| <b>CmacMepId</b>      | Specifies the global MEP ID within the range of 1 to 8191. Select a unique ID for each switch to ensure that the MEPs are unique across the network. The default is 1. This field does not apply for all hardware platforms.                        |

| Name        | Description                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------|
| <b>Bmac</b> | Displays the B-MAC address of the node. This field does not apply for all hardware platforms. |
| <b>Cmac</b> | Displays the C-MAC address of the node. This field does not apply for all hardware platforms. |

### Configuring Explicit CFM

For SPBM B-VLANs, CFM provides two methods for creating MEPs: autogenerated and explicit. You cannot use both. Use the procedures in this section to configure MEPs explicitly.

If you want to create autogenerated CFM MEPs that eliminate the need to configure an MD, MA, and MEP ID, see the procedures in [Autogenerated CFM](#) on page 3857.

For C-VLANs, you can only use the autogenerated method.

#### Note

The CFM show commands that display MD, MA, and MEP information work for both autogenerated and explicitly-configured CFM MEPs.

### Configure CFM MD

Use this procedure to configure a Connectivity Fault Management (CFM) Maintenance Domain (MD). An MD is the part of a network that is controlled by a single administrator. A single MD can contain several Maintenance Associations (MA).

#### Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **CFM**.
3. Click the **MD** tab.
4. Click **Insert**.
5. In the fields provided, specify an index value, name, and level for the MD.
6. Click **Insert**.

### MD Field Descriptions

Use the data in the following table to use the **MD** tab.

| Name           | Description                                                         |
|----------------|---------------------------------------------------------------------|
| <b>Index</b>   | Specifies a maintenance domain entry index.                         |
| <b>Name</b>    | Specifies the MD name.                                              |
| <b>NumOfMa</b> | Indicates the number of MAs that belong to this maintenance domain. |

| Name            | Description                                                         |
|-----------------|---------------------------------------------------------------------|
| <b>Level</b>    | Specifies the MD maintenance level. The default is 4.               |
| <b>NumOfMip</b> | Indicates the number of MIPs that belong to this maintenance domain |
| <b>Type</b>     | Indicates the type of domain.                                       |

### Configure CFM MA

Use this procedure to configure a CFM Maintenance Association (MA). An MA represents a logical grouping of monitored entities within its Domain. It can therefore represent a set of Maintenance Endpoints (MEPs), each configured with the same Maintenance Association ID (MAID) and MD Level, established to verify the integrity of a single service instance.

#### Before You Begin

- You must configure a CFM MD.

#### Procedure

- In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
- Click **CFM**.
- Click the **MD** tab.
- Highlight an existing MD, and then click **MaintenanceAssociation**.
- In the **MA** tab, click **Insert**.
- In the fields provided, specify an index value and name for the MA.
- Click **Insert**.

### MA Field Descriptions

Use the data in the following table to use the **MA** tab.

| Name                    | Description                                                               |
|-------------------------|---------------------------------------------------------------------------|
| <b>DomainIndex</b>      | Specifies the maintenance domain entry index.                             |
| <b>AssociationIndex</b> | Specifies a maintenance association entry index.                          |
| <b>DomainName</b>       | Specifies the MD name.                                                    |
| <b>AssociationName</b>  | Specifies the MA name.                                                    |
| <b>NumOfMep</b>         | Indicates the number of MEPs that belong to this maintenance association. |

### Configure CFM MEP

Use this procedure to configure the CFM Maintenance Endpoint (MEP). A MEP represents a managed CFM entity, associated with a specific Domain Service Access Point (DoSAP) of a service instance, which can generate and receive CFM Protocol Data

Units (PDU) and track any responses. A MEP is created by MEP ID under the context of an MA.

**Procedure**

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **CFM**.
3. Click the **MD** tab.
4. Highlight an existing MD, and then click **MaintenanceAssociation**.
5. In the **MA** tab, highlight an existing MA, and then click **MaintenanceEndpoint**.
6. Click **Insert**.
7. In the fields provided, specify the ID and the administrative state of the MEP.
8. Click **Insert**.

**MEP Field Descriptions**

Use the data in the following table to use the **MEP** tab.

| Name                      | Description                                                                                                                                                                                                                                                                                                                         |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DomainIndex</b>        | Specifies the MD index.                                                                                                                                                                                                                                                                                                             |
| <b>AssociationIndex</b>   | Specifies the MA index.                                                                                                                                                                                                                                                                                                             |
| <b>Id</b>                 | Specifies the MEP ID.                                                                                                                                                                                                                                                                                                               |
| <b>DomainName</b>         | Specifies the MD name.                                                                                                                                                                                                                                                                                                              |
| <b>AssociationName</b>    | Specifies the MA name.                                                                                                                                                                                                                                                                                                              |
| <b>AdminState</b>         | Specifies the administrative state of the MEP. The default is disable.                                                                                                                                                                                                                                                              |
| <b>MepType</b>            | Specifies the MEP type: <ul style="list-style-type: none"> <li>• trunk</li> <li>• sg</li> <li>• endpt</li> <li>• vlan</li> <li>• port</li> <li>• endptClient</li> <li>• nodal</li> <li>• remotetrunk</li> <li>• remotesg</li> <li>• remoteendpt</li> <li>• remoteVlan</li> <li>• remotePort</li> <li>• remoteEndptClient</li> </ul> |
| <b>ServiceDescription</b> | Specifies the service to which this MEP is assigned.                                                                                                                                                                                                                                                                                |

**Configure CFM Nodal MEP**

Use this procedure to configure the CFM nodal Maintenance Endpoint (MEP). The Nodal MEP provides traceability and troubleshooting at the system level for a given

B-VLAN. The Nodal B-VLAN MEPs created on the CP and function as if they are connected to the virtual interface of the given B-VLAN. Because of this they are supported for both port and MLT based B-VLANs.

Nodal MPs provide both MEP and Maintenance Intermediate Point (MIP) functionality for SPBM deployments. Nodal MPs are associated with a B-VLAN and are VLAN encapsulated packets. Each node (chassis) has a given MAC address and communicates with other nodes. The SPBM instance MAC address is used as the MAC address of the Nodal MP.

### Before You Begin

- You must configure a CFM MD, MA, and MEP.

### Procedure

- In the navigation pane, expand **Configuration > VLAN**.
- Click **VLANs**.
- Click the **Advanced** tab.
- Select a VLAN with a type of spbm-bvlan.
- Click **Nodal**.
- In the **NodalMepList** field, specify the nodal MEPs to add to the VLAN.
- Click **Apply**.

### Nodal MEP/MIP Field Descriptions

Use the data in the following table to use the **Nodal MEP/MIP** tab.

| Name                      | Description                                                                                                                               |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NodalMepList</b>       | Specifies the nodal MEPs to add to the VLAN, in the format <mdName.maName.mepId>, for example md10.ma20.30.                               |
| <b>NumOfNodalMep</b>      | Indicates the number of nodal MEPs assigned to this VLAN.                                                                                 |
| <b>NodalMipLevelList</b>  | Specifies a MIP level list.                                                                                                               |
| <b>NumOfNodalMipLevel</b> | Indicates the number of nodal MIP levels assigned to this VLAN that allows MIP functionality to be enabled on a per level per VLAN basis. |

### Configure Layer 2 Ping

Use this procedure to configure a Layer 2 ping inside an SPBM cloud or network. This feature enables CFM to debug Layer 2. It can also help you debug IP shortcuts and the record for the shortcuts' ARP.

### Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.

**Procedure**

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **L2Ping/L2Trace Route**.
3. From the **L2Ping** tab, configure the Layer 2 ping properties.
4. To initiate a Layer 2 ping, highlight an entry and click the **Start** button.
5. To update a Layer 2 ping, click the **Refresh** button.
6. To stop the Layer 2 ping, click the **Stop** button.

**L2Ping Field Descriptions**

Use the data in the following table to use the **L2Ping** tab.

| Name                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>         | Identifies the backbone VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DestMacAddress</b> | Specifies the target MAC address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>HostName</b>       | Specifies the target host name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DestIsHostName</b> | Indicates whether the host name is (true) or is not (false) used for L2Ping transmission.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Messages</b>       | Specifies the number of L2Ping messages to be transmitted. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Status</b>         | <p>Specifies the status of the transmit loopback service:</p> <ul style="list-style-type: none"> <li>• ready: the service is available.</li> <li>• transmit: the service is transmitting, or about to transmit, the L2Ping messages.</li> <li>• abort: the service aborted or is about to abort the L2Ping messages.</li> </ul> <p>This field is also used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time. The default is ready.</p> |
| <b>ResultOk</b>       | <p>Indicates the result of the operation:</p> <ul style="list-style-type: none"> <li>• true: the L2Ping Messages will be (or have been) sent.</li> <li>• false: the L2Ping Messages will not be sent.</li> </ul> <p>The default is true.</p>                                                                                                                                                                                                                                                                                    |
| <b>Priority</b>       | <p>Specifies a 3-bit value to be used in the VLAN header, if present in the transmitted frame. The default is 7.</p>                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>TimeoutInt</b>     | <p>Specifies the interval to wait for an L2Ping time-out. The default value is 3 seconds.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Name               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TestPattern</b> | Specifies the test pattern to use in the L2Ping PDU: <ul style="list-style-type: none"> <li>• allZero: null signal without cyclic redundancy check</li> <li>• allZeroCrc: null signal with cyclic redundancy check with 32-bit polynomial</li> <li>• pseudoRandomBitSequence: pseudo-random-bit-sequence without cyclic redundancy check</li> <li>• pseudoRandomBitSequenceCrc: pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial.</li> </ul> A cyclic redundancy check is a code that detects errors. The default value is allZero. |
| <b>DataSize</b>    | Specifies an arbitrary amount of data to be included in the data TLV, if the data size is selected to be sent. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>FrameSize</b>   | Specifies the frame size. If the frame size is specified then the data size is internally calculated and the calculated data size is included in the data TLV. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SourceMode</b>  | Specifies the source mode of the transmit loopback service: <ul style="list-style-type: none"> <li>• nodal</li> <li>• noVlanMac — Use this value with C-VLAN only. When you select this option, even if a VLAN MAC address exists, the system uses the CFM C-MAC as the BMAC-SA.</li> <li>• smltVirtual — Use the smltVirtual option with B-VLANs only.</li> </ul> The default is nodal.                                                                                                                                                                          |
| <b>SeqNumber</b>   | The transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Result</b>      | Displays the Layer 2 Ping result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### Initiate a Layer 2 Traceroute

#### Note

This procedure does not apply to XA1400 Series.

Use this procedure to trigger a Layer 2 traceroute. This feature enables CFM to debug Layer 2 in an SPBM cloud or network. It can determine the path used by IS—IS to get from one MEP to another, by showing all the hops between. Therefore, it can show where connectivity is lost. It can also work for IP shortcuts.

If you configure **IsTraceTree** to false then EDM performs Traceroute on the unicast path. If you configure **IsTraceTree** to true then EDM performs TraceTree on the multicast tree.

For more information on configuring tracertree, see [Configure a Layer 2 Tracertree](#) on page 3883.

**Important**

To trace a route to a MAC address, the MAC address must be in the VLAN FDB table.

For B-VLANs, you do not have to trigger an **L2Ping** to learn the MAC address because IS-IS populates the MAC addresses in the FDB table.

Linktrace traces the path up to the closest device to that MAC address that supports CFM.

**Before You Begin**

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.

**Procedure**

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. Select the **L2 Traceroute/TraceTree** tab.
4. To start the traceroute, highlight an entry, and then select **Start**.
5. To update the traceroute, select **Refresh**.
6. To stop the traceroute, select **Stop**.

