Server (SA Request/Response mechanism).
- Default MSDP peer and associated policy.
- Multiple default MSDP peers.

- Export of locally registered multicast sources.
- SNMP MIB access (read-only) on all scalar and tabular objects as specified by RFC-4624.

#### Supported Platforms

All platforms that support MSDP.

### **NEW!** Protocol Independent Multicast Multi-switch LAG support on User-created Virtual Routers

Version 33.3.1 adds Protocol Independent Multicast (PIM) Multi-switch LAG (MLAG) support on User-created VRs. This enhancement adds support for the following features:

- IPv4 PIM-Sparse Mode (SM) on MLAG on user-created VRs.
- IPv4 PIM-Dense Mode (DM) on MLAG on user-created VRs.

The VR name must be same on both MLAG peers for PIM MLAG to work.

#### Supported Platforms

All platforms that support PIM MLAG.

#### Limitations

The following features are not supported with this enhancement:

- PIM snooping on MLAG on user-created VRs.
- IPv6 PIM features on MLAG on user-created VRs.
- PIM RP cannot be one of the MLAG peers.
- RP reachability of one MLAG peer cannot be through the other MLAG peers.

### VRFs

Virtual Router and Forwarding instances (VRFs) are similar to VRs. VRFs are created as children of user VRs or *VR-Default*, and each VRF supports Layer 3 routing and forwarding. The routing tables for each VRF are separate from the tables for other VRs and VRFs, so VRFs can support overlapping address space. The primary differences between VRs and VRFs are:

- For each routing protocol added to a VRF, only one process is started in the user VR and VRF. The VRF protocol operates as one instance of the parent VR protocol, and additional child VRFs operate as additional instances of the same parent VR protocol process. VRFs allow a protocol process running in the parent VR to support many virtual router instances.
- ExtremeXOS supports up to 63 VRs and up to many more VRFs. For the maximum number of supported VRFs, see the [ExtremeXOS Release Notes](#).

There are two types of VRFs:

#### VPN VRFs

Support BGP-based Layer 3 VPNs over *MPLS (Multiprotocol Label Switching)*. VPN VRF tables support entries for additional configuration parameters that enable Layer 3 VPN functionality over an BGP/MPLS backbone network.

## Non-VPN VRFs

Support static routes, OSPFv3, and BGP.

Use VRFs instead of VRs when your network plan calls for more than 63 virtual routers or when you want to create Layer 3 VPNs. Use VRs instead of VRFs when the routing protocol you want to use is not supported on a VRF.

When a new VRF is created, by default, no ports are assigned, no [VLAN](#) interface is created, and no support for any routing protocols is added. When you add a protocol to a VRF, an instance of the protocol is created in the protocol process running in the parent VR, if the protocol process exists. If no protocol process is running in the parent VR, a process is started and a protocol instance corresponding to this VRF is created within that process.

The rest of this chapter uses the following terms to identify the different types of VRs and VRFs to which features and commands apply:

- VR—All VRs and VRFs
- VRF—VPN and non-VPN VRFs
- VPN VRF—VPN VRFs only
- Non-VPN VRF—Non-VPN VRFs only

### Note

VRFs are supported only on the platforms listed for the VRF feature in the [Switch Engine v33.3.1 Licensing Guide](#) document. When a SummitStack contains switches that do not support VRFs, the ports on those devices cannot be added to a VRF.

## Local-Only Virtual Routers

Local-only virtual routers (VR) are a form of user-created VRs ([User Virtual Routers](#) on page 2131) that allow for separate logical IP lookup tables, to be used only for IP packets to or from the switch's local IP addresses. Local-only user-created VRs allow for different gateways for routes to a host or subnet, based on the local VLANs on the switch.

Local-only VRs allow bidirectional monitoring of each individual path used to reach the switch itself, where each path may traverse, for example, a different firewall. Switches that support local-only VRs do not forward IP packets in local-only VRs in software or in hardware; they instead use separate lookup tables, including static routes, for packets to or from the switch's local IP addresses.

### Supported Platforms

Local-only VRs are supported on 4120, 4220, 5120, and 5320-24T/24P/16P series switches and stacks with these switches. Other switches support VRs in hardware, rather than support local-only VRs.

### Limitations

IP forwarding is not permitted on local-only VRs, or on VLANs belonging to local-only VRs.

Local-only VRs default to having IP route compression disabled. Enabling IP route compression produces an error.

### Direct Route Leaking Between Virtual Routers

Version 32.4 adds support for leaking direct routes of specified VLAN(s) to a different Virtual Router (VR). Adjacent (directly connected) hosts are also reachable in the specified VR.

#### Note

This feature is an additional method for achieving Inter-VR routing without an external router. You can also allow a static route's gateway to be in a different VR by entering the `configure iproute add` command and specifying **vlan egress\_vlan**, or redistribute routes from one OSPF instance to another OSPF instance in a different VR by entering the `enable ospf export {vr}` command.

Leaked direct routes are created with origin `direct-inter-vr` in the leak-to-VR. These routes have a lower route priority than direct routes and a higher route priority than any other route type.

The route priority of `direct-inter-vr` can be modified using the **iproute priority** command. These routes can be redistributed to the OSPF protocol in the leak-to-VR like any other routes in the VR. OSPF's route redistribution command is also extended as part of this feature and includes the `direct-inter-vr` route type.

#### Note

To ping a directly attached host from the switch command line successfully, the **ping** command must specify the correct VR name (or use the correct command line **VR context**) containing the VLAN with that subnet. If another VR name or VR context is used, the ping will not be successful.

### Direct Route Leaking CLI Commands

Use the `configure iproute add` **direct-inter-vr {ipv4} [{vlan} from\_vlan\_name | vlan from\_vlan\_list] {{vr} to\_vr\_name}** command to add the direct routes of a VLAN or set of VLANs to be leaked to the leak-to-VR.

Use the `configure iproute delete` **direct-inter-vr {ipv4} [{vlan} from\_vlan\_name | vlan from\_vlan\_list] {{vr} to\_vr\_name}** command to delete a direct route of a VLAN or set of VLANs previously leaked to the leak-to-VR.

Use the `show iproute` **direct-inter-vr {ipv4} {from-vr from\_vr\_name} {{vr} to\_vr\_name}** command to display the configuration of Inter-VR direct routes.

### Direct Route Leaking Use Case

A typical use case for this feature is when you have a printer IP directly attached to a switch on a VLAN in VR1. For example, a printer IP 10.1.1.222 on a VLAN names "yellow10" in VR1, with an IP address of 10.1.1.1/24. In this scenario, you want all users in VR1 and VR2 to access the printer using the same IP 10.1.1.222, without requiring an external router.

To accomplish this, you can configure the direct route of VLAN "yellow10" with IP 10.1.1.1/24 to be leaked to VR2. You can create a reverse routed path by configuring the direct route of VLAN "red20" with IP 20.1.1.1/24 in VR2 to be leaked to VR1.

By configuring direct route leaking, hardware and slow path forwarding tables are augmented to include all IP ARP entries on that interface, such as 10.1.1.222, in VR2 in addition to VR1.

#### Note

In this scenario, you do not want users in VR3 to access 10.1.1.0/24, on VR1 and VR2.

### Direct Route Leaking Example Configuration

The following example commands create or configure direct route leaking.

```
create vr VR1

create vlan yellow10 tag 10 vr VR1

configure yellow10 ipaddress 10.1.1.1/24

create vr VR2

create vlan red20 tag 20 vr VR2

configure red20 ipaddress 10.1.1.1/24

configure iproute add 30.1.1.0/24 20.1.1.254 vr VR2

create vr VR3

configure iproute add direct-inter-vr vlan yellow10 vr VR2

configure iproute add direct-inter-vr red20 VR1
```

### Direct Route Leaking Example Show Output

The following example displays **show** command output for this feature:

```
show iproute direct-inter-vr

Inter-VR Direct IPv4 Routes Leaked To Virtual Router: VR1

Leak From VLAN Name VID Primary IP Addr. Leak From Virtual Router

red20 20 20.1.1.1 /24 VR2

Inter-VR Direct IPv4 Routes Leaked To Virtual Router: VR2

Leak From VLAN Name VID Primary IP Addr. Leak From Virtual Router

yellow10 10 10.1.1.1 /24 VR1
```

The following examples display the "div" origin prefix showing Direct-Inter-VR information.

```
show iproute vr vr1

Ori Destination Gateway Mtr Flags VLAN Duration
d 10.1.1.0/24 10.1.1.1 1 -----um--- yellow10 0d:0h:3m:12s
div 20.1.1.0/24 20.1.1.1 1 -----um--- red20 0d:0h:2m:17s
s 30.1.1.0/24 20.1.1.254 1 -G---S-um--- red20 0d:0h:1m:59s

show iproute vr vr2

Ori Destination Gateway Mtr Flags VLAN Duration
div 10.1.1.0/24 10.1.1.1 1 -----um--- yellow10 0d:0h:8m:39s
d 20.1.1.0/24 20.1.1.1 1 -----um--- red20 0d:0h:9m:42s
s 30.1.1.0/24 20.1.1.254 1 -G---S-um--- red20 0d:0h:0m:6s
```

## VR Configuration Context

Each VR and VRF has its own configuration domain or context, in which you can enter commands to configure that VR. Some commands allow you to specify a VR to which the command applies.

For other commands, you must change context to that of the target VR or VRF before you execute the command. The current context is indicated in the command line interface (CLI) prompt by the name of the user VR or VRF. If no name appears in the prompt, the context is *VR-Default*.

For instructions on changing context, see [Changing the VR Context](#) on page 2139.

Commands that apply to the current VR context include all the *BGP (Border Gateway Protocol)*, *OSPF (Open Shortest Path First)*, *OSPFv3 (Open Shortest Path First version 3)*, *PIM*, *IS-IS*, *RIP (Routing Information Protocol)*, and *RIPng (Routing Information Protocol Next Generation)* commands, and the commands listed in the following table. Commands that apply to the current VRF context are limited to BGP commands and the commands listed in [Table 175](#).

**Table 175: Virtual Router Commands**

|                                  |
|----------------------------------|
| [enable   disable] ipforwarding  |
| configure iparp                  |
| configure iparp [add   delete]   |
| [enable   disable] iparp         |
| show iparp                       |
| configure iproute [add   delete] |
| show iproute                     |
| rtlookup                         |
| create [vlan   vman] vlan-name   |
| [enable   disable] igmp          |
| [enable   disable] igmp snooping |

**Table 175: Virtual Router Commands (continued)**

|                                                |
|------------------------------------------------|
| <code>[enable   disable] ipmcforwarding</code> |
| <code>show igmp</code>                         |
| <code>show igmp snooping</code>                |
| <code>show igmp group</code>                   |
| <code>show igmp snooping cache</code>          |

## Managing Virtual Routers

This section describes the options for managing Virtual Routers.

### Creating and Deleting User Virtual Routers

- To create a user VR, use the following command and do not include the type or vr attributes:

```
create virtual-router vr-name {type [vrf | vpn-vrf {vr
parent_vr_name}]}
```

#### Note

User VRs are supported only on the platforms listed for this feature in the [Switch Engine v33.3.1 Licensing Guide](#) document.

A VR name cannot be the same as a VLAN name. You cannot name a user VR with the names *VR-Mgmt*, *VR-Control*, or *VR-Default* because these are the existing default system VRs. For backward compatibility, user VRs also cannot be named VR-0, VR-1 or VR-2 because these three names are the names for the system VRs in ExtremeXOS releases before 11.0.

If you exceed the maximum number of VRs supported on your platform, a message similar to the following appears:

```
Error: Maximum number of User VRs supported by the system is 63
```

- To create a local-only user VR (5120, 5320-24T/P, 5320-16P, 5320-24T-4X-XT, and all 4220 models only), use the following command, and do not include the type or vr attributes:

```
create virtual-router vr-name local-only {type [vrf | vpn-vrf {vr
parent_vr_name}]}
```

- To display the virtual routers, use the following command:

```
show virtual-router {name}
```

- To delete a user VR, use the following command:

#### Note

Before you delete a VR, you must delete all VLANs and child VRFs created in that VR. All of the ports assigned to this VR are deleted and made available to assign to other VRs and VRFs. Any routing protocol that is running on the VR is shut down and deleted gracefully.

```
delete virtual-router vr-name
```

## Creating and Deleting VRFs

- To create a VRF, use the following command and include the type attribute:

```
create virtual-router vr-name {type [vrf | vpn-vrf {vr
parent_vr_name}]}
```

### Note

VRFs are supported only on the platforms listed for this feature in the [Switch Engine v33.3.1 Licensing Guide](#) document. To support a Layer 3 VPN, a VPN VRF must be created under the parent VR that will run the [MPLS](#) protocol.

A VRF name cannot have the same name as a VLAN or VR.

- To create a local-only VRF (5120, 5320-24T/P, 5320-16P, 5320-24T-4X-XT, and all 4220 models only), use the preceding command and include the type attribute:
- To display the VRFs, use the following command:
- To delete a VRF, use the following command:

```
show virtual-router {name}
```

### Note

Before you delete a VRF, you must delete all VLANs and stop all protocols that are assigned to that VRF. All of the ports assigned to a deleted VRF are deleted and made available to assign to other VRs and VRFs. Any routing protocol instance that is assigned to the VRF is deleted gracefully.

```
delete virtual-router vr-name
```

## Enabling and Disabling VRFs

VRFs are enabled when created. If you want to shut down a Layer 3 VPN, you can disable the corresponding VRF, which disables only the corresponding Layer 3 VPN and does not affect other routing services or Layer 3 VPNs.

To enable or disable a VRF, use the following commands:

```
enable virtual-router vrf-name
```

```
disable virtual-router vrf-name
```

## Configuring and Removing a VR Description

A VR description is a text message that can be used to label the VR. The text message is for viewing and [SNMP](#) MIB reports only; it has no affect on VR operation.

To configure or remove a description, use the following commands:

```
configure vr name description string
```

```
unconfigure vr name description
```

## Changing the VR Context

The VR context is introduced in [VR Configuration Context](#) on page 2136.

To switch to a context for a different VR, use the following command:

```
virtual-router {vr-name}
```

The CLI prompt displays the VR context.

## Adding and Deleting Routing Protocols

When a user VR is created, no resources are allocated for routing protocols. You must add the routing protocols needed for your VR before you attempt to configure them. The maximum number of protocols supported is 64.

The commands that follow allow adding the following protocols:

- The basic seven protocols on [VR-Default \(RIP, OSPF, BGP, PIM, ISIS, OSPFv3, and RIPNG\)](#)
- 1 [MPLS](#) protocol instance on any VR (only on platforms that support MPLS)
- 56 additional protocols for user VRs. Any combination of the 7 protocols supported on user VRs (RIP, OSPF, BGP, PIM, ISIS, OSPFv3, and RIPNG) can be assigned to user VRs, up to a maximum number of 56.

When you add a protocol to a user VR, the software starts a process to support the protocol, but it does not enable that protocol. After you add a protocol to a user VR, you must specifically enable and configure that protocol before it starts.

When you add a protocol to a VRF, a protocol process is started in the parent VR (if it is not already started) and a protocol instance is created inside that process for this VRF.

### Note

You must add, configure, and enable a protocol for a VR before you start unicast or multicast forwarding on the VR and before you configure any features (such as VLANs) to use the VR.

- To add a protocol to a VR, use the command:

```
configure vr vr_name [add | delete] protocol [ospf | ospfv3 | rip |
ripng | bgp | isis | pim | mpls]
```

If you add more than the maximum number of protocols, the following message appears:

```
Error: Maximum number of Protocols that can be started in the system is 64
```

- To remove a protocol from a VR, use the command:

```
configure vr vr-name delete protocol protocol-name
```

### Note

Local-only VRs and VRFs do not use routing protocols.

## Configuring Ports to Use One or More Virtual Routers

By default, all the user data ports belong to *VR-Default* and the default *VLAN*, Default. All these ports are used exclusively by VR-Default. To configure a port to use one or more virtual routers, you need to perform one or more of the tasks described in the following sections:

- [Deleting Ports from a Virtual Router](#) on page 2140
- [Adding Ports to a Single Virtual Router](#) on page 2140
- [Adding Ports to Multiple Virtual Routers](#)

### Deleting Ports from a Virtual Router

To configure a port for exclusive use by another VR, or for use by multiple VRs, it must first be deleted from *VR-Default*. You must delete the port from any *VLAN* it belongs to before deleting it from a VR.

To delete a port from a VR, use the command:

```
configure vr vr-name delete ports port_list
```

#### Caution

Do not create Layer 2 connections between ports assigned to different VRs in the same switch. Because each switch supports just one MAC address, every VR in the switch uses the same MAC address. A Layer 2 connection between two VRs can cause external devices to direct traffic to the wrong VR.

### Adding Ports to a Single Virtual Router

When you add a port to a VR, that port can only be used by that VR. To add a port to a single VR, use the command:

```
configure vr vr-name add ports port_list
```

The following example demonstrates how to remove all the ports on slot 3 from the Default *VLAN* in *VR-Default* and add them for the exclusive use of user VR helix:

```
configure vlan default delete ports 3:*
configure vr vr-default delete ports 3:*
configure vr helix add ports 3:*
```

### Adding Ports to Multiple Virtual Routers

To use a port in multiple VRs, do not add the port to a VR as described in [Adding Ports to a Single Virtual Router](#) on page 2140. Instead, add the port to a *VLAN* in the desired VR.

To add the port to a VLAN in the desired VR, use the following command:

```
configure [{vlan} vlan_name | vlan vlan_list] add ports [port_list |
all] {tagged tag | untagged} {{stpd} stpd_name} {dot1d | emistp | pvst-
plus}}
```

#### Note

See [QoS](#) for details about how multiple VRs per port can affect DiffServ and code replacement.

You should configure any protocols you want to use on a user VR before you add a VLAN to the user VR. When IP multicast forwarding will be supported on a user VR, add the PIM protocol before you enable IP multicast forwarding.

The following example demonstrates how to add port 3:5 to user VRs VR-green and VR-blue.

The tagged VLAN bldg\_200 was previously configured in VR-green, and the tagged VLAN bldg\_300 was previously configured in VR-blue.

```
configure vlan default delete ports 3:5
configure vr vr-default delete ports 3:5
configure vlan bldg_200 add ports 3:5 tagged
configure vlan bldg_300 add ports 3:5 tagged
```

## Displaying Ports and Protocols

To display the ports, protocols, and names of protocol processes for a VR, use the following command:

```
show virtual-router {name}
```

## Configuring the Routing Protocols and VLANs

After a user VR is created, the ports are added, and support for any required routing protocols is added, you can configure the VR.

- To create a VLAN in a VR, use the command:

```
create vlan vlan_name {description vlan-description} {vr name}
```

If you do not specify a VR in the create vlan command, the VLAN is created in the current VR context.

VLAN names must conform to the guidelines specified in [Object Names](#) on page 32.

#### Note

All VLAN names and VLAN IDs on a switch must be unique, regardless of the VR in which they are created. You cannot have two VLANs with the same name, even if they are in different VRs.

- To display the VLANs in a specific VR, use the command:

```
show vlan virtual-router vr-name, which is a specific form of this command:
show vlan {virtual-router vr-name}
```

You can also configure routing protocols by using the standard ExtremeXOS software commands. The routing configurations of the different VRs are independent of each other.

## Configuration Tasks for Layer 3 VPNs

### *Layer 3 VPN Configuration Overview*

To configure VR and VRF support for a Layer 3 VPN, do the following:

1. Configure the PE to PE interfaces as follows:
  - a. Select the VR that to which the *MPLS* protocol will be added.
  - b. Assign PE facing VLANs and ports to the VR.
2. Configure the PE to CE interface as follows:
  - a. Create a VPN VRF as described in [Creating and Deleting VRFs](#) on page 2138.
  - b. Assign a VPN ID to the VPN VRF as described in [Configuring a VPN ID](#) on page 2142.
  - c. Assign an RD to the VPN VRF as described in [Configuring the Route Distinguisher](#) on page 2142.
  - d. Configure RTs for the VPN VRF as described in [Configuring Route Targets](#) on page 2142.
  - e. Assign CE facing VLANs and ports to the VRF.
  - f. Configure *BGP* as described in [Configuration Overview](#).

### *Configuring a VPN ID*

A VPN ID is an optional configuration parameter that you can use to associate a Layer 3 VPN ID label with a VRF.

To configure a VPN ID, use the command:

```
configure vr vrf_name vpn-id 3_byte_oui:4_vpn_index
```

### *Configuring the Route Distinguisher*

The Route Distinguisher (RD) is added to the beginning of a VPN customer's IPv4 prefix to create a globally unique VPNv4 prefix for routing over the Layer 3 VPN. The IPv4 hosts that connect to a VRF must have unique IPv4 addresses. To eliminate duplicate IPv4 address issues between VRFs, configure a unique RD for each VRF.

To configure or unconfigure an RD, use the following commands:

```
configure vr vrf_name rd [2_byte_as_num:4_byte_number |
ip_address:2_byte_number | 4_byte_as_num:2_byte_number]

unconfigure vr vrf_name rd
```

### *Configuring Route Targets*

Route Targets (RTs) are used by *BGP* as extended communities that define which VRFs will export and import learned routes. A VRF import RT will receive Layer 3 VPN routes from any PE VRF that is configured to export to that RT. To enable BGP Layer 3 VPN

communications, you must configure import and export RTs on every VRF that will participate in the Layer 3 VPN.

To add, delete, or configure an RT, use the command:

```
configure vr vrf_name route-target [import | export | both] [add | delete] [route_target_extended_community]
```

### Enabling and Disabling Layer 3 VPN SNMP Traps for a VR

To enable or disable Layer 3 VPN SNMP traps for a VR, use the following commands:

```
enable snmp trap l3vpn {vr}
```

#### Note

You must enable this command in the parent VR of VPN-VRF.

```
disable snmp trap l3vpn {vr}
```

## Virtual Router Configuration Example

The following example demonstrates how to:

- Create a user VR named helix.
- Remove ports from the VLAN Default and VR-Default.
- Add ports to user VR helix.
- Add the OSPF protocol to user VR helix.
- Set the VR context to helix, so that subsequent VR commands affect VR helix.
- Create an incoming VLAN named helix-accounting-in.
- Create an outgoing VLAN named helix-accounting-out.
- Add ports that belong to user VR helix to the helix-accounting incoming and outgoing VLANs.

The CLI prompt is shown in this example to show how the VR context appears. At the end of the example, the VR is ready to be configured for OSPF, using ExtremeXOS software commands.

```
* BD10K.1 # create virtual-router helix
* BD10K.2 # configure vlan default delete ports 3:*
* BD10K.3 # configure vr vr-default delete ports 3:*
* BD10K.4 # configure vr helix add ports 3:*
* BD10K.5 # configure vr helix add protocol ospf
* BD10K.6 # virtual-router helix
* (vr helix) BD10K.8 # configure helix-accounting-in add ports 3:1
* (vr helix) BD10K.8 # configure helix-accounting-out add ports 3:2
* (vr helix) BD10K.9 #
```

# VLANs

---

[VLANs Overview](#) on page 2144

[Configuring VLANs on the Switch](#) on page 2154

[Displaying VLAN Information](#) on page 2160

[Private VLANs](#) on page 2161

[VLAN Translation](#) on page 2180

[Port-Specific VLAN Tag](#) on page 2188

This chapter contains information about configuring *VLAN (Virtual LAN)s*, displaying VLAN information, private VLANs, and VLAN translation. In addition, you can learn about the benefits and types of VLANs, along with valuable information about virtual routers.

## VLANs Overview

---

Setting up *VLANs* on the switch eases many time-consuming tasks of network administration while increasing efficiency in network operations.

### Note

The software supports using IPv6 addresses, in addition to IPv4 addresses. You can configure the VLAN with an IPv4 address, IPv6 address, or both. See [IPv6 Unicast Routing](#) on page 934 for complete information on using IPv6 addresses.

The term *VLAN* is used to refer to a collection of devices that communicate as if they were on the same physical LAN.

### Note

ExtremeXOS supports only 4,092 user-configurable VLANs. (VLAN 1 is the default VLAN, and 4,095 is the management VLAN, and you may not configure them.)

Any set of ports (including all ports on the switch) is considered a VLAN. LAN segments are not restricted by the hardware that physically connects them. The segments are defined by flexible user groups that you create with the command line interface (CLI).

### Note

The system switches traffic within each VLAN using the Ethernet MAC address. The system routes traffic between two VLANs using the IP addresses.

## Benefits

Implementing [VLANs](#) on your networks has the following advantages:

- **VLANs help to control traffic**—With traditional networks, broadcast traffic that is directed to all network devices, regardless of whether they require it, causes congestion. VLANs increase the efficiency of your network because each VLAN can be set up to contain only those devices that must communicate with each other.
- **VLANs provide extra security**—Devices within each VLAN can communicate only with member devices in the same VLAN. If a device in VLAN Marketing must communicate with devices in VLAN Sales, the traffic must cross a routing device.
- **VLANs ease the change and movement of devices**—With traditional networks, network administrators spend much of their time dealing with moves and changes. If users move to a different subnetwork, the addresses of each endstation must be updated manually.

## Virtual Routers and VLANs

The ExtremeXOS software supports virtual routers. Each port can belong to multiple s. Ports can belong to different [VLANs](#) that are in different virtual routers.

If you do not specify a virtual router when you create a VLAN, the system creates that VLAN in the default virtual router ([VR-Default](#)). The management VLAN is always in the management virtual router ([VR-Mgmt](#)).

After you create virtual routers, the ExtremeXOS software allows you to designate one of these virtual routers as the domain in which all your subsequent configuration commands, including VLAN commands, are applied. After you create virtual routers, ensure that you are creating each VLAN in the desired virtual router domain. Also, ensure that you are in the correct virtual router domain before you begin modifying each VLAN.

For information on configuring and using virtual routers, see [Virtual Routers](#) on page 2129.

## Types of VLANs

This section introduces the following types of VLANs:

- [Port-Based VLANs](#)
- [Tagged VLANs](#)
- [Protocol-Based VLANs](#)
- [XNV Dynamic VLAN](#) on page 512

### Note

You can have netlogin dynamic VLANs and netlogin MAC-based VLANs. See [Network Login](#) on page 1191 for complete information on netlogin.

VLANs can be created according to the following criteria:

- Physical port
- IEEE 802.1Q tag
- Ethernet, LLC SAP, or LLC/SNAP Ethernet protocol type
- A combination of these criteria

### Port-Based VLANs

In a port-based VLAN, a VLAN name is given to a group of one or more ports on the switch.

At boot-up, all ports are members of the port-based VLAN default. Before you can add any port to another port-based VLAN, you must remove it from the default VLAN, unless the new VLAN uses a protocol other than the default protocol any. An untagged port can be a member of only one port-based VLAN.

On the Extreme Networks switch in [Figure 236](#), ports 9 through 14 are part of VLAN Marketing; ports 25 through 29 are part of VLAN Sales; and ports 21 through 24 and 30 through 32 are in VLAN Finance.

**Figure 236: Example of a Port-Based VLAN on an Extreme Networks Switch**

For the members of different IP VLANs to communicate, the traffic must be routed by the switch, even if the VLANs are physically part of the same switch. This means that each VLAN must be configured as a router interface with a unique IP address.

### Spanning Switches with Port-Based VLANs

To create a port-based VLAN that spans two switches, you must do two things:

1. Assign the port on each switch to the VLAN.

2. Cable the two switches together using one port on each switch per VLAN.

[Figure 237](#) illustrates a single VLAN that spans a BlackDiamond switch and another Extreme Networks switch. All ports on the System 1 switch belong to VLAN Sales. Ports 1 through 29 on the system 2 switch also belong to VLAN Sales. The two switches are connected using slot 8, port 4 on System 1 (the BlackDiamond switch), and port 29 on system 2 (the other switch).

**Figure 237: Single Port-based VLAN Spanning Two Switches**

3. To create multiple VLANs that span two switches in a port-based VLAN, a port on System 1 must be cabled to a port on System 2 for each VLAN you want to have span across the switches.

At least one port on each switch must be a member of the corresponding VLANs as well.

Figure 238 illustrates two VLANs spanning two switches. On System 2, ports 25 through 29 are part of VLAN Accounting; ports 21 through 24 and ports 30 through 32 are part of VLAN Engineering. On System 1, all ports on slot 1 are part of VLAN Accounting; all ports on slot 8 are part of VLAN Engineering.

**Figure 238: Two Port-Based VLANs Spanning Two Switches**

VLAN Accounting spans System 1 and System 2 by way of a connection between System 2, port 29 and System 1, slot 1, port 6. VLAN Engineering spans System 1 and System 2 by way of a connection between System 2, port 32, and System 1, slot 8, port 6.

4. Using this configuration, you can create multiple port-based VLANs that span multiple switches, in a daisy-chained fashion.

### Tagged VLANs

Tagging is a process that inserts a marker (called a tag) into the Ethernet frame. The tag contains the identification number of a specific *VLAN*, called the VLANid (valid numbers are 1 to 4094).

#### Note

The use of 802.1Q tagged packets may lead to the appearance of packets slightly bigger than the current IEEE 802.3/Ethernet maximum of 1,518 bytes. This may affect packet error counters in other devices and may also lead to connectivity problems if non-802.1Q bridges or routers are placed in the path.

### Uses of Tagged VLANs

Tagging is most commonly used to create VLANs that span switches.

The switch-to-switch connections are typically called *trunks*. Using tags, multiple VLANs can span multiple switches using one or more trunks. In a port-based VLAN, each VLAN

requires its own pair of trunk ports, as shown in [Figure 239](#) on page 2150. Using tags, multiple VLANs can span two switches with a single trunk.

Another benefit of tagged VLANs is the ability to have a port be a member of multiple VLANs. This is particularly useful if you have a device (such as a server) that must belong to multiple VLANs. The device must have a Network Interface Card (NIC) that supports IEEE 802.1Q tagging.

A single port can be a member of only one port-based VLAN. All additional VLAN membership for the port must be accompanied by tags.

### Assigning a VLAN Tag

Each VLAN may be assigned an 802.1Q VLAN tag. As ports are added to a VLAN with an 802.1Q tag defined, you decide whether each port uses tagging for that VLAN. The default mode of the switch is to have all ports assigned to the VLAN named default with an 802.1Q VLAN tag (VLANid) of 1 assigned.

Not all ports in the VLAN must be tagged. As traffic from a port is forwarded out of the switch, the switch determines (in real time) if each destination port should use tagged or untagged packet formats for that VLAN. The switch adds and strips tags, as required, by the port configuration for that VLAN.

#### Note

Packets arriving tagged with a VLANid that is not configured on a port are discarded.

[Figure 239](#) illustrates the physical view of a network that uses tagged and untagged traffic.

**Figure 239: Physical Diagram of Tagged and Untagged Traffic**

Figure 240 is a logical diagram of the same network.

**Figure 240: Logical Diagram of Tagged and Untagged Traffic**

In the figures above:

- The trunk port on each switch carries traffic for both VLAN Marketing and VLAN Sales.
- The trunk port on each switch is tagged.
- The server connected to port 25 on System 1 has a NIC that supports 802.1Q tagging.
- The server connected to port 25 on System 1 is a member of both VLAN Marketing and VLAN Sales.
- All other stations use untagged traffic.

As data passes out of the switch, the switch determines if the destination port requires the frames to be tagged or untagged. All traffic coming from and going to the server is tagged. Traffic coming from and going to the trunk ports is tagged. The traffic that comes from and goes to the other stations on this network is not tagged.

### Mixing Port-Based and Tagged VLANs

You can configure the switch using a combination of port-based and tagged VLANs. A given port can be a member of multiple VLANs, with the stipulation that only one of its VLANs uses untagged traffic. In other words, a port can simultaneously be a member of one port-based VLAN and multiple tag-based VLANs.

#### Note

For the purposes of VLAN classification, packets arriving on a port with an 802.1Q tag containing a VLANid of 0 are treated as untagged.

### Protocol-Based VLANs

Protocol-based VLANs enable you to define a packet filter that the switch uses as the matching criteria to determine if a particular packet belongs to a particular VLAN.

Protocol-based VLANs are most often used in situations where network segments contain hosts running multiple protocols. For example, in [Figure 241](#), the hosts are running both the IP and NetBIOS protocols.

The IP traffic has been divided into two IP subnets, 192.207.35.0 and 192.207.36.0. The subnets are internally routed by the switch. The subnets are assigned different VLAN names, Finance and Personnel, respectively. The remainder of the traffic belongs to the VLAN named MyCompany. All ports are members of the VLAN MyCompany.

**Figure 241: Protocol-Based VLANs**

The following sections provide information on using protocol-based VLANs:

- [Predefined Protocol Filters](#) on page 2152
- [Defining Protocol Filters](#) on page 2152
- [Configuring a VLAN to Use a Protocol Filter](#) on page 2153
- [Deleting a Protocol Filter](#) on page 2153

### Predefined Protocol Filters

The following protocol filters are predefined on the switch:

- IP (IPv4)
- IPv6 (IPv6)
- MPLS
- IPX
- NetBIOS
- DECNet
- IPX\_8022
- IPX\_SNAP
- AppleTalk

### Defining Protocol Filters

If necessary, you can define a customized protocol filter by specifying EtherType, Logical Link Control (LLC), or Subnetwork Access Protocol (SNAP). Up to six protocols can be part of a protocol filter. To define a protocol filter:

1. Create a protocol using the following command:

```
create protocol_name
```

For example: `create protocol fred`

The protocol name can have a maximum of 32 characters.

2. Configure the protocol using the following command:

```
configure protocol_name add [etype | llc | snap] hex {[etype | llc | snap] hex}
```

Supported protocol types include:

#### etype—EtherType

The values for etype are four-digit hexadecimal numbers taken from a list maintained by the IEEE. This list can be found at the following URL: <http://standards.ieee.org/regauth/ethertype/index.html>.