**L2 Traceroute/TraceTree Field Descriptions**

Use the data in the following table to use the **L2 Traceroute/TraceTree** tab.

| Name                  | Description                                                                                                   |
|-----------------------|---------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>         | Specifies a value that uniquely identifies the Backbone VLAN (B-VLAN).                                        |
| <b>Priority</b>       | Specifies a 3-bit value to be used in the VLAN header, if present in the transmitted frame. The default is 7. |
| <b>DestMacAddress</b> | Specifies the target MAC address.                                                                             |
| <b>HostName</b>       | Specifies the target host name.                                                                               |
| <b>DestIsHostName</b> | Specifies whether the host name is (true) or is not (false) used for the L2Trace transmission.                |
| <b>Isid</b>           | Specifies the Service Instance Identifier (I-SID).                                                            |

| Name               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IsTraceTree</b> | Specifies whether the multicast tree or unicast path is traced: <ul style="list-style-type: none"> <li>• If you configure <b>IsTraceTree</b> to false then EDM performs Traceroute on the unicast path.</li> <li>• If you configure <b>IsTraceTree</b> to true then EDM performs TraceTree on the multicast tree.</li> </ul>                                                                                                                                                                                        |
| <b>Status</b>      | Indicates the status of the transmit loopback service: <ul style="list-style-type: none"> <li>• ready: the service is available.</li> <li>• transmit: the service is transmitting, or about to transmit, the L2Trace messages.</li> <li>• abort: the service aborted or is about to abort the L2Trace messages.</li> </ul> This field is also used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time. The default is ready. |
| <b>ResultOk</b>    | Indicates the result of the operation: <ul style="list-style-type: none"> <li>• true: the L2Trace messages will be (or have been) sent.</li> <li>• false: the L2Trace messages will not be sent.</li> </ul> The default is true.                                                                                                                                                                                                                                                                                    |
| <b>Ttl</b>         | Specifies the number of hops remaining to this L2Trace. This value is decremented by 1 by each Bridge that handles the L2Trace. The decremented value is returned in the L2Trace. If 0 on output, the L2Trace is not transmitted to the next hop. The value of the time-to-live (TTL) field in the L2Trace is defined by the originating MEP. The default value is 64.                                                                                                                                              |
| <b>SourceMode</b>  | Specifies the source mode: <ul style="list-style-type: none"> <li>• 1: nodal</li> <li>• noVlanMac — Use this value with C-VLAN only. When you select this option, even if a VLAN MAC address exists, the system uses the CFM C-MAC as the BMAC-SA.</li> <li>• 2: smltVirtual—Use this value with B-VLANs only.</li> </ul> The default is 1: nodal.                                                                                                                                                                  |

| Name             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SeqNumber</b> | Specifies the transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Flag</b>      | L2Trace result flag that indicates L2Trace status or error code: <ul style="list-style-type: none"> <li>• none (1): No error</li> <li>• internalError (2): L2Trace internal error</li> <li>• invalidMac (3): Invalid MAC address</li> <li>• mepDisabled (4): MEP must be enabled in order to perform L2Trace</li> <li>• noL2TraceResponse (5): No L2Trace response received</li> <li>• l2TraceToOwnMepMac (6): L2Trace to own MEP MAC is not sent</li> <li>• l2TraceComplete (7): L2Trace completed</li> <li>• l2TraceLookupFailure (8): Lookup failure for L2Trace</li> <li>• l2TraceLeafNode (9): On a leaf node in the I-SID tree</li> <li>• l2TraceNotInTree (10): Not in the I-SID tree</li> <li>• l2TraceSmltNotPrimary (11): Requested SMLT source from non-primary node</li> </ul> |

*View Layer 2 Traceroute Results*

**Note**

This procedure does not apply to XA1400 Series.

Use this procedure to view Layer 2 traceroute results. This feature enables CFM to debug Layer 2. It can also help you debug ARP problems by providing the ability to troubleshoot next hop ARP records.

**About This Task**

You can display Layer 2 tracetree results to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID. For more information, see [View Layer 2 Tracetree Results](#) on page 3886.

**Procedure**

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. Select the **L2Traceroute/TraceTree** tab.
4. Select **Refresh** to update the results.
5. To view the traceroute results, highlight an entry, and then select **Result**.

## L2 Traceroute/Tracetree Result Field Descriptions

Use the data in the following table to use the **L2 Traceroute/Tracetree Result** tab.

| Name                | Description                                                                                                                                                                                                              |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>       | A value that uniquely identifies the Backbone VLAN (B-VLAN).                                                                                                                                                             |
| <b>SeqNumber</b>    | The transaction identifier/sequence number returned by a previous transmit linktrace message command, indicating which L2Trace's response of the L2Trace is going to be returned. The default is 0.                      |
| <b>Hop</b>          | The number of hops away from L2Trace initiator.                                                                                                                                                                          |
| <b>ReceiveOrder</b> | An index to distinguish among multiple L2Trace responses with the same Transaction Identifier field value. This value is assigned sequentially from 1, in the order that the Linktrace Initiator received the responses. |
| <b>Ttl</b>          | Time-to-Live (TTL) field value for a returned L2Trace response.                                                                                                                                                          |
| <b>SrcMac</b>       | MAC address of the MP that responds to the L2Trace request for this L2TraceReply.                                                                                                                                        |
| <b>HostName</b>     | The host name of the replying node.                                                                                                                                                                                      |
| <b>LastSrcMac</b>   | The MAC address of the node that forwarded the L2Trace to the responding node.                                                                                                                                           |
| <b>LastHostName</b> | The host name of the node that forwarded the L2Trace to the responding node.                                                                                                                                             |

### Configure Layer 2 IP Ping

Use this procedure to configure Layer 2 IP ping

#### Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.
- If you want to run a Layer 2 IP Ping for a specific VRF, you must use EDM in the specific VRF context first. For more information, see the procedure for selecting and launching a VRF context view in [Select and Launch a VRF Context View](#) on page 4203.

#### Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **L2Ping/L2Trace Route**.
3. Click the **L2 IP Ping** tab.
4. To add a new entry, click **Insert**, specify the destination IP address and optional parameters, and then click **Insert**.

5. To start the Layer 2 IP ping, highlight an entry, and then click **Start**.
6. To update the Layer 2 IP ping, click the **Refresh** button.
7. To stop the Layer 2 IP ping, click **Stop**.

**L2 IP Ping Field Descriptions**

Use the data in the following table to use the **L2 IP Ping** tab.

| Name              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IpAddrType</b> | Specifies the address type of destination IP Address (only IPv4 is supported).                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>IpAddr</b>     | Specifies the destination IP Address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>VrfId</b>      | Specifies the VRF ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>VrfName</b>    | Specifies the name of the virtual router.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Messages</b>   | Specifies the number of L2IpPing messages to be transmitted per MAC/VLAN pair. Range is 1-200. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Status</b>     | <p>Specifies the status of the transmit loopback service:</p> <ul style="list-style-type: none"> <li>• ready: the service is available.</li> <li>• transmit: the service is transmitting, or about to transmit, the L2IpPing messages.</li> <li>• abort: the service is aborted or about to abort the L2IpPing messages.</li> </ul> <p>This field is also used to avoid concurrency or race condition problems that could occur if two or more management entities try to use the service at the same time. The default is ready.</p> |
| <b>ResultOk</b>   | <p>Indicates the result of the operation:</p> <ul style="list-style-type: none"> <li>• true: L2IpPing Messages will be or have been sent.</li> <li>• false: L2IpPing Messages will not be sent.</li> </ul> <p>The default is true.</p>                                                                                                                                                                                                                                                                                                |
| <b>TimeoutInt</b> | Specifies the interval to wait for an L2IpPing time-out with a range of 1-10 seconds with a default value of 3 seconds.                                                                                                                                                                                                                                                                                                                                                                                                               |

| Name               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TestPattern</b> | <p>Specifies the test pattern to use in the L2IPPing PDU:</p> <ul style="list-style-type: none"> <li>• <b>allZero</b> — null signal without cyclic redundancy check</li> <li>• <b>allZeroCrc</b> — null signal with cyclic redundancy check with 32-bit polynomial</li> <li>• <b>pseudoRandomBitSequence</b> — pseudo-random-bit-sequence without cyclic redundancy check</li> <li>• <b>pseudoRandomBitSequenceCrc</b> — pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial.</li> </ul> <p>A cyclic redundancy check is a code that detects errors.<br/>The default value is allZero.</p> |
| <b>DataSize</b>    | <p>Specifies an arbitrary amount of data to be included in the data TLV, if the data size is selected to be sent. The range is 0–400. The default is 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>PathsFound</b>  | <p>Specifies the number of paths found to execute the command. The default is 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### View Layer 2 IP Ping Results

Use this procedure to view Layer 2 IP ping results.

#### Note

After you trigger Layer 2 IP Ping, you must click the **Refresh** button to update the results.

### Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **L2Ping/L2Trace Route**.
3. Click the **L2 IP Ping** tab.
4. To view the Layer 2 IP ping results, highlight an entry, and then click **Result**.

### L2 IP Ping Result Field Descriptions

Use the data in the following table to use the **L2 IP Ping Result** tab.

| Name              | Description                                     |
|-------------------|-------------------------------------------------|
| <b>IpAddrType</b> | The address type of the destination IP Address. |
| <b>IpAddr</b>     | Destination IP Address.                         |

| Name                    | Description                                                                                                                                                                                                                                                       |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SendOrder</b>        | Specifies the order that sessions were sent. It is an index to distinguish among multiple L2Ping sessions. This value is assigned sequentially from 1. It correlates to the number of paths found.                                                                |
| <b>VrfId</b>            | Specifies the VRF ID.                                                                                                                                                                                                                                             |
| <b>VlanId</b>           | Specifies the VLAN ID found from the Layer 3 lookup and used for transmission.                                                                                                                                                                                    |
| <b>DestMacAddress</b>   | An indication of the target MAC Address transmitted.                                                                                                                                                                                                              |
| <b>PortNum</b>          | Either the value '0', or the port number of the port used for the I2 IP ping.                                                                                                                                                                                     |
| <b>DestHostName</b>     | The host name of the responding node.                                                                                                                                                                                                                             |
| <b>Size</b>             | The number of bytes of data sent.                                                                                                                                                                                                                                 |
| <b>PktsTx</b>           | Number of Packets transmitted for this VLAN/MAC.                                                                                                                                                                                                                  |
| <b>PktsRx</b>           | Number of Packets received for this VLAN/MAC.                                                                                                                                                                                                                     |
| <b>PercentLossWhole</b> | Percentage of packet loss for this VLAN/MAC.                                                                                                                                                                                                                      |
| <b>PercentLossFract</b> | Percentage of packet loss for this VLAN/MAC.                                                                                                                                                                                                                      |
| <b>MinRoundTrip</b>     | Minimum time for round-trip for this VLAN/MAC in us.                                                                                                                                                                                                              |
| <b>MaxRoundTrip</b>     | Maximum time for round-trip for this VLAN/MAC in us.                                                                                                                                                                                                              |
| <b>RttAvgWhole</b>      | Average time for round-trip for this VLAN/MAC in us.                                                                                                                                                                                                              |
| <b>RttAvgFract</b>      | Fractional portion of average time for round-trip.                                                                                                                                                                                                                |
| <b>Flag</b>             | Result flag indicating status or error code: <ul style="list-style-type: none"> <li>• 1 - No error</li> <li>• 2 - Internal error</li> <li>• 3 - Invalid IP</li> <li>• 4 - L2Trace completed</li> <li>• 5 - Lookup failure for IP (no VLAN/MAC entries)</li> </ul> |

*Configure Layer 2 IP Traceroute*

Use this procedure to configure Layer 2 IP traceroute.

**Before You Begin**

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN

- If you want to run a Layer 2 IP Traceroute for a specific VRF, you must use EDM in the specific VRF context first. For more information, see the procedure for selecting and launching a VRF context view in [Select and Launch a VRF Context View](#) on page 4203.

### Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **L2Ping/L2Trace Route**
3. Click the **L2 IP Traceroute** tab.
4. To add a new entry, click **Insert**, specify the destination IP address and, optionally, the TTL value, and then click **Insert**.
5. To start the Layer 2 IP traceroute, highlight an entry, and then click the **Start** button.
6. To update the Layer 2 IP traceroute, click the **Refresh** button.
7. To stop the Layer 2 IP traceroute, click the **Stop** button.

### L2 IP Traceroute Field Descriptions

Use the data in the following table to use the **L2 IP Traceroute** tab.

| Name              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IpAddrType</b> | Specifies the address type of destination IP address (only IPv4 is supported).                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>IPAddr</b>     | Specifies the destination IP Address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>VrfId</b>      | Specifies the VRF ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>VrfName</b>    | Specifies the name of the virtual router.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Ttl</b>        | Specifies the number of hops remaining to this L2Trace. This value is decremented by 1 by each Bridge that handles the L2Trace. The decremented value is returned in the L2Trace. If 0 on output, the L2Trace is not transmitted to the next hop. The default value is 64                                                                                                                                                                                                                                                           |
| <b>Status</b>     | <p>Indicates the status of the transmit loopback service:</p> <ul style="list-style-type: none"> <li>• ready: the service is available.</li> <li>• transmit: the service is transmitting, or about to transmit, the L2Trace messages.</li> <li>• abort: the service is aborted or about to abort the L2Trace messages.</li> </ul> <p>This field is also used to avoid concurrency or race condition problems that could occur if two or more management entities try to use the service at the same time. The default is ready.</p> |

| Name              | Description                                                                                                                                                                                                               |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ResultOk</b>   | Indicates the result of the operation: <ul style="list-style-type: none"> <li>• true: the Trace Messages will be or have been sent.</li> <li>• false: the Trace Messages will not be sent</li> </ul> The default is true. |
| <b>PathsFound</b> | Specifies the number of paths found to execute the L2trace. The default is 0.                                                                                                                                             |

*View Layer 2 IP Traceroute Results*

Use this procedure to view Layer 2 IP traceroute results.

**Note**

After you trigger Layer 2 IP traceroute, you must click the **Refresh** button to update the results.

**Procedure**

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **L2Ping/L2Trace Route**.
3. Click the **L2 IP Traceroute** tab.
4. To view the Layer 2 IP traceroute results, highlight an entry, and then click **Result**.

**L2 IP Traceroute Result Field Descriptions**

Use the data in the following table to use the **L2 IP Traceoute Result** tab.

| Name                | Description                                                                                                                                                                                                                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IpAddrType</b>   | Specifies the address type of destination IP address.                                                                                                                                                                                                                           |
| <b>IpAddr</b>       | Specifies the destination IP address.                                                                                                                                                                                                                                           |
| <b>SendOrder</b>    | Denotes the order that sessions are sent. It is an index to distinguish among multiple L2Trace sessions. It correlates to the number of paths found. This value is assigned sequentially from 1.                                                                                |
| <b>Hop</b>          | Specifies the number of Layer 2 hops away from L2Trace initiator.                                                                                                                                                                                                               |
| <b>ReceiveOrder</b> | Specifies the order that sessions are sent. It is an index to distinguish among multiple L2Trace responses with the same Send Transaction Identifier field value. This value is assigned sequentially from 1, in the order that the Linktrace Initiator received the responses. |
| <b>Ttl</b>          | Specifies the time-to-live (TTL) field value for a returned L2Trace response.                                                                                                                                                                                                   |

| Name                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VrfId</b>          | Specifies the VRF ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>VlanId</b>         | Specifies the VLAN found from Layer 3 lookup and used for transmission.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DestMacAddress</b> | Indicates the target MAC address transmitted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>PortNum</b>        | Specifies either the value '0', or the port number of the port used for the l2trace.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SeqNumber</b>      | Specifies the transaction identifier/sequence number used in linktrace message packet. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SrcMac</b>         | Specifies the MAC address of the MP that responded to L2Trace request for this L2traceReply.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>HostName</b>       | Specifies the host name of the replying node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>LastSrcMac</b>     | Specifies the MAC address of the node that forwarded the L2Trace to the responding node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>LastHostName</b>   | Specifies the host name of the node that forwarded the L2Trace to the responding node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Flag</b>           | L2Trace result flag indicating status or error code: <ul style="list-style-type: none"> <li>• none (1): No error</li> <li>• internalError (2): L2Trace internal error</li> <li>• invalidMac (3): Invalid MAC address</li> <li>• mepDisabled (4): MEP must be enabled in order to perform L2Trace</li> <li>• noL2TraceResponse (5): No L2Trace response received</li> <li>• l2TraceToOwnMepMac (6): L2Trace to own MEP MAC is not sent</li> <li>• l2TraceComplete (7): L2Trace completed</li> <li>• l2TraceLookupFailure (8): Lookup failure for L2Trace</li> </ul> |

### *Trigger a Loopback Test*

Use this procedure to trigger a loopback test.

The LBM packet is often compared to ping. An MEP transmits the loopback message to an intermediate or endpoint within a domain for the purpose of fault verification. This can be used to check the ability of the network to forward different sized frames.

### **Before You Begin**

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP.

- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

**Procedure**

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **CFM**.
3. Click the **LBM** tab.
4. Configure the loopback test properties as required.
5. Click **Apply**.
6. To trigger the loopback test, double-click in the **Status** field, select **transmit**.
7. Click **Apply**.
8. To update the loopback test, click the **Refresh** button.

**LBM Field Descriptions**

Use the data in the following table to use the **LBM** tab.

| Name                    | Description                                                                                                                                                                                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DomainIndex</b>      | Specifies the MD index value.                                                                                                                                                                                                      |
| <b>AssociationIndex</b> | Specifies the MA index value.                                                                                                                                                                                                      |
| <b>Index</b>            | Specifies the Maintenance Endpoint index value.                                                                                                                                                                                    |
| <b>DomainName</b>       | Specifies the MD name.                                                                                                                                                                                                             |
| <b>AssociationName</b>  | Specifies the MA name.                                                                                                                                                                                                             |
| <b>DestMacAddress</b>   | Specifies the remote MAC address to reach the MEP/MIP.                                                                                                                                                                             |
| <b>Messages</b>         | Specifies the number of loopback messages to be transmitted. The default is 1.                                                                                                                                                     |
| <b>VlanPriority</b>     | Specifies the priority. The default is 7.                                                                                                                                                                                          |
| <b>SeqNumber</b>        | Specifies the transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.                                                                                                                 |
| <b>ResultOk</b>         | Indicates the result of the operation: <ul style="list-style-type: none"> <li>• true: The Loopback Messages will be (or have been) sent.</li> <li>• false: The Loopback Messages will not be sent.</li> </ul> The default is true. |

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Status</b>        | <p>Indicates the status of the transmit loopback service:</p> <ul style="list-style-type: none"> <li>• ready: The service is available.</li> <li>• transmit: The service is transmitting, or about to transmit, the Loopback messages.</li> <li>• abort: The service is aborted or about to abort the Loopback messages.</li> </ul> <p>The default is ready.</p>                                                                                                                                                                                                                           |
| <b>Result</b>        | Displays the LBM result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>TimeoutInt</b>    | Specifies the timeout interval in seconds. The default value is 3 seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>InterFrameInt</b> | Specifies the interval between LBM frames with a range of (0..1000) msec and a default value of 500 msec. The value of 0 msec indicates to send the frames as fast as possible. The default is 500.                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>TestPattern</b>   | <p>Specifies the testfill pattern:</p> <ul style="list-style-type: none"> <li>• <b>allZero</b> — null signal without cyclic redundancy check</li> <li>• <b>allZeroCrc</b> — null signal with cyclic redundancy check with 32-bit polynomial</li> <li>• <b>pseudoRandomBitSequence</b> — pseudo-random-bit-sequence without cyclic redundancy check</li> <li>• <b>pseudoRandomBitSequenceCrc</b> — pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial.</li> </ul> <p>A cyclic redundancy check is a code that detects errors. The default value is allZero.</p> |
| <b>DataSize</b>      | Specifies the data type-length-value (TLV) size. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>FrameSize</b>     | Specifies the frame-size. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Sourcemode</b>    | <p>Specifies the source mode of the transmit loopback service:</p> <ul style="list-style-type: none"> <li>• nodal</li> <li>• noVlanMac — Use this value with C-VLAN only. When you select this option, even if a VLAN MAC address exists, the system uses the CFM C-MAC as the BMAC-SA.</li> <li>• smltVirtual — Use the smltVirtual option with B-VLANs only.</li> </ul> <p>The default is nodal.</p>                                                                                                                                                                                     |

*Trigger Linktrace*

Use the following procedure to trigger a linktrace. The link trace message is often compared to traceroute. An MEP transmits the Linktrace Message packet to a maintenance endpoint with intermediate points responding to indicate the path of the traffic within a domain for the purpose of fault isolation. The packet specifies the target MAC address of an MP, which is the SPBM system ID or the virtual SMLT MAC. MPs on the path to the target address respond with an LTR.

**Before You Begin**

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP.
- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

**Procedure**

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **CFM**.
3. Click the **LTM** tab.
4. Configure the linktrace test properties as required.
5. Click **Apply**.
6. To trigger the linktrace test, double-click in the Status field, select **transmit**, and then click **Apply**.

OR

Highlight an entry, and then click **Start**.

7. To update the linktrace, click the **Refresh** button.
8. To stop the linktrace, click **Stop**.
9. To view the results of the linktrace, click **Result**.