#### Note

Protocol-based VLAN for Etype from 0x0000 to 0x05ff are not classifying as per filter. When traffic arrive with these Etypes, it is classified to native VLAN rather protocol based vlan.

#### llc—LLC Service Advertising Protocol (SAP)

The values for llc are four-digit hexadecimal numbers that are created by concatenating a two-digit LLC Destination SAP (DSAP) and a two-digit LLC Source SAP (SSAP).

#### snap—EtherType inside an IEEE SNAP packet encapsulation

The values for snap are the same as the values for etype, described previously. For example:

```
configure protocol fred add llc feff
configure protocol fred add snap 9999
```

A maximum of 16 customized protocol filters can be active at a time.

**Note**

For more information about SNAP for Ethernet protocol types, see TR 11802-5:1997 (ISO/IEC) [ANSI/IEEE std. 802.1H, 1997 Edition].

### Configuring a VLAN to Use a Protocol Filter

To configure a VLAN to use a protocol filter, use the following command:

```
configure {vlan} [vlan_name | vlan_list] protocol {filter} filter_name
```

### Deleting a Protocol Filter

If a protocol filter is deleted from a VLAN, the VLAN is assigned a protocol filter of 'any'. You can continue to configure the VLAN. However, no traffic is forwarded to the VLAN until a protocol is assigned to it.

### Precedence of Tagged Packets Over Protocol Filters

If a VLAN is configured to accept tagged packets on a particular port, incoming packets that match the tag configuration take precedence over any protocol filters associated with the VLAN.

## Default VLAN

The default switch configuration includes one default VLAN that has the following properties:

- The VLAN name is default.
- It contains all the ports on a new or initialized switch.
- The default VLAN is untagged on all ports. It has an internal VLANid of 1; this value is user-configurable.

## VLAN Names

VLAN names must conform to the guidelines listed in [Object Names](#) on page 32.

VLAN names can be specified using the **[Tab]** key for command completion. VLAN names are locally significant. That is, VLAN names used on one switch are only meaningful to that switch. If another switch is connected to it, the VLAN names have no significance to the other switch.

**Note**

We recommend that you use VLAN names consistently across your entire network.

You must use mutually exclusive names for the following:

- VLANs
- VMANs
- IPv6 tunnels
- SVLANs
- CVLANs
- BVLANS

## Configuring VLANs on the Switch

Refer to the following sections for instruction on configuring VLANs on a switch:

- [VLAN Configuration Overview](#) on page 2154
- [Creating and Deleting VLANs](#) on page 2155
- [Managing a VLAN IP Address](#) on page 2155
- [Configuring a VLAN Tag](#) on page 2156
- [Adding and Removing Ports from a VLAN](#) on page 2156
- [Adding and Removing VLAN Descriptions](#) on page 2157
- [Renaming a VLAN](#) on page 2157
- [Enabling and Disabling VLANs](#) on page 2157
- [VLAN Configuration Examples](#) on page 2158

## VLAN Configuration Overview

The following procedure provides an overview of [VLAN](#) creation and configuration:

1. Create and name the VLAN.  

```
create [{vlan} vlan_name | vlan vlan_list] {tag tag } {description vlan-description } {vr name }
```
2. If needed, assign an IP address and mask (if applicable) to the VLAN as described in [Managing a VLAN IP Address](#) on page 2155.
3. If any ports in this VLAN will use a tag, assign a VLAN tag.  

```
configure {vlan} vlan_name tag tag {remote-mirroring}
```
4. Assign one or more ports to the VLAN.  

As you add each port to the VLAN, decide if the port will use an 802.1Q tag.
5. For the management VLAN on the switch, configure the default IP route for [VR-Mgmt](#).

### Note

See [IPv4 Unicast Routing](#) for information on configuring default IP routes or adding secondary IP addresses to VLANs.

### *VLAN ID and VLAN ID List Specification*

As of ExtremeXOS 16.1, you can now refer to a [VLAN](#) by VID as an alternative. Specifying lists of VIDs is a useful shortcut to all users that can reduce the number of commands required to configure the switch.

For example consider a case where two ports should be added to four tagged VLANs. Normally this would require four commands:

```
configure vlan red add ports 2,10 tagged
configure vlan blue add ports 2,10 tagged
configure vlan green add ports 2,10 tagged
configure vlan orange add ports 2,10 tagged
```

Assuming the tags for the VLANs are 100, 200, 300, 400 respectively this configuration can be accomplished with a single command:

```
configure vlan 100,200,300,400 add ports 2, 10 tagged
```

**Note**

Commands enhanced with VID list support operate in a “best effort” fashion. If one of the VIDs in a VID list do not exist the command is still executed for all of the VIDs in the list that do exist. No error or warning is displayed for the invalid VIDs unless all of the specified VIDs are in valid.

## Creating and Deleting VLANs

- To create a VLAN, use the following command:  

```
create [{vlan} vlan_name | vlan vlan_list] {tag tag } {description vlan-description } {vr name }
```
- To delete a VLAN, use the following command:  

```
delete vlan vlan_name | vlan_list
```

## Managing a VLAN IP Address

**Note**

If you plan to use this VLAN as a control VLAN for an EAPS (*Extreme Automatic Protection Switching*) domain, do not assign an IP address to the VLAN.

- Configure an IP address and mask for a VLAN.

**Note**

IPv4 addresses with 31-bit prefixes can be configured on network VLANs and the management VLAN. Applications and protocols can use these IPv4 addresses.

```
configure [{vlan} vlan_name | vlan vlan_id] ipaddress [ipaddress
{netmask} | {ipNetmask} | ipv6-link-local | {eui64} ipv6_address_mask]
```

#### Note

Each IP address and mask assigned to a VLAN must represent a unique IP subnet. You cannot configure the same IP subnet on different VLANs on the same .

The software supports using IPv6 addresses, in addition to IPv4 addresses. You can configure the VLAN with an IPv4 address, IPv6 address, or both. See [IPv6 Unicast Routing](#) on page 934 for complete information on using IPv6 addresses.

- Remove an IP address and mask for a VLAN.

```
unconfigure [{vlan} vlan_name | vlan vlan_id] ipaddress
{ipNetmask} | {ipNetmask} | ipv6-link-local | {eui64} ipv6_address_mask}
```

## Configuring a VLAN Tag

To configure a VLAN, use the following command:

```
configure {vlan} vlan_name tag tag {remote-mirroring}
```

## Adding and Removing Ports from a VLAN

- To add ports to a VLAN, use the following command:

The system returns the following message if the ports you are adding are already EAPS primary or EAPS secondary ports:

```
WARNING: Make sure Vlan1 is protected by EAPS, Adding EAPS ring ports to a VLAN could
cause a loop in the network.
Do you really want to add these ports? (y/n)
```

The system returns the following message if the ports that you are adding are untagged ports already associated with an untagged VLAN, and you are adding them to a different untagged VLAN or tagged VLAN

```
Port 1 untagged has been auto-moved from VLAN "Default" to "v2".
```

You can enable direct movement of untagged ports by enabling auto-move globally with the `configure vlan untagged-ports auto-move [on | off |inform]` command.

- To remove ports from a VLAN, use the following command:

## Adding and Removing VLAN Descriptions

A VLAN description is a string of up to 64 characters that you can configure to describe the VLAN. It is displayed by several show vlan commands and can be read by using SNMP (Simple Network Management Protocol) to access the VLAN's ifAlias MIB object.

- To add a description to a VLAN, use the following command:

```
configure {vlan} vlan_name description [vlan-description | none]
```

- To remove a description from a VLAN, use the following command

```
unconfigure {vlan} vlan_name description
```

## Renaming a VLAN

To rename an existing VLAN, use the following command:

```
configure {vlan} vlan_name | vlan_id name name
```

The following rules apply to renaming VLANs:

- You cannot change the name of the default VLAN.
- You cannot create a new VLAN named default.

## Enabling and Disabling VLANs

You can enable or disable individual VLANs. The default setting is that all VLANs are enabled.

Consider the following guidelines before you disable a VLAN:

- Disabling a VLAN stops all traffic on all ports associated with the specified VLAN.
- You cannot disable any VLAN that is running any Layer 2 protocol traffic.

When you attempt to disable a VLAN running Layer 2 protocol traffic (for example, the VLAN Accounting), the system returns a message similar to the following:

```
VLAN accounting cannot be disabled because it is actively used by an L2 Protocol
```

- You can disable the default VLAN; ensure that this is necessary before disabling the default VLAN.
- You cannot disable the management VLAN.
- You cannot bind Layer 2 protocols to a disabled VLAN.
- You can add ports to and delete ports from a disabled VLAN.

1. Disable a VLAN by running:

```
disable vlan vlan_name | vlan_list
```

2. After you have disabled a VLAN, re-enable that VLAN.

```
enable vlan vlan_name | vlan_list
```

## VLAN Configuration Examples

### Note

To add an untagged port to a VLAN you create, you must first delete that port from the default VLAN. If you attempt to add an untagged port to a VLAN before deleting it from the default VLAN, you see the following error message:  
Error: Protocol conflict when adding untagged port 1:2. Either add this port as tagged or assign another protocol to this VLAN.

The following example creates a port-based VLAN named accounting:

```
create vlan accounting
configure accounting ipaddress 132.15.121.1
configure default delete port 2:1-2:3,2:6,4:1,4:2
configure accounting add port 2:1-2:3,2:6,4:1,4:2
```

### Note

Because VLAN names are unique, you do not need to enter the keyword `vlan` after you have created the unique VLAN name. You can use the VLAN name alone (unless you are also using this name for another category such as STPD (*Spanning Tree Domain*) or EAPS, in which case we recommend including the keyword `vlan`).

The following stand-alone switch example creates a port-based VLAN named development with an IPv6 address:

```
create vlan development
configure development ipaddress 2001:0DB8::8:800:200C:417A/64
configure default delete port 1-3
configure development add port 1-3
```

The following example creates a protocol-based VLAN named ipsales.

Slot 5, ports 6 through 8, and slot 6, ports 1, 3, and 4-6 are assigned to the VLAN. In this example, you can add untagged ports to a new VLAN without first deleting them from the default VLAN, because the new VLAN uses a protocol other than the default protocol.

```
create vlan ipsales
configure ipsales protocol ip
configure ipsales add port 5:6-5:8,6:1,6:3-6:6
```

The following example defines a protocol filter, `myprotocol` and applies it to the VLAN named `myvlan`. This is an example only, and has no real-world application.

```
create protocol myprotocol
configure protocol myprotocol add etype 0xf0f0
configure protocol myprotocol add etype 0xffff
create vlan myvlan
configure myvlan protocol myprotocol
```

To disable the protocol-based VLAN (or any VLAN) in the above example, use the following command:

```
disable vlan myprotocol
```

To re-enable the VLAN, use the following command:

```
enable vlan myprotocol
```

## IP and MAC Anycast

The IP and MAC anycast feature enables you to configure the anycast gateway MAC to be used by VLANs that enable IP anycast. Using this feature, you can set the same IP address and MAC address on all edge technology devices. This allows seamless IP mobility in the network for edge devices.

### Note

IP and MAC anycast should be used only with VXLAN tenant VLANs. IP and MAC anycast should not be used with any protocols other than MLAG, since it might cause MAC flaps.

### Note

Switching through a VXLAN tunnel to a remote L3 Anycast gateway is not supported.

To configure IP/MAC anycast:

1. Enable IP anycast on the desired VLANs by using the following command:

```
enable ip anycast {vlan} vlan_name
```

2. Specify the anycast gateway MAC address that is used by VLANs that enable IP anycast by using the following command:

```
configure ip anycast mac [none | mac]
```

3. To specify that configured secondary IP addresses respond to ARP requests with the anycast MAC address, use the following command and specify the anycast option:

```
configure [{vlan} vlan_name | vlan vlan_id] add secondary-ipaddress
anycast [ip_address {netmask} | ipNetmask]
```

4. To configure a source VLAN to use as the source IP address in the BOOTPrelay packet, use the following command:

```
configure bootprelay dhcp-agent source-vlan {vlan_name} {vr vrid}
```

5. To enable or disable a reply to multicast or anycast echo requests, use the following commands:

```
enable icmp ipv6 [ignore-multicasts | ignore-anycasts]
```

```
disable icmp ipv6 [ignore-multicasts | ignore-anycasts]
```

To view IP and MAC anycast information:

- For IP anycast status (enabled or disabled), use the following command:

```
show vlan {virtual-router vr-name}
```

- For IP anycast MAC information, use the following command:

```
show ipconfig {ipv4} {vlan vlan_name | tunnel tunnel_name}
```

- For IPv6 anycast MAC information, use the following command:

```
show ipconfig ipv6 {vlan vlan_name | tunnel tunnel_name}
```

- To view configured secondary IP addresses on a VLAN, use the following command:

```
show vlan {virtual-router vr-name}
```

- To view the selected source VLAN for BOOTPrelay, use the command `show bootprelay configuration {ipv4 | ipv6} {{vlan vlan_name } | {vr vr_name}}` .
- To view configuration information for ICMP multicast and anycast echo requests, use the following command:

```
show ipconfig ipv6
```

## Displaying VLAN Information

To display general VLAN settings and information, use the following commands:

- `show vlan {virtual-router vr-name}`
- `show vlan vlan_name {ipv4 | ipv6}`
- `show vlan [tag tag | detail] {ipv4 | ipv6}`
- `show vlan description`
- `show vlan {vlan_name | vlan_list} statistics {no-refresh | refresh }`

### Note

To display IPv6 information, you must use either the `show vlan detail` command or `show vlan` command with the name of the specified VLAN.

To display the VLAN information for other ExtremeXOS software features, use the following commands:

- `show {vlan} vlan_name dhcp-address-allocation`
- `show {vlan} vlan_name dhcp-config`
- `show {vlan} vlan_name eaps`
- `show {vlan} vlan_name security`
- `show {vlan} {vlan_name | vlan_list} stpd`

You can display additional useful information on VLANs configured with IPv6 addresses by issuing the command:

```
show ipconfig ipv6 vlan vlan_name
```

To display protocol information, issue the command:

```
show protocol {name}
```

## Private VLANs

---

The following sections provide detailed information on private VLANs:

- [PVLAN Overview](#) on page 2161
- [Configuring PVLANS](#) on page 2170
- [Displaying PVLAN Information](#) on page 2173
- [PVLAN Configuration Example 1](#) on page 2174
- [PVLAN Configuration Example 2](#) on page 2176

## PVLAN Overview

PVLANS offer the following features:

- VLAN translation
- VLAN isolation

### Note

PVLAN features are supported only on the platforms listed for this feature in the [Switch Engine v33.3.1 Licensing Guide](#) document.

### *VLAN Translation in a PVLAN*

VLAN translation provides the ability to translate the 802.1Q tags for several VLANs into a single VLAN tag. VLAN translation is an optional component in a PVLAN.

VLAN translation allows you to aggregate Layer 2 VLAN traffic from multiple clients into a single uplink VLAN, improving VLAN scaling. [Figure 242](#) shows an application of VLAN translation.

**Figure 242: VLAN Translation Application**

In the figure, VLANs 101, 102, and 103 are subscriber VLANs that carry data traffic while VLANs 201, 202, and 203 are subscriber VLANs that carry voice traffic. The voice and data traffic are combined on integrated access devices (IADs) that connect to the VLAN translation switch. Each of the three clusters of phones and PCs uses two VLANs to separate the voice and data traffic. As the traffic is combined, the six VLANs are translated into two network VLANs, VLAN1 and VLAN2. This simplifies administration, and scales much better for large installations.

Conceptually, this is very similar to Layer 3 VLAN aggregation (superVLANs and subVLANs).

The primary differences between these two features are:

- VLAN translation is strictly a Layer 2 feature.
- VLAN translation does not allow communication between the subscriber VLANs.

### *VLAN Isolation*

VLAN isolation provides Layer 2 isolation between the ports in a VLAN. [Figure 243](#) shows an application of VLAN isolation.

**Figure 243: VLAN Isolation Application**

In this figure, ports in the Guest VLAN have access to services on the network VLAN, but Guest VLAN ports cannot access other Guest VLAN ports over Layer 2 (or the Marketing or Engineering VLANs). This provides port-to-port security at Layer 2.

#### *PVLAN Components*

Figure 244 shows the logical components that support PVLAN configuration in a switch.

**Figure 244: Private VLAN Switch Components**

There is one network VLAN in each PVLAN. Ports within a network VLAN, called network ports, can communicate with all VLAN ports in the PVLAN. Network devices that connect to the network VLAN ports are considered to be on the network side of the switch.

The network VLAN aggregates the uplink traffic from the other VLANs, called subscriber VLANs, for egress communications on a network VLAN port. A network port can serve only one PVLAN, but it can serve one or more subscriber VLANs. Ingress communications on the network VLAN port are distributed to the appropriate subscriber VLANs for distribution to the appropriate ports. Devices that connect to subscriber VLAN ports are considered to be on the subscriber side of the switch.

**Note**

PVLAN network-tagged packets are allowed to ingress on subscriber VLAN ports.

Tag translation within the PVLAN is managed at the egress ports. To enable tag translation for uplink traffic from the subscriber VLANs, you must enable tag translation on the appropriate network VLAN port. Tag translation is automatically enabled on subscriber VLAN egress ports when the subscriber VLAN is created and the port is added to the VLAN as tagged. Egress traffic from a subscriber VLAN is always tagged with the subscriber VLAN tag when the port is configured as tagged.

A non-isolated subscriber VLAN is basically a standard VLAN that can participate in tag translation through the network VLAN when VLAN translation is enabled on the network VLAN port.

You can choose to not translate tags on a network VLAN port, but this is generally used only for extending a PVLAN to another switch. A non-isolated subscriber VLAN that does not use tag translation is functionally equivalent to a regular VLAN, so it is better to create non-isolated VLANs only when you plan to use tag translation.

Ports in a non-isolated VLAN can communicate with other ports in the same VLAN, ports in the network VLAN, and destinations on the network side of the switch. As with

standard VLANs, non-isolated ports cannot communicate through Layer 2 with ports in other subscriber VLANs.

In [Figure 244](#) on page 2164, the Engineering and Marketing VLANs are configured as non-isolated subscriber VLANs, which means that they act just like traditional VLANs, and they can participate in tag translation when VLAN translation is enabled on a network VLAN port that leads to network side location.

VLAN isolation within the PVLAN is established by configuring a VLAN to be an isolated subscriber VLAN and adding ports to the isolated VLAN. Unlike normal VLANs, ports in an isolated VLAN cannot communicate with other ports in the same VLAN over Layer 2 or Layer 3. The ports in an isolated VLAN can, however, communicate with Layer 2 devices on the network side of the PVLAN through the network VLAN. When the network VLAN egress port is configured for tag translation, isolated VLAN ports also participate in uplink tag translation. When isolated subscriber VLAN ports are configured as tagged, egress packets are tagged with the isolated VLAN tag. As with standard VLANs and non-isolated VLANs, isolated ports cannot communicate through Layer 2 with ports in other subscriber VLANs.

#### *PVLAN Support over Multiple Switches*

A PVLAN can span multiple switches. [Figure 244](#) on page 2164 shows a PVLAN that is configured to operate on two switches.

**Figure 245: Private VLAN Support on Multiple Switches**

A PVLAN can span many switches. For simplicity, this example shows only two switches, but you can extend the PVLAN to additional switches by adding connections between the network VLANs in each switch. The ports that connect two PVLAN switches must be configured as regular tagged ports. The network and subscriber VLANs on each switch must be configured with the same tags.

#### **Note**

Although using the same VLAN names on all PVLAN switches might make switch management easier, there is no software requirement to match the VLAN names. Only the tags must match.

When a PVLAN is configured on multiple switches, the PVLAN switches function as one PVLAN switch. Subscriber VLAN ports can access the network VLAN ports on any of the PVLAN switches, and non-isolated VLAN ports can communicate with ports in the same VLAN that are located on a different physical switch. An isolated VLAN can span multiple switches and maintain isolation between the VLAN ports.

The network and subscriber VLANs can be extended to other switches that are not configured for the PVLAN (as described in [Extending Network and Subscriber VLANs to Other Switches](#) on page 2166). The advantage to extending the PVLAN is that tag translation and VLAN isolation is supported on the additional switch or switches.

#### *Extending Network and Subscriber VLANs to Other Switches*

A network or subscriber VLAN can be extended to additional switches without a PVLAN configuration on the additional switches.

You might want to do this to connect to existing servers, switches, or other network devices. You probably do not want to use this approach to support clients, as tag translation and VLAN isolation are not supported unless the PVLAN is configured on all PVLAN switches as described in [PVLAN Support over Multiple Switches](#) on page 2165.

Figure 246 illustrates PVLAN connections to switches outside the PVLAN.

**Figure 246: Private VLAN Connections to Switches Outside the PVLAN**

In this configuration, Switch 1, Network VLAN Port 21 connects to a Switch 3 port that only supports the Network VLAN. The Network VLAN Port 21 on Switch 1 is configured as “translated,” which translates subscriber VLAN tags to the network VLAN tag for

access to the Network VLAN extension on Switch 3. Switch 3, Port 24 is configured as tagged and only accepts traffic with the Network VLAN Tag. Switch 3 serves as an extension of the Network VLAN and can be used to connect to network devices such as servers or an internet gateway.

Switch 2, port 22 supports the Network, NonIsolated, and Isolated VLANs, but no PVLAN is configured.

Because port 22 supports multiple VLANs that are part of the PVLAN, and because these Switch 2 VLANs are not part of the PVLAN, Switch 1, port 24, must be configured as a PVLAN endpoint, which establishes the PVLAN boundary. Switch 2, port 22, is configured as a regular tagged VLAN port.

For most applications, it would be better to extend the PVLAN to Switch 2 so that the PVLAN features are available to the Switch 2 VLANs.

The configuration of Switch 2 behaves as follows:

- The Switch 2 NonIsolated VLAN ports can communicate with the NonIsolated VLAN ports on Switch 1, but they cannot participate in VLAN translation.
- The Switch 2 Isolated VLAN ports can communicate with other Switch 2 Isolated VLAN ports.
- The Switch 2 Isolated VLAN ports cannot participate in VLAN translation.
- The Switch 2 Isolated VLAN ports can receive broadcast and multicast info for the Isolated VLAN.
- Traffic is allowed from the Switch 1 Isolated VLAN ports to the Switch 2 Isolated VLAN ports.

### *MAC Address Management in a PVLAN*

Each device that connects to a PVLAN must have a unique MAC address within the PVLAN. Each MAC address learned in a PVLAN requires multiple *FDB (forwarding database)* entries. For example, each MAC address learned in a non-isolated subscriber VLAN requires two FDB entries, one for the subscriber VLAN and one for the network VLAN. The additional FDB entries for a PVLAN are marked with the P flag in the `show fdb` command display.

The following sections describe the FDB entries created for the PVLAN components and how to estimate the impact of a PVLAN on the FDB table:

- [Non-Isolated Subscriber VLAN](#)
- [Isolated Subscriber VLAN](#)
- [Network VLAN](#)
- [Calculating the Total FDB Entries for a PVLAN](#)

#### **Non-Isolated Subscriber VLAN**

When a MAC address is learned on a non-isolated subscriber VLAN port, two entries are added to the FDB table:

- MAC address, non-isolated subscriber VLAN tag, and the port number
- MAC address, network VLAN tag, port number, and a special flag for tag translation

The network VLAN entry is used when traffic comes in from the network ports destined for an non-isolated port.

### Isolated Subscriber VLAN

When a new MAC address is learned on an isolated subscriber VLAN port, two entries are added to the FDB table:

- MAC address, isolated subscriber VLAN tag, port number, and a flag that indicates that the packet should be dropped
- MAC address, network VLAN tag, port number, and a special flag for tag translation

Ports in the isolated VLAN do not communicate with one another.

If a port in the isolated VLAN sends a packet to another port in the same VLAN that already has an entry in the FDB, that packet is dropped. You can verify the drop packet status of an FDB entry by using the `show fdb` command. The D flag indicates that packets destined for the listed address are dropped.

The network VLAN entry is used when traffic comes in from the network ports destined for an isolated port.

### Network VLAN

When a new MAC address is learned on a network VLAN port, the following entry is added to the FDB table: MAC address, network VLAN tag, and port number.

For every subscriber VLAN belonging to this PVLAN, the following entry is added to the FDB table: MAC address, subscriber VLAN tag, and port number

### Calculating the Total FDB Entries for a PVLAN

The following formula can be used to estimate the maximum number of FDB entries for a PVLAN:

$$\text{FDBtotal} = [(\text{MACnon-iso} + \text{MACiso}) * 2 + (\text{MACnetwork} * (\text{VLANnon-iso} + \text{VLANiso} + 1))]$$

The formula components are as follows:

- MACnon-iso = number of MAC addresses learned on all the non-isolated subscriber VLANs
- MACiso = number of MAC addresses learned on all the isolated subscriber VLANs
- MACnetwork = number of MAC addresses learned on the network VLAN
- VLANnon-iso = number of non-isolated subscriber VLANs
- VLANiso = number of isolated subscriber VLANs

#### Note

The formula above estimates the worst-case scenario for the maximum number of FDB entries for a single PVLAN. If the switch supports additional PVLANS, apply the formula to each PVLAN and add the totals for all PVLANS. If the switch also support standard VLANs, there will also be FDB entries for the standard VLANs.

### Layer 3 Communications

For PVLANS, the default switch configuration controls Layer 3 communications exactly as communications are controlled in Layer 2.

For example, Layer 3 communications is enabled between ports in a non-isolated subscriber [VLAN](#), and disabled between ports in an isolated subscriber VLAN. Ports in a non-isolated subscriber VLAN cannot communicate with ports in other non-isolated subscriber VLANs.

You can enable Layer 3 communications between all ports in a PVLAN. For more information, see [Managing Layer 3 Communications in a PVLAN](#) on page 2173.

### PVLAN Limitations

The Private [VLAN](#) feature has the following limitations:

- Requires more [FDB](#) entries than a standard VLAN.
- VLAN tag duplication is not allowed.
- VLAN name duplication is not allowed.
- Each MAC address learned in a PVLAN must be unique. A MAC address cannot exist in two or more VLANs that belong to the same PVLAN.
- MVR cannot be configured on PVLANS.
- A VMAN cannot be added to a PVLAN.
- A PBB network (BVLAN) cannot be added to a PVLAN.
- [EAPS](#) control VLANs cannot be either subscriber or network VLANs.
- For PVLAN with [STP \(Spanning Tree Protocol\)](#) implementation, irrespective of port translation configuration in the Network VLAN, it is recommended to add both the Network VLAN and all subscriber VLANs to the STP.
- For PVLAN with EAPS implementation, irrespective of port translation configuration in the Network VLAN, it is recommended to add both the Network VLAN and all subscriber VLANs to the EAPS ring.
- [ESRP \(Extreme Standby Router Protocol\)](#) can only be configured on network VLAN ports (and not on subscriber VLAN ports). To support ESRP on the network VLAN, you must add all of the VLANs in the PVLAN to ESRP.
- There is no [NetLogin](#) support to add ports as translate to the network VLAN, but the rest of NetLogin and the PVLAN features do not conflict.
- [IGMP \(Internet Group Management Protocol\)](#) snooping is performed across the entire PVLAN, spanning all the subscriber VLANs, following the PVLAN rules. For VLANs that are not part of a PVLAN, IGMP snooping operates as normal.
- PVLAN and VPLS are not supported on the same VLAN.
- When two switches are part of the same PVLAN, unicast and multicast traffic require a tagged trunk between them that preserves tags (no tag translation).
- Subscriber VLANs in a PVLAN cannot exchange multicast data with VLANs outside the PVLAN and with other PVLANS. However, the network VLAN can exchange multicast data with VLANs outside the PVLAN and with network VLANs in other PVLANS.

- PVLAN does not support IPv6.
- DHCP does not work on subscriber VLANs because an IP address can not be assigned to the subscriber VLAN.

#### Note

A maximum of 80% of 4K VLANs can be added to a PVLAN. Adding more VLANs will display the following log error:

```
<Error:HAL.VLAN.Error>Slot-<slot>: Failed to add egress vlan translation entry on port <port> due to "Table full".
```

If two or more member VLANs have overlapping ports (where the same ports are assigned to both VLANs), each additional VLAN member with overlapping ports must have a dedicated loopback port. To state it another way, one of the VLAN members with overlapping ports does not require a dedicated loopback port, and the rest of the VLAN members do require a single, dedicated loopback port within each member VLAN.

#### Note

There is a limit to the number of unique source MAC addresses on the network VLAN of a PVLAN that the switch can manage. It is advised not to exceed the value shown in the item "FDB (maximum L2 entries)" in the Supported Limits table of the [ExtremeXOS Release Notes](#).

## Configuring PVLANS

The following section describes how to configure a private [VLAN](#).

### Creating PVLANS

To create a [VLAN](#), you need to do the following:

1. Create the PVLAN.
  2. Add one VLAN to the PVLAN as a network VLAN.
  3. Add VLANs to the PVLAN as subscriber VLANs.
- To create a PVLAN, use the following command:  

```
create private-vlan name {vr vr_name}
```
  - To add a network VLAN to the PVLAN, create and configure a tagged VLAN, and then use the following command to add that network VLAN:  

```
configure private-vlan name add network vlan_name
```
  - To add a subscriber VLAN to the PVLAN, create and configure a tagged VLAN, and then use the following command to add that subscriber VLAN:  

```
configure private-vlan name add subscriber vlan_name {non-isolated} {loopback-port port}
```

By default, this command adds an isolated subscriber VLAN. To create a non-isolated subscriber VLAN, you must include the non-isolated option.

### Configuring Network VLAN Ports for VLAN Translation

When subscriber VLAN traffic exits a network VLAN port, it can be untagged, tagged (with the subscriber VLAN tag), or translated (to the network VLAN tag).

#### Note

All traffic that exits a subscriber VLAN port uses the subscriber VLAN tag, unless the port is configured as untagged. There is no need to configure VLAN translation (from network to subscriber VLAN tag) on subscriber VLAN ports.

1. To configure network VLAN ports for VLAN translation, use the following command and specify the network VLAN and port numbers:
2. If you want to later reconfigure a port that is configured for VLAN translation so that it does not translate tags, use the following command and specify either the tagged or the untagged option:

```
configure {vlan} vlan_name | vlan_list add ports port_list private-vlan translated
```

```
configure {vlan} vlan_name | vlan_list add ports [port_list | all]
{tagged | untagged} {{stpd} stpd_name} {dot1d | emistp | pvst-plus}}
```

### Configuring Non-Isolated Subscriber VLAN Ports

The process for configuring non-isolated VLAN ports requires two tasks:

- Add a VLAN to the PVLAN as a non-isolated subscriber VLAN.
- Assign ports to the non-isolated subscriber VLAN.

These tasks can be completed in any order, but they must both be completed before a port can participate in a PVLAN. When configuration is complete, all egress traffic from the port is translated to the VLAN tag for that non-isolated VLAN (unless the port is configured as untagged).

#### Note

To configure VLAN translation for network VLAN ports, see [Configuring Network VLAN Ports for VLAN Translation](#) on page 2171.

- To add a non-isolated subscriber VLAN to the PVLAN, use the following command:
- To add ports to a non-isolated VLAN (before or after it is added to the PVLAN), use the following command:

```
configure private-vlan name add subscriber vlan_name non-isolated
```

```
configure {vlan} vlan_name | vlan_list add ports [port_list | all]
{tagged | untagged} {{stpd} stpd_name} {dot1d | emistp | pvst-plus}}
```

If you specify the tagged option, egress traffic uses the non-isolated VLAN tag, regardless of the network translation configuration on any network port with which these ports communicate. Egress traffic from a non-isolated VLAN port never carries the network VLAN tag.

### Configuring Isolated Subscriber VLAN Ports

When a port is successfully added to an isolated VLAN, the port is isolated from other ports in the same VLAN, and all egress traffic from the port is translated to the VLAN tag for that VLAN (unless the port is configured as untagged).

#### Note

To configure VLAN translation for network VLAN ports, see [Configuring Network VLAN Ports for VLAN Translation](#) on page 2171.

The process for configuring ports for VLAN isolation requires two tasks:

- Add a VLAN to the PVLAN as an isolated subscriber VLAN.
- Assign ports to the isolated subscriber VLAN.

These tasks can be completed in any order, but they must both be completed before a port can participate in an isolated VLAN.

- To add an isolated subscriber VLAN to the PVLAN, use the following command:

```
configure private-vlan name add subscriber vlan_name
```

- To add ports to an isolated VLAN (before or after it is added to the PVLAN), use the following command:

```
configure {vlan} vlan_name | vlan_list add ports [port_list | all]
{tagged | untagged} [{stpd} stpd_name] {dot1d | emistp | pvst-plus}}
```

If you specify the tagged option, egress traffic uses the isolated VLAN tag, regardless of the network translation configuration on any network port with which these ports communicate. Egress traffic from an isolated VLAN port never carries the network VLAN tag.

### Configuring a PVLAN on Multiple Switches

To create a PVLAN that runs on multiple switches, you must configure the PVLAN on each switch and set up a connection between the network VLANs on each switch. The ports at each end of the connection must be configured as tagged ports that do not perform tag translation.

To configure these types of ports, use the following command:

```
configure {vlan} vlan_name add ports port_list tagged
```

### Configuring a Network or Subscriber VLAN Extension to Another Switch

You can extend a network or subscriber VLAN to another switch without configuring a PVLAN on that switch. This configuration is introduced in [Extending Network and Subscriber VLANs to Other Switches](#) on page 2166.

- To configure the port on the switch that is outside of the PVLAN, use the following command:

```
configure {vlan} vlan_name add ports port_list tagged
```

### Adding a Loopback Port to a Subscriber VLAN

ExtremeSwitching series switches, whether or not included in a SummitStack, require a loopback port for certain configurations. If two or more subscriber VLANs have

overlapping ports (where the same ports are assigned to both VLANs), each of the subscriber VLANs with overlapping ports must have a dedicated loopback port.