**LTM Field Descriptions**

Use the data in the following table to use the **LTM** tab.

| Name                    | Description                                                                                                                   |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>DomainIndex</b>      | Specifies the MD index value.                                                                                                 |
| <b>AssociationIndex</b> | Specifies the MA index value.                                                                                                 |
| <b>Index</b>            | Specifies the MEP index value.                                                                                                |
| <b>DomainName</b>       | Specifies the MD name.                                                                                                        |
| <b>AssociationName</b>  | Specifies the MA name.                                                                                                        |
| <b>VlanPriority</b>     | Specifies the VLAN priority, a 3-bit value to be used in the VLAN tag, if present in the transmitted frame. The default is 7. |
| <b>DestMacAddress</b>   | Specifies the remote MAC address to reach the MEP.                                                                            |

| Name             | Description                                                                                                                                                                                                                                                                                                                                                         |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Ttl</b>       | Indicates the number of hops remaining to this LTM. This value is decremented by 1 by each bridge that handles the LTM. The decremented value is returned in the LTR. If the value is 0 on output, the LTM is not transmitted to the next hop. The value of the TTL field in the LTM is specified at the originating MEP. The default value is 64.                  |
| <b>SeqNumber</b> | Specifies the transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.                                                                                                                                                                                                                                                  |
| <b>ResultOk</b>  | Indicates the result of the operation: <ul data-bbox="899 653 1479 779" style="list-style-type: none"><li>• true: The Loopback Messages will be (or have been) sent.</li><li>• false: The Loopback Messages will not be sent.</li></ul> The default is true.                                                                                                        |
| <b>Status</b>    | Indicates the status of the transmit loopback service: <ul data-bbox="899 905 1479 1062" style="list-style-type: none"><li>• ready: The service is available.</li><li>• transmit: The service is transmitting, or about to transmit, the LTM messages.</li><li>• abort: The service is aborted, or about to abort, the LTM message.</li></ul> The default is ready. |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><b>Flag</b></p>       | <p>Displays the LTM result flag indicating LTM status or error code. Each value represents a status or error case:</p> <ul style="list-style-type: none"> <li>• 1 - No error</li> <li>• 2 - LTM internal error</li> <li>• 3 - Unknown Remote Maintenance Endpoint</li> <li>• 4 - Invalid Remote Maintenance Endpoint MAC Address</li> <li>• 5 - Unset Remote Maintenance Endpoint MAC address</li> <li>• 6 - MEP must be enabled in order to perform LTM</li> <li>• 7 - No LTR response received</li> <li>• 8 - Linktrace to own MEP MAC is not sent</li> <li>• 9 - Endpoint must be enabled in order to perform LTM</li> <li>• 10 - Pbt-trunk must be enabled in order to perform LTM</li> <li>• 11 - LTM completed</li> <li>• 12 - LTM leaf node</li> </ul> |
| <p><b>SourceMode</b></p> | <p>Specifies the source mode of the transmit loopback service:</p> <ul style="list-style-type: none"> <li>• nodal</li> <li>• noVlanMac — Use this value with C-VLAN only. When you select this option, even if a VLAN MAC address exists, the system uses the CFM C-MAC as the B-MAC-SA.</li> <li>• smltVirtual — Use the smltVirtual option with B-VLANs only.</li> </ul> <p>The default is nodal.</p>                                                                                                                                                                                                                                                                                                                                                       |

*View Linktrace Results*

Use this procedure to view linktrace results.

**Note**

After you trigger linktrace, you must click the **Refresh** button to update the results.

**Procedure**

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **CFM**.
3. Click the **LTM** tab.
4. Highlight an entry, and then click **Result**.

### Link Trace Replies Field Descriptions

Use the data in the following table to use the **Link Trace Result** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DomainIndex</b>          | Indicates the Maintenance Domain Index.                                                                                                                                                                                                                                                                                                                    |
| <b>AssociationIndex</b>     | Indicates the Maintenance Association Index.                                                                                                                                                                                                                                                                                                               |
| <b>MepId</b>                | Indicates the Maintenance EndPoint ID.                                                                                                                                                                                                                                                                                                                     |
| <b>SeqNumber</b>            | Indicates the transaction identifier/sequence number returned by a previous transmit linktrace message command, indicating which LTM response is going to be returned. The default is 0.                                                                                                                                                                   |
| <b>Hop</b>                  | Indicates the number of hops away from the LTM initiator.                                                                                                                                                                                                                                                                                                  |
| <b>ReceiveOrder</b>         | Indicates the index value used to distinguish among multiple LTRs with the same LTR Transaction Identifier field value. This value is assigned sequentially from 1, in the order that the Linktrace Initiator received the LTRs.                                                                                                                           |
| <b>Ttl</b>                  | Indicates the TTL field value for a returned LTR.                                                                                                                                                                                                                                                                                                          |
| <b>DomainName</b>           | Indicates the Maintenance Domain Name.                                                                                                                                                                                                                                                                                                                     |
| <b>AssociationName</b>      | Indicates the Maintenance Association Name.                                                                                                                                                                                                                                                                                                                |
| <b>Forwarded</b>            | Indicates if a LTM was forwarded by the responding MP, as returned in the FwdYes flag of the flags field.                                                                                                                                                                                                                                                  |
| <b>TerminalMep</b>          | Displays a boolean value stating whether the forwarded LTM reached a MEP enclosing its MA, as returned in the Terminal MEP flag of the Flags field.                                                                                                                                                                                                        |
| <b>LastEgressIdentifier</b> | Displays an octet field holding the Last Egress Identifier returned in the LTR Egress Identifier TLV of the LTR. The Last Egress Identifier identifies the MEP Linktrace Indicator that originated, or the Linktrace Responder that forwarded, the LTM to which this LTR is the response. This is the same value as the Egress Identifier TLV of that LTM. |

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NextEgressIdentifier</b> | Displays an octet field holding the Next Egress Identifier returned in the LTR Egress Identifier TLV of the LTR. The Next Egress Identifier Identifies the Linktrace Responder that transmitted this LTR, and can forward the LTM to the next hop. This is the same value as the Egress Identifier TLV of the forwarded LTM, if any. If the FwdYes bit of the Flags field is false, the contents of this field are undefined, and the field is ignored by the receiver. |
| <b>RelayAction</b>          | Indicates the value returned in the RelayAction field.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SrcMac</b>               | Displays the MAC address of the MP that responded to the LTM request for this LTR.                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>IngressAction</b>        | Displays the value returned in the IngressAction Field of the LTM. The value ingNoTlv indicates that no Reply Ingress TLV was returned in the LTM.                                                                                                                                                                                                                                                                                                                      |
| <b>IngressMac</b>           | Displays the MAC address returned in the ingress MAC address field. If the rcCfmLtrReplyIngress object contains the value ingNoTlv(5), then the contents of this field are meaningless.                                                                                                                                                                                                                                                                                 |
| <b>EgressAction</b>         | Displays the value returned in the Egress Action Field of the LTM. The value egrNoTlv(5) indicates that no Reply Egress TLV was returned in the LTM.                                                                                                                                                                                                                                                                                                                    |
| <b>EgressMac</b>            | Displays the MAC address returned in the egress MAC address field. If the rcCfmLtrReplyEgress object contains the value egrNoTlv(5), then the contents of this field are meaningless.                                                                                                                                                                                                                                                                                   |

*Configure a Layer 2 Tracetree*

**Note**

This procedure does not apply to XA1400 Series.

Use this procedure to configure a Layer 2 Tracetree. This feature enables CFM to debug Layer 2. Layer 2 Tracetree allows a user to trigger a multicast LTM message by specifying the B-VLAN and I-SID. The command allows the user to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID.

**Note**

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [VOSS Release Notes](#). As an alternative, use CLI.

## Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP.
- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

## About This Task

If you configure **IsTraceTree** to false, then EDM performs Traceroute on the unicast path. If you configure **IsTraceTree** to true, then EDM performs TraceTree on the multicast tree.

### Note

This command is supported on SPBM B-VLANs only, not C-VLANs.

## Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. From the **L2 Traceroute/TraceTree** tab, configure the Layer 2 tracetree properties.
4. In the **IsTraceTree** field double-click and select **true** for EDM to perform Tracetree on the multicast tree.
5. Select **Apply**.
6. Select **Refresh** to update the results.

## L2Tracetree Field Descriptions

Use the data in the following table to use the **L2Tracetree** tab.

| Name                  | Description                                                                                                                                                                                                                                                   |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>         | Identifies the Backbone VLAN.                                                                                                                                                                                                                                 |
| <b>Priority</b>       | Specifies a 3-bit value to be used in the VLAN header, if present in the transmitted frame. The default is 7.                                                                                                                                                 |
| <b>DestMacAddress</b> | Specifies the target MAC address.                                                                                                                                                                                                                             |
| <b>HostName</b>       | Specifies the target host name.                                                                                                                                                                                                                               |
| <b>DestIsHostName</b> | Indicates whether the host name is (true) or is not (false) used for L2Tracetree transmission.                                                                                                                                                                |
| <b>Isid</b>           | Specifies the service instance identifier (I-SID).                                                                                                                                                                                                            |
| <b>IsTraceTree</b>    | Specifies whether the multicast tree or unicast path is traced. If you configure <b>IsTraceTree</b> to false then EDM performs Traceroute on the unicast path. If you configure <b>IsTraceTree</b> to true then EDM performs TraceTree on the multicast tree. |

| Name              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Status</b>     | <p>Specifies the status of the transmit loopback service:</p> <ul style="list-style-type: none"> <li>• ready: the service is available.</li> <li>• transmit: the service is transmitting, or about to transmit, the L2Tracetree messages.</li> <li>• abort: the service aborted or is about to abort the L2Tracetree messages.</li> </ul> <p>This field is also used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time. The default is ready.</p> |
| <b>ResultOk</b>   | <p>Indicates the result of the operation:</p> <ul style="list-style-type: none"> <li>• true: the L2Tracetree Messages will be (or have been) sent.</li> <li>• false: the L2Tracetree Messages will not be sent</li> </ul> <p>The default is true.</p>                                                                                                                                                                                                                                                                                     |
| <b>Ttl</b>        | <p>Specifies the Time-to-Live value. Indicates the number of hops remaining to this L2Tracetree. The tracetree is decremented by one by each bridge that handles the Layer 2 tracetree and the decremented value is returned to the tracetree. If the output is 0, then the L2Tracetree is not transmitted to the next hop. The value of the TTL field in the L2Tracetree is transmitted by the originating MEP is controlled by a managed object. The default is 64.</p>                                                                 |
| <b>SourceMode</b> | <p>Specifies the source mode of the transmit loopback service:</p> <ul style="list-style-type: none"> <li>• nodal</li> <li>• noVlanMac — Use this value with C-VLAN only. When you select this option, even if a VLAN MAC address exists, the system uses the CFM C-MAC as the BMAC-SA.</li> <li>• smltVirtual — Use the smltVirtual option with B-VLANs only.</li> </ul> <p>The default is nodal.</p>                                                                                                                                    |

| Name             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SeqNumber</b> | The transaction identifier/sequence number of the first loopback message (to be) sent. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Flag</b>      | Specifies the L2Tracetree result flag, which indicates the L2Tracetree status or error code. Each sum represents a status or error: <ul style="list-style-type: none"> <li>• 1 — No error</li> <li>• 2 — L2Tracetree internal error</li> <li>• 3 — Invalid MAC address</li> <li>• 4 — MEP must be enabled in order to perform L2Tracetree</li> <li>• 5 — No L2Tracetree response received</li> <li>• 6 — L2Tracetree to own MEP MAC is not sent</li> <li>• 7 — L2Tracetree completed</li> <li>• 8 — Lookup failure for L2Tracetree</li> <li>• 9 — On a leaf node in the I-SID tree</li> <li>• 10 — Not in the I-SID tree</li> <li>• 11 — Requested SMLT source from nonprimary node</li> </ul> |

### View Layer 2 Tracetree Results

#### Note

This procedure does not apply to XA1400 Series.

Use this procedure to view Layer 2 Tracetree results. The Layer 2 Tracetree command is a proprietary command that allows a user to trigger a multicast LTM message by specifying the B-VLAN and I-SID. This command allows the user to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID.

#### Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [VOSS Release Notes](#). As an alternative, use CLI.

### Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **L2Ping/L2Trace Route**.
3. Select the **L2 Traceroute/TraceTree** tab.
4. In the **IsTraceTree** field double-click and select **true** for EDM to perform Tracetree on the multicast tree.
5. Select **Apply**.
6. Select **Refresh** to update the results.
7. To view the tracetre results, highlight an entry, and then select **Result**.

### L2 Traceroute/Tracetree Result Field Descriptions

Use the data in the following table to use the **L2 Traceroute/Tracetree Result** tab.

| Name                | Description                                                                                                                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>       | A value that uniquely identifies the Backbone VLAN (B-VLAN).                                                                                                                                                                 |
| <b>SeqNumber</b>    | The transaction identifier/sequence number returned by a previous transmit linktrace message command, that indicates which response of the L2Tracetree is going to be returned. The default is 0.                            |
| <b>Hop</b>          | The number of hops away from L2Tracetree initiator.                                                                                                                                                                          |
| <b>ReceiveOrder</b> | An index to distinguish among multiple L2Tracetree responses with the same Transaction Identifier field value. This value is assigned sequentially from 1, in the order that the Linktrace Initiator received the responses. |
| <b>Ttl</b>          | Time-to-Live (TTL) field value for a returned L2Tracetree response.                                                                                                                                                          |
| <b>SrcMac</b>       | MAC address of the MP that responds to the L2Tracetree request for this L2tractreeReply.                                                                                                                                     |
| <b>HostName</b>     | The host name of the replying node.                                                                                                                                                                                          |
| <b>LastSrcMac</b>   | The MAC address of the node that forwarded the L2Tracetree to the responding node.                                                                                                                                           |
| <b>LastHostName</b> | The host name of the node that forwarded the L2Tracetree to the responding node.                                                                                                                                             |

#### Configure Layer 2 Trace Multicast Route on a VLAN

**Note**

This procedure does not apply to XA1400 Series.

Use this procedure to configure the Layer 2 tracemroute on the VLAN (Layer 2). This procedure queries the SPBM multicast module to determine the B-VLAN, I-SID, and nickname for the S and G streams. The nickname and I-SID are used to create a multicast MAC address.

**Note**

If you want to run a Layer 2 tracemroute on a VRF, make sure you are in the proper VRF context.

## Before You Begin

On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.

## Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > L2Ping/L2Trace Route**.
2. Select the **L2MCAST Traceroute** tab.
3. Select **Insert** to insert the Layer 2 MCAST Traceroute.
4. Enter the **SrcIpAddr**.
5. Enter the **GroupIpAddr**.
6. Enter the **ServiceType**. If you want to perform a Layer 2 tracemroute on a VLAN, select **vlan**. If you want to perform a Layer 2 tracemroute on a Layer 3 GRT, select **vrfid**.

### Note

If you want to perform a Layer 2 tracemroute on a Layer 2 or a Layer 3 VRF, review the following procedure [Configuring Layer 2 tracemroute on a VRF](#).

7. In the **ServiceId** field, enter the VLAN ID.
8. Enter the **Priority**.
9. Enter the **Ttl** value.
10. Select **Insert**.
11. Select **Apply** to save your changes.
12. To start the Layer 2 tracemoute, set the Status to transmit and select **Start**.
13. Update the Layer 2 tracemroute by selecting **Refresh**.
14. To stop the Layer 2 tracemroute, select **Stop**.
15. To see the result, select **Result**.

## L2 MCAST Traceroute Field Descriptions

Use the data in the following table to use the **L2 MCAST Traceroute** tab.

| Name                   | Description                                                                            |
|------------------------|----------------------------------------------------------------------------------------|
| <b>SrcIpAddrType</b>   | Specifies the source IP address type as IPv4.                                          |
| <b>SrcIpAddr</b>       | Specifies the source IP address of the flow where the multicast trace tree originates. |
| <b>GroupIpAddrType</b> | Specifies the group IP address type as IPv4.                                           |
| <b>GroupIpAddr</b>     | Specifies the group IP address.                                                        |
| <b>ServiceType</b>     | Specifies where you configure the Layer 2 tracemroute. This is either VLAN or VRF.     |
| <b>ServiceId</b>       | Specifies the VLAN ID.                                                                 |
| <b>VRFName</b>         | Specifies the VRF name.                                                                |
| <b>Priority</b>        | Specifies the priority value. The value is between 0 and 7.                            |

| Name             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Ttl</b>       | Specifies the returned trace response. The TTL value is between 1 and 255.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SeqNumber</b> | Specifies the transaction identifier/sequence number of the first message to be sent.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Status</b>    | <p>Specifies the status of the transmit loopback service:</p> <ul style="list-style-type: none"> <li>• ready: Specifies the service is available.</li> <li>• transmit: Specifies the service is transmitting, or about to transmit the trace messages.</li> <li>• abort: Specifies the services is aborted or about to abort the trace messages.</li> </ul> <p>The column will also be used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time.</p> |
| <b>ResultOK</b>  | <p>Specifies the result of the operation:</p> <ul style="list-style-type: none"> <li>• true: The trace messages will be or have been sent.</li> <li>• false: The trace messages will not be sent.</li> </ul>                                                                                                                                                                                                                                                                                                                               |
| <b>Flag</b>      | <p>Specifies the result flag indicating that the Layer 2 trace status or error code. Each value represents a status or error case.</p> <ul style="list-style-type: none"> <li>• 1 — No error</li> <li>• 2 — Internal Error</li> <li>• 3 — Mep must be enabled to perform the trace</li> <li>• 4 — No response received</li> <li>• 5 — Trace completed</li> <li>• 6 — On a leaf node in the I-SID tree</li> <li>• 7 — No data I-SID was found for S, G</li> </ul>                                                                           |

*Configure Layer 2 Tracemroute on a VRF*

**Note**

This procedure does not apply to XA1400 Series.

Use this procedure to configure the Layer 2 tracemroute on the VRF (Layer 3). This procedure queries the SPBM multicast module to determine the B-VLAN, I-SID and nickname for the S and G streams. The nickname and I-SID are used to create a multicast MAC address.

**Note**

If you want to run a Layer 2 tracemroute on a VRF, make sure you are in the proper VRF context.

To perform a Layer 3 tracemroute on a VLAN, see [Configure Layer 2 Trace Multicast Route on a VLAN](#) on page 3887.

## Before You Begin

On the source and destination nodes, you must configure a CFM MD, MA, and MEP, and assign a nodal MEP to the B-VLAN.

## Procedure

1. In the navigation pane, expand **Configuration > VRF Context View > Set VRF Context View**.
2. Select a VRF, and then select the **Launch VRF Context View** tab.
3. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > L2Ping/L2Trace Route**.
4. Select the **L2MCAST Traceroute** tab.
5. Select **Insert**.
6. Type the **SrcIpAddr**.
7. Type the **GroupIpAddr**.
8. Select the **ServiceType**. If you want to perform a Layer 2 tracemroute on a Layer 2 VRF, select **vlan**. If you want to perform a Layer 2 tracemroute on a Layer 3 VRF, select **vrfid**.
9. In the **ServiceId**, type the VLAN ID.
10. Type the **Priority**.
11. Type the **Ttl** value.
12. Select **Insert**.
13. Select **Apply** to save your changes.
14. To start the Layer 2 tracemoute, configure the Status to transmit, and then select **Start**.
15. To update the Layer 2 tracemroute, select **Refresh**.
16. To stop the Layer 2 tracemroute, select **Stop**.
17. To see the result, select **Result**.

## L2 MCAST Traceroute Field Descriptions

Use the data in the following table to use the **L2 MCAST Traceroute** tab.

| Name                   | Description                                                                            |
|------------------------|----------------------------------------------------------------------------------------|
| <b>SrcIpAddrType</b>   | Specifies the source IP address type as IPv4.                                          |
| <b>SrcIpAddr</b>       | Specifies the source IP address of the flow where the multicast trace tree originates. |
| <b>GroupIpAddrType</b> | Specifies the group IP address type as IPv4.                                           |
| <b>GroupIpAddr</b>     | Specifies the group IP address.                                                        |
| <b>ServiceType</b>     | Specifies where you configure the Layer 2 tracemroute. This is either VLAN or VRF.     |
| <b>ServiceId</b>       | Specifies the VLAN ID.                                                                 |
| <b>VRFName</b>         | Specifies the VRF name.                                                                |
| <b>Priority</b>        | Specifies the priority value. The value is between 0 and 7.                            |

| Name             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Ttl</b>       | Specifies the returned trace response. The TTL value is between 1 and 255.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SeqNumber</b> | Specifies the transaction identifier/sequence number of the first message to be sent.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Status</b>    | <p>Specifies the status of the transmit loopback service:</p> <ul style="list-style-type: none"> <li>• ready: Specifies the service is available.</li> <li>• transmit: Specifies the service is transmitting, or about to transmit the trace messages.</li> <li>• abort: Specifies the services is aborted or about to abort the trace messages.</li> </ul> <p>The column will also be used to avoid concurrency or race condition problems that can occur if two or more management entities try to use the service at the same time.</p> |
| <b>ResultOK</b>  | <p>Specifies the result of the operation:</p> <ul style="list-style-type: none"> <li>• true: The trace messages will be or have been sent.</li> <li>• false: The trace messages will not be sent.</li> </ul>                                                                                                                                                                                                                                                                                                                               |
| <b>Flag</b>      | <p>Specifies the result flag indicating that the Layer 2 trace status or error code. Each value represents a status or error case.</p> <ul style="list-style-type: none"> <li>• 1 — No error</li> <li>• 2 — Internal Error</li> <li>• 3 — Mep must be enabled to perform the trace</li> <li>• 4 — No response received</li> <li>• 5 — Trace completed</li> <li>• 6 — On a leaf node in the I-SID tree</li> <li>• 7 — No data I-SID was found for S, G</li> </ul>                                                                           |

*View Layer 2 Trace Multicast Route Results*

**Note**

This procedure does not apply to XA1400 Series.

Use this procedure to view Layer 2 tracemroute results.

**Note**

If you want to run a Layer 2 tracemroute on a VRF, make sure you are in the proper VRF context.

**Procedure**

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > L2Ping/L2Trace Route**.
2. Select the **L2 MCAST Traceroute** tab.
3. To view the CFMI2 trace multicast route results, highlight an entry and select **Result**.

## L2tracemroute Result Field Descriptions

Use the data in the following table to use the **L2tracemroute Result** tab.

| Name                | Description                                                                                                                                                                                                                               |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>       | Specifies a value that uniquely identifies the C-VLAN.                                                                                                                                                                                    |
| <b>SeqNumber</b>    | Specifies the transaction identifier/sequence number returned by a previous transmit linktrace message command. Indicates which I2 tracemroute response is going to be returned.                                                          |
| <b>Hop</b>          | Specifies the number of hops away from the I2 tracemroute initiator.                                                                                                                                                                      |
| <b>ReceiveOrder</b> | Specifies an index to distinguish among multiple I2 tracemroute responses with the same transaction identifier field value. This value is assigned sequentially from 1, in the order that the linktrace initiator received the responses. |
| <b>Ttl</b>          | Specifies the TTL value for a returned I2 tracemroute response.                                                                                                                                                                           |
| <b>SrcMac</b>       | Specifies the MAC address of the MP that responds to the I2 tracemroute request for this I2 tracemrouteReply.                                                                                                                             |
| <b>HostName</b>     | Specifies the host name of the replying node.                                                                                                                                                                                             |
| <b>LastSrcMac</b>   | Specifies the MAC address of the node that forwarded the I2 tracemroute to the responding node.                                                                                                                                           |
| <b>LastHostName</b> | Specifies the host name of the node that forwarded the I2 tracemroute to the responding node.                                                                                                                                             |

## CFM Configuration Example

This section provides a configuration example for Connectivity Fault Management (CFM).

### CFM Configuration Example

The following sections show the steps required to configure CFM.