The loopback port can be added when the subscriber VLAN is added to the PVLAN.

If you need to add a loopback port to an existing subscriber VLAN, use the following command:

```
configure {vlan} vlan_name vlan-translation add loopback-port port
```

### *Managing Layer 3 Communications in a PVLAN*

The default configuration for Layer 3 PVLAN communications is described in [Layer 3 Communications](#).

To enable Layer 3 communications between all ports in a PVLAN, use the following command:

```
configure iparp add proxy [ipNetmask | ip_addr {mask}] {vr vr_name} {mac
| vrrp} {always}
```

Specify the IP address or subnet specified for the network VLAN in the PVLAN. Use the **always** option to ensure that the switch will reply to ARP requests, regardless of the VLAN from which it originated.

### *Delete PVLANs*

To delete an existing PVLAN, use the command:

```
delete private-vlan name
```

### *Remove a VLAN from a PVLAN*

When you remove a VLAN from a PVLAN, you remove the association between a VLAN and the PVLAN. Both the VLAN and PVLAN exist after the removal.

To remove a network or subscriber VLAN from a PVLAN, use the following command:

```
configure private-vlan name delete [network | subscriber] vlan_name
```

### *Deleting a Loopback Port from a Subscriber VLAN*

To delete a loopback port from a subscriber VLAN, use the command:

```
configure {vlan} vlan_name vlan-translation delete loopback-port
```

## Displaying PVLAN Information

This section describes how to display private VLAN information.

### *Displaying Information for all PVLANs*

To display information on all the PVLANs configured on a switch, use the command:

```
show private-vlan
```

*Displaying Information for a Specific PVLAN*

To display information about a single PVLANs, use the command:

```
show {private-vlan} name
```

*Displaying Information for a Network or Subscriber VLAN*

To display information about a network or subscriber VLAN, use the command:

```
show vlan {virtual-router vr-name}
```

The following flags provide PVLAN specific information:

**s flat**

Identifies a network VLAN port that the system added to a subscriber VLAN. All subscriber VLANs contain network VLAN ports that are marked with the s flag.

**L flag**

Identifies a subscriber VLAN port that is configured as a loopback port.

**t flag**

Identifies a tagged network VLAN port on which tag translation is enabled. The t flag only appears in the show vlan display for network VLANs.

**e flag**

Identifies a network VLAN port that is configured as an endpoint. The e flag only appears in the show vlan display for network VLANs.

*Displaying PVLAN FDB Entries*

To view all FDB entries including those created for a PVLAN, use the command:

```
show fdb {blackhole {netlogin [all | mac-based-vlans]} | netlogin [all | mac-based-vlans] | permanent {netlogin [all | mac-based-vlans]} | mac_addr {netlogin [all | mac-based-vlans]} | ports port_list {netlogin [all | mac-based-vlans]} | vlan vlan_name | vlan_list {netlogin [all | mac-based-vlans]} | {{vpls} {vpls_name}}}
```

The P flag marks additional FDB entries for PVLANs.

## PVLAN Configuration Example 1

[Figure 247](#) on page 2175 shows a PVLAN configuration example for a medical research lab.

**Figure 247: PVLAN Configuration Example 1**

The medical research lab hosts lots of visiting clients. Each client has their own room, and the lab wants to grant them access to the internet through a local web proxy server but prevent them from accessing other visiting clients. There is a lab in the building where many research workstations are located. Workstations within the lab require access to other lab workstations, the internet, and file servers that are connected to a switch in another building. Visiting clients should not have access to the Research *VLAN* devices or the file servers on the remote switch.

The PVLAN in [Figure 247](#) contains the following PVLAN components:

- Network VLAN named Main, which provides internet access through the proxy web server and access to file servers on the remote switch.
- Isolated subscriber VLAN named ClientConnections, which provides internet access for visiting clients and isolation from other visiting clients, the Research VLAN devices, and the remote file servers.
- Non-isolated subscriber VLAN named Research, which provides internet access and enables communications between Research VLAN devices and the remote file servers.

1. The first configuration step is to create and configure the VLANs on the local switch:

```
create vlan Main
configure vlan Main add port 1:*
configure vlan Main tag 100
create vlan ClientConnections
configure vlan ClientConnections add port 2:*
configure vlan ClientConnections tag 200
create vlan Research
configure vlan Research add port 3:*
configure vlan Research tag 300
```

2. The remote switch VLAN is configured as follows:

```
create vlan Main
configure vlan Main add port 1:*
configure vlan Main tag 100
```

3. The next step is to create the PVLAN on the local switch and configure each of the component VLANs for the proper role:

```
create private-vlan MedPrivate
configure private-vlan "MedPrivate" add network "Main"
configure private-vlan "MedPrivate" add subscriber "ClientConnections"
configure private-vlan "MedPrivate" add subscriber "Research" non-isolated
```

4. The final step is to configure VLAN translation on the local switch so that Research VLAN workstations can connect to the file servers on the remote switch:

```
configure Main add ports 1:1 private-vlan translated
```

5. To view the completed configuration, enter the `show private-vlan` command as follows:

```
show private-vlan

Name VID Protocol Addr Flags Proto Ports Virtual
Active router
/Total

MedPrivate
Network VLAN:
- main 100 -----
Non-Isolated Subscriber VLAN:
- Research 300 -----
Isolated Subscriber VLAN:
- ClientConnections 200 -----
 ANY 2 /48 VR-Default
 ANY 2 /96 VR-Default
 ANY 2 /52 VR-Default
```

## PVLAN Configuration Example 2

Figure 248 shows a PVLAN configuration example for a motel.

**Figure 248: PVLAN Configuration Example 2**

This motel has guest rooms, a conference room, and their web proxy server on the first floor, and guest rooms on the second floor. The motel has three ExtremeSwitching switches. There is one on the first floor in a closet, one on the first floor in the conference room, and one on the second floor.

The PVLAN in [Figure 248](#) contains the following PVLAN components:

- A VLAN called Main that contains the web proxy server.
- A VLAN called ConfRoom that contains the ports for the conference room connections.
- A VLAN called ClientConnections that contains client PC connections for the guest rooms.

The goals for the motel network are as follows:

- Provide internet access for the ConfRoom and ClientConnections VLANs through the web proxy server.
- Prevent communications between the ConfRoom and ClientConnections VLANs.
- Enable communications between clients on the ClientConnections VLAN only within the conference room.
- Enable communications between devices on the ConfRoom VLAN.
- Prevent communications between the PCs in the ClientConnections VLAN that are not in the conference room.

Notice the following in this example:

- The ExtremeSwitching switches in the first floor closet and on the second floor contain the Main VLAN with a tag of 100. This VLAN is connected via a tagged port between the first and second floor switches.
- The switch in the conference room does not contain the Main VLAN and cannot be a PVLAN member.
- All of the switches have the ClientConnections VLAN, and it uses VLAN tag 200.
- All of the switches have the ConfRoom VLAN, and it uses VLAN tag 300.
- The Conference Room switch connects to the rest of the network through a tagged connection to the switch in the first floor closet.
- Because the switch in the first floor closet is a PVLAN member and uses the same port to support two subscriber VLANs, a loopback port is required in all subscriber VLANs, except the first configured subscriber VLAN (this applies to all switches).

#### Note

The following examples contain comments that follow the CLI comment character (#). All text that follows this character is ignored by the switch and can be omitted from the switch configuration.

The following commands configure the switch in the first floor closet:

```
Create and configure the VLANs.
create vlan Main
configure vlan Main add port 1
configure vlan Main tag 100
configure vlan Main add port 2 tagged
create vlan ClientConnections
configure vlan ClientConnections tag 200
configure vlan ClientConnections add port 5-19
configure vlan ClientConnections add port 20 tagged
create vlan ConfRoom
configure vlan ConfRoom tag 300
configure vlan ConfRoom add port 21-30
configure vlan ConfRoom add port 20 tagged

Create and configure the PVLAN named Motel.
create private-vlan Motel
configure private-vlan Motel add network Main
configure private-vlan Motel add subscriber ClientConnections # isolated subscriber VLAN
configure private-vlan "Motel" add subscriber "ConfRoom" non-isolated loopback-port 30
configure private-vlan Motel add subscriber ConfRoom non-isolated
If you omit the loopback-port command, the above command produces the following error
message:
```

```
Cannot add subscriber because another subscriber vlan is already present on the same
port, assign a loopback port when adding the subscriber vlan to the private vlan
```

```
show vlan "ConfRoom"
VLAN Interface with name ConfRoom created by user
Admin State: Enabled Tagging: 802.1Q Tag 300
Virtual router: VR-Default
IPv6: None
STPD: None
Protocol: Match all unfiltered protocols
Loopback: Disabled
NetLogin: Disabled
QosProfile: None configured
Egress Rate Limit Designated Port: None configured
Private-VLAN Name: Motel
VLAN Type in Private-VLAN: Non-Isolated Subscriber
Ports: 13. (Number of active ports=1)
Untag: 21, 22, 23, 24, 25, 26, 27,
28, 29
Tag: 1s, 2s, 20, *30L
Flags: (*) Active, (!) Disabled, (g) Load Sharing port
(b) Port blocked on the vlan, (m) Mac-Based port
(a) Egress traffic allowed for NetLogin
(u) Egress traffic unallowed for NetLogin
(t) Translate VLAN tag for Private-VLAN
(s) Private-VLAN System Port, (L) Loopback port
(x) VMAN Tag Translated port
(F) Dynamically added by Fabric Attach
(G) Multi-switch LAG Group port
(H) Dynamically added by MVRP
(I) Dynamically added by IDM
(U) Dynamically added uplink port
(V) Dynamically added by VM Tracking

Note that the loopback port is flagged with an "L" and listed as a tagged port, and the
network VLAN ports are flagged with an "s" and listed as tagged ports.
```

The following commands configure the switch on the second floor:

```
create and configure the VLANs
create vlan Main
configure vlan Main tag 100
configure vlan Main add port 2 tagged
create vlan ClientConnections
configure vlan ClientConnections tag 200
configure vlan ClientConnections add port 5-20
create vlan ConfRoom
configure vlan ConfRoom tag 300
Create and configure the PVLAN named Motel.
create private-vlan Motel
configure private-vlan Motel add network Main
configure private-vlan Motel add subscriber ClientConnections # isolated subscriber VLAN
configure private-vlan Motel add subscriber ConfRoom non-isolated
```

The following commands configure the switch in the conference room:

```
create and configure the VLANs
create vlan ClientConnections
configure vlan ClientConnections tag 200
configure vlan ClientConnections add port 1-19
configure vlan ClientConnections add port 20 tag
create vlan ConfRoom
configure vlan ConfRoom tag 300
configure vlan ConfRoom add port 21-30
```

```
configure vlan ConfRoom add port 20 tag
The VLANs operate as extensions of the VLANs on the Summit in the first floor closet.
There is no PVLAN configuration on this switch.
```

## VLAN Translation

The [VLAN](#) translation feature described in this section provides the same VLAN translation functionality that is provided for PVLANS. This is described in [VLAN Translation in a PVLAN](#) on page 2161.

### Note

The VLAN translation feature is supported only on the platforms listed for this feature in the license tables in the [Switch Engine v33.3.1 Licensing Guide](#) document.

[Figure 249](#) shows how VLAN translation is configured in the switch.

**Figure 249: VLAN Translation Switch Configuration**

VLAN1 is configured as a translation VLAN. The translation VLAN is equivalent to the network VLAN in the PVLAN implementation of VLAN translation.

VLANs 101, 102, and 103 are configured as member VLANs of translation VLAN1. The member VLANs are equivalent to the non-isolated subscriber VLANs in the PVLAN implementation of VLAN translation.

This configuration enables tag translation between the translation VLAN and the member VLANs. All member VLANs can communicate through the translation VLAN, but they cannot communicate through Layer 2 with each other.

## VLAN Translation Behavior

You should be aware of the behavior of [unicast](#), [broadcast](#), and [multicast](#) traffic when using [VLAN](#) translation.

### Unicast Traffic

Traffic on the member VLANs can be either tagged or untagged.

Traffic is switched locally between client devices on the same member VLAN as normal. Traffic cannot be switched between clients on separate member VLANs. Traffic from any member VLAN destined for the translation VLAN is switched and the VLAN tag is translated appropriately. Traffic from the translation VLAN destined for any member VLAN is switched and the VLAN tag is translated.

### Broadcast Behavior

Broadcast traffic generated on a member VLAN is replicated in every other active port of that VLAN as normal.

In addition, the member VLAN traffic is replicated to every active port in the translation VLAN and the VLAN tag is translated appropriately. Broadcast traffic generated on the translation VLAN is replicated to every other active port in this VLAN as usual. The caveat in this scenario is that this traffic is also replicated to every active port in every member VLAN, with VLAN tag translation. In effect, the broadcast traffic from the translation VLAN leaks onto all member VLANs.

### Multicast Behavior

IGMP snooping can be enabled on member and translation VLANs so that multicast traffic can be monitored within the network.

IGMP snooping software examines all IGMP control traffic that enters the switch. IGMP control traffic received on a VLAN translation port is forwarded by the CPU to all other ports in the translation group. Software VLAN translation is performed on the packets which cross the translation boundary between member and translation VLANs. The snooping software detects ports joining and leaving multicast streams. When a VLAN translation port joins a multicast group, an FDB entry is installed only on receiving a data miss for that group. The FDB entry is added for the requested multicast address and contains a multicast PTAG. When a VLAN translation port leaves a multicast group, the port is removed from the multicast list. The last VLAN translation port to leave a multicast group causes the multicast FDB entry to be removed.

## VLAN Translation Limitations

The VLAN translation feature has the following limitations:

- Requires more FDB entries than a standard VLAN.
- VLAN tag duplication is not allowed.
- VLAN name duplication is not allowed.
- Each MAC address learned in the translation and member VLANs must be unique. A MAC address cannot exist in two or more VLANs that belong to the same VLAN translation domain.
- MVR cannot be configured on translation and member VLANs.
- A VMAN cannot be added to translation and member VLANs.
- A PBB network (BVLAN) cannot be added to translation and member VLANs.

- *EAPS* control VLANs cannot be either translation or member VLANs.
- EAPS can only be configured on translation VLAN ports (and not on member VLAN ports). To support EAPS on the network VLAN, you must add all of the translation and member VLANs to the EAPS ring.
- *STP* can only be configured on translation VLAN ports (and not on member VLAN ports). To support STP on the translation VLAN, you must add the translation VLAN and all of the member VLANs to STP.
- *ESRP* can only be configured on translation VLAN ports (and not on member VLAN ports). To support ESRP on the network VLAN, you must add the translation VLAN and all of the member VLANs to ESRP.
- There is no *NetLogin* support to add ports as translate to the translation VLAN, but the rest of NetLogin and the PVLAN feature do not conflict.
- *IGMP* snooping is performed across the entire VLAN translation domain, spanning all the member VLANs. For VLANs that are not part of a VLAN translation domain, IGMP snooping operates as normal.
- VLAN translation and VPLS are not supported on the same VLAN.
- Member VLANs in a VLAN translation domain cannot exchange multicast data with VLANs outside the VLAN translation domain. However, the translation VLAN can exchange multicast data with VLANs outside the VLAN translation domain and with translation VLANs in other VLAN translation domains.

### Interfaces

Use the following information for selecting and configuring *VLAN* translation interfaces:

- A single physical port can be added to multiple member VLANs, using different VLAN tags.
- Member VLANs and translation VLANs can include both tagged and untagged ports.

## Configuring Translation VLANs

To create a translation *VLAN*, do the following:

1. Create the VLAN that will become the translation VLAN.
2. Add a tag and ports to the prospective translation VLAN.
3. Add member VLANs to the prospective translation VLAN.

A prospective translation VLAN becomes a translation VLAN when the first member VLAN is added to it.

- To add a member VLAN to a translation VLAN, use the following command:  

```
configure {vlan} vlan_name vlan-translation add member-vlan
member_vlan_name {loopback-port port}
```
- To delete a member VLAN from a translation VLAN, use the following command:  

```
configure {vlan} vlan_name vlan-translation delete member-vlan
[member_vlan_name | all]
```
- To view the translation VLAN participation status of a VLAN, use the following command:  

```
show vlan {virtual-router vr-name}
```

## Displaying Translation VLAN Information

This section describes how to display translation [VLAN](#) information.

### Displaying Information for a Translation or Member VLAN

To display information about a translation or member [VLAN](#), use the command:

```
show vlan {virtual-router vr-name}
```

### Displaying Translation VLAN FDB Entries

To view all [FDB](#) entries including those created for a translation [VLAN](#), use the command:

```
show fdb {blackhole {netlogin [all | mac-based-vlans]} | netlogin [all | mac-based-vlans] | permanent {netlogin [all | mac-based-vlans]} | mac_addr {netlogin [all | mac-based-vlans]} | ports port_list {netlogin [all | mac-based-vlans]} | vlan vlan_name | vlan_list {netlogin [all | mac-based-vlans]} | {{vpls} {vpls_name}}}
```

The T flag marks additional FDB entries for translation VLANs.

## VLAN Translation Configuration Examples

The following configuration examples show [VLAN](#) translation used in three scenarios:

- [Basic VLAN Translation](#) on page 2183
- [VLAN Translation with ESRP Redundancy](#) on page 2184
- [VLAN Translation with STP Redundancy](#) on page 2185

### Basic VLAN Translation

The example in [Figure 250](#) configures a basic [VLAN](#) translation network. This network provides VLAN translation between four member VLANs and a single translation VLAN.

**Figure 250: VLAN Translation Configuration Example**

The following configuration commands create the member VLANs:

```
create vlan v101
configure v101 tag 101
configure v101 add ports 1:1 tagged
create vlan v102
configure v102 tag 102
configure v102 add ports 1:1 tagged
create vlan v103
configure v103 tag 103
configure v103 add ports 1:2 tagged
```

```
create vlan v104
configure v104 tag 104
configure v104 add ports 1:2 tagged
```

The following configuration commands create the translation VLAN and enable VLAN translation:

```
create vlan v1000
configure v1000 tag 1000
configure v1000 add ports 2:1 tagged
configure v1000 vlan-translation add member-vlan v101
configure v1000 vlan-translation add member-vlan v102 loopback-port 1:23
configure v1000 vlan-translation add member-vlan v103
configure v1000 vlan-translation add member-vlan v104 loopback-port 1:24
```

### VLAN Translation with ESRP Redundancy

The example in [Figure 251](#) configures a VLAN translation network with ESRP redundancy.

The SW2 and SW3 VLAN translation switches are protected by an ESRP control VLAN. The master ESRP switch performs the translation and provides the connectivity to the backbone. If a failure occurs, the slave ESRP switch takes over and begins performing the translation.

**Figure 251: ESRP Redundancy Configuration Example**

The following configuration commands create the member VLANs on SW1:

```
create vlan v101
configure v101 tag 101
configure v101 add ports 1:1 tagged
configure v101 add ports 1:3 tagged
configure v101 add ports 1:4 tagged
create vlan v102
configure v102 tag 102
configure v102 add ports 1:1 tagged
configure v102 add ports 1:3 tagged
configure v102 add ports 1:4 tagged
create vlan v103
configure v103 tag 103
configure v103 add ports 1:2 tagged
```

```
configure v103 add ports 1:3 tagged
configure v103 add ports 1:4 tagged
create vlan v104
configure v104 tag 104
configure v104 add ports 1:2 tagged
configure v104 add ports 1:3 tagged
configure v104 add ports 1:4 tagged
```

The configuration for SW2 and SW3 is identical for this example.

The following configuration commands create the member VLANs on SW2:

```
create vlan v101
configure v101 tag 101
configure v101 add ports 1:3 tagged
create vlan v102
configure v102 tag 102
configure v102 add ports 1:3 tagged
create vlan v103
configure v103 tag 103
configure v103 add ports 1:3 tagged
create vlan v104
configure v104 tag 104
configure v104 add ports 1:3 tagged
```

This set of configuration commands creates the translation VLANs and enables VLAN translation on SW2:

```
create vlan v1000
configure v1000 tag 1000
configure v1000 add ports 2:1 tagged
configure v1000 vlan-translation add member-vlan v101
configure v1000 vlan-translation add member-vlan v102
configure v1000 vlan-translation add member-vlan v103
configure v1000 vlan-translation add member-vlan v104
```

The final set of configuration commands creates the ESRP control VLAN and enables ESRP protection on the translation VLAN for SW2:

```
create vlan evlan
configure evlan add ports 2:2
enable esrp evlan
configure evlan add domain-member v1000
```

The following configuration commands create the translation VLAN and enable VLAN translation on VLANs that have overlapping ports:

```
configure v1000 vlan-translation add member-vlan v102 loopback-port 1:22
configure v1000 vlan-translation add member-vlan v103 loopback-port 1:23
configure v1000 vlan-translation add member-vlan v104 loopback-port 1:24
```

### *VLAN Translation with STP Redundancy*

The example in [Figure 252](#) configures a [VLAN](#) translation network with redundant paths protected by [STP](#).

Parallel paths exist from the member VLAN portion of the network to the translation switch. STP ensures that the main path for this traffic is active and the secondary path is blocked. If a failure occurs in the main path, the secondary paths are enabled.

**Figure 252: STP Redundancy Configuration Example**

The following configuration commands create the member VLANs and enable STP on SW1:

```
create vlan v101
configure v101 tag 101
configure v101 add ports 1:1 tagged
configure v101 add ports 1:3 tagged
configure v101 add ports 1:4 tagged
create vlan v102
configure v102 tag 102
configure v102 add ports 1:2 tagged
configure v102 add ports 1:3 tagged
configure v102 add ports 1:4 tagged
create vlan v103
configure v103 tag 103
configure v103 add ports 1:3 tagged
configure v103 add ports 1:4 tagged
create vlan v104
configure v104 tag 104
configure v104 add ports 1:3 tagged
configure v104 add ports 1:4 tagged
create stpd stp1
configure stp1 tag 101
configure stp1 add vlan v101
configure stp1 add vlan v102
configure stp1 add vlan v103
configure stp1 add vlan v104
enable stpd stp1
```

These configuration commands create the member VLANs and enable STP on SW2:

```
create vlan v103
configure v103 tag 103
configure v103 add ports 1:1 tagged
configure v103 add ports 1:3 tagged
configure v103 add ports 1:4 tagged
create vlan v104
configure v104 tag 104
configure v104 add ports 1:2 tagged
configure v104 add ports 1:3 tagged
configure v104 add ports 1:4 tagged
create vlan v101
configure v101 tag 101
configure v101 add ports 1:3 tagged
configure v101 add ports 1:4 tagged
create vlan v102
configure v102 tag 102
configure v102 add ports 1:3 tagged
configure v102 add ports 1:4 tagged
create stpd stp1
configure stp1 tag 101
configure stp1 add vlan v101
configure stp1 add vlan v102
configure stp1 add vlan v103
configure stp1 add vlan v104
enable stpd stp1
```

This set of configuration commands creates the member VLANs and enables STP on SW3:

```
create vlan v101
configure v101 tag 101
configure v101 add ports 1:3 tagged
configure v101 add ports 1:4 tagged
create vlan v102
configure v102 tag 102
configure v102 add ports 1:3 tagged
configure v102 add ports 1:4 tagged
create vlan v103
configure v103 tag 103
configure v103 add ports 1:3 tagged
configure v103 add ports 1:4 tagged
create vlan v104
configure v104 tag 104
configure v104 add ports 1:3 tagged
configure v104 add ports 1:4 tagged
create stpd stp1
configure stp1 tag 101
configure stp1 add vlan v101
configure stp1 add vlan v102
configure stp1 add vlan v103
configure stp1 add vlan v104
enable stpd stp1
```

The final set of configuration commands creates the translation VLAN and enables VLAN translation on SW3:

```
create vlan v1000
configure v1000 tag 1000
configure v1000 add ports 2:1 tagged
configure v1000 vlan-translation add member-vlan v101
configure v1000 vlan-translation add member-vlan v102
```

```
configure v1000 vlan-translation add member-vlan v103
configure v1000 vlan-translation add member-vlan v104
```

The following configuration commands create the translation VLAN and enable VLAN translation on VLANs that have overlapping ports:

```
configure v1000 vlan-translation add member-vlan v102 loopback-port 1:22
configure v1000 vlan-translation add member-vlan v103 loopback-port 1:23
configure v1000 vlan-translation add member-vlan v104 loopback-port 1:24
```

## Port-Specific VLAN Tag

The Port-specific [VLAN](#) feature adds a layer of specificity between the port tag and the VLAN/VMAN tag: a port-specific VLAN tag. This feature adds the following functionality to the existing VLAN:

- Ability to associate a tag to a VLAN port. This tag is used as a filter to accept frames with matching VID. It is also used as the tag of the outgoing frames.
- Ability to add multiple VLAN ports on the same physical port as long as those VLAN ports are associated with different tags.
- Allows the existing untagged and tagged VLAN ports to be part of the VLAN.
- Ability to learn MAC address on port, tag and VLAN instead of only on the port. As a consequence of the previous point, ability to add static MAC address to port, tag and VLAN.
- Ability to specify limit-learning and MAC lockdown on a port, tag and VLAN, instead of only on the port.
- Rate limiting and counting of frames with matching VIDs is supported with the existing [ACL \(Access Control List\)](#).

The Port-specific VLAN tag allows tagged VLAN ports to be configured with tag values. When the tag is not configured, it is implicit that the tag of the tagged port is the tag of the VLAN. We call the tag of the port the "port tag", and the tag of the VLAN the "base tag". The port tag is used to determine the eligibility of the frames allowed to be part of the VLAN. Once the frame is admitted to the VLAN port, the base tag is used. From a functional standpoint, the frame tag is rewritten to the base tag.

The base tag then is translated to the port tag for the outgoing frame.

### Note

The port tag is equal to the base tag when the port tag is not specified, so the current VLAN behavior is preserved.

Untagged VLAN ports also have port tag, which is always the same as the base tag. Outgoing frames are untagged. The untagged VLAN port always has an implicit port tag that's always equal to the base tag. There can be only one untagged VLAN port on a physical port. It receives untagged frames, and tagged frames, and transmits only untagged frames.

A tagged VLAN port can have a port tag configured, or not. When not configured, the port tag is equal to the base tag. There can be more than one tagged VLAN port on a

physical port. It receives tagged frames with tag equals to the port tag, and transmits tagged frames with port tag.

When the VLAN is assigned to L2VPN, the base tag is the tag that is carried by the pseudo-wire when the dot1q include is enabled. It can be viewed that VPLS PW port tag is equal to the base tag. To assign a VLAN with a port-specific tag to an L2VPN, use the existing `configure vpls vpls_name add service vlan vlan_name` command.

Since every tagged VLAN port has different VIDs, forwarding between them on the same physical port (hairpin switching) is possible. From the external traffic point of view, the frame tags are rewritten from the receive port tag to the transmit port tag. Since each port tag is a different VLAN port, a frame that has to be broadcasted to multiple VLAN ports is sent out multiple times with different tags when the VLAN ports are on the same physical port. Each port + port tag is an individual VLAN port.

MAC addresses are learned on the VLAN port. This means that the port in the FDB entry is the port + port tag. A unicast frame destined to a MAC address that is in the FDB is sent out of the associated VLAN port. As mentioned earlier, there is only one MAC address learned on the VLAN. If the MAC address is learned on a different port or a different tag, it is a MAC move. It is transmitted out of the physical port only on the associated VLAN port tagged with the port tag when the VLAN port is tagged.

When there are multiple tagged VLAN ports on the transmit port, only one frame with the right tag is transmitted. It is transmitted untagged on an untagged VLAN port. Accordingly, the static MAC address is configured on a VLAN port. This means that the port tag is specified when the tag is not equal to the base tag. The command to flush FDB does not need to change. But, a VLAN port-specific flush needs to be implemented to handle the case when a VLAN port is deleted. This flush is internal and not available through the CLI.

Per VLAN port (port + tag) rate limiting and accounting is achieved by the existing ACL. Use match condition `vlan-id` to match the port VID. You can use action `count` and `byte-count` for accounting. And you can use `show access-list counter` to view the counters. Action meter can be used for rate limiting. To create a meter, use the `create meter` command, and configure the committed rate and maximum burst size.

## Supported Platforms

Port-Specific VLAN Tag is supported on the following platforms:

- ExtremeSwitching X460-G2 (supported from ExtremeXOS 15.6)
- ExtremeSwitching X690

## Port-Specific Tags in L2VPN

You can assign a VLAN with port specific tag to VPLS/VPWS using the `configure vpls vsi add service vlan vl` command. Because this is a single VLAN, the base VID is used when dot1q include is enable. For example, when VLAN 100 that has ports on

Ethernet port 1 with port tag 10 and 11 is assigned to L2VPN, the tag that is carried by the pseudo wire is 100. The configuration for this example is as follows:

```
create vlan exchange tag 100
config vlan exchange add ports 1 tagged 10
config vlan exchange add ports 1 tagged 11
config vpls vsil add service vlan exchange
```

Similarly, the following is an example for VPWS. There can only be a single VLAN port in the VLAN for assignment to VPWS to be successful:

```
create vlan exchange tag 100
config vlan exchange add ports 1 tagged 10
config l2vpn vpws pw1 add service vlan exchange
```

### *VLAN Port State*

VLAN port state is the same as the state of the Ethernet port.

### *ACLs*

You can use the existing match `vlan-id` [ACL](#) to accomplish counting and metering. You can assign the ACL to both ingress and egress port. The followings are the examples of such configuration. The port 3 tag is 4 and the port 4 tag is 5. These ACLs will match the frame vlan-ID, and the vlan-ID specified in the match criteria is independent of the port tag.

```
Content of acl.pol
entry tag_1 {
 if {
 vlan-id 4;
 } then {
 packet-count tag_1_num_frames;
 meter tag_1_meter;
 }
}
entry tag_2 {
 if {
 vlan-id 5;
 } then {
 byte-count tag_2_num_bytes;
 meter tag_2_meter;
 }
}
Content of acl_egress.pol
entry tag_1_egr {
 if {
 vlan-id 4;
 } then {
 packet-count tag_1_egr_num_frames;
 meter tag_1_egr_meter;
 }
}
entry tag_2_egr {
 if {
 vlan-id 5;
 } then {
 byte-count tag_2_egr_num_bytes;
 meter tag_2_egr_meter;
 }
}
```

## Configuring Port-Specific VLAN Tags

The following specific commands are modified by the port-specific `VLAN` tag:

- `clear fdb`: Only clears on physical port or VLAN, not on a vlan port.
- `delete fdb`: All or specific MAC address, or specific MAC address on a VLAN.
- `enable/disable flooding ports`: Only on physical port (applies to all VLAN ports).
- `enable/disable learning`: Only on physical port (applies to all VLAN ports on the same physical port), or on a VLAN (applies to all VLAN ports of the VLAN).
- `show fdb stats`: Only on physical port or VLAN, not on a VLAN port.

Use the following commands to configure Port-specific VLAN tags:

- To configure the port-specific tag, use the `configure ports port_list {tagged tag} vlan vlan_name [limit-learning number {action [blackhole | stop-learning]} | lock-learning | unlimited-learning | unlocklearning]` command.
- To specify the port tag when you need to put multiple vlans into a broadcast domain, use the `configure {vlan} vlan_name addports [port_list | all] {tagged{tag} | untagged} [{stpd} stpd_name] {dot1d | emistp | pvst-plus}}` command.
- To specify a port tag to delete a VLAN port that has a different tag from the VLAN tag, use the `configure {vlan} vlan_name deleteports [all | port_list {tagged tag}]` command.
- To display output of a vlan that has a port-specific tag, use the `show vlan` command.
- To display port info that has port-specific tag statistics, use the `show port info detail` command.
- To adds a permanent, static entry to the `FDB`, use the `create fdb mac_addr vlan vlan_name [ports port_list {tagged tag} | blackhole]` command.
- To show output where the port tag is displayed, use the `show fdb` command.

# VMAN (PBN)

---

[VMAN Overview](#) on page 2192

[VMAN Configuration Options and Features](#) on page 2198

[Configuration](#) on page 2201

[Displaying VMAN Information](#) on page 2204

[Configuration Examples](#) on page 2204

The virtual metropolitan area network (VMAN) feature allows you to scale a Layer 2 network and avoid some of the management and bandwidth overhead required by Layer 3 networks.

## Note

If a failover occurs, VMAN operation is not interrupted. The system has hitless failover—network traffic is not interrupted during a failover.

## VMAN Overview

---

The VMAN feature is defined by the IEEE 802.1ad standard, which is an amendment to the IEEE 802.1Q *VLAN (Virtual LAN)* standard.

A VMAN is a virtual Metropolitan Area Network (MAN) that operates over a physical MAN or Provider Bridged Network (PBN). This feature allows a service provider to create VMAN instances within a MAN or PBN to support individual customers. Each VMAN supports tagged and untagged VLAN traffic for a customer, and this traffic is kept private from other customers that use VMANs on the same PBN.

The PBN uses Provider Bridges (PBs) to create a Layer 2 network that supports VMAN traffic. The VMAN technology is sometimes referred to as VLAN stacking or Q-in-Q.

## Note

*Virtual MAN (VMAN)* is an Extreme Networks term that became familiar to Extreme Networks customers before the 802.1ad standard was complete. The term VMAN is used in the ExtremeXOS software and also in this document to support customers who are familiar with the term. The term PBN is also used in this guide to establish the relationship between this industry standard technology and the Extreme Networks VMAN feature.

[Figure 253](#) shows a VMAN, which spans the switches in a PBN.

**Figure 253: VMAN in PBN**

The entry points to the VMAN are the access ports on the VMAN edge switches. Customer VLAN (CVLAN) traffic that is addressed to locations at other VMAN access ports enters the ingress access port, is switched through the VMAN, and exits the egress access port. If you do not configure any frame manipulation options, the CVLAN frames that exit the VMAN are identical to the frames that entered the VMAN.

VMAN access ports operate in the following roles:

- Customer Network Port (CNP)
- Customer Edge Port (CEP, which is also known as Selective Q-in-Q)

The CEP role, which is configured in software as a `cep vman port`, connects a VMAN to specific CVLANs based on the CVLAN CVID. The CNP role, which is configured as an untagged `vman port`, connects a VMAN to all other port traffic that is not already mapped to the port CEP role. These roles are described later.

All other VMAN ports (except the access ports) operate as VMAN network ports, which are also known as Provider Network Ports (PNPs) in the 802.1ad standard. The VMAN network ports connect the PBs that form the core of the VMAN. During configuration, the VMAN network ports are configured as tagged VMAN ports.

[Figure 254](#) on page 2194 shows one VMAN, but a PBN can support multiple VMAN instances, which are sometimes called VMANs or Service VLANs (SVLANs). VMANs allow you to partition the PBN for customers in the same way that VLANs allow you to partition a Layer 2 network. For example, you can use different VMANs to support different customers on the PBN, and the PBN delivers customer traffic only to the PBN ports that are configured for appropriate VMAN.

A VMAN supports two tags in each Ethernet frame, instead of the single tag supported by a VLAN Ethernet frame. The inner tag is referred to as the customer tag (C-tag), and this optional tag is based on the CVLAN tag if the source VLAN is a tagged VLAN. The outer tag is referred to as the service tag (S-tag) or VMAN tag or SVLAN tag, and it is the tag that defines to which SVLAN a frame belongs. [Figure 254](#) on page 2194 shows the frame manipulation that occurs at the VMAN edge switch.

**Figure 254: Tag Usage at the VMAN Access Switch**

In this example, the switch accepts CVLAN frames on VMAN access ports 1:1 and 1:2. The switch then adds the S-tag to the frames and switches the frames to network ports 2:1 and 2:2. When the 802.1ad frames reach the PB egress port, the egress switch removes the S-tag, and the CVLAN traffic exits the egress access port in its original form.

When the switch in the figure above acts as the egress switch for a VMAN, VMAN frames arrive on network ports 2:1 and 2:2. The switch accepts only those frames with the correct S-tag, removes the S-tags, and switches those frames to access ports 1:1 and 1:2. Unless special configuration options are applied, the egress frames are identical to ingress CVLAN frames. (Configuration options are described in [VMAN Configuration Options and Features](#) on page 2198.)

[Figure 255](#) shows that the S-tags and C-tags used in VMAN frames contain more than just customer and service VLAN IDs.

**Figure 255: S-tag and C-tag Components**

Each S-tag and C-tag contains an ethernet type, a Class of Service (CoS), and a SVLAN ID (SVID) or CVLAN ID (CVID). The ethernet type is described in [Secondary Ethernet Support](#) on page 2199, and the CoS is described in [QoS Support](#) on page 2200.

The SVID is the VLAN tag you assign to a VMAN when you create it (see the [configure vman vman\\_name tag tag](#) command). The CVID represents the CVLAN tag for tagged VLAN traffic.

Switch ports support VMAN roles and features, which are described in the following sections:

- [Customer Network Ports](#)
- [Customer Edge Ports](#)
- [CVID Translation](#)
- [CVID Egress Filtering](#)

## Customer Network Ports

Customer Network Ports (CNPs) are edge switch ports that accept all tagged and untagged CVLAN traffic and route it over a single VMAN. A CNP is simpler to configure than a CEP, because it supports one VMAN on a physical port and requires no configuration of CVIDs. The VMAN service provider does not need to know anything about the CVLAN traffic in the VMAN. The service provider simply manages the VMAN, and the ingress CVLAN traffic is managed by the customer or another service provider. This separation of CVLAN and VMAN management reduces the dependence of the separate management teams on each other, and allows both management teams to make changes independent of the other.

### Note

The CNP term is defined in the IEEE 802.1ad standard and is also called a port-based service interface. The CNP operation is similar to a MEF 13 UNI Type 1.2, and in releases before ExtremeXOS 12.6, CNPs were known as VMAN access ports or untagged vman ports. With the addition of CEPs, the term VMAN access port is now a generic term that refers to CNPs and CEPs.

A PBN can support up to 4094 VMANs, and each VMAN can support up to 4094 CVLANs. Because each CNP connects to only one VMAN, the maximum number of customer VMANs on an edge switch is equal to the total number of switch ports minus one, because at least one port is required to serve as the PNP (Provider Network Port).

## Customer Edge Ports

Each *CEP (Customer Edge Port)* supports the configuration of connections or mappings between individual CVLANs and multiple VMANs.

This provides the following benefits:

- Each physical port supports multiple customers (each connecting to a separate VMAN).
- Each switch supports many more customer VMANs using CEPs instead of CNPs.

To define the connections between CVLANs and SVLANs, each CEP uses a dedicated CVID map, which defines the supported CVIDs on the CEP and the destination VMAN for each CVID. For example, you can configure a CEP to forward traffic from five specific

CVLANs to VMAN A and from ten other specific CVLANs to VMAN B. During VMAN configuration, certain ports are added to the VMAN as CEPs, and certain CVIDs on those ports are mapped to the VMAN. To enable customer use of a VMAN, service providers must communicate the enabled CVIDs to their customers. The customers must use those CVIDs to access the VMAN.

**Note**

The CEP term is defined in the IEEE 802.1ad standard and is also called a *C-tagged service interface*. The CEP operation is similar to a MEF 13 UNI Type 1.1.

### *Assigning Port CVID on Port-based or CEP VMAN Service*

As of ExtremeXOS 21.1, an optional port CVID parameter has been added to the existing untagged and CEP VMAN port configuration options. When present, any untagged packet received on the port is double tagged with the configured port CVID and the SVID associated with the VMAN. If the port is untagged, packets received with a single CID still have the SVID added. If the port is CEP, only untagged and any specifically configured CVIDs are allowed. As double tagged ports are received from tagged VMAN ports and forwarded to untagged VMAN ports, the SVID associated with the VMAN is stripped. Additionally, the CVID associated with the configured port CVID is also stripped in the same operation. If the port is CEP and CEP egress filtering is enabled, only the specified port CVID and CVIDs are allowed to egress.

Much like the CVIDs configured as part of the CEP feature, the configured port CVID is not represented by a VLAN within ExtremeXOS. The implication is that protocols and individual services cannot be applied to the Port CVID alone. Protocols and services are instead applied to the VMAN and/or port as the VMAN represents the true layer-2 broadcast domain. Much like regular untagged and CEP VMAN ports, MAC FDB (forwarding database) learned occurs on the VMAN so duplicate MAC addresses received on multiple CVIDs which are mapped to the same VMAN can be problematic.

Even when the additional Port CVID is configured, the port still has all of the attributes of a regular untagged VMAN port. This means that any single c-tagged packets received on the same port will have just the SVID associated with the VMAN added to the packet. Likewise, any egress packet with a CVID other than the configured Port CVID will have just the SVID stripped. This is not true when the Port CVID specification is part of the CEP configuration, added in ExtremeXOS 16.2.1.

### *Coexistence with Tagged VLANs Interfaces, CEP VMAN Interfaces, and Tagged VMAN Interfaces*

Since the port-cvid configuration still has the attributes of a regular untagged VMAN, all of the VLAN and VMAN exclusion and compatibility rules of a regular untagged VMAN port also apply. A list of these rules is contained in “EXOS Selective Q-in-Q”. In ExtremeXOS 21.1, when port-cvid is specified as part of CEP, there can only be one such port-cvid on the port. Any adjacent CEP CVIDs will not be included in the same CVID range.

### *Protocol and Feature Interactions*

This feature leverages existing untagged and CEP VMAN port infrastructure, therefore any protocol that works with a regular untagged and CEP VMAN port will also work when the optional Port CVID is additionally configured.

Protocols that locally originate control packets, such as *STP (Spanning Tree Protocol)* and ELRP which are used for loop prevention, will transmit packets as natively untagged on the wire when the port is an untagged VMAN member. These untagged packets will also be able to be received and processed by ExtremeXOS. This makes STP edge safeguard + BPDU guard or ELRP effective ways to detect and react to network loops on the device. However, since control packets are transmitted as untagged upstream devices may need additional configuration support to properly detect remote loops not directly attached to the device.

Other effective loop prevention mechanisms work without any interaction with untagged VMAN ports. For example, turning physical port auto-polarity off will prevent an accidental looped cable from becoming active. Likewise, storm-control rate limiting of broadcast and flood traffic can be applied in this environment to minimize the effects of a network loop. In addition to detecting, preventing, and minimizing the effects of a network loop, user *ACL (Access Control Lists)* can be applied to gain visibility and control of L2, L3, and L4 match criteria even with double tagged packets. All applicable ACL action modifiers are available in this environment. IP multicast pruning within a VMAN can be accomplished via normal *IGMP (Internet Group Management Protocol)* snooping. ExtremeXOS supports full IGMP snooping and IP multicast pruning of single tagged and double tagged packets. However, when an IP address is configured on the VMAN, the IGMP protocol engine will transmit single tagged packets on tagged VMAN ports or untagged packets on untagged VMAN ports so upstream switch configuration and support may be necessary to properly propagate group memberships across the network.

CVID Translation

To support CVLANs that are identified by different CVIDs on different CEPs, some switches support a feature called CVID translation, which translates the CVID received at the VMAN ingress to a different CVID for egress from the VMAN (see [Figure 256](#)).

Figure 256: CVID Translation

You can use a CLI command to configure CVID translation for a single CVID or for a range of CVIDs, and you can enter multiple commands to define multiple CVIDs and

ranges for translation. The commands can be applied to a single port or a list of ports, and after configuration, the configuration applied to a port is retained by that port.

#### Note

CVID translation is available only on the platforms listed for this feature in the [Switch Engine v33.3.1 Licensing Guide](#) document.

CVID translation can reduce the number of CVIDs that can be mapped to VMANs.

## CVID Egress Filtering

CVID egress filtering permits the egress from VMAN to CEP of only those frames that contain a CVID that has been mapped to the source VMAN; all other frames are blocked. For example, Customer Edge Port A in [Figure 257](#) is configured to support CVIDs 10-29, and Customer Edge Port B is configured to support CVIDs 10-19. If CVID egress filtering is enabled on Customer Edge Port B, frames with CVIDs 20-29 will not be forwarded at the egress of Customer Edge Port B.

**Figure 257: CVID Egress Filtering**

You can enable CVID egress filtering for a single CEP or for all CEPs with a CLI command. You can also repeat the command to enable this feature on multiple CEPs.

#### Note

CVID egress filtering is available only on the platforms listed for this feature in the [Switch Engine v33.3.1 Licensing Guide](#) document.

When this feature is enabled, it reduces the maximum number of CVIDs that can be mapped to VMANs. The control of CVID egress filtering applies to fast-path forwarding. When frames are forwarded through software, CVID egress filtering is always enabled.

## VMAN Configuration Options and Features

As of ExtremeXOS 16.1, you can now refer to a VMAN by VID as an alternative. Specifying lists of VIDs is a useful shortcut to all users that can reduce the number of commands required to configure the switch.

#### Note

Commands enhanced with VID list support operate in a “best effort” fashion. If one of the VIDs in a VID list do not exist the command is still executed for all of the VIDs in the list that do exist. No error or warning is displayed for the invalid VIDs unless all of the specified VIDs are invalid.

## ACL Support

The ExtremeXOS software includes VMAN (PBN) [ACL](#) support for controlling VMAN frames.

VMAN ACLs define a set of match conditions and modifiers that can be applied to VMAN frames. These conditions allow specific traffic flows to be identified, and the modifiers allow a translation to be performed on the frames.

## Secondary Ethertype Support

The C-tag and S-tag components that are added to all VMAN (PBN) frames include C-ethertype and S-ethertype components that specify an ethertype value for the customer [VLAN](#) and VMAN, respectively.

### Note

This feature is supported only on the platforms listed for this feature in the license tables in the [Switch Engine v33.3.1 Licensing Guide](#) document.

The C-tag and S-tag components that are added to all VMAN (PBN) frames include C-ethertype and S-ethertype components that specify an ethertype value for the customer VLAN and VMAN, respectively. The I-tag used in PBBN frames also includes an ethertype value. When a VLAN or VMAN frame passes between two switches, the ethertype is checked for a match. If the ethertype does not match that of the receiving switch, the frame is discarded.

The default ethertype values are:

- VLAN port (802.1q frames): 0x8100
- Primary VMAN port (802.1ad frames): 0x88A8
- Secondary VMAN port (802.1ad frames): Not configured

The secondary ethertype support feature applies only to VMANs. The ethertype value for VLAN frames is standard and cannot be changed.

If your VMAN transits a third-party device (in other words, a device other than an Extreme Networks device), you must configure the ethertype value on the Extreme Networks device port to match the ethertype value on the third-party device to which it connects.

The secondary ethertype support feature allows you to define two ethertype values for VMAN frames and select either of the two values for each port.

For example, you can configure ports that connect to other Extreme Networks devices to use the default primary ethertype value, and you can configure ports that connect to other equipment to use the secondary ethertype value, which you can configure to match the requirements of that equipment.

When you create a VMAN, each VMAN port is automatically assigned the primary ethertype value. After you define a secondary ethertype value, you can configure a port to use the secondary ethertype value. If two switch ports in the same VMAN use different ethertype values, the switch substitutes the correct value at each port. For

example, for VMAN edge switches and transit switches, the switch translates an ingress ethertype value to the network port ethertype value before forwarding. For egress traffic at VMAN edge switches, no translation is required because the switch removes the S-tag before switching packets to the egress port.

You can set the primary and secondary ethertypes to any value, provided that the two values are different.

## QoS Support

The VMAN (PBN) feature interoperates with many of the [QoS \(Quality of Service\)](#) and HQoS features supported in the ExtremeXOS software.

One of those features is egress queue selection, which is described in the next section. For more information on other QoS and HQoS features that work with VMANs, see [Quality of Service](#) on page 1414.

## Egress Queue Selection

This feature examines the 802.1p value or Diffserv code point in a VMAN (PBN) S-tag and uses that value to direct the packet to the appropriate queue on the egress port.

### Note

This feature is supported only on the platforms listed for this feature in the license tables in the [Switch Engine v33.3.1 Licensing Guide](#) document.

On some systems you can configure this feature to examine the values in the C-tag or the S-tag. For more information, see the list in the [Switch Engine v33.3.1 Licensing Guide](#) document.. For instructions on configuring this feature, see [Selecting the Tag used for Egress Queue Selection](#) on page 2204.

## VMAN Double Tag Support

The VMAN double tag feature adds an optional port CVID parameter to the existing untagged VMAN port configuration. When present, any untagged packet received on the port will be double tagged with the configured port CVID and SVID associated with the VMAN. Packets received with a single CVID on the same port will still have the SVID added. As double tagged packets are received from tagged VMAN ports and forwarded to untagged VMAN ports, the SVID associated with the VMAN is stripped. Additionally, the CVID associated with the configured Port CVID is also stripped in the same operation.

Much like the CVIDs configured as part of the CEP feature, the configured Port CVID is not represented by a [VLAN](#) within ExtremeXOS. The implication is that protocols and individual services cannot be applied to the Port CVID alone. Protocols and services are instead applied to the VMAN and/or port as the VMAN represents the true layer-2 broadcast domain. Much like regular untagged VMAN ports, MAC [FDB](#) learning occurs on the VMAN, so duplicate MAC addresses received on multiple CVIDs that are mapped to the same VMAN can be problematic. Even when the additional Port CVID is configured, the port still has all of the attributes of a regular untagged VMAN port. This

means that any single c-tagged packets received on the same port will have just the SVID associated with the VMAN added to the packet. Likewise, any egress packet with a CVID other than the configured Port CVID will have the SVID stripped.

See [Coexistence with Tagged VLANs Interfaces, CEP VMAN Interfaces, and Tagged VMAN Interfaces](#) on page 2196.

See [Protocol and Feature Interactions](#) on page 2196.

## Configuration

### Configuring VMANs (PBNs)

#### *Guidelines for Configuring VMANs*

The following are VMAN configuration guidelines for all platforms:

- Duplicate customer MAC addresses that ingress from multiple VMAN access ports on the same VMAN can disrupt the port learning association process in the switch.
- VMAN names must conform to the guidelines described in [Object Names](#) on page 32.
- You must use mutually exclusive names for:
  - [VLANs](#)
  - VMANs
  - IPv6 tunnels
- VMAN ports can belong to load-sharing groups.
- You can enable or disable jumbo frames before configuring VMANs. You can enable or disable jumbo frames on individual ports. See [Configuring Ports on a Switch](#) on page 216 for more information on configuring jumbo frames.
- [STP](#) operation on CVLAN components in a PEB as described in IEEE 802.1ad is not supported.
- The initial version of this feature does not implement an XML API.
- Multiple VMAN roles can be combined on one port with certain VLAN types as shown in [Table 176](#).

**Table 176: Port Support for Combined VMAN Roles and VLANs**

| Platform                                 | Combined CNP, CEP, and Tagged VLAN <sup>a,b</sup> | Combined PNP, CNP, and CEP <sup>a,b,c</sup> | Combined PNP and Tagged VLAN | Combined PNP and Untagged VLAN |
|------------------------------------------|---------------------------------------------------|---------------------------------------------|------------------------------|--------------------------------|
| All ExtremeSwitching Universal platforms | X                                                 | X                                           | X <sup>d</sup>               | X                              |

**Note**

If you already configured VLANs and VMANs on the same stand-alone switch using ExtremeXOS 11.4 or later, you cannot change the VMAN ethertype from 0X8100 without first removing either the VLAN or VMAN configuration.

*Procedure for Configuring VMANs*

This section describes the procedure for configuring VMANs. Before configuring VMANs, review [Guidelines for Configuring VMANs](#) on page 2201. To configure a VMAN, complete the following procedure at each switch that needs to support the VMAN:

1. If you are configuring a SummitStack, or an ExtremeSwitching series switch, enable jumbo frames on the switch.

**Note**

You must enable jumbo frames before configuring VMANs on these systems.

2. Create a VMAN using the command:

```
create vman vman_name | vman_list vr vr_name
```

3. Assign a tag value to the VMAN using the command:

```
configure vman vman_name | vman_list tag tag_id
```

4. To configure PNP ports on a PEB or PB, use the following command with the tagged option:

```
configure vman vman_name | vman_id add ports [all | port_list]
{untagged | tagged}
```

5. To configure CNP ports on a PEB, use the following command with the untagged option:

```
configure vman vman_name add ports [all | port_list] {untagged |
tagged}
```

**Note**

You must configure CNP ports as untagged, so that the S-tag is stripped from the frame on egress. If the port-cvid is configured, any untagged packet received on the port will be double tagged with the configured port CVID and the SVID associated with the VMAN. Packets received with a single CVID on the same port will still have the SVID added as usual. As double tagged packets are received from tagged VMAN ports and forwarded to untagged VMAN ports, the SVID associated with the VMAN is stripped. Additionally, the CVID associated with the configured port CVID is also stripped in the same operation.

<sup>a</sup> Subsets of this group are also supported. That is, any two of these items are supported.

<sup>b</sup> When a CNP is combined with a CEP or tagged VLAN, any CVIDs not explicitly configured for a CEP or tagged VLAN are associated with the CNP.

<sup>c</sup> A PNP (tagged VMAN) and a CNP (untagged VMAN) or CEP cannot be combined on a port for which the selected VMAN ethertype is 0x8100.

<sup>d</sup> If the secondary VMAN ethertype is selected for the port, it must be set to 0x8100.

6. To configure CEP ports on a PEB, do the following:
  - a. Use the following command to establish a physical port as a CEP and configure CVID mapping and translation:
 

```
configure vman vman_name | vman_id add ports port_list cep [cvid
<cvid or cvid_range> { translate <cvid or cvid_range> } } | port-
cvid <port_cvid>] }
```
  - b. Use the following commands to add or delete CVIDs for a CEP and manage CVID mapping and translation:
 

```
configure vman vman_name | vman_id ports port_list add cvid {cvid |
cvid_range} {translate cvid | cvid_range }
configure vman vman_name ports port_list delete cvid {cvid |
cvid_range }
```
  - c. Use the following commands to manage CVID egress filtering for a CEP:
 

```
enable vman cep egress filtering ports {port_list | all}
disable vman cep egress filtering ports {port_list | all}
```
7. Configure additional VMAN options as described in [Configuring VMAN Options](#) on page 2203.
8. To configure a VLAN to use a VMAN, configure the VLAN on the switch port at the other end of the line leading to the VMAN access port.

## Configuring VMAN Options

### Configuring the Ethertype for VMAN Ports

The ethertype is a component of VLAN and VMAN frames. It is introduced in [Secondary Ethertype Support](#) on page 2199.

#### Note

This feature is supported only on the platforms listed for this feature in the license tables in the [Switch Engine v33.3.1 Licensing Guide](#) document.

To configure the ethertype for VMAN (PBN) ports, do the following:

1. Configure the primary and secondary (if needed) VMAN ethertype values for the switch using the following command:
 

```
configure vman ethertype hex_value [primary | secondary]
```

By default, all VMAN ports use the primary ethertype value.
2. If you plan to use a secondary ethertype, select the secondary ethertype for the appropriate VMAN ports using the following command:
 

```
configure port port_list ethertype {primary | secondary}
```

### Selecting the Tag used for Egress Queue Selection

By default, switches that support the enabling and disabling of this feature use the 802.1p value in the S-tag to direct the packet to the queue on the egress port.

#### Note

This feature is supported and configurable only on the platforms listed for this feature in the license tables in the [Switch Engine v33.3.1 Licensing Guide](#) document.

- Configure egress queue dot1p examination of the C-tag using:  
`enable dot1p examination inner-tag port [all | port_list]`
- Return to the default selection of using the 802.1p value in the S-tag using:  
`disable dot1p examination inner-tag ports [all | port_list]`

#### Note

See [Quality of Service](#) on page 1414 for information on configuring and displaying the current 802.1p and DiffServ configuration for the S-tag 802.1p value. To enable dot1p examination for inner-tag, dot1p examination for outer-tag must be disabled using the command `disable dot1p examination ports [all | port_list]`

## Displaying VMAN Information

Use the following commands to display information on one or all VMANs.

```
show {vman} vman_name {ipv4 | ipv6}
```

```
show vman [tag tag_id | detail] {ipv4 | ipv6}
```

```
show {vman} vman_name eaps
```

#### Note

The display for the `show vman` command is different depending on the platform and configuration you are using. See the [Switch Engine v33.3.1 Command References](#) for complete information on this command.

You can also display VMAN information, as well as all the VLANs, by issuing the `show ports information detail` command. And you can display the VMAN ethernet type and secondary etherType port\_list by using the `show vman etherType` command

## Configuration Examples

### VMAN CEP Example

The following configuration configures a VMAN CEP to support up to 10 customer VLANs for each of three VMANs.

```
create vman cust1
```

```

create vman cust2
create vman cust3
config vman cust1 tag 1000
config vman cust2 tag 1001
config vman cust3 tag 1002
config vman cust1 add port 22 tag
config vman cust2 add port 22 tag
config vman cust3 add port 23 tag
config vman cust1 add port 1 cep cvid 100 - 109
config vman cust2 add port 1 cep cvid 110 - 119
config vman cust3 add port 1 cep cvid 120 - 129
enable vman cep egress filtering ports 1

```

Port 1 serves as the CEP, and egress filtering is enabled on the port. Ports 22 and 23 serve as CNPs, providing the connection between the CEP port and the rest of each VMAN.

## Multiple VMAN Ethertype Example

Figure 258 shows a switch that is configured to support the primary ethertype on three ports and the secondary ethertype on a fourth port.

The primary VMAN (PBN) ethertype is changed from the default value, but that is not required.

**Figure 258: Multiple VMAN Ethertype Example**

The following configuration commands accomplish what is shown above:

```

configure vman ethertype 0x9100 primary
configure vman ethertype 0x8100 secondary
#
configure port 2:2 ethertype secondary
#
create vman vman300
configure vman vman300 tag 300

```

```

configure vman vman300 add port 1:1, 2:1, 2:2 tagged
configure vman vman300 add port 1:2 untagged
```

- [Managing VRRP](#) on page 2232
- [Displaying VRRP Information](#) on page 2232
- [VRRP Configuration Examples](#) on page 2233

This chapter assumes that you are already familiar with the Virtual Router Redundancy Protocol (VRRP). If not, refer to the following publications for additional information:

- RFC 2338—Virtual Router Redundancy Protocol (VRRP)
- RFC 2787—Definitions of Managed Objects for the Virtual Router Redundancy Protocol
- RFC 3768—Virtual Router Redundancy Protocol (VRRP) Version 2 for IPv4  
[www.ietf.org/rfc/rfc3768.txt](http://www.ietf.org/rfc/rfc3768.txt)
- RFC 5798—Virtual Router Redundancy Protocol (VRRP) Version 3 for IPv4 and IPv6  
<http://tools.ietf.org/html/rfc5798>
- Draft IETF VRRP Specification v2.06 <http://tools.ietf.org/html/draft-ietf-vrrp-spec-v2-06>

## VRRP Overview

---

*VRRP (Virtual Router Redundancy Protocol)*, like the *ESRP (Extreme Standby Router Protocol)*, allows multiple switches to provide redundant routing services to users.

VRRP is used to eliminate the single point of failure associated with manually configuring a default gateway address on each host in a network. Without using VRRP, if the configured default gateway fails, you must reconfigure each host on the network to use a different router as the default gateway. VRRP provides a redundant path for the hosts. Using VRRP, if the default gateway fails, the backup router assumes forwarding responsibilities. An example VRRP topology is shown in [Figure 259](#).

**Figure 259: Simple VRRP Network**

Switches A and B are both configured with the same VRRP router ID on the same [VLAN \(Virtual LAN\)](#), which establishes a VRRP relationship between the two routers. Because a single switch can support multiple VRRP relationships, each relationship is referred to as a *VRRP router instance*. Within a VRRP router instance, any VRRP router can become the master, but only one VRRP router can be master at a time. The master processes all client communications, and the other VRRP routers in the VRRP routing instance stand by, ready to take over if the master is no longer available.

Each switch in a VRRP topology has its own unique IP and MAC addresses, which are required for basic IP connectivity. For each VRRP router instance, there are shared VRRP IP and MAC addresses, which are used for network client communications. The VRRP router IP address is configured on all VRRP routers in a VRRP routing instance, and it is configured as the default gateway address on network clients. If the master VRRP router becomes unavailable, the backup VRRP router takes over using the same VRRP router IP address.

If the VRRP router IP address matches the actual VLAN IP address of the IP address owner has the highest priority value (255) and will always become the master when VRRP is enabled and operating correctly. If the switch or the VRRP process on the switch stops responding, a backup switch (Switch B in [Figure 260](#)) takes over the master role and serves as the default gateway for network clients.

VRRP supports multiple backup routers. If the master VRRP router stops working, one of the backup routers takes over as described in [ESRP Master Election](#) on page 603.

VRRP also supports multiple VRRP router instances, which can be used to enable load sharing. The following figure shows a VRRP load-sharing configuration.

**Figure 260: VRRP Load-sharing Configuration**

Switches A and B in the above figure are each configured with two VRRP router instances. Switch A is the IP address owner and default master for VRRP instance 1, and Switch B is the IP address owner and default master for VRRP instance 2. Half the network clients are configured to use VRRP instance 1 as the primary gateway and VRRP instance 2 as the backup gateway. The other half of the network clients are configured to use VRRP instance 2 as the primary gateway and VRRP instance 1 as the backup gateway. When both switches are operating with VRRP, each switch supports half the clients in a load-sharing topology. If either switch fails, or if VRRP is disabled on a switch, the remaining switch supports all network clients.

**Note**

We recommend that you do not enable VRRP on aggregated VLANs, which are also known as super VLANs.

## VRRP Guidelines

The following guidelines apply to using VRRP.

- VRRP packets are encapsulated IP packets.
- The VRRP IPv4 multicast address is 224.0.0.18.
- The VRRP IPv6 multicast address is ff02::12.
- The maximum number of supported VRIDs per interface is 255 for V3-v2 version mode, and 255 for v2 or v# version mode.
- An interconnect link between VRRP routers should not be used, except when VRRP routers have hosts directly attached.
- VRRP instance scale is dependent on platform and license. Please refer to the ExtremeXOS release notes for details.
- Up to 255 unique VRIDs can be configured on the router.
- VRRP and other L2 redundancy protocols can be simultaneously enabled on the same switch.

- When VRRP and BOOTP/*DHCP (Dynamic Host Configuration Protocol)* relay are both enabled on the switch, the relayed BOOTP agent IP address is the actual switch IP address, not the virtual IP address.
- We do not recommend simultaneously enabling VRRP and *ESRP* on the same switch.
- VRRP and ESRP cannot be configured on the same *VLAN* or port. This configuration is not allowed.
- RFC 5798 describes a situation where a master VRRP router takes on a duplicate IP address due to interaction with the duplicate address detection (DAD) feature. To prevent such duplicate addresses, the DAD feature is disabled whenever a VRRP router is configured for IPv6 or IPv4.
- A VRRP router instance can be configured with multiple IP addresses on the same subnet or on different subnets, provided that all virtual IP addresses match the subnet address of a VLAN on the switch. For example, if a host switch has VLAN IP addresses in the 1.1.1.x and 2.2.2.x subnets, then that VRRP router instance can contain virtual IP addresses in both those subnets as well.
- If a VRRP router instance is assigned priority 255, then the host router must own all the IP addresses assigned to the VRRP router instance. That is, each virtual IP address must match an IP address configured for a VLAN on the router.
- When a VRRPv2 instance spans routers using ExtremeXOS version 12.6 and earlier and routers using ExtremeXOS version 12.7 and later, routers using ExtremeXOS version 12.6 and earlier log packet-size warning messages.
- VRRP scaling numbers differs based on the license and hardware used; please refer the release notes for individual scaling limits.

**Note**

A maximum of 511 VRRP instances are allowed without One-To-Many Mirroring. If using OTM Mirroring, only 507 VRRP instances are allowed. You can increase VRRP scaling limit by using VRRP grouping (see [VRRP Grouping to Increase VR Scaling](#) on page 2223).

**Note**

The behavior of ExtremeXOS 30.1 has changed if locally configured IP addresses are used to determine network reachability. For details, see the `ping` command.

## VRRP Master Election

When a *VRRP* configured network starts, VRRP uses an election algorithm to dynamically assign master responsibility to one of the VRRP routers on the network.

The VRRP master is determined by the following factors:

- VRRP priority—Possible values are 0 through 255. Value 255 is reserved for the VRRP router IP address owner, and value 0 is reserved for the master router, to indicate it is releasing master responsibility. Values 1–254 can be configured on backup routers to influence which backup router becomes the master when the master VRRP router

is no longer available. The higher number has higher priority. The default value for backup routers is 100.

- Higher IP address—If multiple backup routers have the same configured priority, the router with the highest IP address becomes the master.

If the master router becomes unavailable, the election process begins and the backup router that wins the election assumes the role of master.

**Note**

In VRRP IPv6, master election happens based on the interface link local address when the priorities are the same. The highest link local address switch is selected as the VRRP master.

A new master is elected when one of the following things happen:

- VRRP is disabled on the master router.
- Loss of communication occurs between master and backup router(s).

If VRRP is disabled on the master interface, the master router sends an advertisement with the priority set to 0 to all backup routers. This signals the backup routers that they do not need to wait for the master down interval to expire, and the master election process can begin immediately.

The master down interval is set using the following formula: 3 x advertisement interval + skew time.

The advertisement interval is a user-configurable option, and the skew time is  $(256 - \text{priority}) / 256$ .

**Note**

The formula for VRRPv2;  $((256 - \text{priority}) / 256)$ . The VRRPv3 Skew time calculation will be different. Please refer to RFC 5798 (<http://tools.ietf.org/html/rfc5798>), Skew time.  $((256 - \text{priority}) \times \text{Master\_Adver\_Interval}) / 256$

**Note**

An extremely busy CPU can create a short dual master situation. To avoid this, increase the advertisement interval.

## VRRP Master Preemption

VRRP master preemption is a feature that allows a VRRP backup router with a higher VRRP priority to take control from a lower priority backup that is acting as the master.

VRRP election occurs as described in [ESRP Master Election](#) on page 603. VRRP preemption occurs when a VRRP backup router is added to the network or recovers,

and that backup router has a higher priority than the current backup VRRP that is operating as the master.

**Note**

The VRRP router IP address owner always preempts, independent of the VRRP preemption setting.

When a VRRP backup router preempts the master, it does so in one of the following ways:

- If the preempt delay timer is configured for between 1 and 3600 seconds and the lower-priority master is still operating, the router preempts the master when the timer expires.
- If the preempt delay timer is configured for 0, the router preempts the master after three times length of the hello interval.
- If the higher priority router stops receiving advertisements from the current master for three times the length of the hello interval, it takes over mastership immediately.

The preempt delay timer provides time for a recovering router to complete start up before preempting a lower-priority router. If the preempt delay timer is configured too low, traffic is lost between the time the preempting router takes control and the time when it has completed startup.

## VRRP Tracking

Tracking information is used to track various forms of connectivity from the VRRP router to the outside world.

### *VRRP Tracking Mode*

When a VRRP tracked entity fails, the VRRP router behavior is controlled by the tracking mode. The mode can be all, or any. The default mode is all.

When the mode is all, the master role is relinquished when one of the following events occur:

- All of the tracked VLANs fail.
- All of the tracked routes fail.
- All of the tracked pings fail.

**Note**

Mastership is relinquished and the switch goes to INIT state.

When the mode is any, the master role is relinquished when any of the tracked VLANs, routes, or pings fail.

### *VRRP VLAN Tracking*

You can configure VRRP to track active VLANs (active ports in a VLAN or Loopback) of up to eight specified VLANs as criteria for failover.