#### Note

The following commands are not supported on all hardware platforms:

- cfm maintenance-domain
- cfm maintenance-association
- vlan nodal-mip-level

#### Switch A

```
MAINTENANCE-DOMAIN CONFIGURATION
```

```

cfm maintenance-domain "spbm" index 1 maintenance-level 6

MAINTENANCE-ASSOCIATION CONFIGURATION

cfm maintenance-association "spbm" "2" index 1
cfm maintenance-association "spbm" "3" index 2

MAINTENANCE-ENDPOINT CONFIGURATION

cfm maintenance-endpoint "spbm" "2" 1 state enable
cfm maintenance-endpoint "spbm" "3" 1 state enable

VLAN NODAL MEP/MIP CONFIGURATION

vlan nodal-mep 2 spbm 2 1
vlan nodal-mip-level 2 6
vlan nodal-mep 3 spbm 3 1
vlan nodal-mip-level 3 6
    
```

**Switch B**

```

MAINTENANCE-DOMAIN CONFIGURATION

cfm maintenance-domain spbm index 1 maintenance-level 6

MAINTENANCE-ASSOCIATION CONFIGURATION

cfm maintenance-association "spbm" "2" index 1
cfm maintenance-association "spbm" "3" index 2

MAINTENANCE-ENDPOINT CONFIGURATION

cfm maintenance-endpoint "spbm" "2" 2 state enable
cfm maintenance-endpoint "spbm" "3" 2 state enable

VLAN NODAL MEP/MIP CONFIGURATION

vlan nodal-mep 2 spbm 2 2
vlan nodal-mip-level 2 6
vlan nodal-mep 3 spbm 3 2
vlan nodal-mip-level 3 6
    
```

*CFM Sample Output*

The following sections show sample CFM output.

L2ping can use the system ID or the router name. The example below shows a case where the VLAN and MAC are given.

**show isis adjacencies**

```

Switch:1# show isis adjacencies
=====
                        ISIS Adjacencies
=====
INTERFACE L STATE  UPTIME      PRI  HOLDTIME  SYSID          HOST-NAME  STATUS  AREA  AREA-NAME
-----
Port1/3   1  UP    00:37:37   127  22       0014.0dbf.a3df  Switch-Lab1  ACTIVE  HOME
area-9.00.02
Port1/19  1  UP    1d 05:09:16 127  25       0014.0da2.b3df  Switch-Lab2  BACKUP  HOME  area-9.00.02
-----
Home:    2 out of 2 interfaces have formed an adjacency
    
```

```
Remote: 0 out of 0 interfaces have formed an adjacency
-----
```

### L2 ping with vlan

```
Switch:1# l2 ping vlan 500 mac 00.14.0d.bf.a3.df

Please wait for l2ping to complete or press any key to abort

----00:14:0d:bf:a3:df    L2 PING Statistics----  0(68) bytes of data
1 packets transmitted, 0 packets received,   100.00% packet loss
```

### L2 ping with vlan

```
Switch:1# l2 ping vlan 500 routernodename MONTI0

Please wait for l2ping to complete or press any key to abort

----00:14:0d:a2:b3:df    L2 PING Statistics----  0(68) bytes of data
1 packets transmitted, 1 packets received,   0.00% packet loss
round-trip (us)          min/max/ave/stdv =  26895/26895/26895.00/ 0.00
```

### L2 traceroute with vlan

```
Switch:1# l2 traceroute vlan 500 routernodename MONTI0

Please wait for l2traceroute to complete or press any key to abort

l2traceroute to MONTI0 (00:14:0d:a2:b3:df),  vlan 500
0  PETER4          (00:15:9b:11:33:df)
1  MONTI0          (00:14:0d:a2:b3:df)
```

### L2 tracetree with vlan

```
Switch:1# l2 tracetree 500 1

Please wait for l2tracetree to complete or press any key to abort

l2tracetree to 53:55:10:00:00:01,  vlan 500 i-sid 1 nickname 5.55.10 hops 64
1  PETER4          00:15:9b:11:33:df -> MONTI0          00:14:0d:a2:b3:df
2  MONTI0          00:14:0d:a2:b3:df -> LEE2            00:15:e8:b8:a3:df
```

L2ping and L2traceroute can also be used with an IP address. The following outputs show examples using an IP address.

### L2 ping with IP address

```
Switch:1# l2 ping ip-address 192.0.2.10

Please wait for l2ping to complete or press any key to abort

L2 PING Statistics : IP 192.0.2.10, paths found 1, paths attempted 1

## Software Troubleshooting Tool Configuration

This section provides troubleshooting information for common software problems.

### Troubleshooting Tool Fundamentals

This section provides conceptual information about the methods and monitoring tools you can use for troubleshooting problems. This section also contains precautionary notices that you must read for the safe operation of the network.

#### *Troubleshooting Overview*

The types of problems that typically occur with networks involve connectivity and performance. This section also contains precautionary notices that you must read for the safe operation of the switch. The switch supports a diverse range of network architectures and protocols, some of which maintain and monitor connectivity and isolate connectivity faults.

In addition, the switch supports a wide range of diagnostic tools that you can use to monitor and analyze traffic, capture and analyze data packets, trace data flows, view statistics, and manage event messages.

Certain protocols and tools are tailored for troubleshooting specific switch network topologies. Other tools are more general in their application and you can use them to diagnose and monitor ingress and egress traffic on the switch.

If connectivity problems occur and the source of the problem is unknown, it is usually best to follow the Open Systems Interconnection (OSI) network architecture layers. Confirm that your physical environment, such as the cable and port connections, operates without failures before moving up to the network and application layers.

To gather information about a problem, consider the following information:

- Consider the OSI model when you troubleshoot. Start at Layer 1 and move upwards. The Address Resolution Protocol (ARP) can cause problems; ARP operates at Layer 2 to resolve MAC addresses to IP addresses (Layer 3).
- Device-specific tools and protocols can help you gather information. This document outlines switch-specific tools.
- You can use client- and server-based tools from Microsoft, Linux, and UNIX. For example, you can use Windows tools like `ifconfig`, `ipconfig`, `winipcfg`, and `route print` to obtain IP information and routing tables. Servers also maintain route tables.

The following command output shows example output of the `route print` command.