If no active ports remain on the specified VLANs, the router automatically relinquishes master status based on the tracking mode.

When a tracking condition is in a failed state, VRRP behaves as though it is locally disabled; so it is neither master nor backup (which are both active states).

#### *VRRP Route Table Tracking*

You can configure VRRP to track specified routes in the route table as criteria for VRRP failover.

If any of the configured routes are not available within the route table, the router automatically relinquishes master status based on the tracking mode.

#### **Note**

MPLS (Multiprotocol Label Switching) LSPs are not considered to be part of VRRP route tracking.

#### *VRRP Ping Tracking*

You can configure VRRP to track connectivity using a simple ping to any outside responder.

The responder may represent the default route of the router, or any device meaningful to network connectivity of the master VRRP router. If pinging the responder consecutively fails the specified number of times, the router automatically relinquishes master status based on the tracking mode.

## VRRP Address Support for IPv4

For IPv4 traffic, a primary IPv4 address is selected from the set of real interface addresses. VRRP advertisements are always sent using the primary IPv4 address as the source of the IPv4 packet.

The VRRP MAC address for an IPv4 VRRP router instance is an IEEE 802 MAC address in the following hexadecimal format (in Internet-standard bit-order):

```
00-00-5E-00-01-<vrid>
```

The first three octets are derived from the IANA Organizational Unique Identifier (OUI). The next two octets (00-01) indicate the address block assigned to the VRRP router for the IPv4 protocol, and VRID is the VRRP instance identifier. This mapping provides for up to 255 IPv4 VRRP routers on a network.

When a VRRP router instance becomes active, the master router issues a gratuitous ARP response that contains the VRRP router MAC address for each VRRP router IP address.

The master also always responds to ARP requests for VRRP router IP addresses with an ARP response containing the VRRP MAC address. Hosts on the network use the VRRP router MAC address when they send traffic to the default gateway.

## VRRP Address Support for IPv6

IPv6 VRRP router advertisements are always sent using the VRRP virtual link-local address as the source address.

Hosts on the LAN can use this link-local address as their default route gateway. If no VRRP link-local address is configured, a default value is derived as follows:

```
FE80::5E00:02{VRID}
```

VRID is the VRRP instance identifier.

### Note

The host portion of this address corresponds to the virtual MAC address associated with the VRRP router.

When a backup VRRP router assumes the role of master, it must use the same link-local address in router advertisements as the previous master. Therefore, when configuring a backup VRRP router, you must either configure a virtual link local address that matches the link local address on the IP address owner or allow the virtual link local address to default to the derived value in the same manner as on the master.

Router advertisement prefixes are configured based on the VRRP IP addresses. The mask used for the prefix will be the smallest mask used by all VRRP IP addresses on a VLAN interface. The ExtremeXOS software supports multiple IPv6 addresses on an interface that can overlap. For example, you can add both 200d::1/48 and 200d::2/96 to a VLAN. IPv6 VRRP routers advertise the smallest mask that applies to all VRRP IP addresses. In this example, if VRRP IP address 200d::100 is added, the mask is 48.

The VRRP MAC address for an IPv6 VRRP router instance is an IEEE 802 MAC address in the following hexadecimal format (in Internet-standard bit-order):

```
00-00-5E-00-02-<vrid>
```

The first three octets are derived from the IANA OUI. The next two octets (00-02) indicate the address block assigned to the VRRP router for IPv6 protocol, and VRID is the VRRP instance identifier. This mapping provides for up to 255 IPv6 VRRP routers on a network.

When a VRRP router assumes the role of master, it issues an unsolicited neighbor discovery (ND) neighbor advertisement message for each of the VRRP router IP addresses.

The master also always responds to ND neighbor solicitations with ND neighbor advertisements using the VRRP MAC address.

## NTP VRRP Virtual IP support

This feature allows switches to configure the VRRP virtual IP as an NTP server address. The NTP server, when configured on the VRRP master, listens on the actual IP and virtual IP address for NTP clients.

On the VRRP backup node, only one socket is opened and bound to the physical IP address alone. Once a node transitions to the VRRP master, the ExtremeXOS software re-triggers a listen on the interface to ntpd for it to open a socket and bind to the VRRP VIP.

A flag configuration is added for the IPv4 cases, and these are propagated to [VLAN](#) Manager clients. NTP uses this to trigger a listen on the interface. For the master node to process non-ping packets destined to the VIP, the software already has a configuration command in VRRP (accept-mode on/off).

**Note**

If you want to configure VRRP VIP as the server address on NTP clients, enable accept mode.

*Limitations*

The following limitations exist for NTP VRRP Virtual IP support:

- ExtremeSwitching switches configured as NTP clients need to have the bootrom version: 2.0.1.7
- We do not recommend FHRP Virtual IPs for NTP configuration because they can cause undesirable behavior when the NTP servers are not in sync, or if the delay is asymmetric. Ensure that both servers derive their clock information from the same source.

This problem can be more acute if a node connected to VRRP peers using and VRRP is in active-active mode. In this case, it is possible that every other packet could be sent to a different switch due to [LAG \(Link Aggregation Group\)](#) hashing at the remote node.

## VRRPv3 Interoperation with VRRPv2

RFC 5798 states that VRRPv2 and VRRPv3 interoperation is optional, and that mixing these two versions should only be done when transitioning from VRRPv2 to VRRPv3.

VRRPv2 and VRRPv3 interoperation should not be implemented as a permanent solution.

This release supports configuration for the following modes of operation: VRRPv2, VRRPv3, and VRRPv2 and VRRPv3 interoperation.

## VRRP Fabric Routing

Prior to ExtremeXOS 21.1, [VRRP](#) had one master router which would do L3 routing and one or more backup routers which would do L2 forwarding of packets to the master router. This caused loss of bandwidth in the links that connect the master and backup routers. This issue is present in any topology wherein host traffic is flowing via backup router. In case of multiple backup routers, traffic from hosts attached to some backup routers would have to traverse multiple links to reach the master router. This caused loss of bandwidth in multiple links towards the master.

The VRRP fabric routing feature introduced in ExtremeXOS 21.1 allows the backup router to take part in L3 routing for the packets it receives with DA=VMAC. A backup router enabled with this feature is called a Fabric Routing Enabled Backup (FREB) router. This feature allows load sharing of traffic between VRRP routers and saves the bandwidth of links connecting the master and backup. This bandwidth saved can be used to provide better connectivity between the segments of the network wherein each segment is connected to only one VRRP router directly. This solution is applicable for all topologies such as , *EAPS (Extreme Automatic Protection Switching)*, or *STP (Spanning Tree Protocol)*.

The VRRP FREB router receives and processes VRRP advertisements from the master, but does not generate advertisements. Broadcast ARP requests and multicast neighbor solicitations to resolve the virtual IP are responded to by the master router. The Fabric Routing Enabled Backup router behaves as mentioned in RFC 5798 with the following exceptions:

- The backup router performs forwarding functionality, similar to the master.
- The backup router responds to unicast ARP/Neighbor Solicitation requests it receives.

#### *Configuring VRRP Fabric Routing*

To configure the fabric routing feature, enter the following command:

```
configure vrrp vlan vlan_name vrid vridval fabric-routing [on | off]
```

This configuration can be present on all VRRP routers, regardless of VRRP state of the router. Fabric routing will be enabled only when the VRRP router is in backup state.

#### *Fabric Routing Functionality*

The *VRRP* backup router enabled with fabric routing mode is called a VRRP FREB router (Fabric Routing Enabled Backup router). The VRRP FREB router is responsible for the following:

- Performing routing for the packets destined for subnets other than the received interface's subnet. These packets should also have a destination MAC matching Virtual MAC. These packets will be routed by hardware.
- Forwarding the packets having a Destination IP matching Virtual IP, towards VRRP Master. These packets will have Destination MAC matching Virtual MAC. These packets will be forwarded by hardware.
- Responding for unicast ARP requests with target IP matching Virtual IP.
- Responding for unicast Neighbor Solicitation requests with target IP matching Virtual IP.
- Does not respond to broadcast ARP / multicast Neighbor solicitations targeted for Virtual IP.
- Does not respond for *ICMP (Internet Control Message Protocol)* requests destined for Virtual IP.
- Does not generate gratuitous ARP/ Neighbor Advertisements.
- Does not advertise Router Advertisement Prefixes in this state.

### VRRP Router Accepts Packets Destined to Virtual IP

Only the master serves as protocol servers like NTP, telnet, SSH, etc and accepts connections destined to the virtual IP. By doing so, hosts always connect to the same by using the virtual IP, at any given point of time. This ensures that the host is getting a consistent response from the protocol server. This arrangement allows the host to reach the NTP server using the same IP i.e. virtual IP, even if VRRP mastership moves to a different router. A network monitoring tool is another example, which can use virtual IP to collect data about VRRP domain, by connecting to current VRRP Master. It is not recommended to change the configurations of the switch, when a management session is connected using virtual IP. When VRRP FREB router sits in between the host and VRRP Master router, FREB router does hardware forwarding of these packets from host towards VRRP Master, at Layer 3.

**Figure 261: VRRP Fabric Routing**

#### Note

A caveat is that TTL/hop count is decremented for the packets destined for virtual IP, when forwarded by FREB. This may be a problem to run any protocol that expects TTL not to be decremented, between host and Master.

Hosts can generate unicast ARP to validate a ARP cache entry. Similarly, unicast Neighbor Solicitation is generated to perform Neighbor Unreachability Detection for a neighbor. These requests are periodic. The unicast ARP/NS requests will be responded by FREB, if it receives the request. A downside of allowing VRRP Master to respond

these requests is that it may take considerable CPU cycles when large numbers of hosts are present in VRRP domain.

### Enabling Fabric Routing Mode

A *VRRP* router configured with fabric routing mode will be in backup state. There is some difference in behavior based on enabling sequence which is described below.

When enabling VRRP VR after configuring fabric routing mode, assume that fabric routing mode has already been configured for VRRP VR and VR is administratively enabled now. Initially the VRRP state machine will start from INIT state. It will move to backup state and wait for Master\_Down\_Interval duration to receive an advertisement from current master. Based on VRRP Master election (as described earlier in the sections), VRRP router will either become master or will assume forwarding responsibility while in backup state (i.e., FREB). Waiting in backup state avoids a burst of messages exchanged in software during the transition. This is useful in scaled setups.

#### Note

For the duration it waits in backup state, traffic will be forwarded to the VRRP master where it gets routed. This behavior is same as existing behavior without fabric routing.

When configuring fabric route mode when the VR is already in backup state, if the VR has received advertisements within the last advertisement interval, the router will take forwarding responsibility immediately.

The hold off timer will be applied before FREB starts IP forwarding. In case of reboot or process restart, the VR will wait for 60 seconds before taking forwarding responsibility. This will allow the routing protocols in the restarting system to converge.

To enable fabric routing, use the following command:

```
configure vrrp vlan [vlan_name | vlan_list] [vridval | all] {group
group_name} fabric-routing [on | off]
```

To configure a specific VRRP instance as FREB:

```
configure vrrp vlan v1 vrid 1 fabric-routing on
```

To configure all the VRRP instances as FREB:

```
configure vrrp all fabric-routing on
```

Configured fabric routing can be seen in the show command output of the `show vrrp detail` or `show vrrp vlan vlan` CLI command:

```
sh vrrp detail
VLAN: v1 VRID: 1 VRRP: Disabled State: Backup
Virtual Router: VR-Default
Priority: 100(backup) Advertisement Interval: 1 sec
Version: v2 Preempt: Yes Preempt Delay: 0 sec
Virtual IP Addresses:
Accept mode: Off
```

```

Host-Mobility: Off
Host-Mobility Exclude-Ports:
Tracking mode: ALL
Tracked Pings: -
Tracked IP Routes: -
Tracked VLANs: -
Fabric Routing: On

* indicates a tracking condition has failed

```

### Fabric Routing Limitations

The following are limitation of [VRRP](#) fabric routing:

- VRRP fabric routing is not supported for the configuration of virtual IP address being same as interface IP address (i.e., IP owner case).
- VRRP fabric routing is not supported for PVLAN and VLAN aggregation topologies.

## VRRP and Hitless Failover

### Note

This section applies to SummitStack only.

The primary node executes the switch's management functions, and the backup acts in a standby role. Hitless failover transfers switch management control from the primary to the backup and maintains the state of [VRRP](#). While VRRP supports hitless failover, you do not explicitly configure hitless failover support; rather, if you have two nodes installed, hitless failover is available.

To support hitless failover, the primary node replicates VRRP protocol data units (PDUs) to the backup, which allows the nodes to run VRRP in parallel. Although both nodes receive VRRP PDUs, only the primary transmits VRRP PDUs to neighboring switches and participates in VRRP.

To initiate hitless failover on a network that uses VRRP:

1. Confirm that the primary and backup nodes are synchronized and have identical software and switch configurations using the `show switch {detail}` command. The output displays the status of the nodes, with the primary node showing MASTER and the backup node showing BACKUP (InSync).
  - a. If the primary and backup nodes are not synchronized and both nodes are running a version of ExtremeXOS that supports synchronization, proceed to step 2 in [STP and Hitless Failover—SummitStack Only](#) on page 1740.
  - b. If the primary and backup nodes are synchronized, proceed to step 3 in [STP and Hitless Failover—SummitStack Only](#) on page 1740.
2. If the primary and backup nodes are not synchronized, use the `synchronize` command to replicate all saved images and configurations from the primary to the backup. After you confirm the primary and backup nodes are synchronized, proceed to step 3 in [STP and Hitless Failover—SummitStack Only](#) on page 1740.
3. If the primary and backup nodes are synchronized, use the `run failover` (formerly `run msm-failover`) command to initiate failover.

For more detailed information about verifying the status of the nodes and system redundancy, see [Understanding System Redundancy](#) on page 83. For more information about hitless failover, see [Understanding Hitless Failover Support](#) on page 88.

**Note**

For complete information about software licensing, including how to obtain and upgrade your license and what licenses are appropriate for these features, in the [Switch Engine v33.3.1 Licensing Guide](#) document.

## VRRP Host Mobility

VRRP host mobility solves the asymmetric routing problem associated with VRRP where the path to return to an end host may be different and longer than necessary. This feature uses host routes to indicate where in the network an end host resides. Using other routing protocols such as OSPF (Open Shortest Path First), other routers will then pick the shortest path back to the end host when multiple paths are available via ECMP (Equal Cost Multi Paths) route entries.

### *Asymmetric Routing and VRRP*

The optimum flow path for frames sourced by clients is that they are forwarded by the first encountered router in the path. The optimum flow path for return frames for these flows is through the same router that forwarded the initial frames of the flow. This is referred to as a symmetric routing path. Unfortunately, standard VRRP elects one of a group of routers to forward frames from a client, but the return path may be through any of the routers in the VRRP group. This condition is known as asymmetric routing. In the following figure there are three devices that are routers in a VRRP group servicing the 192.168.1.0/24 network with the VRRP virtual gateway 192.168.1.1. Router R2 has been elected VRRP master and this is the only router that will route frames from the clients to the core, even though the clients are not locally connected to the master. The other devices bridge frames from the clients to the master; therefore, the frames from User55 and User77 must traverse two devices when routing the frame to the core.

**Figure 262: Asymmetric Routing and VRRP (1)**

R1, R2, and R3 all advertise 192.168.1.0/24 to the core. This means that return traffic to the users will be sent from the core to any of these routers. A non-optimal path for the flows in either direction may result. Flows from User 55 to Core would traverse R1, R2. The return path could traverse R3, R2, and R1.

**Figure 263: Asymmetric Routing and VRRP (2)**

Fabric Routing solves part of this path problem by allowing the backup routers to forward frames for the clients without having to send the frame to the master router for the group. Now frames from User 55 will be routed by the first router that receives the frame (R1). Unfortunately, the return path to User 55 from the core is still via Equal Cost Multipath (ECMP) to any of the routers. Again, the frame may have to still traverse R3, R2, and finally R1 to reach User 55 from the core.

### *Host Mobility Solving Asymmetric Routing*

The host mobility feature uses ARP/ND to learn each user connected to the IP Network on the router that is closest to the end host. It then uses routing protocols such as OSPF to advertise the hosts IP/IPv6 address. These “Host Routes” will be advertised to other routers making them the preferred route to the end host’s IP address. As the host route propagates through the network the most efficient path to the end host will be revealed as every other path will have an additional cost. With host mobility, User 55’s complete route will be advertised to R2, R3 and the core. The core will then receive a route to User 55’s address from all three routers. The most direct route will have less hops and a lower cost than the routes reported by R2 and R3. When traffic destined to User 55 enters the core the most direct path (R1) is selected.

### *VRRP Host Mobility Feature Detail*

The ExtremeXOS Host-Mobility feature is implemented using the user space application VRRP, which listens for ARP/ND updates from the kernel using the *FDB (forwarding database)*. When ARP/ND entries are inserted into the kernel, the FDB notifies the host-mobility application. If the new ARP/ND entry exists on an interface that has VRRP, host-mobility is configured on the VRRP & VRID pair, and the port is not being excluded, the host-mobility application will create a host route in the route table.

The host routes in the route table will be propagated via existing routing protocols such as OSPF.

As ARP/ND entries are removed from the kernel, the host-mobility portion of the VRRP application is notified. Normally if the interface is still up when entries are removed, the host-mobility application sends an ARP/ND packet to the IP address of the host associated with the ARP/ND entry to resolve the address again. The FDB attempts to resolve ARP addresses when near the age period. Due to the FDB keeping ARPs up to date, host-mobility does not need to try to resolve aging entries when aging. When the entry is removed by a clear CLI command, FDB does not send an ARP. When the entry is removed, Host-Mobility requests an ARP. After 5 seconds, if no route has been added, the host routes are removed from the route table.

Ports are designated as host or router ports; by default the ports are host ports. ARP/ND entries learned on router ports do not generate host route entries. Only ARP/ND entries learned on host ports generate route entries. Host route entries are removed if the ARP/ND entry is learned or changes to a router port.

When a host moves from one switch to another on the same layer 2 network, a new host route is created from the new location. In this case there may be two host routes throughout the network advertising for the same host. While not optimal, this situation does not cause any network delivery problems. Eventually the original host route is removed when the ARP/ND entry is removed from the switch or moves from a host port to a router port.

A redistribution command is required for OSPF or other routing protocols to distribute the new host routes. The command to redistribute is “enable ospf export host-mobility cost 0 type ase-type-2”. A new routing “Origin” type is added to route table for host-mobility routes.

Since OSPF will redistribute host-mobility routes, it is possible that a route could be learned for a host that the local device can reach at a lesser cost. Host-mobility monitors routes added by OSPF. If OSPF adds a route that is part of a subnet that the device is a member of, then host-mobility triggers ARP/ND to be performed. By performing ARP/ND, the lower cost route to host is added as an ARP/ND entry in the proper table and is used while routing traffic. If no response is received, then the OSPF route will continue to be used instead.

## VRRP Grouping to Increase VR Scaling

To achieve scaling of *VRRP* VR instances above 511 to as high as 2,048, selected VRRP VRs must be grouped as instructed by the user. Groups involving the same set of VRRP VRs are configured in all VRRP routers. A single chosen VR out of the group (primary VR) transmits/receives VRRP advertisements at the configured interval. Other VRs (secondary VRs) in the group transmit/receive at a much slower rate. This requires a much fewer number of VRRP advertisements exchanged, and reduces CPU resource usage, increasing scaling. All VRs in a group assume same VRRP state in a given router.

VRRP Fabric Routing needs to be enabled on all member VRs of a group in participating VRRP routers. This does not have any effect when a VR (or group of VRs) is master; but, when a higher priority master becomes available, this VR transitions to Fabric Routing-enabled backup, instead of regular backup. Since the Fabric Routing feature enables VRRP backup routers to load share by Layer 3 forwarding, and conforms to RFC 5798, this mode is preferred over using a regular backup router. However, if you want the regular master-backup configuration, you can use a separate VRID that is not used by VRs in any group.

### *VRRP Grouping Limitations*

- All *VRRP* VLANs participating in same group should have same topology in a given router.
- VRRP groups and individual VRs can not be mixed when VRs use the same VRID and are configured to operate in regular master-backup mode.
- Fabric Routing must be enabled for the group of VRs if the same VRID is repeated in multiple groups.
- When the number of VRs configured on a router exceeds 511, you must switch to high-scale mode (use VRRP grouping) to obtain scaling to 2,048 VR instances.
- The same group does not support combinations of some IPv4 VRs and some IPv6 VRs. Separate groups must be used for each type.

## VRRP Grouping Description

**Figure 264: Example VRRP Group Configuration**

Figure 264 shows an example configuration of two different groups in simple topology. Group A is configured with 10 VRRP VRs, each VR on a separate VLAN, and using separate VRID. The same set of VRRP VLANs are grouped together on both routers. All the VRRP VLANs on Group A have the same topology with respect to Router 1 and Router 2. If a VLAN on Router 1 goes down due to link faults or I/O slot failure, other VLANs also go down (that is, all VLANs in the group share the same fate).

This is a typical topology for which this scaling is well suited. If the VLAN going down event triggers VRRP state change in one VLAN, a VRRP state change occurs on other VLANs also. This example has four hosts on different VLANs belonging to group A; traffic from hosts may get hashed to either of the MLAG links and reach either the VRRP master (RTR1) or the Fabric Routing-enabled backup router (RTR2). Both routers perform routing for host traffic. Group B has a different set of 10 VRRP VRs that were configured on a different set of VLANs and with a different set of VRIDs from that

of Group A. Routers are configured for regular master-backup states (unlike Group A which has master-FREB states).

#### Note

If you want a regular master-backup operation on a particular group for some reason, do not reuse the VRIDs configured in other groups or other individual VRs.

### Enabling Fabric Routing on VRs

Enabling Fabric Routing is only required if a VRID is reused in more than one group. Only these groups of VRs need to be enabled for Fabric Routing in all participating *VRRP* routers.

Grouping Reusing VRIDs in Different Groups (Fabric Routing Mode)

Table 177 shows an example configuration that reuses VRIDs in multiple groups. All three groups are configured on each VRRP router. Notice that Groups A and C have the same set of *VLANs*, but VRID is interchanged between the VLANs. Since all three groups are sharing the same VRIDs, Fabric Routing needs to be enabled on VRs in all three groups.

**Table 177: VRRP Grouping Example #1**

| Group A |           | Group B |           | Group C |           |
|---------|-----------|---------|-----------|---------|-----------|
| VLAN    | VRRP VRID | VLAN    | VRRP VRID | VLAN    | VRRP VRID |
| V1      | 1         | V10     | 1         | V1      | 4         |
| V2      | 2         | V11     | 2         | V2      | 3         |
| V3      | 3         | V12     | 3         | V3      | 2         |
| V4      | 4         | V13     | 4         | V4      | 1         |

Grouping with Unique VRIDs

All VRs in Group I use VRID 1 in Table 178. All VRs in Group J use VRID 2. In this configuration, all VR groups do not need to be enabled for Fabric Routing. Group I can operate in master-FREB mode, and Group J can choose to operate in master-backup mode. In this case, only VRs in Group I need to be enabled for Fabric Routing.

**Table 178: VRRP Grouping Example #2**

| Group I |           | Group J |           | Group K |           |
|---------|-----------|---------|-----------|---------|-----------|
| VLAN    | VRRP VRID | VLAN    | VRRP VRID | VLAN    | VRRP VRID |
| V1      | 1         | V10     | 2         | V1      | 3         |
| V2      | 1         | V11     | 2         | V2      | 3         |
| V3      | 1         | V12     | 2         | V3      | 3         |
| V4      | 1         | V13     | 2         | V4      | 3         |

Grouping with Multiple VRIDs per Group with VRIDs Not Repeated

It is possible to have an individual VR when there are some groups already in the same router. This may be useful when this router has two VRRP peer routers and it has to operate in group mode with one peer, but has to operate in individual VR mode with another peer at the same time. In that case, an individual VR must be configured with a unique VRID that is not used in any of the groups or other individual VRs. This unique VRID is required only if either a group or individual VR is operating in master-backup mode. However, if all groups and individual VRs are operating in master-FREB mode, then VRIDs used within a group can be assigned to individual VRs.

**Table 179: VRRP Grouping Example #3**

| Group L |           | Group M |           | Group N |           |
|---------|-----------|---------|-----------|---------|-----------|
| VLAN    | VRRP VRID | VLAN    | VRRP VRID | VLAN    | VRRP VRID |
| V1      | 1         | V10     | 5         | V1      | 9         |
| V2      | 2         | V11     | 6         | V2      | 10        |
| V3      | 3         | V12     | 7         | V3      | 11        |
| V4      | 4         | V13     | 8         | V4      | 12        |

#### Characteristics of VRs in a Group

When VRs are grouped together you need to choose a VR from the group and configure it as the primary VR using the CLI. Other VRs belonging to the group need to be added as secondary VRs. When a group is operational, the following approach maintains the same state across all VRs:

- The primary VR sends VRRP advertisements at the configured interval.
- All the VRs in the group have the same VRRP state in a given router.
- Only the primary VR registers for tracking objects (iproute tracking, ping tracking, VLAN tracking) and processes tracked events. If any tracking configuration is present on secondary VRs, they are not effective when the VR is part of a group.
- Secondary VRs inherit the priority of the primary VR. This is useful because when you want to change the priority of a group, you only need to change priority of the single primary VR.
- The pre-empt configuration of the primary VR is applied for the group. If these configurations (pre-empt allowed, pre-empt delay) are present in secondary VRs, they are not effective.
- The advertisement interval configuration on a secondary VR is also not effective.

Other per VR configurations/properties should continue to work as-is, such as accept-mode and host-mobility. All secondary VRs send advertisements at 40 seconds intervals. Sending advertisements help Layer 2 switches in the network to learn VMACs on a secondary VR's VLAN. Sending at a slower rate reduces processing load at control plane, on VRRP peers.

The other properties of individual VRs present in a group are not altered from their current behavior.

### Switching Between Individual VR Mode and High-Scale Mode (Group)

It may be preferable to run in individual VR mode until VR count exceeds its maximum limit (511 instances), as it gives more flexibility with respect to topology choices and 'per-VLAN routing control for the same VRID'. It will allow the VRs configured in different VLANs configured with same VRID to be in different routing states (for example, one VR can be master and that VLAN can do routing, but the other VR can be backup and that VLAN can do Layer 2 forwarding towards the master).

When you try to configure and enable a VR beyond 511 VRs, you are notified to configure `VRRP` groups and add VRs to appropriate groups. VRs configured on VLANs following the same topology can be grouped together. There can be multiple groups for the same topology for administrative reasons, or for running with different VRRP configurations (like advertisement interval, etc.), or with different Fabric Routing mode.

Alternatively, groups can be configured beforehand and kept for future use. Similarly, VRs can be added to the group beforehand. The groups can be kept in a disabled state (`disable vrrp group group_name {configuration | members}`) until you are notified to configure VRRP groups (VR count exceeds 511). When groups are in the disabled state, the VRs present in the group configuration run in individual VR mode.

During switchover, it is recommended to execute the commands:

```
disable vrrp
```

```
disable vrrp group group_name members
```

After adding VRs to group, and enabling group configuration, execute the commands:

```
enable vrrp
```

```
enable vrrp group group_name members
```

Keeping VRs in disabled state during transition, and then enabling afterwards, ensures that the bulk transfer of VR information across the system occurs more easily.

You can switch to individual VR mode from high-scale mode by disabling all VRRP groups. Since the limit of VRs in individual mode is 511, ensure that greater than 511 VRs are not enabled before disabling the group configuration.

When a group is already operational (the group is enabled, and also its member VRs are enabled), additional VR can be added to the group. It is recommended to disable the VR before adding it to a group that is currently running and forwarding traffic. Enable the VR after it is added to group in all participating routers. This avoids traffic loss during the transition to group mode.

You can have few individual VRs outside of groups. If you are transitioning to high-scale mode when an individual VR is present, disable all VRs (`disable vrrp`) before the transition and enable all VRs (`enable vrrp`) after the transition.

For a list of all VRRP group commands, see [Configuring VRRP Groups](#) on page 2231.

**Note**

If a large number of VRs are added under the same group, the advertisement interval of the primary VR of the group should be increased to multiples of seconds. This reduces the processing load on the VRRP backup router and avoids protocol flaps. For a large IPv6 group, chose an advertisement interval of a greater value than the value of a similarly sized IPv4 group.

## Configuring VRRP

---

The following procedure can be used to configure a simple *VRRP* topology:

1. Configure the VRRP IP address owner router as follows:
  - a. Create a *VLAN* to serve as the VRRP router VLAN.
  - b. Add an IP address to the VRRP VLAN.
  - c. Enable IP forwarding on VRRP VLAN.
  - d. Add the VRRP version for the VRRP instance (see [Configuring VRRP Version Support](#) on page 2230).
  - e. Create the VRRP router instance for the intended VRRP master (see [Creating and Deleting VRRP Router Instances](#) on page 2229).
  - f. Add the IP address defined in Step 1b as a VRRP router IP address (see [Adding and Deleting VRRP Router IP Addresses](#) on page 2229).
  - g. Enable VRRP on the switch (see [Enabling and Disabling VRRP and VRRP Router Instances](#) on page 2232).
2. Configure each backup VRRP router as follows:
  - a. Create a VLAN to serve as the VRRP router VLAN. This name must match the name used for the appropriate VRRP IP address owner.
  - b. Add an IP address to the VRRP VLAN. This address must be different from the IP address assigned to the intended VRRP master, but it must use the same subnet.
  - c. Enable IP forwarding on VRRP VLAN.
  - d. Create the VRRP router instance that will serve as the backup instance (see [Creating and Deleting VRRP Router Instances](#) on page 2229).
  - e. Configure the priority for the backup VRRP router to a value in the range of 1–254 (see [Configuring VRRP Router Priority](#) on page 2230).
  - f. Add the same VRRP router IP address that was added to the intended VRRP master instance (see [Adding and Deleting VRRP Router IP Addresses](#) on page 2229).
  - g. Enable VRRP on the switch (see [Enabling and Disabling VRRP and VRRP Router Instances](#) on page 2232).
3. Configure network workstations to use the VRRP router IP address as the default gateway address.

## Creating and Deleting VRRP Router Instances

- To create a VRRP router instance, use the following command:  
`create vrrp vlan vlan_name vrid vridval`
- To delete a VRRP router instance, use the following command:  
`delete vrrp vlan vlan_name vrid vridval`

## Adding and Deleting VRRP Router IP Addresses

- To add a VRRP router IP address to a switch, use the following command:  
`configure vrrp vlan vlan_name vrid vridval add ipaddress`

### Note

A VRRP routing instance can support IPv4 or IPv6 addresses, but it cannot support both.

- To delete a VRRP router IP address from a switch, use the following command:  
`configure vrrp vlan vlan_name vrid vridval delete ipaddress`

## Adding an IPv6 Link Local Address to a VRRP Router

To add an IPv6 link local address to a VRRP router, enter the following command:

```
configure vrrp vlan vlan_name vrid vridval add virtual-link-local
vll_addr
```

## Configuring the VRRP Router Advertisement Interval

To configure the VRRP router advertisement interval, use the following command:

```
configure vrrp vlan vlan_name vrid vridval advertisement-interval
interval [{seconds} | centiseconds]
```

### Note

We recommend that you configure the same router advertisement interval in all VRRP routers. VRRPv3 supports a 40 second maximum advertisement interval.

### Note

If the advertisement interval is different on the master and backup switches, the master switch's advertisement interval is used by the backup as well.

## Configuring VRRP Router Advertisement by Link Local Address Only

To configure the router discovery advertisements to send only with VRRP link local address on the VRRP-enabled VLAN interface, use the following command:

```
configure {vlan} vlan_name router-discovery {ipv6} vrrp-lla-only on_off
```

## Configuring Master Preemption

- To enable VRRP master preemption and configure the preempt delay timer, use the following command:

```
configure vrrp vlan vlan_name vrid vridval preempt {delay seconds}
```

- To disable VRRP master preemption, use the following command:

```
configure vrrp vlan vlan_name vrid vridval dont-preempt
```

## Configuring VRRP Router Priority

To configure the priority for a VRRP router, use the following command:

```
configure vrrp vlan vlan_name vrid vridval priority priorityval
```

### Note

If VRRPv3 and VRRPv2 routers participate in VRRP instance, the VRRPv3 routers should be configured with a higher priority to ensure that they win master elections over VRRPv2 routers.

## Configuring the Accept Mode

To configure the accept mode, enter the following command:

```
configure vrrp vlan vlan_name vrid vridval accept-mode [on | off]
```

## Configuring NTP VRRP Virtual IP support

To configure the VRRP virtual IP as NTP server address, enter the following command:

```
configure vrrp vlan vlan_name vrid vridval accept mode [on|off]
```

Enabling the accept mode allows the switch to process non-ping packets that have a destination IP set to the virtual IP address.

## Configuring VRRP Version Support

To configure VRRP version support, use the following command:

```
configure vrrp vlan vlan_name vrid vridval version [v3-v2 | v3 | v2]
```

## Configuring VRRP Tracking

### Configuring the Tracking Mode

To configure the tracking mode, enter the following command:

```
configure vrrp vlan vlan_name vrid vridval track-mode [all | any]
```

### Adding and Deleting Tracked Routes

- To add a tracked route, enter the following command:  

```
configure vrrp vlan vlan_name vrid vridval add track-iproute
ipaddress/masklength
```
- To delete a tracked route, enter the following command:  

```
configure vrrp vlan vlan_name vrid vridval delete track-iproute
ipaddress/masklength
```

### Adding and Deleting Tracked VLANs

- To add a tracked VLAN, enter the following command:  

```
configure vrrp vlan vlan_name vrid vridval add track-vlan
target_vlan_name
```
- To delete a tracked VLAN, enter the following command:  

```
configure vrrp vlan vlan_name vrid vridval delete track-vlan
target_vlan_name
```

### Adding and Deleting Tracked Pings

- To add a tracked ping, enter the following command:  

```
configure vrrp vlan vlan_name vrid vridval add track-ping ipaddress
frequency seconds miss misses {success successes}
```
- To delete a tracked ping, enter the following command:  

```
configure vrrp vlan vlan_name vrid vridval delete track-ping ipaddress
```

## Configuring VRRP Fabric Routing

To configure the fabric routing feature, enter the following command:

```
configure vrrp vlan [vlan_name | vlan_list] [vridval | all] { group
group_name } fabric-routing [on | off]
```

## Configuring Host Mobility

To configure host-mobility, enter the following command:

```
configure vrrp [{ vlan } [vlan_name | vlan_list] vrid [vridval | vrid_list
| all]] host-mobility [{ on | off } { exclude-ports [add | delete]
port_list }]
```

In general, the port that is not connected to host is added in exclude-ports to avoid unnecessary host route.

## Configuring VRRP Groups

To create VRRP groups:

```
create vrrp group group_name
```

To delete VRRP groups:

```
delete vrrp group group_name
```

To add/delete primary VRs or secondary VRs:

```
configure vrrp group group_name add [primary-vr | secondary-vr] [{vlan}
vlan_name vrid vridval | vlan vlan_list {vrid vrid_list}]
```

```
configure vrrp group group_name delete [primary-vr | secondary-vr
[{vlan} vlan_name vrid vridval | vlan vlan_list {vrid vrid_list} |
all]]
```

To enable VRRP groups:

```
enable vrrp group group_name {configuration | members}
```

To disable VRRP groups:

```
disable vrrp group group_name {configuration | members}
```

To show VRRP group information:

```
show vrrp group group_name
```

For an example VRRP group configuration, see [VRRP Groups Configuration Example](#) on page 2234.

---

## Managing VRRP

### Enabling and Disabling VRRP and VRRP Router Instances

- To enable VRRP or a VRRP router instance, enter the following command:  

```
enable vrrp {vlan vlan_name vrid vridval}
```
- To disable VRRP or a VRRP router instance, enter the following command:  

```
disable vrrp {vlan vlan_name vrid vridval}
```

### Clearing VRRP Counters

To clear the VRRP counters, enter the following command:

```
clear counters vrrp [{vlan vlan_name} {vrid vridval}]
```

---

## Displaying VRRP Information

### Displaying VRRP Router Information

To display VRRP router information for one or all VRs, enter the following command:

```
show vrrp {virtual-router {vr_name}} {detail}
```

## Displaying VRRP Router Information and Statistics for VLANs

To display *VRRP* information or statistics for a *VLAN*, enter the following command:

- Display VRRP information or statistics for a VLAN.

```
show vrrp vlan vlan_name | vlan_list {stats}
```

## Displaying VRRP Tracking Information

To view the status of tracked devices, enter the following command:

```
show vrrp {virtual-router {vr_name}} {detail}
```

## VRRP Configuration Examples

### Simple VRRP Network Examples

The topology for a simple *VRRP* network example is shown in [Figure 259](#) on page 2208.

Switch A is the IP address owner, and Switch B is configured as the backup.

The configuration commands for switch A are as follows:

```
configure vlan vlan1 ipaddress 192.168.1.3/24
enable ipforwarding vlan vlan1
create vrrp vlan vlan1 vrid 1
configure vrrp vlan vlan1 vrid 1 priority 255
configure vrrp vlan vlan1 vrid 1 add 192.168.1.3
enable vrrp
```

The configuration commands for switch B are as follows:

```
configure vlan vlan1 ipaddress 192.168.1.5/24
enable ipforwarding vlan vlan1
create vrrp vlan vlan1 vrid 1
configure vrrp vlan vlan1 vrid 1 add 192.168.1.3
enable vrrp
```

### VRRP Load Sharing Example

You can use two or more *VRRP*-enabled switches to provide a fully redundant VRRP configuration that supports load sharing on your network.

The topology for a load sharing example is shown in [Figure 260](#) on page 2209. Switch A is the IP address owner for VRRP router instance 1 and the backup for VRRP instance 2. Switch B is the IP address owner for VRRP router instance 2 and the backup for VRRP instance 1.

The configuration commands for switch A are as follows:

```
configure vlan vlan1 ipaddress 192.168.1.3/24
enable ipforwarding vlan vlan1
```

```
create vrrp vlan vlan1 vrid 1
configure vrrp vlan vlan1 vrid 1 priority 255
configure vrrp vlan vlan1 vrid 1 add 192.168.1.3
create vrrp vlan vlan1 vrid 2
configure vrrp vlan vlan1 vrid 2 add 192.168.1.5
enable vrrp
```

The configuration commands for switch B are as follows:

```
configure vlan vlan1 ipaddress 192.168.1.5/24
enable ipforwarding vlan vlan1
create vrrp vlan vlan1 vrid 2
configure vrrp vlan vlan1 vrid 2 priority 255
configure vrrp vlan vlan1 vrid 2 add 192.168.1.5
create vrrp vlan vlan1 vrid 1
configure vrrp vlan vlan1 vrid 1 add 192.168.1.3
enable vrrp
```

## VRRP Tracking

Tracking information is used to track various forms of connectivity from the VRRP router to the outside world.

## VRRP Groups Configuration Example

### Note

This configuration example assumes that VRs are already created and configured with regular VRRP parameters, but not yet enabled (`enable vrrp {vlan [vlan_name | vlan_list] vrid [vridval | vrid_list]}` command is not yet executed). If VRs are already enabled, disable all the VRs (`disable vrrp {vlan [vlan_name | vlan_list] vrid [vridval | vrid_list]}`).

1. Create VRRP group "groupA":

```
create vrrp group "groupA"
```

2. Add primary VR before adding any secondary VRs to the group:

```
configure vrrp group "groupA" add primary-vr vlan "vlan1" vrid 1
```

3. Add secondary VRs one at a time:

```
configure vrrp group "groupA" add secondary-vr vlan "vlan2" vrid 2
configure vrrp group "groupA" add secondary-vr vlan "vlan3" vrid 3
configure vrrp group "groupA" add secondary-vr vlan "vlan4" vrid 4
configure vrrp group "groupA" add secondary-vr vlan "vlan5" vrid 5
```

Or alternatively, VLAN tag range and VRID range can be specified. In this case, vlan1 has vlan-id 101, vlan2 has vlan-id 102, etc.:

```
configure vrrp group "groupA" add secondary-vr vlan 102-105 vrid 2-5
```

4. Configure fabric routing on all the member VRs in the given group:

```
configure vrrp group "groupA" fabric-routing on
```

5. Apply group configuration on member VRs. Before enabling the group, member VRs are operating in individual VR mode:

```
enable vrrp group groupA
```

6. Enable all VRs using the global command, if there is only one group:

```
enable vrrp
```

or enable only member VRs of this group:

```
enable vrrp group groupA members
```

After configuring VRRP groups, the following appears for the below show commands:

```
show vrrp group
```

| Group Name | Priority | State | Count | Members | TP/TR/TV/P/T | /FR |
|------------|----------|-------|-------|---------|--------------|-----|
| groupA(En) | 100      | MSTR  | 6     |         | 0 0 0 Y 1    | Y   |

En-Enabled, Ds-Disabled, Pri-Priority, T-Advert Timer, P-Preempt  
 TP-Tracked Pings, TR-Tracked Routes, TV-Tracked VLANs, FR-Fabric Routing,  
 MX-Mixed values

```
show vrrp vlan1
VLAN: vlan1 VRID: 1 VRRP: Enabled State: MASTER
Virtual Router: VR-Default
Priority: 100(backup) Advertisement Interval: 1 sec
Version: v3-v2 Preempt: Yes Preempt Delay: 0 sec
Virtual IP Addresses:
Accept mode: Off Group : groupA (Enabled)
Host-Mobility: Off
Host-Mobility Exclude-Ports:
Checksum: Include pseudo-header
Tracking mode: ALL
Tracked Pings: -
Tracked IP Routes: -
Tracked VLANs: -
Fabric Routing: On

* indicates a tracking condition has failed
```

# VXLAN

VXLAN is a network virtualization technology that leverages existing Layer 3 infrastructures to create tenant overlay networks. VXLAN addresses the requirements of a multi-tenant data center network infrastructure by:

- Increasing virtual network scalability to 16 million instances. This allows for tenant *VLAN (Virtual LAN)* isolation whereby multiple tenants can manage their own VLAN/VMAN and MAC address spaces.
- Adding an encapsulation that effectively hides VM MAC addresses from the physical network that results in physical networking devices to have smaller MAC and IP table sizes.
- Allowing for Layer 2 adjacency across IP networks by which DC network operators protect their investment in their current infrastructure. Additionally operators can distribute traffic loads across links efficiently using Layer 3 ECMP.

## VXLAN Overview

---

VXLAN is a Layer 2 overlay scheme over a Layer 3 network. Overlays are called VXLAN segments and only VMs and physical machines (tenants) within the same segment have Layer 2 connectivity. VXLAN segments are uniquely identified using an identifier called the VXLAN Network Identifier (VNI). The VNI is a 24-bit identifier; therefore, an administrative domain can support up to 16 million overlay networks.

As the scope of the MACs originated by tenants is restricted by the VNI, overlapping MAC addresses across segments can be supported without traffic leaking between tenant segments. When a tenant frame traverses a VXLAN overlay network, it is encapsulated by a VXLAN header that contains the VNI. This frame is further encapsulated in a UDP header and L2/L3 headers.

VXLAN can add up to a 54-byte header to the tenant VM's frame. For VXLAN to work correctly, this requires that the IP MTU be set to at least 1554 bytes on the network-side interfaces. IP MTU of 1554 should also be set on all transit nodes which carry VXLAN traffic. The point at which a tenant frame is encapsulated (or decapsulated) is referred to as a VXLAN Tunnel Endpoint (or VTEP). VTEPs are typically located on hypervisors but may also be located on physical network switches. Network switches that act as a VTEP are referred to as VXLAN gateways.

The role to encapsulate/decapsulate a frame is performed by a VXLAN Tunnel Endpoint (VTEP), also referred to as a VXLAN gateway. A VXLAN gateway can be a Layer 2 gateway or Layer 3 gateway depending on its capacity. A Layer 2 gateway acts as a bridge connecting VXLAN segments to VLAN segments. A Layer 3 gateway performs all that of Layer 2 gateway, and capable of routing traffic between tenant VLANs/VMANs.

At tunnel initiation, a gateway looks up the destination MAC address of the frame received from the tenant VM. If the MAC address to remote VTEP IP binding is known, the gateway adds the VXLAN header and the IP/UDP header to the frame and forwards toward the DC network. A gateway node that terminates a tunnel removes the encapsulation headers from the packet and determines the bridge domain of the inner frame by examining the VXLAN network identifier (VNID) received in the VXLAN header. The gateway then looks up the inner MAC destination address (DA) in the tenant VLAN's/VMAN's filtering database and decides either to flood or forward the frame to tenant ports.

The VXLAN segments with the same virtual network ID form a virtual network with one Ethernet broadcast domain.

**Note**

Universal switches support Layer 3 gateways.

## Supported Platforms

VXLAN is supported on ExtremeSwitching Universal switches, and stacks with Universal slots only.

### Note

4120 and 4220 Series do not support VXLAN.

## Limitations

The following capabilities are not supported in ExtremeXOS:

- Ability to assign more than one VNI to a virtual network.
- IPv6 addresses for local and remote VTEPs.
- Assigning source IP for VXLAN gateway encapsulation:
  - Per
  - Per virtual network or VNI
- Support for adding more than one tenant VLAN/VMAN per VNI.
- A physical port being part of both a tenant VLAN/VMAN and an underlay (Network) VLAN.
- Support for heterogeneous stack environments where at least one of the stack nodes is not VXLAN capable.
- More than one next-hop on a (network) port.
- Multicast underlay IP network, except PIM-SSM.
- Multiple VRs.
- With VXLAN for 5320 and 5420 series switches, MACSec-enabled shared ports cannot be used as a VXLAN tenant/network port.

## Interactions with Existing ExtremeXOS Features

| Feature/Capability                                                                 | Tenant Network           | Underlay Network         | Rest of the Switch  |
|------------------------------------------------------------------------------------|--------------------------|--------------------------|---------------------|
| VLAN with: Multiple C-Tags on the same port or different C-Tags on different ports | Future                   | Future                   | No new restrictions |
| Port-Specific Tag (PSTag)                                                          | ExtremeXOS 31.2 or later | Not supported            | No new restrictions |
| MAC-based and Protocol-based VLANs                                                 | Not supported            | Not supported            | No new restrictions |
| VMANs                                                                              | Supported                | Not supported            | No new restrictions |
| CEP                                                                                | Not supported            | Not supported            | No new restrictions |
| Configuring <i>LAG (Link Aggregation Group)</i> on ports (static and LACP)         | ExtremeXOS 21.1 or later | ExtremeXOS 21.1 or later | No new restrictions |

| Feature/Capability                                                                              | Tenant Network           | Underlay Network         | Rest of the Switch       |
|-------------------------------------------------------------------------------------------------|--------------------------|--------------------------|--------------------------|
| Configuring on ports                                                                            | ExtremeXOS 21.1 or later | ExtremeXOS 21.1 or later | ExtremeXOS 21.1 or later |
| Limit learning and MAC locking                                                                  | ExtremeXOS 31.2 or later | Not supported            | ExtremeXOS 21.1 or later |
| Configuring IP (v4/v6) address on a VLAN                                                        | ExtremeXOS 21.1 or later | ExtremeXOS 21.1 or later | No new restrictions      |
| Enabling IP and IPMC forwarding                                                                 | ExtremeXOS 22.5 or later | ExtremeXOS 21.1 or later | No new restrictions      |
| Interface virtual router configuration                                                          | ExtremeXOS 22.5 or later | ExtremeXOS 21.1 or later | No new restrictions      |
| Spanning tree (802.1d, RSTP, <i>MSTP (Multiple Spanning Tree Protocol)</i> , EMISTP, and PVST+) | Not supported            | ExtremeXOS 21.1 or later | No new restrictions      |
| Ring protocols ( <i>EAPS (Extreme Automatic Protection Switching)</i> and ERPS)                 | ExtremeXOS 21.1 or later | ExtremeXOS 21.1 or later | No new restrictions      |
| <i>VRRP (Virtual Router Redundancy Protocol)</i>                                                | ExtremeXOS 22.5 or later | ExtremeXOS 21.1 or later | No new restrictions      |
| ESRP                                                                                            | Not supported            | ExtremeXOS 21.1 or later | No new restrictions      |
| <i>IGMP (Internet Group Management Protocol) Snooping</i>                                       | Not supported.           | ExtremeXOS 21.1 or later | No new restrictions      |
| Unicast routing protocols                                                                       | Not supported.           | ExtremeXOS 21.1 or later | No new restrictions      |
| PIM (SM, DM, SSM)                                                                               | Not supported            | ExtremeXOS 21.1 or later | No new restrictions      |
| PIM Bidir                                                                                       | Not supported            | Future                   | No new restrictions      |
| MVR                                                                                             | Not supported            | Future                   | No new restrictions      |

#### Note

1. MLAG requires entire switch to move to software learning mode.
2. MAC locking and limit learning features require software learning mode.
3. ExtremeXOS will require that all underlay VLANs be part of the same VR. This VR can be user-created or system-created.
4. This does not imply that VXLAN encapsulated packets will be snooped. IGMP snooping for multicast contained entirely within the operator network will work.
5. Current hardware has no support for adding an MPLS label to a VXLAN encapsulated frame. So remote VTEPs cannot be reachable through a MPLS network.
6. XNV dynamic VLANs, IDM role-based VLANs and MVRP require a global VLAN ID space and hence are not supported.
7. Single-hop BFD can be configured on operator VLANs.
8. All multicast traffic are treated as unknown.
9. Multi-chassis Link Aggregation (MLAG) does not function if the Inter-Switch Connection (ISC) port is added to an untagged tenant VMAN.
10. Non-Tenant VLANs/VMANs do not function if the port also has an untagged tenant VMAN.

## Overlay Routing

Tenants may have multiple overlays across a data center network where different VLANs belonging to the same tenant are mapped to different VXLAN Network

Identifiers (VNIs). Tenants require routing between the VLANs, and VXLAN gateway nodes would need to act as Layer 3 gateways that are capable of routing traffic between tenant VLANs. Inter-overlay routing involves routing:

- Routing traffic from a tenant VLAN into a tunnel with the destination overlay's VNI.
- Routing traffic from a tunnel to a tenant VLAN that is different from the tenant VLAN associated with the VNI in the received packet's VXLAN header.
- Routing traffic from a tunnel to the same or different tunnel.

A VXLAN tunnel endpoint (VTEP) is designated as the gateway for an overlay by manually configuring it or by running a first hop redundancy protocol (FHRP), such as *VRRP* on the tenant VLAN on the gateways and letting the protocol determine the placement of the router. ARP is not learned by VXLAN tunnels when the destination MAC address is the VRRP MAC address.

**Note**

Routing between a normal VLAN and a VXLAN tenant VLAN is supported on allExtremeSwitching Universal platforms.

**Note**

When MLAG and VRRP is configured on the tenant VLAN, VRRP should be active-active mode between the MLAG peers.

## Routing Traffic into Tunnels

When a VTEP is configured as a Layer 3 gateway, traffic from an access VLAN port destined for an endpoint (that is reachable through a VXLAN tunnel on a different subnet) is routed by the VTEP.

In [Figure 265](#), Layer 3 traffic is sourced from 20.20.20.1 and is destined for 10.10.10.2. The gateway for H2 to reach 10.10.10.2 is VTEP A. When traffic ingresses VTEP A, it is routed, and since the neighbor entry for 10.10.10.2 indicates that it is reachable through VTEP B, VTEP A encapsulates traffic with VNI “Red” and sends it over the tunnel to VTEP B. At VTEP B, traffic is decapsulated and is Layer 2 forwarded to H3.

**Figure 265: Routing into a Tunnel**

#### *Supported Platforms*

Routing traffic into tunnels is supported on all ExtremeSwitching Universal switches.

## Routing Traffic from Tunnels

When a Layer 3 gateway router is reachable across the VXLAN cloud, traffic needs to traverse the VXLAN cloud encapsulated, and the gateway at the edge of VXLAN network decapsulates traffic and would then have to route the traffic. Continuing the example from the previous subsection, the Layer 3 router for the “Red” subnet is VTEP A. Traffic in the H3 to H2 direction is VXLAN-encapsulated and Layer 2 forwarded to VTEP A. VTEP A decapsulates the traffic, performs a route lookup, and then routes traffic onto VLAN “Green” (see [Figure 266](#)).

**Figure 266: Routing from a Tunnel**

#### *Supported Platforms*

Routing VXLAN network identifier (VNID) traffic from tunnels is supported on all ExtremeSwitching Universal switches.

## Routing in and out of Tunnels (RIOT)

VTEPs acting as Layer 3 gateways would also have to support routing traffic that ingresses the VTEP on a VXLAN tunnel whose next hop is reachable through another tunnel. In [Figure 267](#), H3 determines that the gateway to reach H4 is VTEP A. Traffic from H3 is VXLAN-encapsulated with VNI “Red” and Layer 2 forwarded to VTEP A by VTEP B. VTEP A decapsulates the traffic, performs a route lookup, and then determines that H4 is reachable through VTEP C. VTEP A now encapsulates the traffic with VNI “Green” and Layer2 forwards the traffic toward VTEP C.

**Figure 267: Routing in and out of a Tunnel**

#### Supported Platforms

Routing traffic in and out of tunnels is supported on all ExtremeSwitching Universal switches.

## Route and Neighbor Distribution

Overlay route information can be configured on gateways using:

- Static configuration (for routes that have next hops reachable over the VXLAN network).
- Overlay routing protocols such as *OSPF (Open Shortest Path First)*, *RIP (Routing Information Protocol)* etc. (not supported).

## Time to Live (TTL) Processing

In ExtremeXOS, Layer 3 gateways process time to live (TTLs) information by treating a VXLAN tunnel as a single hop when an overlay IP packet traverses the tunnel.

## Differentiated Services Code Point (DSCP)/IP Type of Service (ToS) processing

Underlay and overlay networks have a common Differentiated Services Code Point (DSCP)/IP Type of Service (ToS) space.

## Optimized VXLAN Replication Using Underlay Multicast

---

Starting with ExtremeXOS 31.2, VXLAN supports underlay multicast (multicast tunnel). This feature provides support for the following:

- OSPF/BGP underlay and EVPN.
- Dynamic virtual networks.
- Bud node operation (a VTEP acting as both transit and tunnel terminating node).
- MLAG.
- Ability to configure VXLAN multicast tunnels in existing VXLAN deployments.
- Spine node can be a non-VTEP in leaf-spine topologies.
- Bandwidth preservation through optimized replication.
- Flexible choice of Multicast Distribution Tree (MDT).
- Option for automatic group address assignment for each VNI.

## Head-End Replication

The default method for flooding the broadcast/unicast/multicast (BUM) traffic from VXLAN overlay to remote VTEPs is through head-end replication over VXLAN underlay. This means the originating VTEP sends a separate copy to each of the destination VTEPs over VXLAN unicast tunnel to each VTEP.

**Figure 268: Head-end Replication**

On receiving overlay BUM traffic, VTEP 100.100.100.1 VXLAN encapsulates and sends two copies – one copy is destined to VTEP 101.101.101.1 and the other to 102.102.102.1.

**Note**

RED VNI does not span to VTEP 103.103.103.1.

## Underlay Multicast Distribution Tree

A multicast group address is assigned to a virtual network VNI. Each VTEP must use the same multicast group address for a given VNI. This must be administratively ensured.

When a VTEP discovers a remote VTEP, it learns the VNIs supported by the remote VTEP. The discovering VTEP triggers PIM (S, G) joins to the remote VTEP, for the multicast groups corresponding to the supported VNIs. As a result, a multicast distribution tree (MDT) is formed for each multicast group or each VNI.

**Figure 269: Underlay Multicast Distribution Tree**

The RED VNI is assigned with 232.1.1.1 and GREEN VNI is assigned with 232.1.1.2. Observe the PIM joins triggered by each VTEP. The MDT for RED VNI is RED dash-tree (232.1.1.1) and the MDT for GREEN VNI is GREEN dash-tree (232.1.1.2).

The overlay BUM traffic is VXLAN encapsulated with multicast group IP (corresponding to the VNI) as the outer destination IP and sent over the MDT. At the very best scenario, the originating VTEP sends only one copy out. The replication is done en route hop-by-hop by the routers in the multicast tree present in L3 network. The routers in the L3 network must support PIM-SSM but need not be VXLAN aware.

The following figure illustrates how VTEP 100.100.100.1 VXLAN encapsulates the traffic with destination IP as 232.1.1.1 and sends one copy out. The traffic flows across the L3 network over the MDT and reaches 101.101.101.1 and 102.102.102.1:

## Automatic Group Assignment and MDT Choices

It is possible to automatically assign multicast group address for each VNI. The group address is picked from a user configured address range. The address is derived as depicted in the below figure. The group prefix is obtained by AND'ing group address and mask. The group suffix bits come from the VXLAN network identifier (VNID).

`configure virtual-network multicast group 232.1.1.0 255.255.255.0`

Using the command featured in the previous figure, it is possible to choose different variants of MDT as shown here:

1. Each virtual network VNI can be assigned with discrete multicast group address. Meaning, each virtual network uses a dedicated MDT. The following command auto-assigns separate group address to each VNI:

`configure virtual-network multicast group 232.0.0.0 255.0.0.0`

2. Single multicast group address can be used for all virtual network VNIs. A single MDT is used for overlay BUM traffic on all VNIs. The following command auto-assigns 232.1.1.1 to all VNIs:

```
configure virtual-network multicast group 232.1.1.1 255.255.255.255
```

3. A combination of (1) and (2) can be used. That is, a cluster of VNIs can use one multicast group address. Another cluster can use a different multicast group address. The following command forms four cluster of VNIs and uses four shared MDTs:

```
configure virtual-network multicast group 232.1.1.0 255.255.255.252
```

| Virtual Network VNIs        | Shared MDT |
|-----------------------------|------------|
| 1, 5, 9, 13, 17, and so on  | 232.1.1.1  |
| 2, 6, 10, 14, 18, and so on | 232.1.1.2  |
| 3, 7, 11, 15, 19, and so on | 232.1.1.3  |
| 4, 8, 12, 16, 20, and so on | 232.1.1.0  |

In any of the previous options, a single VNI cannot use more than one multicast group address.

## Supported Platforms

All ExtremeSwitching Universal platforms.

## Limitations

This feature has the following limitations:

- Supported only for overlay BUM traffic.
- Supported only with PIM-SSM.
- BUD node operation is not supported with MLAG.
- Multicast group range used for this feature must not be configured/used for regular multicast traffic.

### Note

This feature should not be used with Assisted Replication.

## Unicast and Multicast VXLAN

In multicast VXLAN, the VNI is mapped to a multicast group and multicast tunnels are used to distribute broadcast, unknown unicast and multicast (BUM) tenant traffic to remote endpoints (VTEPs). This requires that the Layer 3 network supports multicast.

Unicast VXLAN uses unicast tunnels, and the BUM traffic is head-end replicated to each of the remote endpoints

## Virtual Network Flood Modes

---

In ExtremeXOS, a virtual network operates in one of the following flood modes:

- Flood mode standard (default)
- Flood mode explicit
- Flood mode multicast

These modes determine the way the remote endpoints are created/learned, and the way the tenant BUM traffic is handled.

### Flood Mode Standard

- The remote endpoints dynamically are learned using [OSPFVXLAN](#) extensions (see [OSPFv2 VXLAN Extensions](#) on page 2256) or Multiprotocol BGP (MBGP) support for VXLAN (see [Multiprotocol Border Gateway Protocol \(MBGP\) Support for VXLAN](#) on page 2257). Alternately, remote endpoints can be statically configured and attached to a virtual network using the CLI.
- The tenant BUM traffic is head-end replicated to each of the configured/learned remote endpoints on that virtual network.

For a configuration sample, see [Configuration Example for Flood Mode Standard](#) on page 2269.

### Flood Mode Explicit

- The remote endpoints can only be statically configured by attaching them to BUM [FDB \(forwarding database\)](#) entries using the CLI.
- The tenant BUM traffic is head-end replicated to each of the configured remote endpoints for the corresponding FDB entry.
- By explicitly adding BUM FDB entries, this mode provides flexibility in splitting the BUM entries to individual broadcast, unknown unicast, and unknown multicast entries.

For a configuration sample, see [Configuration Example for Flood Mode Explicit](#) on page 2269.

### Flood Mode Multicast

- The remote endpoints are learned in the same manner as in flood mode standard.
- The tenant BUM traffic is replicated by the underlay multicast distribution tree.

**Note**

This mode requires L3 multicast support on the underlay network.

**Note**

The only difference from standard flood mode is the way the tenant BUM traffic is handled.

**Note**

This mode should not be used with Assisted Replication.

## Assisted Replication

---

The following sections explain the Assisted Replication feature.

### Assisted Replication Overview

Assisted Replication works in conjunction with the BGP control plane and the "ipv4-vxlan" proprietary address-family. When this address-family is enabled the configured replication role and local tunnel endpoint are advertised using BGP updates, and each router selects the active replicator such that each router selects the same device. If a device is configured as a replicator, but is not selected it assumes the role of a leaf.

Optimized Ingress Replication for EVPN is an IETF RFC (currently in draft 6, Standards Track) that enhances the ingress replication model of broadcast, unknown, unicast, and multicast (BUM) traffic handling without putting any further burden on the underlay. For example, using multicast-based trees for BUM traffic required a multicast protocol in the underlay, such as PIM. With Optimized Replication all BC/MC frames are still unicasted through the underlay, requiring no new protocols for packet delivery, but done so in a more efficient manner. Assisted replication is an enhancement to BUM traffic handling within the ExtremeXOS VXLAN (Virtual Extensible LAN) gateway feature.

**Note**

ExtremeXOS VTEPs should *not* be configured as leaf.

**Note**

This feature should not be used with Optimized VXLAN Replication using Underlay Multicast.

To get a better understanding how the assisted replication works, you must first understand what head-end replication is.

#### *Head-End Replication*

ExtremeXOS handles BUM traffic in VXLAN environments using head-end replication. Head-end replication means that each local tunnel end-point (LTEP) must replicate the frame and VXLAN encapsulate it for each remote tunnel end-point (RTEP) on the virtual network (VNI). The primary benefit of head-end replication is that it imposes no new restrictions or requirements on the underlay. All frames are unicast IP VXLAN frames, just like the normal/learned VXLAN frames. In [Figure 270](#), you can see for a given switch what the head-end replication looks for this VNI. In this case, the total copies sent by the ingress switch is  $N+M+3$ , all of which must traverse the uplinks from the ingress switch.

**Figure 270: Example Head-End Replication Topology**

#### *Assisted Replication*

Assisted replication can be thought of as moving the head-end replication from every end-point to a small set of replicator nodes. The end result is the same, however, as each end-point receives a unique copy of the BC/MC frame (unique because it is unicasted directly to the end-point). Assuming the replicators are placed in the spine or core of the network, the actual number of frames traversing any single link can be greatly reduced.

In [Figure 271](#), the ingress switch needs to only send one copy of the BC/MC frame to the replicator. The replicator is then responsible for replicating the frame to all the end-nodes in the VNI. One switch can be the replicator for all VNIs in the VXLAN network, or multiple switches can be configured as the replicator for a specific set of respective VNIs.

**Figure 271: Example Assisted Replication Topology**

There is no restriction on the number of replicators used in a topology. Each VNI can have its own dedicated replicator, or multiple VNI can share a replicator as shown in [Figure 272](#). This would be a network operator decision based on the amount of BC/MC traffic generated on a particular VNI. Note that both [Figure 271](#) and [Figure 272](#) show the path from one particular end-point to the other end-points, when in fact these paths are bi-directional and all end-points on a VNI send BC/MC to (and receive BC/MC

from) the replicator. However, when the replicator role per VNI is split up, the restriction applies that a particular switch can only operate in one role: replicator or leaf.

#### Note

In non-EVPN environments there is no control plane learning, and there is no way for endpoints to learn the location of the user MAC addresses. In EVPN environments, which have a control plane learning model, leaf nodes learn remote addresses from the EVPN control plane, and learning is disabled on the tunnels.

**Figure 272: Assisted Replication with Multiple Replicators**

#### *Assisted Replication Roles*

Each switch participating in Assisted Replication is given a role. The role defines whether the switch acts as a regular node (meaning Assisted Replication is not used), a replicator node, or a leaf node:

- **Regular network virtualization edge node (RNVE)**—RNVE is a regular network virtualization edge node, meaning it does not participate in the Assisted Replication, but does participate in VXLAN. This is the default role for a switch. If not defined as leaf or replicator, the switch performs normal head-end replication. RNVE nodes cannot be mixed with Assisted Replication (leaf or replicator) nodes.
- **Replicator node**—The replicator is the switch that performs the BC/MC replication for configured VNIs. There can be different replicators defined for any set of VNIs. The replicator is responsible for delivering BC/MC frames to all end-points (leafs) for a given VNI. There can only be one replicator configured per VNI.
- **Leaf node**—The leaf nodes are all other nodes participating in Assisted Replication in a VNI, excluding the replicator. Leaf nodes forward BC/MC frames to the defined replicator for the virtual network, and receive BC/MC frames from the replicator (originated from other leafs). If configured as a leaf node, the switch is configured with the IP address of the replicator for the VNI. The role of leaf is not implied on a switch. You must configure it for this role, since the default role is RNVE (meaning no Assisted Replication).

For information about configuring Assisted Replication, see [Configuring Assisted Replication](#) on page 2268.

## Assisted Replication Benefits

There are a couple benefits of deploying the Assisted Replication feature:

- **Reduces capacity edge nodes/higher capacity replicators**—Using Assisted Replication allows for the edge nodes to be designed with lesser VXLAN replication capabilities, since they may not need perform broadcast or multicast replication. At the same time, switches that have exceptional replication capabilities, can be targeted for use in the role of replicator.
- **Leaf-to-spine (or edge-to-core) bandwidth utilization**—In a traditional VXLAN environment with head-end replication, the leaf/edge node has to replicate a frame to multiple RTEPs over a finite number of paths/next-hops. The number of paths may be greater in a pure leaf-spine environment compared to the traditional edge/core environment, but in either case, the bandwidth consideration from leaf-to-spine or edge-to-core is typically scaled based on requirements of nodes that will be attached. The more BC/MC frames that need be replicated from the node, the more of this precious bandwidth it consumes as the number of RTEPs increases. At the same time, as more and more replication transmits are sent out a given port, the latency of the latter frames increases. Using Assisted Replication, if the replicator is placed in a strategic location, the bandwidth utilization is reduced. For example in a leaf-spine topology where a spine has a link to every leaf, then the replication is no more than one frame out any link. In a non leaf-spine topology, the replicator could be located on a device that has plenty of bandwidth and links to the edges of the network.

For information about configuring Assisted Replication, see [Configuring Assisted Replication](#) on page 2268.

## Assisted Replication Operation

The Assisted Replication feature operates as follows.

### *Configuring Roles*

The first step for using the Assisted Replication feature is to configure the switches as replicator. After this step is complete, the Assisted Replication feature is ready to operate.

### *Node Discovery*

Assisted Replication depends on the discovery of tunnel end-points. There are currently a few different methods for this to happen within ExtremeXOS, including static configuration, or EVPN. The Assisted Replication feature is part of the OTM process and learns of the remote tunnel end-points (RTEPs) directly from there, and does not care how the end-points are discovered.

### *Frame Encapsulation*

Assisted Replication feature only uses VXLAN Unicast-IPv4 encapsulation.

### Leaf Operation

The leaf nodes have three general task:

- Forward frames received on a local access port to the other local access ports that are a member of the underlying tenant VLAN.
- Forward, by VXLAN encapsulation, the frame to the selected replicator following the VLAN-to-VNI mapping.
- Receive a VXLAN encapsulated frame from the replicator and de-cap it, and then forward it to the local access ports that are a member of the underlying tenant VLAN.

When a node is originally configured for VXLAN it will build BUM flood lists that include all local access ports for the tenant VLAN as well as all remote TEPs participating in the VNI. When the node is then configured as a leaf, the system modifies the underlying BC/MC flood list to still include the local access ports for the tenant VLAN, but then only add the selected replicator as a tunnel destination.

#### Note

If a node is configured as a leaf, but it has no selected replicator (either it was not configured, or no node has been configured to advertise as such), no replication takes place, except to local access ports. This occurs to prevent duplication of frames that can occur when combining head-end with Assisted Replication.

For information about configuring Assisted Replication, see [Configuring Assisted Replication](#) on page 2268.

## Assisted Replication with VXLAN Access Points

Access points (APs) have LTEPs defined on each AP, which connect to one, and only one, replicator. Unicast and BUM traffic traverses the same path up the VXLAN tunnel to the replicator. Unicast traffic is forwarded out the correct path towards the destination similar to the way RIOT works (see [Routing in and out of Tunnels \(RIOT\)](#) on page 2243), but in this case the VXLAN traffic is not routed in/out, but rather switched in/out. BUM traffic is replicated to all other APs on the VNI, as well as local access ports. The restriction of a single replicator allows the replicator to have local access ports without negative effect.

Similar to regular Assisted Replication functionality, the role of the replicator in an AP topology includes replicating BUM traffic on behalf of the sending VXLAN VTEP (AP in this case). The APs do not have the necessary hardware or CPU cycles to perform the VXLAN BUM replication, so the replicator offloads the work load from the AP. At the same time, the replicator is also the only RTEP known by the APs, so all unicast VXLAN traffic is also forwarded through the replicator to its ultimate RTEP destination.

## Assisted Replication Supported Platforms

Assisted Replication is supported on all Universal switches:

## Assisted Replication Limitations

In addition to restrictions imposed by VXLAN (or EVPN), the following are currently *not* supported:

- Mixed replicator/leaf functionality. A switch can be configured as a replicator *or* a leaf for all virtual network identifiers (VNI).
- Assisted replication control plane (as defined in *draft-ietf-bess-evpn-optimized-ir*).
- Local attachment (access interface) for VNI on the replicators when there is more than one active replicator per VNI.
- Mixing assisted replication with head-end replication per VNI.
- Assisted replication when not used in an EVPN or VXLAN topology.
- Combining assisted replication with IGMP/MLD snooping on the tenant VLAN, or PIM on the tenant VLAN.

Additional limitations:

- Without the control plane, a replicator must assume all other end-points are leafs.
- Stacks that do not support VXLAN are not supported.
- Only a single replicator per VNI is supported.
- The replicator can support a maximum of 250 attached leaf nodes.

## OSPFv2 VXLAN Extensions

ExtremeXOS leverages *OSPF* to advertise and learn VTEPs dynamically in a VXLAN network. OSPFv2 advertises a triplet of VNI/Endpoint IP Address/Advertising Router ID through OSPFv2 domain using type 11 opaque link state advertisements (LSAs). The OSPFv2 VXLAN LSA link state ID uses opaque type 128. The remaining 24 bits of the field are set to the VXLAN VNI. Each locally configured VNI corresponds to a single opaque LSA advertised by the router. The OSPFv2 VXLAN LSA payload contains one top level TLV which specifies the locally configured IPv4 endpoint address on the advertising router.

The OSPFv2 VXLAN opaque LSA is only advertised if `ospf vxlan-extensions` is enabled using the `enable ospf vxlan-extensions` command.

### Note

- OSPF vxlan-extensions can only be enabled when OSPFv2 is disabled.
- The remote endpoints learned by OSPF are not saved to the configuration.
- The OSPFv2 VXLAN opaque LSA is only advertised if OSPF VXLAN extensions is enabled.

**Figure 273: OSPFv2 VLXLAN Extensions**

**Note**

Routers in OSPF network should be capable of transmitting type 11 opaque LSAs defined in *RFC5250*.

## Multiprotocol Border Gateway Protocol (MBGP) Support for VXLAN

The *BGP (Border Gateway Protocol)* is a general purpose routing protocol that runs over TCP. Routes can be carried on different address family (afi) and sub-address family (safi) combinations as specified in the Multiprotocol BGP (MBGP) extensions.

The BGP implementation for ExtremeXOS supports carrying VXLAN VNI and L2TP combinations as MBGP routes using a proprietary afi/safi combination. Even though supported L2TPs are IPv4, the VXLAN routes can be carried over IPv6 peering sessions.

To enable or disable IPv4 VXLAN capability on a per peer basis, use the commands:

```
enable bgp neighbor [all | remoteaddr] capability [ipv4-unicast | ipv4-
multicast | ipv6-unicast | ipv6-multicast | vpnv4 | route-refresh |
ipv4-vxlan | l2vpn-evpn]
```

```
disable bgp neighbor [all | remoteaddr] capability [ipv4-unicast | ipv4-
multicast | ipv6-unicast | ipv6-multicast | vpnv4 | route-refresh |
ipv4-vxlan | l2vpn-evpn]
```

### Limitations

- The ability to carry VXLAN routes cannot be enabled on a per peer group basis.
- BGP graceful restart is not supported on the MBGP/VXLAN feature.

**Figure 274: VXLAN over MBGP**

**Note**

ExtremeXOS must be version 22.3 or later. Core or Premier licensing may apply (see [Switch Engine v33.3.1 Licensing Guide](#)).

## Address Resolution Protocol (ARP) Learning over Tunnels

Layer 3 gateways support learning *ARP (Address Resolution Protocol)* entries for neighbors reachable through a tunnel. Gateways process ARP requests that ingress the switch from a tunnel, and respond to those requests by sending unicast ARP responses over the tunnel. Similarly, gateways broadcast ARP requests to both physical ports and tunnels and process ARP responses received from a neighbor that is reachable through a tunnel.

For VXLAN MLAG configurations, ExtremeXOS 30.5 supports checkpointing of ARP entries learned on the checkpoint-able VXLAN tenant VLAN to the MLAG peer. This helps in avoiding unwanted flooding of ARP requests when the request hashes to the MLAG peers that do not have the ARP entries learned from the tunnel. It also avoids unwanted flooding when the peer that has the ARP reboots.

## Address Resolution Protocol (ARP) Suppression

*ARP* traffic makes up a large percentage of broadcast traffic within data centers. This traffic is even more taxing when multiple overlay networks share a common underlay network—as is the case with tunneling technologies like VXLAN. Therefore it is desirable to reduce ARP traffic.

This can be done by allowing Virtual Tunnel End Points (VTEPs) to proxy ARP requests and reply on behalf of the remote endpoint. VTEPs snoop ARP replies, exiting the virtual network tunnel to learn the remote endpoint's IP to MAC mapping. The VTEP stores this in its ARP cache for the tenant VLAN. Snooped ARP entries are viewable with the normal `iparp` commands for the tenant VLAN. VTEPs also snoop gratuitous ARPs exiting the tunnel; these may also cause the ARP cache to be updated. ARP entries are also learned from frames entering the tunnel from the tenant VLAN.

When a VTEP intercepts an ARP request it attempts to lookup the IP address in its ARP cache. If an ARP cache entry is found, the VTEP does an immediate ARP reply to the requester; this avoids flooding to both the VLAN and remote tunnel endpoints. The

source MAC in the reply is that of the remote endpoint for which the VTEP is proxying the request. On an ARP cache miss, the VTEP floods the request on the VLAN and to the remote tunnel endpoints. Additionally, the VTEP may answer an ARP request on behalf of a locally attached tenant if the tenant is on a different port than the ARP request was received on —this is proxying within the tenant VLAN.

ARP features enabled on the tenant VR (for example, gratuitous protect) may cause provoke actions for ARPs exiting the tunnel. These features should behave the same for local ARPs and ARPs processed from the tunnel. This includes configurable options such as timers and refresh.

This feature may be used even if the tenant VLAN does not have an IP interface. In that case, ARP cache entries are still learned. If an entry needs to be refreshed, the ARP request is sent with a source protocol address of all zeros. This is functionally equivalent to an ARP probe. This feature is disabled by default for configured virtual networks.

To enable/disable ARP suppression on a VXLAN tenant VLAN, use the following command:

```
configure vlan vlan_name suppress [arp-only | none]
```

To configure the filter mode for ARP suppression, use the following command:

```
configure forwarding iparp suppression filters [per-port | per-vlan]
```

To view ARP information, use the following command:

```
show iparp {ip_addr | mac | [{vlan} vlan_name | vlan vlan_list] | permanent} {port port | vr vr_name}
```

## Dynamic Virtual Networks

ExtremeXOS 30.3 introduces the ability to globally enable dynamic virtual network creation by using the following command:

```
configure virtual-network dynamic [on | off]
```

Dynamic virtual network is disabled by default. Creating or deleting BGP Auto-peering enables/disables automatic virtual network creation.

The status of this command is visible in the following command:

```
show virtual-network {vn_name | vxlan vni vni | [vlan vlan_name | vman vman_name] }
```

When this feature is enabled, the following occurs for a new VLAN-NSI mapping:

1. A dynamic virtual network is created. The virtual network name is generated with a system reserved prefix.
2. VXLAN VNI is configured for the virtual network. The VNID is same as the value of NSI.
3. The VLAN is configured as a tenant VLAN.

When a VLAN-NSI mapping is deleted, the dynamically created virtual network along with the VNI and VLAN associations are purged.

## Dynamic Virtual Networks Properties

- All restrictions for static virtual network, both configuration and functional, also apply to dynamic virtual networks.
- A dynamic virtual network is not saved to the configuration and is not persistent across reboots.
- IGMP snooping is internally disabled for a VLAN dynamically configured as tenant VLAN of a virtual network.
- When a dynamic virtual network is renamed, it becomes static and can be saved to the configuration.
- You can delete a dynamic virtual network from the CLI. It is recreated if dynamic virtual network feature is on, and the conditions are met.
- The default reserved prefix pattern for a dynamic virtual network name is SYS\_VNET\_xxxxxxx, where xxxxxxx is VNID (in the lines of dynamic VLANs – SYS\_VLAN\_xxx).
- If SYS\_VNET\_ prefix is already in use by virtual networks in an older configuration, best effort is made to choose one of the following non-conflicting prefixes – SYS\_VNET\_DYN\_, SYS\_VNET\_AUTO\_, SYS\_VNET\_AUTOGEN\_.

## Edge Automation

Edge Automation connects Extreme virtual tunnel endpoints (VTEPs) with other network devices, such as switches or wireless access points (APs), by establishing a VXLAN tunnel to them, thereby receiving ~~VXLAN~~-encapsulated traffic from the devices. Virtual networks and local tunnel endpoints (LTEPs) must already be configured on the VTEPs, and only remote virtual tunnel endpoint (RTEP) creation is dynamic.

The information about the devices (name, IP address, MAC address, etc.) is stored in a VNI-device database. The name of this VNI-device database is set using ExtremeXOS commands or ExtremeCloud Connector.

Edge Automation supports . However, no checkpointing of states between MLAG peers takes place. For MLAG to work seamlessly, VXLAN and server configuration must be provisioned identically on the MLAG peers.

Edge Automation supports stacking, and the local cache information is synced between the primary and backup. Only the primary switch is connected to the VNI-device database, and data synced between primary and backup switches is used for RTEP creation on the backup switch. After failover, the backup switch becomes the primary switch, and it becomes connected to the VNI-device database. Any notifications being processed during failover are lost.

## Supported Platforms

Edge Automation works on all platforms that support VXLAN.

## Limitations

- Virtual networks and LTEPs are not configured automatically. They must be configured using existing methods.
- The VNI-device database must be reachable using Mgmt-VR.
- You can only configure one database. If you need to create a new database, the existing database must be deleted first before adding the new database.
- This feature works only with Extreme Campus Controller. It does not work with any third-party applications.
- Any existing limitations on dynamic RTEPs apply to RTEPs created by Edge Automation.
- If a database's password is changed, and if the same is configured on ExtremeXOS, then the connection between ExtremeXOS and the database is re-established, causing a brief loss of connectivity.
- If a network device supports multiple IP addresses, the first IPv4 address is used for RTEP creation.
- Traffic between ExtremeXOS and the database is un-encrypted.

For information about configuring Edge Automation, see [Configuring Edge Automation](#) on page 2266.

## VXLAN Learning

Filtering databases on the gateways need to be populated (either through configuration or by dynamic learning) with remote MAC-to-VTEP bindings on the gateways to avoid unnecessary replication of tenant traffic.

## Dynamic Learning

Dynamic learning of remote MACs involves:

- VTEP discovery—When a VNI is configured on a gateway, other VTEPs in the network would somehow have to discover the existence of the VTEP(s) this gateway is configured with.

### Note

VTEP discovery is only supported using *OSPF* extension. But not through receiving an encapsulated frame.

- Remote MAC to IP—When an encapsulated frame is received from a remote VM, a VTEP needs adds an entry in its filtering database that binds the remote VM's MAC to the IP address of the remote VTEP

VXLAN supports standard and explicit-remotes flooding modes:

- Explicit-remotes mode—VTEPs participating in a VNI are created statically either by the user or the controller.
- Standard mode—OSPF and BGP are used to signal existence of other VTEPs. Traffic from unknown VTEPs is dropped and MAC to IP bindings are never learned.

Additionally the MAC-to-remote IP binding is added to the filtering database associated with the VNI's overlay network. The received encapsulated frame can either be addressed to the VTEP directly (in the case of known unicast) or to a multicast group that the VTEP joined.

Gateways will need to age remote VTEPs as done with MAC-to-IP bindings to ensure that the number of remote VTEPs does not remain monotonically non-decreasing over time.

A VM's MAC-to-IP binding may change if it has been migrated using Vmotion. As with [FDB](#) learning, VTEPs need to dynamically detect these moves based on received traffic and update their filtering databases.

## Load Balancing

VXLAN allows networks to leverage Layer 3 ECMP to efficiently distribute traffic loads across the network. To enable a level of entropy for load balancing on VM to VM traffic, ExtremeXOS derives the source UDP port in the encapsulated frame from the tenant packets. Transit nodes need to be configured to use appropriate mechanism to exploit the entropy.

```
configure sharing address-based custom ipv4 L3-and-L4
configure forwarding sharing L3_L4
```

### Note

The Inner packet tag (tenant tag) is not used in entropy calculation.

## Quality of Service

VXLAN gateway uses a DSCP value of 0 when the tenant packet is not IP. Otherwise, it copies the tenant DSCP value to the outer IP header. In order to overwrite this, user must configure an [ACL \(Access Control List\)](#) rule. This ACL is general and applied to all virtual networks. The following is an example of this ACL rule:

```
entry map {
 if {
 protocol udp;
 destination-port 4789;
 }
 then {
 qosprofile qp3;
 replace-dscp;
 replace-dot1p;
 }
}
```

Then, the following command is used to put the outer DSCP value to a fixed value of 32:

```
configure diffserv replacement qp3 code-point 32
```

As indicated in the example above, the dot1p value can also be replaced. In the absence of the ACL, VXLAN gateway copies the tenant dot1p value to the network. The replacement happens on the outer headers as the example above illustrates. [QoS \(Quality of Service\)](#) examination (dot1p or diffserv) happens on the first header. On the tenant port, it is examining the ethernet and IP header of tenant frames. On the

network port, it is examining the outer Ethernet and IP header. There is no change to the existing support for treatment of packets, such as rate-limiting and queuing.

## Redundant Access

Because the VXLAN gateway node can become a single point of failure, it is important to dual-home devices or clusters to a pair of gateways. While there may be multiple mechanisms to accomplish this, using is the best solution due to its simplicity and because it imposes no additional constraints on the tenant devices except that they support *LAG*.

## Multi-switch Link Aggregation (MLAG)

The following topology has a pair of server clusters that are dual-homed to a pair of VXLAN gateways with three tenants:

**Figure 275: VXLAN Gateways with Three Tenants**

Traffic from the tenant VMs that are part of an can hash toward either gateway node. This can result in GW3 learning the same VM's MAC from different VTEPs. To avoid MAC toggling on remote VTEPs, ExtremeXOS requires that users configure a special local tunnel endpoint address on MLAG nodes that will be used for tenant *VLANs/VMANs* that have MLAG ports.

For a configuration example, see [Configuration Example for MLAG](#) on page 2270.

Additional considerations:

- Since the tenant VLAN/VMAN IDs can be reused, ExtremeXOS needs to allow multiple VLANs/VMANs with the same tag to be dual homed using the same MLAG peers. This requires tenant traffic be encapsulated over the ISC link to help distinguish traffic from different tenant VLANs/VMANs.
- Only one copy of BUM traffic from a tenant VM should be forwarded to the network.
- MLAG peers have a mechanism in place to block BUM traffic coming from the network to not be sent back into the network through the other peers.
- When one of the MLAG peers loses connectivity to the underlay network, reachability can be established through the ISC. This requires you to configure an underlay VLAN that includes the ISC ports and run a routing protocol over the ISC. Using the correct metric values ensures that this VLAN is not preferred by the peers to reach remote nodes during steady state and would be used only when all other connectivity to the underlay network is down.

**Note**

Multi-peer MLAG is not supported.

- MLAG with alternate IP configuration, disables the local MLAG ports when the MLAG peer is alive, but the ISC port alone goes down. This feature is used to prevent duplication of packets if MLAG peers are part of larger L2 domain. For VXLAN, MLAG peers connect to an L3 cloud on their upstream (northbound) interface and they share the same L3 ECMP IP address. Other VTEPs use L3 ECMP to send traffic to one of the MLAG peers. With an alternate IP configured and ISC going down, traffic hashing towards an MLAG peer, which disabled its MLAG ports, results in dropped traffic. So it is recommended not to configure MLAG alternate IP feature on VXLAN VTEPs.

**Note**

In a VXLAN and MLAG environment where a node has two MLAG peers, even when MLAG alternate IP address is not configured, traffic disruption likely occurs when an ISC connection is lost between any of the MLAG peers.

- MLAG does not function if the Inter-Switch Connection (ISC) port is added to an untagged tenant VMAN.

## Statistics

Per virtual network and per remote endpoint counters are supported. Both byte and packet counts are available.

Virtual network counters display the sum of all counters from all remote endpoints associated with the virtual network. Packets that arrived encapsulated on the VXLAN network port are counted on the virtual network as Rx bytes/packets (network side), and also, are counted as Tx bytes/packets (access side). For example, if 10 packets are received from remote endpoint 1.1.1.2 on virtual network vnet44, Rx Frames are 10, since 10 frames are received on the virtual network from the network interface (VXLAN encapsulated packets). Also, TX frames are 10, since 10 frames are transmitted on the virtual network tenant interface (native, non-VXLAN encapsulated packets). Similarly, on the other direction.

Remote endpoint counters display the sum of all counters from all virtual networks associated with the remote endpoint. Currently, it is not possible to display the counters for a given virtual network/remote endpoint pair.

## VXLAN + VMAN Customer Edge Ports Support

---

The following VMAN with Customer Edge Ports (CEP) can be configured as VXLAN Tenant VMANs:

- CEP with or without VLAN Translation
- CEP with port-cvid
- VMAN ports with Egress cvid Filtering
- VMAN ports with a secondary Ethertype

### Note

This support does not apply to VPX Extended Ports.

### Note

Egress filtering cannot be configured on network ports. If configured, there will be a drop in (VXLAN/MPLS) tunneled packets.

## Policy and VXLAN

---

Version 32.6 adds support for policy and VXLAN static provisioning. Virtual networks and tenant VLANs must be statically created. NetLogin and static policy profiles facilitate user authentication through RADIUS and attach the users to the appropriate VLANs that are provisioned already.

Only a limited number of users (100 or fewer) is supported. Because the maximum number of policy profiles supported is 63, this feature can be used with a maximum of 63 virtual networks.

## Limitations

- Dynamic VLANs are not supported.
- Dynamic virtual networks are not supported.
- Non-policy mode is not supported.
- RIOT is not supported.
- The policy must have TCI overwrite enabled.

## Configuring VXLAN

---

The following section show how to configure VXLAN.

## Adding and Deleting Tunnel Terminating Ports

When a port is added as VXLAN (virtual-network) network port, traffic from VXLAN tunnel (where it is terminated) is sent downstream to the tenants (hosts). If that port

is not part of virtual network network-port, traffic arriving from the tunnel (if tunnel ends here), traffic is not sent downstream to tenants. This port designation determines which ports can receive traffic from VXLAN tunnels. However, traffic from the tenant (host) to the virtual network (where tunnel originates) flows regardless.

To add ports that can terminate tunnels carrying VXLAN or NVGRE encapsulated traffic, use the following command:

```
configure virtual-network add network ports [all | portlist]
```

To delete ports that can terminate tunnels carrying VXLAN or NVGRE encapsulated traffic, use the following command:

```
configure virtual-network delete network ports [all | portlist]
```

## Configuring Local Endpoints

The local VTEP IP address is used as source IP address in VXLAN encapsulated frames and is configured using the `configure virtual-network local-endpoint [ ipaddress ipaddress { vr vr_name } | none ]` command.

### Note

A VTEP can have only one local endpoint IP.

## Enabling and Disabling Remote Endpoints

To enable a remote endpoint, use the following command:

```
enable virtual-network remote-endpoint vxlan [ipaddress ipaddress {vr vr_name} | all]
```

To manually disable a remote endpoint, use the following command:

```
disable virtual-network remote-endpoint vxlan [ipaddress ipaddress {vr vr_name} | all]
```

To see if a remote endpoint is enabled or disabled, use the following command:

```
show virtual-network {vn_name} remote-endpoint vxlan {vni vni}
{ipaddress ipaddress {vr vr_name}}
```

## Configuring Edge Automation

### *Creating and Deleting Databases*

To create a database, use the following command:

```
create database database_name
```

To delete a database, use the following command:

```
delete database database_name
```

#### *Configuring Databases*

To add a server to a database, use the following command:

```
configure database database_name add server [host_name | ip_address]
{port port_number} {password [encrypted encrypted_password | password]}
```

To delete a server from a database, use the following command:

```
configure database database_name delete server [host_name | ip_address |
all]
```

To change the password of a databases, use the following command:

```
configure database database_name server [host_name | ip_address]
password [encrypted encrypted_password | password]
```

To change the time interval between retries, use the following command:

```
configure database max-retry-interval retry_interval
```

To connect or disconnect a database, use the following command:

```
configure automation edge [connect | disconnect] database database_name
```

#### *Displaying Edge Automation Information*

To view information about servers connected to databases, use the following command:

```
show database database_name
```

To view information about databases, use the following command:

```
show automation edge devices {vni vni}
```

To view information about database network devices, use the following command:

```
show automation edge devices {vni vni}
```

## configure database max-retry-interval

```
configure database max-retry-interval retry_interval
```

#### *Description*

Specifies the maximum value for exponentially increasing time interval between retries for an Automation Edge remote VXLAN network identifier (VNI)-device database.

*Syntax Description*

|                                 |                                                                                                                            |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>database</code>           | Makes time interval retries remote VNI-database.                                                                           |
| <code>max-retry-interval</code> | Specifies setting the maximum value for exponentially increasing time interval between retries.                            |
| <code>retry_interval</code>     | Specifies the value for the maximum time interval between retries in seconds. The default is 600. The range is 1 to 3,600. |

*Default*

If not specified, the maximum retry interval is 600 seconds.

*Usage Guidelines*

N/A.

*Example*

The following example sets the maximum retry interval to 800 seconds:

```
configure database max-retry-interval 800
```

*History*

This command was first available in ExtremeXOS 31.1 as a demonstration feature.

This command is fully supported in ExtremeXOS 31.2.

*Platform Availability*

This command is available on all Universal switches supported in this document.

## Configuring Assisted Replication

To configure the assisted replication role on a switch, or if the switch role is replicator, to also configure the default selected replicator for all virtual networks created subsequently, use the following command:

```
configure virtual-network replication-role [rnve | replicator | leaf
{selected-replicator-default ipaddress}]
```

To view virtual network information, use the following command:

```
show virtual-network {vn_name | vxlan vni vni | [vlan vlan_name | vman
vman_name] }
```

## Configuring Policy and VXLAN

The following examples configure policy and VXLAN with various options.

```
create vlan "v123"
```

```
configure vlan v123 tag 123
```

```

create virtual-network "test" flooding standard

configure virtual-network "test" vxlan vni 1003

configure virtual-network "test" add vlan v123

configure policy profile 1 name "policy" pvid-status "enable" pvid 123
cos-status

enable netlogin ports 1 mac

configure netlogin add mac-list 00:00:01:00:00:00

```

## Configuration Samples

### Configuration Example for Flood Mode Standard

This configuration example shows how to configure VXLAN in flood mode standard:

#### Note

Only VXLAN-specific commands are shown.

```

configure virtual-network local-endpoint ipaddress 1.1.1.1
create virtual-network VNET1
configure virtual-network VNET1 vxlan vni 1
disable igmp snooping tenant1
configure virtual-network VNET1 add vlan tenant1
enable ospf vxlan-extensions

```

Remote endpoints are learned dynamically using *OSPF* VXLAN extensions. These are not saved to the configuration. Alternately, you can create a static remote endpoint using the following commands:

```

create virtual-network remote-endpoint vxlan ipaddress 2.2.2.2
configure virtual-network VNET1 add remote-endpoint vxlan ipaddress 2.2.2.2

```

Issuing the preceding commands on an existing dynamic remote endpoint changes it to a static remote endpoint. Static remote endpoints are saved to the configuration and persistent across reboots.

### Configuration Example for Flood Mode Explicit

This configuration example shows how to configure VXLAN in flood mode explicit:

#### Note

Only VXLAN specific commands has been listed here.

```

configure virtual-network local-endpoint ipaddress 1.1.1.1
create virtual-network VNET1 flooding explicit-remotes
configure virtual-network VNET1 vxlan vni 1
disable igmp snooping tenant1
configure virtual-network VNET1 add vlan tenant1

```

The following commands dictate tenant broadcast traffic to be sent to remote endpoints 2.2.2.2 and 3.3.3.3:

```
create fdb broadcast vlan tenant1 vxlan ipaddress 2.2.2.2
configure fdb broadcast vlan tenant1 add vxlan ipaddress 3.3.3.3
```

The unknown unicast and multicast tenant traffic is controlled by using the following command options:

```
create fdb unknown-unicast
create fdb unknown-multicast ...
```

## Configuration Example for MLAG

This configuration example shows how to configure with VXLAN. In the following example:

- The MLAG switches are operating as independent *OSPF* routers. They must use different router IDs.
- The same local endpoint address is configured on both switches.
- The ISC link also functions as a routed link with a high metric. The link is also used when one switch loses all underlay connectivity.

### Switch #1 Configuration

```
create vlan "ospf_loop"
enable loopback-mode vlan ospf_loop
configure vlan ospf_loop ipaddress 10.10.10.141 255.255.255.255
enable ipforwarding vlan ospf_loop
config ospf routerid 10.10.10.141
create vlan "route-isc"
configure vlan route-isc ipaddress 100.0.0.141 255.255.255.0
enable ipforwarding vlan route-isc
configure ospf vlan route-isc cost 65535
create vlan "vltep"
enable loopback-mode vlan vltep
configure vlan vltep ipaddress 10.10.10.200 255.255.255.255
enable ipforwarding vlan vltep
configure virtual-network local-endpoint ipaddress 10.10.10.200 vr "VR-Default"
```

### Switch #2 Configuration

```
create vlan "ospf_loop"
enable loopback-mode vlan ospf_loop
configure vlan ospf_loop ipaddress 10.10.10.142 255.255.255.255
enable ipforwarding vlan ospf_loop
config ospf routerid 10.10.10.142
create vlan "route-isc"
configure vlan route-isc ipaddress 100.0.0.142 255.255.255.0
enable ipforwarding vlan route-isc
configure ospf vlan route-isc cost 65535
create vlan "vltep"
enable loopback-mode vlan vltep
configure vlan vltep ipaddress 10.10.10.200 255.255.255.255
enable ipforwarding vlan vltep
configure virtual-network local-endpoint ipaddress 10.10.10.200 vr "VR-Default"
```

*Flood Mode Multicast*

```
configure virtual-network local-endpoint ipaddress 1.1.1.1
create virtual-network VNET1 flooding multicast group 232.1.1.1
configure virtual-network VNET1 vxlan vni 1
disable igmp snooping tenant1
configure virtual-network VNET1 add vlan tenant1
enable ospf vxlan-extensions
```

# Glossary

---

## AAA

Authentication, Authorization, and Accounting is a system in IP-based networking to control which computer resources specific users can access and to keep track of the activity of specific users over the network.

## ACL

An Access Control List is a mechanism for filtering packets at the hardware level. Packets can be classified by characteristics such as the source or destination MAC, IP address, IP type, or QoS queue. Once classified, the packets can be forwarded, counted, queued, or dropped.

## ad hoc mode

An 802.11 networking framework in which devices or stations communicate directly with each other, without the use of an AP.

## ARP

Address Resolution Protocol is part of the TCP/IP suite used to dynamically associate a device's physical address (MAC address) with its logical address (IP address). The system broadcasts an ARP request, containing the IP address, and the device with that IP address sends back its MAC address so that traffic can be transmitted.

## AS

In OSPF, an Autonomous System is a connected segment of a network topology that consists of a collection of subnetworks (with hosts attached) interconnected by a set of routes. The subnetworks and the routers are expected to be under the control of a single administration. Within an AS, routers may use one or more interior routing protocols and sometimes several sets of metrics. An AS is expected to present to other autonomous systems an appearance of a coherent interior routing plan and a consistent picture of the destinations reachable through the AS. An AS is identified by a unique 16-bit number.

## ATM

Asynchronous Transmission Mode is a start/stop transmission in which each character is preceded by a start signal and followed by one or more stop signals. A variable time interval can exist between characters. ATM is the preferred technology for the transfer of images.

## BGP

Border Gateway Protocol is a router protocol in the IP suite designed to exchange network reachability information with BGP systems in other autonomous systems. You use a fully meshed configuration with BGP.

BGP provides routing updates that include a network number, a list of ASs that the routing information passed through, and a list of other path attributes. BGP works with cost metrics to choose the best available path; it sends updated router information only when one host has detected a change, and only the affected part of the routing table is sent.

BGP communicates within one AS using Interior BGP (IBGP) because BGP does not work well with IGP. Thus the routers inside the AS maintain two routing tables: one for the IGP and one for IBGP. BGP uses exterior BGP (EBGP) between different autonomous systems.

## BPDU

In STP, a Bridge Protocol Data Unit is a packet that initiates communication between devices. BPDU packets contain information on ports, addresses, priorities, and costs and they ensure that the data ends up where it was intended to go. BPDU messages are exchanged across bridges to detect loops in a network topology. The loops are then removed by shutting down selected bridge interfaces and placing redundant switch ports in a backup, or blocked, state.

## bridge

In conventional networking terms, bridging is a Layer 2 function that passes frames between two network segments; these segments have a common network layer address. The bridged frames pass only to those segments connected at a Layer 2 level, which is called a broadcast domain (or VLAN). You must use Layer 3 routing to pass frames between broadcast domains (VLANs).

In wireless technology, bridging refers to forwarding and receiving data between radio interfaces on APs or between clients on the same radio. So, bridged traffic can be forwarded from one AP to another AP without having to pass through the switch on the wired network.

## BSS

Basic Service Set is a wireless topology consisting of one access point connected to a wired network and a set of wireless devices. Also called an infrastructure network. See also *[IBSS \(Independent Basic Service Set\)](#)*.

## CCM

In CFM, Connectivity Check Messages are frames transmitted periodically by a MEP to ensure connectivity across the maintenance entities to which the transmitting MEP belongs. The CCMs contain a unique ID for the specified domain. Because a failure to receive a CCM indicates a connectivity fault in the network, CCMs proactively check for network connectivity.

## CEP

Customer Edge Port, also known as Selective Q-in-Q or C-tagged Service Interface, is a role that is configured in software as a CEP VMAN port, and connects a VMAN to specific CVLANs based on the CVLAN CVID. The CNP role, which is configured as an untagged VMAN port, connects a VMAN to all other port traffic that is not already mapped to the port CEP role.

## **CFM**

Connectivity Fault Management allows an ISP to proactively detect faults in the network for each customer service instance individually and separately. CFM comprises capabilities for detecting, verifying, and isolating connectivity failures in virtual bridged LANs.

## **CHAP**

Challenge-Handshake Authentication Protocol is one of the two main authentication protocols used to verify a user's name and password for PPP Internet connections. CHAP is more secure because it performs a three-way handshake during the initial link establishment between the home and remote machines. It can also repeat the authentication anytime after the link has been established.

## **CIST root port**

In an NSTO environment, the port on the CIST regional root bridge that connects to the CIST root bridge is the CIST root port. The CIST root port is the master port for all MSTIs in that MSTP region, and it is the only port that connects the entire region to the CIST root bridge.

## **CLI**

Command Line Interface. The CLI provides an environment to issue commands to monitor and manage switches and wireless appliances.

## **CoS**

Class of Service specifies the service level for the classified traffic type.

## **DCB**

Data Center Bridging is a set of IEEE 802.1Q extensions to standard Ethernet, that provide an operational framework for unifying Local Area Networks (LAN), Storage Area Networks (SAN) and Inter-Process Communication (IPC) traffic between switches and endpoints onto a single transport layer.

## **DHCP**

Dynamic Host Configuration Protocol allows network administrators to centrally manage and automate the assignment of IP addresses on the corporate network. DHCP sends a new IP address when a computer is plugged into a different place in the network. The protocol supports static or dynamic IP addresses and can dynamically reconfigure networks in which there are more computers than there are available IP addresses.

## **DoS attack**

Denial of Service attacks occur when a critical network or computing resource is overwhelmed so that legitimate requests for service cannot succeed. In its simplest form, a DoS attack is indistinguishable from normal heavy traffic. ExtremeXOS software has configurable parameters that allow you to defeat DoS attacks.

## **DSCP**

Differentiated Services Code Point is a field in the header of IP packets that is used for packet classification purposes.

## DSSS

Direct-Sequence Spread Spectrum is a transmission technology used in Local Area Wireless Network (LAWN) transmissions where a data signal at the sending station is combined with a higher data rate bit sequence, or chipping code, that divides the user data according to a spreading ratio. The chipping code is a redundant bit pattern for each bit that is transmitted, which increases the signal's resistance to interference. If one or more bits in the pattern are damaged during transmission, the original data can be recovered due to the redundancy of the transmission. (Compare with *[FHSS \(Frequency-Hopping Spread Spectrum\)](#)*.)

## EAP-TLS/EAP-TTLS

EAP-TLS Extensible Authentication Protocol - Transport Layer Security. A general protocol for authentication that also supports multiple authentication methods, such as token cards, Kerberos, one-time passwords, certificates, public key authentication and smart cards.

IEEE 802.1x specifies how EAP should be encapsulated in LAN frames.

In wireless communications using EAP, a user requests connection to a WLAN through an access point, which then requests the identity of the user and transmits that identity to an authentication server such as RADIUS. The server asks the access point for proof of identity, which the access point gets from the user and then sends back to the server to complete the authentication.

EAP-TLS provides for certificate-based and mutual authentication of the client and the network. It relies on client-side and server-side certificates to perform authentication and can be used to dynamically generate user-based and session-based WEP keys.

EAP-TTLS (Tunneled Transport Layer Security) is an extension of EAP-TLS to provide certificate-based, mutual authentication of the client and network through an encrypted tunnel, as well as to generate dynamic, per-user, per-session WEP keys.

Unlike EAP-TLS, EAP-TTLS requires only server-side certificates.

(See also *[PEAP \(Protected Extensible Authentication Protocol\)](#)*.)

## EAPS

Extreme Automatic Protection Switching is an Extreme Networks-proprietary version of the Ethernet Automatic Protection Switching protocol that prevents looping Layer 2 of the network. This feature is discussed in RFC 3619.

## ECMP

Equal Cost Multi Paths is a routing algorithm that distributes network traffic across multiple high-bandwidth OSPF, BGP, IS-IS, and static routes to increase performance. The Extreme Networks implementation supports multiple equal cost paths between points and divides traffic evenly among the available paths.

## edge safeguard

Loop prevention and detection on an edge port configured for RSTP. Configuring edge safeguard on RSTP edge ports can prevent accidental or deliberate misconfigurations (loops) resulting from connecting two edge ports together or from connecting a hub or other non-STP switch to an edge port. Edge safeguard also limits the impact of broadcast storms that might occur on edge ports. This advanced loop

prevention mechanism improves network resiliency but does not interfere with the rapid convergence of edge ports.

**EDP**

Extreme Discovery Protocol is a protocol used to gather topology information about neighboring Extreme Networks switches.

**ELRP**

Extreme Loop Recovery Protocol is an Extreme Networks-proprietary protocol that allows you to detect Layer 2 loops.

**ERPS**

Ethernet Ring Protection Switching provides fast protection and recovery switching for Ethernet traffic in a ring topology. It also ensures that the Ethernet layer remains loop-free. It is defined in ITU/T G.8032.

**ESRP**

Extreme Standby Router Protocol is an Extreme Networks-proprietary protocol that provides redundant Layer 2 and routing services to users.

**ESRP group**

An ESRP group runs multiple instances of ESRP within the same VLAN (or broadcast domain). To provide redundancy at each tier, use a pair of ESRP switches on the group. See [\*ESRP \(Extreme Standby Router Protocol\)\*](#).

**event**

Any type of occurrence on a switch that could generate a log message or require an action. For more, see [\*syslog\*](#).

**Extreme Defender for IoT**

Extreme Defender for IoT provides unique in-line security for mission critical and/or vulnerable IoT devices. Placed between the IoT device and the network, the Defender for IoT solution helps secure and isolate IoT devices protecting them from internal and external hacking attempts, viruses, malware and ransomware, DDoS attacks, and more. Designed to be simple and flexible, Defender for IoT can be deployed over any network infrastructure to enable secure IoT management without significant network changes.

The solution is comprised of the Extreme Defender Application Software and the Defender Adapter (SA201) or AP3912i access point. ExtremeCloud IQ Controller is the supported platform for the Extreme Defender Application.

For more information, see <https://www.extremenetworks.com/products/wi-fi-management/extremecloud-iq-controller/extremecloud-iq-controller>.

**ExtremeAnalytics for ExtremeCloud IQ - Site Engine**

ExtremeAnalytics™ for ExtremeCloud™ IQ - Site Engine, formerly Purview™, is a network powered application analytics and optimization solution that captures and analyzes context-based application traffic to deliver meaningful intelligence about applications, users, locations, and devices. ExtremeAnalytics for ExtremeCloud IQ - Site Engine provides data to show how applications are being used. This can

be used to better understand customer behavior on the network, identify the level of user engagement, and assure business application delivery to optimize the user experience. The software also provides visibility into network and application performance allowing IT to pinpoint and resolve performance issues in the infrastructure whether they are caused by the network, application, or server. Learn more at <https://www.extremenetworks.com/product/extremeanalytics-for-extremecloud-iq-site-engine/>.

## ExtremeCloud IQ Controller

Extreme Campus Controller has been rebranded to ExtremeCloud IQ Controller. The new ExtremeCloud IQ Controller supports Campus/Centralized sites only.

The ExtremeCloud IQ Controller is a next generation orchestration application offering all the mobility services required for modern unified access deployments offering simplified integration with ExtremeCloud IQ to take advantage of Cloud Visibility into the network. The ExtremeCloud IQ Controller extends the simplified workflows of the ExtremeCloud public cloud application to on-prem/private cloud deployments.

The ExtremeCloud IQ Controller includes comprehensive critical network services for wireless and wired connectivity, wireless device secure onboarding, distributed and centralized data paths, role-based access control through the Application Layer, integrated location services, and IoT device onboarding through a single platform.

Built on architecture with the latest technology, the embedded operating system supports application containers that enable future expansion of value added applications for the unified access edge.

## ExtremeCloud IQ - Site Engine

ExtremeCloud™ IQ - Site Engine (formerly known as Extreme Management Center and Netsight), is a web-based control interface that provides centralized visibility into your network. ExtremeCloud IQ - Site Engine reaches beyond ports, VLANs, and SSIDs and provides detailed control of individual users, applications, and protocols. When coupled with wireless and Identity & Access Management products, ExtremeCloud IQ - Site Engine becomes the central location for monitoring and managing all the components in the infrastructure. Learn more at <https://www.extremenetworks.com/product/extremecloud-iq-site-engine/>.

## ExtremeCloud™ IQ

ExtremeCloud™ IQ is an industry-leading and visionary approach to cloud-managed networking, built from the ground up to take full advantage of the Extreme Networks end-to-end networking solutions. ExtremeCloud IQ delivers unified, full-stack management of wireless access points, switches, and routers and enables onboarding, configuration, monitoring, troubleshooting, reporting, and more. Using innovative machine learning and artificial intelligence technologies, ExtremeCloud IQ analyzes and interprets millions of network and user data points, from the network edge to the data center, to power actionable business and IT insights, and deliver new levels of network automation and intelligence. Learn more about ExtremeCloud IQ at <https://www.extremenetworks.com/support/documentation/extremecloud-iq/>.

## ExtremeControl for ExtremeCloud IQ - Site Engine

ExtremeControl for ExtremeCloud™ IQ - Site Engine, formerly Extreme Access Control™ (EAC), is a set of management software tools that use information gathered by a hardware engine to control policy to all devices on the network. The software allows you to automate and secure access for all devices on the network from a central dashboard, making it easier to roll out security and identity policies across the wired and wireless network. Learn more at <https://www.extremenetworks.com/product/extremecontrol-for-extremecloud-iq-site-engine/>.

### ExtremeWireless

ExtremeWireless products and solutions offer high-density Wi-Fi access, connecting your organization with employees, partners, and customers everywhere they go. The family of wireless products and solutions includes APs, wireless appliances, and software. Learn more about ExtremeWireless at <http://www.extremenetworks.com/products/wireless/>.

### ExtremeXOS

ExtremeXOS, a modular switch operating system, is designed from the ground up to meet the needs of large cloud and private data centers, service providers, converged enterprise edge networks, and everything in between. Based on a resilient architecture and protocols, ExtremeXOS supports network virtualization and standards-based SDN capabilities like VXLAN gateway and OpenStack Cloud orchestration. ExtremeXOS also supports comprehensive role-based policy.

### FDB

The switch maintains a database of all MAC address received on all of its ports and uses this information to decide whether a frame should be forwarded or filtered. Each forwarding database (FDB) entry consists of the MAC address of the sending device, an identifier for the port on which the frame was received, and an identifier for the VLAN to which the device belongs. Frames destined for devices that are not currently in the FDB are flooded to all members of the VLAN. For some types of entries, you configure the time it takes for the specific entry to age out of the FDB.

### FHSS

Frequency-Hopping Spread Spectrum is a transmission technology used in Local Area Wireless Network (LAWN) transmissions where the data signal is modulated with a narrowband carrier signal that 'hops' in a random but predictable sequence from frequency to frequency as a function of time over a wide band of frequencies. This technique reduces interference. If synchronized properly, a single logical channel is maintained. (Compare with *DSSS (Direct-Sequence Spread Spectrum)*.)

### gratuitous ARP

When a host sends an ARP request to resolve its own IP address, it is called gratuitous ARP.

### IBSS

An IBSS is the 802.11 term for an ad hoc network. See *ad hoc mode*.

### ICMP

Internet Control Message Protocol is the part of the TCP/IP protocol that allows generation of error messages, test packets, and operating messages. For example, the ping command allows you to send ICMP echo messages to a remote IP device to test for connectivity. ICMP also supports traceroute, which identifies intermediate hops between a given source and destination.

#### **IGMP**

Hosts use Internet Group Management Protocol to inform local routers of their membership in multicast groups. Multicasting allows one computer on the Internet to send content to multiple other computers that have identified themselves as interested in receiving the originating computer's content. When all hosts leave a group, the router no longer forwards packets that arrive for the multicast group.

#### **IGP**

Interior Gateway Protocol refers to any protocol used to exchange routing information within an AS. Examples of Internet IGPs include RIP and OSPF.

#### **LAG**

A Link Aggregation Group is the logical high-bandwidth link that results from grouping multiple network links in link aggregation (or load sharing). You can configure static LAGs or dynamic LAGs (using the LACP).

#### **LLDP**

Link Layer Discovery Protocol conforms to IEEE 802.1ab and is a neighbor discovery protocol. Each LLDP-enabled device transmits information to its neighbors, including chassis and port identification, system name and description, VLAN names, and other selected networking information. The protocol also specifies timing intervals in order to ensure current information is being transmitted and received.

#### **LSDB**

In OSPF, a Link State Database is a database of information about the link state of the network. Two neighboring routers consider themselves to be adjacent only if their LSDBs are synchronized. All routing information is exchanged only between adjacent routers.

#### **MD5**

Message-Digest algorithm is a hash function that is commonly used to generate a 128-bit hash value. It was designed by Ron Rivest in 1991. MD5 is officially defined in RFC 1321 - The MD5 Message-Digest Algorithm.

#### **MEP**

In MEP, a Maintenance End Point is an end point for a single domain, or maintenance association. The MEP may be either an UP MEP or a DOWN MEP.

#### **MIB**

Management Information Bases make up a database of information (for example, traffic statistics and port settings) that the switch makes available to network management systems. MIB names identify objects that can be managed in a network and contain information about the objects. MIBs provide a means to configure

a network device and obtain network statistics gathered by the device. Standard, minimal MIBs have been defined, and vendors often have private enterprise MIBs.

## MIC

Message Integrity Check (or Code), also called 'Michael', is part of WPA and TKIP. The MIC is an additional 8-byte code inserted before the standard 4-byte ICV appended in by standard WEP to the 802.11 message. This greatly increases the difficulty in carrying out forgery attacks.

Both integrity check mechanisms are calculated by the receiver and compared against the values sent by the sender in the frame. If the values match, there is assurance that the message has not been tampered with.

## MLAG

The Multi-switch Link Aggregation Group feature allows users to combine ports on two switches to form a single logical connection to another network device. The other network device can be either a server or a switch that is separately configured with a regular LAG (or appropriate server port teaming) to form the port aggregation.

## MPLS

Multiprotocol Label Switching speeds up network traffic. When forwarding packets, the Layer 2 (Switching) label is used to avoid complex destination lookups in the routing table. MPLS uses Label Switched Paths (LSPs) to establish the network path. The packet will be labeled so that service providers can decide the best way to keep traffic flowing. The Multiprotocol Label Switching Transport Profile (MPLS-TP) extensions to MPLS are designed to meet service provider requirements and are used as a network layer technology in transport networks. MPLS-TP gives service providers a reliable packet-based technology that is based on circuit-based transport networking. MPLS-TP is expected to be a low cost level 2 technology (if the limited profile is implemented in isolation) that will provide QoS, end-to-end OAM and protection switching.

## MSDP

Multicast Source Discovery Protocol is used to connect multiple multicast routing domains. MSDP advertises multicast sources across Protocol Independent Multicast-Sparse Mode (PIM-SM) multicast domains or Rendezvous Points (RPs). In turn, these RPs run MSDP over TCP to discover multicast sources in other domains.

## MSTI

Multiple Spanning Tree Instances control the topology inside an MSTP region. An MSTI is a spanning tree domain that operates within a region and is bounded by that region; and MSTI does not exchange BPDUs or send notifications to other regions. You can map multiple VLANs to an MSTI; however, each VLAN can belong to only one MSTI. You can configure up to 64 MSTIs in an MSTP region.

## MSTP

Multiple Spanning Tree Protocol, based on IEEE 802.1Q-2003 (formerly known as IEEE 892.1s), allows you to bundle multiple VLANs into one STP topology, which also provides enhanced loop protection and better scaling. MSTP uses RSTP as the converging algorithm and is compatible with legacy STP protocols.

## NetLogin

Network login provides extra security to the network by assigning addresses only to those users who are properly authenticated. You can use web-based, MAC-based, or IEEE 802.1X-based authentication with network login. The two modes of operation are campus mode and ISP mode.

## netmask

A netmask is a string of 0s and 1s that mask, or screen out, the network part of an IP address, so that only the host computer part of the address remains. A frequently-used netmask is 255.255.255.0, used for a Class C subnet (one with up to 255 host computers). The ".0" in the netmask allows the specific host computer address to be visible.

## OSPF

An interior gateway routing protocol for TCP/IP networks, Open Shortest Path First uses a link state routing algorithm that calculates routes for packets based on a number of factors, including least hops, speed of transmission lines, and congestion delays. You can also configure certain cost metrics for the algorithm. This protocol is more efficient and scalable than vector-distance routing protocols. OSPF features include least-cost routing, ECMP routing, and load balancing. Although OSPF requires CPU power and memory space, it results in smaller, less frequent router table updates throughout the network. This protocol is more efficient and scalable than vector-distance routing protocols.

## OSPFv3

Open Shortest Path First version 3 is one of the routing protocols used with IPV6 and is similar to OSPF.

## PEAP

Protected Extensible Authentication Protocol is an IETF draft standard to authenticate wireless LAN clients without requiring them to have certificates. In PEAP authentication, first the user authenticates the authentication server, then the authentication server authenticates the user. If the first phase is successful, the user is then authenticated over the SSL tunnel created in phase one using EAP-Generic Token Card (EAP-GTC) or Microsoft Challenged Handshake Protocol Version 2 (MSCHAP V2). (See also [EAP-TLS/EAP-TTLS](#).)

## PoE

The Power over Ethernet standard (IEEE 802.3af) defines how power can be provided to network devices over existing Ethernet connections, eliminating the need for additional external power supplies.

## QoS

Quality of Service is a technique that is used to manage network resources and guarantee a bandwidth relationship between individual applications or protocols. A communications network transports a multitude of applications and data, including high-quality video and delay-sensitive data such as real-time voice. Networks must provide secure, predictable, measurable, and sometimes guaranteed services. Achieving the required QoS becomes the secret to a successful end-to-end business solution.

## RADIUS

RADIUS is a client/server protocol and software that enables remote access servers to communicate with a central server to authenticate dial-in users and authorize their access to the requested system or service. RADIUS allows a company to maintain user profiles in a central database that all remote servers can share. It provides better security, allowing a company to set up a policy that can be applied at a single administered network point. With RADIUS, you can track usage for billing and for keeping network statistics.

#### **rate limiting**

In QoS, rate limiting is the process of restricting traffic to a peak rate (PR).

#### **rate shaping**

In QoS, rate shaping is the process of reshaping traffic throughput to give preference to higher priority traffic or to buffer traffic until forwarding resources become available.

#### **RIP**

This IGP vector-distance routing protocol is part of the TCP/IP suite and maintains tables of all known destinations and the number of hops required to reach each. Using Routing Information Protocol, routers periodically exchange entire routing tables. RIP is suitable for use only as an IGP.

#### **RIPng**

Routing Information Protocol Next Generation is one of the routing protocols used with IPv6 and is similar to RIP.

#### **RSTP**

Rapid Spanning Tree Protocol, described in IEEE 802.1w, is an enhanced version of STP that provides faster convergence. The Extreme Networks implementation of RSTP allows seamless interoperability with legacy STP.

#### **segment**

In Ethernet networks, a section of a network that is bounded by bridges, routers, or switches. Dividing a LAN segment into multiple smaller segments is one of the most common ways of increasing available bandwidth on the LAN.

#### **SNMP**

Simple Network Management Protocol is a standard that uses a common software agent to remotely monitor and set network configuration and runtime parameters. SNMP operates in a multivendor environment, and the agent uses MIBs, which define what information is available from any manageable network device. You can also set traps using SNMP, which send notifications of network events to the system log.

#### **SNTP**

Simple Network Time Protocol is used to synchronize the system clocks throughout the network. An extension of NTP, SNTP can usually operate with a single server and allows for IPv6 addressing.

#### **SSH**

Secure Shell, sometimes known as Secure Socket Shell, is a UNIX-based command interface and protocol of securely gaining access to a remote computer. With SSH commands, both ends of the client/server connection are authenticated using a digital certificate, and passwords are protected by being encrypted. At Extreme Networks, the SSH is a separate software module, which must be downloaded separately. (SSH is bundled with SSL in the software module.)

## SSL

Secure Socket Layer is a protocol for transmitting private documents using the Internet. SSL works by using a public key to encrypt data that is transferred over the SSL connection. SSL uses the public-and-private key encryption system, which includes the use of a digital certificate.

## STP

Spanning Tree Protocol, defined in IEEE 802.1d, used to eliminate redundant data paths and to increase network efficiency. STP allows a network to have a topology that contains physical loops; it operates in bridges and switches. STP opens certain paths to create a tree topology, thereby preventing packets from looping endlessly on the network. To establish path redundancy, STP creates a tree that spans all of the switches in an extended network, forcing redundant paths into a standby, or blocked, state.

STP allows only one active path at a time between any two network devices (this prevents the loops) but establishes the redundant links as a backup if the initial link should fail. If STP costs change, or if one network segment in the STP becomes unreachable, the spanning tree algorithm reconfigures the STP topology and re-establishes the link by activating the standby path.

## STPD

Spanning Tree Domain is an STP instance that contains one or more VLANs. The switch can run multiple STPDs, and each STPD has its own root bridge and active path. In the Extreme Networks implementation of STPD, each domain has a carrier VLAN (for carrying STP information) and one or more protected VLANs (for carrying the data).

## syslog

A protocol used for the transmission of event notification messages across networks, originally developed on the University of California Berkeley Software Distribution (BSD) TCP/IP system implementations, and now embedded in many other operating systems and networked devices. A device generates a messages, a relay receives and forwards the messages, and a collector (a syslog server) receives the messages without relaying them.

syslog uses the UDP as its underlying transport layer mechanism. The UDP port that has been assigned to syslog is 514. (RFC 3164)

## UDP

User Datagram Protocol is an efficient but unreliable, connectionless protocol that is layered over IP (as is TCP). Application programs must supplement the protocol to provide error processing and retransmitting data. UDP is an OSI Layer 4 protocol.

## VLAN

The term VLAN is used to refer to a collection of devices that communicate as if they are on the same physical LAN. Any set of ports (including all ports on the switch) is considered a VLAN. LAN segments are not restricted by the hardware that physically connects them. The segments are defined by flexible user groups you create with the CLI.

## **VMAN**

In ExtremeXOS software, Virtual MANs are a bi-directional virtual data connection that creates a private path through the public network. One VMAN is completely isolated from other VMANs; the encapsulation allows the VMAN traffic to be switched over Layer 2 infrastructure. You implement VMAN using an additional 892.1Q tag and a configurable EtherType; this feature is also known as Q-in-Q switching.

## **VR-Control**

This virtual router is part of the embedded system in Extreme Networks switches. VR-Control is used for internal communications between all the modules and subsystems in the switch. It has no ports, and you cannot assign any ports to it. It also cannot be associated with VLANs or routing protocols. (Referred to as VR-1 in earlier ExtremeXOS software versions.)

## **VR-Default**

This virtual router is part of the embedded system in Extreme Networks switches. VR-Default is the default VR on the system. All data ports in the switch are assigned to this VR by default; you can add and delete ports from this VR. Likewise, VR-Default contains the default VLAN. Although you cannot delete the default VLAN from VR-Default, you can add and delete any user-created VLANs. One instance of each routing protocol is spawned for this VR, and they cannot be deleted. (Referred to as VR-2 in earlier ExtremeXOS software versions.)

## **VR-Mgmt**

This virtual router is part of the embedded system in Extreme Networks switches. VR-Mgmt enables remote management stations to access the switch through Telnet, SSH, or SNMP sessions; and it owns the management port. The management port cannot be deleted from this VR, and no other ports can be added. The Mgmt VLAN is created VR-Mgmt, and it cannot be deleted; you cannot add or delete any other VLANs or any routing protocols to this VR. (Referred to as VR-0 in earlier ExtremeXOS software versions.)

## **VRRP**

The Virtual Router Redundancy Protocol specifies an election protocol that dynamically assigns responsibility for a virtual router to one of the VRRP routers on a LAN. The VRRP router controlling the IP address(es) associated with a virtual router is called the master router, and forwards packets sent to these IP addresses. The election process provides dynamic failover in the forwarding responsibility should the master router become unavailable. In case the master router fails, the virtual IP address is mapped to a backup router's IP address; this backup becomes the master router. This allows any of the virtual router IP addresses on the LAN to be used as the default first-hop router by end-hosts. The advantage gained from using VRRP is a higher availability default

path without requiring configuration of dynamic routing or router discovery protocols on every host. VRRP is defined in RFC 2338.

## VXLAN

VXLAN is a network virtualization technology that leverages existing Layer 3 infrastructures to create tenant overlay networks. VXLAN addresses the requirements of a multi-tenant data center network infrastructure by:

- Increasing virtual network scalability to 16 million instances. This allows for tenant VLAN (Virtual LAN) isolation whereby multiple tenants can manage their own VLAN/VMAN and MAC address spaces.
- Adding an encapsulation that effectively hides VM MAC addresses from the physical network that results in physical networking devices to have smaller MAC and IP table sizes.
- Allowing for Layer 2 adjacency across IP networks by which DC network operators protect their investment in their current infrastructure. Additionally operators can distribute traffic loads across links efficiently using Layer 3 ECMP.

## WLAN

Wireless Local Area Network.

## XNV

Extreme Network Virtualization is an ExtremeXOS feature that enables the software to support VM port movement, port configuration, and inventory on network switches.

## ping

```
ping {count count {start-size start-size} | continuous {start-size
start-size} | {start-size start-size {end-size end-size}}} {udp}
{dont-fragment} {ttl ttl} {tos tos} {interval interval} {vr vrid}
{ipv4 host | ipv6 host} {from} {with record-route}
```

### Description

Enables you to send User Datagram Protocol (UDP) or *ICMP (Internet Control Message Protocol)* echo messages or to a remote IP device.

### Syntax Description

|                   |                                                                                                                                                                                                                                                                                           |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>count</i>      | Specifies the number of ping requests to send.                                                                                                                                                                                                                                            |
| <i>start-size</i> | Specifies the size, in bytes, of the packet to be sent, or the starting size if incremental packets are to be sent.                                                                                                                                                                       |
| continuous        | Specifies that UDP or ICMP echo messages to be sent continuously. This option can be interrupted by pressing <b>[Ctrl] + C</b> .                                                                                                                                                          |
| <i>end-size</i>   | Specifies an end size for packets to be sent.                                                                                                                                                                                                                                             |
| udp               | Specifies that the ping request should use UDP instead of ICMP.                                                                                                                                                                                                                           |
| dont-fragment     | Sets the IP to not fragment the bit.                                                                                                                                                                                                                                                      |
| ttl               | Sets the TTL value.                                                                                                                                                                                                                                                                       |
| <i>tos</i>        | Sets the TOS value.                                                                                                                                                                                                                                                                       |
| <i>interval</i>   | Sets the time interval between sending out ping requests.                                                                                                                                                                                                                                 |
| vr                | Specifies the virtual route to use for sending out the echo message. If not specified, <i>VR-Default</i> is used.<br><br><b>Note:</b> User-created VRs are supported only on the platforms listed for this feature in the <a href="#">Switch Engine v33.3.1 Licensing Guide</a> document. |
| ipv4              | Specifies IPv4 transport.                                                                                                                                                                                                                                                                 |
| ipv6              | Specifies IPv6 transport.<br><br><b>Note:</b> If you are contacting an IPv6 link local address, you must specify the <i>VLAN (Virtual LAN)</i> you are sending the message from: ping <b>ipv6</b> link-local address %vlan_name host.                                                     |

|                          |                                                                                                         |
|--------------------------|---------------------------------------------------------------------------------------------------------|
| <i>host</i>              | Specifies a host name or IP address (either v4 or v6).                                                  |
| <i>from</i>              | Uses the specified source address. If not specified, the address of the transmitting interface is used. |
| <i>with record-route</i> | Sets the traceroute information.                                                                        |

## Default

N/A.

## Usage Guidelines

The `ping` command is used to test for connectivity to a specific host.

You use the `ipv6` variable to ping an IPv6 host by generating an ICMPv6 echo request message and sending the message to the specified address. If you are contacting an IPv6 link local address, you must specify the VLAN you are sending the message from, as shown in the following example (you must include the % sign):

```
ping ipv6 link-local address %vlan_name host.
```

The `ping` command is available for both the user and administrator privilege level.

When the IPv6 host ping fails, the following error message appears:

```
Error: cannot determine outgoing interface. Link local address must be of form LLA%
vlan_name.
```

Due to upgrading ExtremeXOS 30.1 to 4.14 Linux kernel, ping success to local IP addresses does not depend on link-layer status. Earlier releases of ExtremeXOS had customized Linux behavior that meant that pinging a local VLAN interface would fail when the local interface was down. However, in ExtremeXOS 30.1, pinging a local VLAN interface that is down will result in a successful ping.

If you have an asymmetric routing to a specific destination (where the traffic from the source to the destination uses one path, and the return traffic uses another), use this command with option 7, **with record-route**.

For example:

```
ping <destination address> with record-route
ping <destination address> from <source-address> with record-route
```

For more information about this option, see [enable ip-option record-route](#).

## Example

The following example enables continuous ICMP echo messages to be sent to a remote host:

```
ping continuous 123.45.67.8
```

The following example uses the with record-route option:

```
ping 10.2.1.1 from 10.2.1.2 with record-route
Ping(ICMP) 10.2.1.1: 4 packets, 8 data bytes, interval 1 second(s).
16 bytes from 10.2.1.1: icmp_seq=0 ttl=63 time=10 ms
RR: 10.2.1.2 10.2.0.21 10.2.1.1 10.2.1.1 10.2.0.1 10.2.1.2
```

## History

---

This command was first available in ExtremeXOS 10.1.

The **ipv6** option was added in ExtremeXOS 11.2.

The IPv6 error message was modified in ExtremeXOS 15.2.

Ping success to local IP addresses not depend on link-layer status added in ExtremeXOS 30.1.

## Platform Availability

---

This command is available on all Universal switches supported in this document.

## telnet

```
telnet {vr vr_name} [host_name | remote_ip] {port}
```

### Description

---

Allows you to Telnet from the current command-line interface session to another host.

### Syntax Description

---

|                  |                                                                                                                                                                                                            |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>vr</i>        | Specifies use of a virtual router.<br><br><b>Note:</b> User-created VRs are supported only on the platforms listed for this feature in the <a href="#">Switch Engine v33.3.1 Licensing Guide</a> document. |
| <i>vr_name</i>   | Specifies the name of the virtual router.                                                                                                                                                                  |
| <i>host_name</i> | Specifies the name of the host.                                                                                                                                                                            |
| <i>remote_ip</i> | Specifies the IP address of the host.                                                                                                                                                                      |
| <i>port</i>      | Specifies a TCP port number. The default is port 23.                                                                                                                                                       |

### Default

---

- Telnet—enabled.
- Virtual router—Uses all virtual routers on the switch for outgoing Telnet requests.
- Port—23.

### Usage Guidelines

---

Only VT100 emulation is supported.

Before you can start an outgoing Telnet session, you need to configure the switch IP parameters. To open a Telnet connection, you must specify the host IP address or the host name of the device you want to connect to. Check the user manual supplied with the Telnet facility if you are unsure of how to do this. Although the switch accepts IPv6 connections, you can only Telnet from the switch to another device with an IPv4 address.

You must configure DNS in order to use the *host\_name* option.

---

## Host Name and Remote IP Address Character Restrictions

---

This section provides information about the characters supported by the switch for host names and remote IP addresses.

When specifying a host name or remote IP address, the switch permits only the following characters:

- Alphabetical letters, upper case and lower case (A-Z, a-z)
- Numerals (0-9)
- Period ( . )
- Dash ( - ) Permitted only for host names
- Underscore ( \_ ) Permitted only for host names
- Colon ( : )

When naming or configuring an IP address for your network server, remember the requirements listed above.

---

## Virtual Router Requirements

---

The `vr_name` option specifies the name of the virtual router. The valid virtual router names at system boot-up are *VR-Mgmt*, *VR-Control*, and *VR-Default*; however, you can only Telnet on VR-Mgmt and VR-Default. In ExtremeXOS 10.1, the valid virtual routers are VR-0, VR-1, and VR-2 respectively, and Telnet used VR-0 by default. For more information about virtual routers, see [Virtual Routers](#).

---

## Example

---

The following command starts a Telnet client communication to the host at IP address 123.45.67.8:

```
telnet 123.45.67.8
```

The following command starts a Telnet client communication with a host named sales:

```
telnet sales
```

---

## History

---

This command was first available in ExtremeXOS 10.1.

Support for the following virtual routers was added in ExtremeXOS 11.0: VR-Mgmt and VR-Default.

---

## Platform Availability

---

This command is available on all Universal switches supported in this document.

# virtual-router

virtual-router {vr-name}

## Description

Changes the VR context.

## Syntax Description

|         |                               |
|---------|-------------------------------|
| vr-name | Specifies the name of the VR. |
|---------|-------------------------------|

## Default

N/A.

## Usage Guidelines

Use this command to change the VR context for subsequent commands. When you issue the command, the prompt changes to reflect the VR domain. Configuration commands for Layer 3 routing protocols, creating VLANs, and deleting VLANs apply only to the current VR context.

Use this command with no name, or use the name "VR-Default" to return to the default configuration domain.

Under a VR configuration domain, any VR commands are applied only to that VR. The VR commands consist of all the BGP (Border Gateway Protocol), OSPF (Open Shortest Path First), PIM, and RIP (Routing Information Protocol) commands, and the commands listed in the following table.

**Table 180: VR Commands**

|                                              |
|----------------------------------------------|
| [enable   disable] ipforwarding              |
| clear iparp                                  |
| clear counters iparp <sup>12</sup>           |
| configure iparp <sup>12</sup>                |
| configure iparp [add   delete] <sup>12</sup> |
| [enable   disable] iparp <sup>12</sup>       |

<sup>12</sup> Other commands are available with these listed.

**Table 180: VR Commands (continued)**

|                                                |
|------------------------------------------------|
| show iparp <sup>12</sup>                       |
| configure iproute [add   delete] <sup>12</sup> |
| show iproute <sup>12</sup>                     |
| show ipstats <sup>12</sup>                     |
| rtlookup                                       |
| create [vlan   vman] <i>vlan-name</i>          |
| [enable   disable] igmp                        |
| [enable   disable] igmp snooping <sup>12</sup> |
| [enable   disable] ipmcforwarding              |
| show igmp                                      |
| show igmp snooping                             |
| show igmp group                                |
| show igmp snooping cache                       |
| [enable   disable] mld                         |
| [enable   disable] mld snooping                |
| show mld                                       |
| show mld snooping                              |
| show mld group                                 |

The VR context simplifies configuration because you do not have to specify the VR for each individual protocol configuration command. The current VR context is indicated in the CLI prompt.

For example, if you wish to configure OSPF for the user VR *vr-manufacturing*, you would change the VR context to that of *vr-manufacturing*. All the subsequent OSPF commands would apply to that VR, unless the context is changed again.

A VR is identified by a name (up to 32 characters long). The name must be unique among the VLAN (Virtual LAN) and VR names on the switch. For backward compatibility, you cannot name a virtual router VR-0, VR-1, or VR-2. VR names are case insensitive.

When a new VR is created, by default, no ports are assigned, no VLAN interface is created, and no support for any routing protocols is added.

## Example

The following example changes the VR context to "vr-acme":

```
virtual-router vr-acme
```

## History