```

```

- Other network problems can give the impression that a device has a problem. For instance, problems with a Domain Name Service (DNS) server, another switch, firewall, or access point can appear to be routing problems.

### *Debug Files*

The switch stores debug files in the intflash directory.

The debug file is in a zipped format and contains information to help debug the device, including:

- a memory snapshot
- logs
- traces

This best practice is to delete these files to ensure enough space exists in the internal flash. New files do not overwrite old files. You must remove the files; otherwise, the internal flash may not have enough free space for necessary activities, for example, to store a core dump file if the switch fails, or you may not have the space to transfer a new release to the internal flash to upgrade your switch.

The switch stores a maximum of 32 files for each debug file for each slot, depending on the file size of each debug file. The internal flash provides 2 GB of storage. The system displays a message on the console to inform you when less than 700 MB is available.

The **debug-file remove** command can delete the following types of debug files:

- core
- archive
- PMEM
- dmalloc
- flrec
- wd\_stats

If you want to delete a specific file, you must use the **remove** command.

### **SNMP**

The switch does not support SNMP for the **show debug-file** or the **debug-file remove** commands.

### *Digital Diagnostic Monitoring*

Use Digital Diagnostic Monitoring (DDM) to monitor laser operating characteristics such as temperature, voltage, current, and power. This feature works during active laser operation without affecting data traffic. Transceivers in various form factors support DDM. Use the CLI command **show pluggable-optical-modules {basic|config|detail|temperature|voltage}** to make use of DDM functionality.

An interface that supports DDM is a Digital Diagnostic Interface (DDI). These devices provide real-time monitoring of individual DDI transceivers on a variety of switches and routers. The DDM software provides warnings or alarms when the temperature, voltage, laser bias current, transmitter power or receiver power fall outside of vendor-specified thresholds during initialization.

For information about DDM and supported transceivers, see [Extreme Optics](#) website and [Port Performance Management](#) on page 2832.

|                                              | VSP 4900 Series | VOSS 8.1           |
|                                              | VSP 7200 Series | VOSS 4.2.1         |
|                                              | VSP 7400 Series | VOSS 8.0           |
|                                              | VSP 8200 Series | VSP 8200 4.0       |
|                                              | VSP 8400 Series | VOSS 4.2           |
|                                              | VSP 8600 Series | VSP 8600 4.5       |
| XA1400 Series                                | VOSS 8.0.50     |                    |

The Flight Recorder is a high level term for the framework in place on the switch to store both history and current state information for various kernel, system, and application data with minimal overhead to execution. This data can later be accessed on-demand when debugging systems issues to give engineers the best possible troubleshooting information. Functionally, the Flight Recorder consists of two elements; Persistent Memory and Always-on Trace.

The Persistent Memory feature stores information in volatile memory outside of any process. This feature provides information on crashes, errors, and outages that are not the result of a power failure. Persistent Memory data not saved to non-volatile storage before a power failure will be lost. Persistent Memory snapshots are taken when:

- a critical process stops functioning
- a process stops responding
- the hardware watchdog activates
- the user initiates a snapshot in the CLI

The Always-on Trace feature creates an ongoing, circular log of every trace call recently executed regardless of the trace level enabled by the user. The Always-On Trace feature uses circular logging, and therefore stores the most recent traces of the process.

Flight Recorder functionality is provided only through CLI. This feature uses the following commands:

- **flight-recorder all {slot[-slot][, ...]}**

The command creates a flight-recorder snapshot, trace and archive.

- **flight-recorder archive {slot[-slot][, ...]}**

This command creates a tarball of flight-recorder files, log files, and configuration files.

- **flight-recorder snapshot {slot[-slot][, ...]}.**

This command takes a snapshot of PMEM data.

- **flight-recorder trace {slot[-slot][, ...]}**

This command takes a snapshot of always-on-trace data.

Port Mirroring

**Table 279: Port Mirroring product support**

| Feature                                 | Product         | Release introduced |
|-----------------------------------------|-----------------|--------------------|
| Ingress mirroring (port and flow-based) | 5320 Series     | Fabric Engine 8.6  |
|                                         | 5420 Series     | VOSS 8.4           |
|                                         | 5520 Series     | VOSS 8.2.5         |
|                                         | 5720 Series     | Fabric Engine 8.7  |
|                                         | 7520 Series     | Fabric Engine 8.10 |

|                                         | VSP 4450 Series | VSP 4000 4.0       |
|                                         | VSP 4900 Series | VOSS 8.1           |
|                                         | VSP 7200 Series | VOSS 4.2.1         |
|                                         | VSP 7400 Series | VOSS 8.0           |
|                                         | VSP 8200 Series | VSP 8200 4.0       |
|                                         | VSP 8400 Series | VOSS 4.2           |
|                                         | VSP 8600 Series | VSP 8600 4.5       |
| XA1400 Series                           | VOSS 8.0.50     |                    |
| Egress mirroring (port-based)           | 5320 Series     | Fabric Engine 8.6  |
|                                         | 5420 Series     | VOSS 8.4           |
|                                         | 5520 Series     | VOSS 8.2.5         |
|                                         | 5720 Series     | Fabric Engine 8.7  |
|                                         | 7520 Series     | Fabric Engine 8.10 |
|                                         | 7720 Series     | Fabric Engine 8.10 |
|                                         | VSP 4450 Series | VSP 4000 4.0       |
|                                         | VSP 4900 Series | VOSS 8.1           |
|                                         | VSP 7200 Series | VOSS 4.2.1         |
|                                         | VSP 7400 Series | VOSS 8.0           |
|                                         | VSP 8200 Series | VSP 8200 4.0       |
|                                         | VSP 8400 Series | VOSS 4.2           |
|                                         | VSP 8600 Series | VSP 8600 4.5       |
| XA1400 Series                           | VOSS 8.0.50     |                    |

True egress port-based mirroring that produces an identical copy of an outgoing packet is supported only on the VSP 4450 Series. On all other platforms, the mirrored copy does not reflect changes that occur in the switch to the outgoing packet (for example, packet fields that are updated during IP routing). As a result, the mirrored copy is not identical to the outgoing packet.

Use the port mirroring feature to monitor and analyze network traffic. Port mirroring supports both ingress (incoming traffic) and egress (outgoing traffic) port mirroring. When you enable port mirroring, the system forwards ingress or egress packets normally from the mirrored (source) port, and sends a copy of the packet to the mirroring (destination) port.

### Port Mirroring Overview

Port mirroring causes the switch to make a copy of a traffic flow and send the copy to a device for analysis. Use port mirroring in diagnostic sniffing—use the mirror to view the packets in the flow without breaking the physical connection to place a packet sniffer inline. You can also use mirroring for security reasons.

You can use egress mirroring to monitor packets as they leave specified ports. Egress mirroring on the switch is done at the end of the ingress pipeline. Since packet modifications occur in the egress pipeline, some of the changes will not be reflected in the mirrored version of the packet. Changes that occur in the egress pipeline may be reflected in the mirrored packet due to the metadata that is carried with the packet. Metadata notifies the egress pipeline what to change.

Use a network analyzer to observe and analyze packet traffic at the mirroring port. Unlike other methods that analyze packet traffic, the packet traffic is uninterrupted and packets flow normally through the mirrored port.

You can mirror to a port or list of ports or a MultiLink Trunking (MLT) group. The switch supports one-to-many, many-to-one, and many-to-many mirroring configurations.

### Ingress and Egress Mirrored Ports

You can use all ports in the system to function as an ingress port for mirroring (mirrored port), an egress port for mirroring (mirrored port), or as a mirroring port (where all the mirrored traffic is redirected). The number of mirroring ports (also called destination ports) that you can configure is limited by the hardware. The hardware limitation is four ports simultaneously (where each mirroring direction counts as one). For example, if two mirroring ports are designated to mirror both ingress and egress traffic then all four mirroring ports are consumed.

The following table describes ingress mirroring functionality. Only one type of mirroring destination is supported at a time. You cannot mirror the same port to multiple

classes of destinations, for example, MLT. However, you can mirror to multiple physical destinations.

**Important**

Mirroring packets from one NNI port to another NNI port is not supported. Mirror to access ports, not NNI ports.

Flow or ACL-based mirroring is not supported for ingress and egress on VSP 8600 Series.

**Table 280: Ingress mirroring functionality**

| Function                                                                                      | Support information                                 |
|-----------------------------------------------------------------------------------------------|-----------------------------------------------------|
| Ingress port mirroring and ingress flow mirroring                                             | Supported. Maximum of four mirror-to-ports per box. |
| One port to one port                                                                          | Supported                                           |
| One to MLT group [for threat protection system (TPS applications)]                            | Supported                                           |
| One to many (multicast group ID/VLAN)                                                         | Not supported                                       |
| One to one (remote mirrored destination)                                                      | Not supported                                       |
| Many to one (multiple mirrored ports to one mirroring port)                                   | Supported                                           |
| Many to MLT group                                                                             | Supported                                           |
| Many to many (VLAN/multicast group ID) (multiple ports with several different destinations)   | Not supported                                       |
| Many to one (relation between Remote Mirror Source [RMS] and Remote Mirror Termination [RMT]) | Not supported                                       |
| VLAN and port combination as a mirroring destination                                          | Not supported                                       |
| Ingress flow mirroring                                                                        | Supported                                           |
| Allow filters to specify a separate destination for each access control entry                 | Supported                                           |

The following table describes egress mirroring functionality.

**Table 281: Egress mirroring functionality**

| Function                                                    | Support information |
|-------------------------------------------------------------|---------------------|
| Egress port mirroring                                       | Supported           |
| One port to one port                                        | Supported           |
| One to MLT groups (for TPS applications)                    | Supported           |
| One to many (multicast group ID/VLAN)                       | Not supported       |
| Many to one (multiple mirrored ports to one mirroring port) | Supported           |
| Many to MLT group                                           | Supported           |

**Table 281: Egress mirroring functionality (continued)**

| Function                                                                                      | Support information |
|-----------------------------------------------------------------------------------------------|---------------------|
| Many to many (multicast group ID) (multiple ports with several different destinations)        | Supported           |
| Many to one (relation between Remote Mirror Source [RMS] and Remote Mirror Termination [RMT]) | Not supported       |
| VLAN and port combination as mirroring destination                                            | Not supported       |
| Egress flow mirroring                                                                         | Supported           |
| Allow filter to specify a separate destination for each access control entry                  | Supported           |

**Port Configuration**

You can specify a destination multilink trunking (MLT) group, a destination port or set of ports.

There are two port mirroring modes: rx (ingress, that is, inPort) and tx (egress, that is, outPort). In rx mode, when you configure the ACE mirror or ACL global options to mirror packets, use the ACE to configure the mirroring destination port.

**Note**

XA1400 Series does not support ACL global action to mirror packets.

To modify a port mirroring instance, first disable the instance. Also, to change a port or MLT entry, first remove whichever parameter is attached to the entry, and then add the required entry.

**ACLs, ACEs, and Port Mirroring**

You can use filters to reduce the amount of mirrored traffic. You can configure the mirroring action globally in an access control list (ACL), or for a specific access control entry (ACE) by using the ACE mirror actions. If you use the global action, mirroring applies to all ACEs that match in an ACL.

To use filters with port mirroring, apply an ACL to the mirrored port in the egress and ingress directions. Traffic patterns that match the ACL or ACE with an action of permit are forwarded to the destination and also to the mirroring port. Traffic patterns that match an ACE with an action of drop (deny) are not forwarded to the destination, but still reach the mirroring port. For example, for an ACL or ACE with a match action of permit, packets are mirrored to the specified mirroring destination on the ACE. If you enable a port or VLAN filter, then that filter is the mirroring filter.

You can specify more than one mirroring destination by using multiple ACEs. Use each ACE to specify a different destination.

You can configure a port-based and a flow-based mirroring filter on the same port. If such a case occurs, then the flow-based mirror takes precedence.

**Note**

XA1400 Series does not support ACL global action to mirror packets.

For information about how to configure ACLs and ACEs for port mirroring using CLI, see the following sections:

- [Configuring Global Mirroring Actions with an ACL](#) on page 3932
- [Configure ACE Actions to Mirror](#) on page 3933

For information about how to configure ACLs and ACEs for port mirroring using EDM, see the following sections:

- [Configure ACLs for Mirroring](#) on page 3956
- [Configure ACEs for Mirroring](#) on page 3958

### Port Mirroring Considerations and Restrictions

Although you can configure the switch to monitor both ingress and egress traffic, some restrictions apply:

- VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, VSP 8400 Series, VSP 8600 Series, and XA1400 Series do not support true egress mirroring because packets are mirrored prior to the completion of packet processing, so egress mirrored packets can differ from the packets egressing the port.

Only VSP 4450 Series supports true egress mirroring.

**Note**

To mirror the egress traffic for VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, VSP 8400 Series, and VSP 8600 Series platforms, you can use the NEXT-hop device ingress mirroring to capture the egress packets of the switch.

- Mirrored traffic shares ingress queue and fabric bandwidth with normal traffic and therefore can impact normal traffic. Therefore, use these features with this potential consequence in mind and enable them only for troubleshooting, debugging, or for security purposes such as packet sniffing, intrusion detection, or intrusion prevention.
- You can configure as many ingress mirroring flows as you have filters.
- To avoid VLAN members from seeing mirrored traffic, you must remove mirroring (destination) ports from all VLANs.
- The MAC drops an error packet, for example, packets that are too short or too long. Control packets consumed by the MAC (802.3x flow control) are also not mirrored.
- Certain control packets generated by the CP cannot be egress mirrored, such as those in the following list:
  - BPDU
  - EAPoL
  - IP Directed Broadcast

- LACP
  - LLDP
  - Multicast routed packets
  - NAAP
  - NLB
  - Nodal CFM
  - TDP
  - VLACP
- The system displays ingress multicast packets in egress mirroring.
  - On the VSP 7400 Series, if incoming traffic from the same source port is simultaneously ingress mirrored on an incoming port into one I-SID and egress mirrored on another outgoing port into a different I-SID, the mirrored packet carries an I-SID associated with ingress mirroring.
  - On the VSP 7400 Series, the original CVLAN tag on the mirrored packet is preserved for only one mirrored I-SID if the offset ID is 1. The original CVLAN tag is not preserved in a mirrored packet for all other remaining mirrored I-SIDs if the offset ID is in the range 2 to 1000.
  - On the VSP 7400 Series, any incoming traffic that does not contain a VLAN tag is not mirrored into an I-SID if the offset ID is in the range 2 to 1000. It is mirrored to an I-SID only if the offset ID is 1.
  - On the XA1400 Series the global mirrored action is not supported.
  - On the XA1400 Series you can configure the ACE to perform the mirroring operation. You can use the ACE mirror parameter, to configure a specific mirror to an MLT ID, port, or port list. Filters are not applied on mirrored packets.
  - On the XA1400 Series you can configure a port mirror and a flow based ACE mirror action on the same port.
  - For VSP 4900 Series or VSP 7400 Series:
    - To use an Extreme Integrated Application Hosting port with a connect type as OVS or SR-IOV for Port Mirroring, associate VLAN 4091 to the virtual machine (VM) vport to send the mirrored packets to the VM.

#### Port Mirroring Resources

Port mirroring resources are limited to four ports simultaneously (where each mirroring direction counts as one). For example, if two mirroring ports are designated to mirror both ingress and egress traffic then all four mirroring ports are consumed.

Port mirroring shares these four resources with other applications such as port mirroring RSPAN, Fabric Extend, Application Telemetry, IPFIX, and ACL with mirror

action. Each one of these applications consumes at least one port mirroring resource. (port mirroring RSPAN consumes two if you configure both Ingress and Egress modes.)

### Important

To enable any one of the preceding applications, you must have at least one free mirroring resource. If all four port mirroring resources are already in use, the switch displays a `Resource not available` error message when you try to enable the application.

The VSP 8600 Series uses the four reserved resources for port mirroring and ACLs that have a mirroring action. For the other applications, this restriction does not apply because the VSP 8600 Series uses mirroring resources that do not come out of the four reserved port mirroring resources.

If you receive a `Resource not available` error message, you can use the **show mirror-resources** command to view information about mirror resource usage. For more information, see [Displaying Mirror Resource Usage](#) on page 3932.

The **show mirror-resources** command is not available on all platforms. Use CLI command completion Help to determine if the command is available on your switch.

## General Diagnostic Tools

The switch has diagnostic features available with Enterprise Device Manager (EDM) and Command Line Interface (CLI). You can use these diagnostic tools to help you troubleshoot operational and configuration issues. You can perform such tasks as configuring and displaying log files, viewing and monitoring port statistics, tracing a route, running loopback and ping tests, and viewing the address resolution table.

### Traceroute

Traceroute determines the path a packet takes to reach a destination by returning the sequence of hops (IP addresses) the packet traverses.

According to RFC1393, traceroute operates by: "sending out a packet with a time-to-live (TTL) of 1. The first hop then sends back an ICMP error message indicating that the packet could not be forwarded because the TTL expired. The packet is then resent with a TTL of 2, and the second hop returns the TTL expired. This process continues until the destination is reached. The purpose behind this is to record the source of each ICMP TTL exceeded message to provide a trace of the path the packet took to reach the destination."

### Ping

Ping is a simple and useful diagnostic tool to determine reachability. When you use ping, the switch sends an ICMP echo request to a destination IP address. If the destination receives the packet, it responds with an ICMP echo response.

If a ping test is successful, the destination is alive and reachable. Even if a router is reachable, it could have improperly working interfaces or corrupted routing tables.

## Trace

Use trace commands to provide detailed data collection about software modules on the switch. The trace toolset can be used to trace multiple modules simultaneously and provides options to specify the verbosity level of the output.

You can enable trace logging through the boot config trace-logging flag.

### Caution

#### Risk of traffic loss

Using the trace tool inappropriately can cause a CPU lockup conditions, loss of access to the switch, loss of protocols, and service degradation.

### Tip

While these occurrences are uncommon, when using the trace level tool, minimize this risk. The following actions are:

- In situations where trace data is required concurrently from multiple modules, consider troubleshooting during a maintenance window if feasible. Consider a maintenance window period if the switch is stable but CPU utilization is high and CPU traces (example trace levels 9 and 11) are required to diagnose the cause.
- Run trace commands from the console port when the CPU utilization is already high. While you can enable or disable tracing when directly connected to the console port.

Activate tracing on one software module at a time.

- Initially activate tracing at lower verbosity settings (that is, 2 rather than 3). Increase to verbosity level 3 or 4 only if required, and after level 2 runs safely.
- Avoid leaving traces active for extended periods of time. For high CPU utilizations, a few seconds (typically less than 5 seconds) is generally sufficient to identify the cause for sustained high CPU utilization.

*Fabric RSPAN (Mirror to I-SID)*

**Table 282: Fabric RSPAN product support**

| Feature                        | Product         | Release introduced                                      |
|--------------------------------|-----------------|---------------------------------------------------------|
| Fabric RSPAN (Mirror to I-SID) | 5320 Series     | Fabric Engine 8.6                                       |
|                                | 5420 Series     | VOSS 8.4                                                |
|                                | 5520 Series     | VOSS 8.2.5                                              |
|                                | 5720 Series     | Fabric Engine 8.7                                       |
|                                | 7520 Series     | Fabric Engine 8.10                                      |
|                                | 7720 Series     | Fabric Engine 8.10                                      |
|                                | VSP 4450 Series | VOSS 6.0<br>Flow-based mirroring into single I-SID only |
|                                | VSP 4900 Series | VOSS 8.1                                                |
|                                | VSP 7200 Series | VOSS 6.0                                                |
|                                | VSP 7400 Series | VOSS 8.0                                                |
|                                | VSP 8200 Series | VOSS 6.0                                                |
|                                | VSP 8400 Series | VOSS 6.0                                                |
|                                | VSP 8600 Series | Not Supported                                           |
| XA1400 Series                  | Not Supported   |                                                         |

Remote mirroring is an important functionality that helps in:

- Intrusion Detection or Intrusion Prevention Systems
- Network Port debugging and packet capture
- Mirror and Monitor traffic to central collector or analyzers
- Mirror and Monitor traffic to distributed collectors or analyzers

With the Fabric RSPAN (Mirror to I-SID) feature, mirrored traffic captured from any switch in the network is sent to a remote switch over an SPB cloud for traffic analysis. With this feature, you can monitor traffic on ports from different switches connected in the network, using just one network analyzer connected to a remote switch which acts as a collector. The source device where the traffic is mirrored to an I-SID, is known as Mirroring BEB (Backbone Edge Bridge), and the remote device where the traffic analyzer is connected for mirrored traffic analysis is known as Monitoring BEB.

The traffic source on the mirroring BEB is supported in the following ways:

- Port based mirroring — Any packet incoming or outgoing through a port is mirrored to a monitoring I-SID configured for that port.
- Flow based mirroring — Any particular packet flow configured in the system using filter based ACLs is mirrored to a monitoring I-SID configured for that flow.

### Fabric RSPAN (Mirror to I-SID) Restrictions and Requirements

- Remote mirroring of traffic is not supported on NNI ports, Fabric Extend Layer 2 core ports, and Open Networking Adapter (ONA) devices and ports.
- Mirroring resources will be shared between Fabric RSPAN and regular port mirroring. Fabric RSPAN uses one out of four resources for mirroring if the mode is configured as Rx (Ingress) mirroring. In case of mode Tx (Egress) mirroring, it uses one more entry with same TX-LB port. Hence if mode Rx and Tx are configured for Fabric RSPAN, then only two unique destination ports can be used for regular port mirroring. For example, if you configure Fabric RSPAN on the switch, the regular port mirroring functionality can use only three unique destination ports. And, if all the four unique ports are used by the port mirroring functionality, you cannot configure Fabric RSPAN functionality on that node.
- When the monitor I-SID used for mirroring Fabric RSPAN traffic ingressing to I-SID is used to mirror regular traffic into SPB network, it will remove the customer tag in the mirrored packets. Hence, as a best practice, use different monitor I-SIDs for mirroring regular traffic and Fabric RSPAN traffic.
- Monitoring egress-ports and egress-mlt will not support regular production network traffic.
- The QoS value must be same for all mirror entries having common monitor I-SID, as the BMAC QoS is mapped to a monitor I-SID. QoS value configured for a specific monitor I-SID overrides the existing value for all mirroring entries sharing the same monitor I-SID.
- Do not configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.
- Egress flow-based I-SID mirroring is not supported.
- VSP 7400 Series does not support the following combinations for I-SID mirroring:
  - Deny option for Filter ACL with monitor-isid-offset for Inport/Invlan/InVSN
  - Redirect-Next-Hop along with monitor-isid-offset when monitor-isid-offset is greater than 1
  - Remove Tag option along with monitor-isid-offset
- For VSP 4900 Series or VSP 7400 Series:
  - To use an Extreme Integrated Application Hosting port as an analyzer port on a monitoring BEB for Fabric RSPAN (Mirror to I-SID), you must associate outer-tag 4091 to egress port 1/s1 or 1/s2 if the connect type is OVS or SR-IOV. Use the **monitor-by-isid <1-1000> map-to-vid <1-4093>** command to configure VLAN 4091 for Fabric RSPAN.

## Software Troubleshooting Tool Configuration Using CLI

Use the tools described in this section to perform troubleshooting procedures using CLI.

*Using CLI for Troubleshooting*

You can use CLI to provide diagnostic information.

**Procedure**

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Disable scrolling of the output display:

```
terminal more disable
```

3. View configuration file information:

```
more WORD<1-99>
```

4. Capture the output for the following command after you observe a problem with the device:

```
show running-config [verbose] [module {app-telemetry | boot | cfm |
cli | diag | dvr | eap | endpoint-tracking | energy-saver | fa | fhs
| filter | ike | ip | ipfix | ipsec | ipv6 | iqagent | isis | i-sid |
lACP | license | lldp | lst | macsec | mlt | naap | nls | ntp | ovsdb
| port | qos | radius | restconf | rmon | sflow | security | slamon |
slpp | smtp | spbm | stg | sys | tacacs | virtualservice | vlan | web
| vxlan}]
```

5. Capture the output for the following command after you observe a problem with the device:

```
show tech
```

**Note**

`show tech` is an alias for `show fulltech`. Both commands provide the same output.

6. Capture the output for the following commands after you observe a problem with the device:

**Note**

The **`show interfaces gigabitEthernet statistics rmon`** command displays information only if you previously configured **`rmon stats`** or **`rmon history`**.

- `show interfaces gigabitEthernet statistics <dhcp-relay [vrf WORD<1-16>][vrfids WORD<0-512>] [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`
- `show interfaces gigabitEthernet statistics lacp [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`
- `show interfaces gigabitEthernet statistics rate-limiting [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`
- `show interfaces gigabitEthernet statistics policer [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`

- `show interfaces gigabitEthernet statistics rmon [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]`
- `show interfaces gigabitEthernet statistics verbose [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]`
- `show interfaces gigabitEthernet statistics vlacp [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]`

7. Capture the output for the following command after you observe a problem with the device:

**Note**

Product Notice: If you run this command on an XA1400 Series switch, most of the values report as zero (0). To see port-level error counters for XA1400 Series, use the `show io nic-counters` command instead.

```
show interfaces gigabitEthernet error [collision|ospf|verbose] [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]
```

**Examples**

Due to the length of command output, the following examples are truncated.

Capture the output for the following commands after you observe a problem with the device:

```
Switch:1>enable
Switch:1#show running-config module cli

## Variable Definitions

The following table defines parameters for the **more** command.

| Variable                      | Value                                                                                                                                                            |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>WORD&lt;1-99&gt;</code> | Specifies the file name to view. Provide the filename in one of the following formats: <code>a.b.c.d:&lt;file&gt;</code> , <code>/intflash/&lt;file&gt;</code> . |

The following table defines parameters for the **show running-config** command.

| Variable                                                                                                                                                                                                                                                                                                                                                                                                                | Value                                                                                                                                                                                                                                                                              |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>module {app-telemetry   boot   cfm   cli   diag   dvr   eap   endpoint-tracking   energy-saver   fa   fhs   filter   ike   ip   ipfix   ipsec   ipv6   iqagent   isis   i-sid   lacp   license   lldp   lst   macsec   mlt   naap   nls   ntp   ovsdb   port   qos   radius   restconf   rmon   sflow   security   slamon   slpp   smtp   spbm   stg   sys   tacacs   virtualservice   vlan   web   vxlan}</code> | Specifies the command group for which you request configuration settings.<br><br><b>Note:</b><br>All configuration modules are not supported on all hardware platforms. For information about feature support, see <a href="#">Fabric Engine and VOSS Feature Support Matrix</a> . |
| <code>verbose</code>                                                                                                                                                                                                                                                                                                                                                                                                    | Specifies a complete list of all configuration information about the switch.                                                                                                                                                                                                       |

The following table defines parameters for the **show interfaces gigabitEthernet statistics** command.

| Variable                                                                                                                        | Value                                                                |
|---------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| <code>dhcp-relay [vrf WORD&lt;1-16&gt; ] [vrfids WORD&lt;0-512&gt; {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Displays port Dynamic Host Configuration Protocol (DHCP) statistics. |
| <code>lacp {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>                                                         | Displays Link Aggregation Control Protocol (LACP) statistics.        |
| <code>rate-limiting {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>                                                | Displays port ingress rate-limiting statistics.                      |
| <code>rmon {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} [history]</code>                                               | Displays Remote Network Monitoring (RMON) statistics.                |

| Variable                                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <code>vlacp [history] {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | <p>Displays port Virtual Link Aggregation Control Protocol (VLACP) statistics.</p> <ul style="list-style-type: none"> <li>• <code>history</code>—Displays the VLACP port counter profile.</li> <li>• <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code></li> </ul> <p>Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p> |

The following table defines parameters for the **show interfaces gigabitEthernet error** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>collision</code>                                             | Displays port collision error information.                                                                                                                                                                                                                                                                                                                           |
| <code>ospf</code>                                                  | Displays ports Open Shortest Path First (OSPF) error information.                                                                                                                                                                                                                                                                                                    |
| <code>verbose</code>                                               | Displays all port error information.                                                                                                                                                                                                                                                                                                                                 |
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | <p>Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p> |

### Display NIC Counters

**Note**

This procedure only applies to XA1400 Series.

Use the following procedure to display the NIC statistics and counters.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display NIC counter statistics:  

```
show io nic-counters
```

**Example**

```
Switch:1# show io nic-counters
```

```
===== PORT 1 NIC STATS =====

## Using Software Record Dumps

### About This Task

Capture a dump of the software records from ingress traffic to help troubleshoot performance problems. Generally, a verbosity level of 1 suffices.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Dump software record information:  
dump ar <1-12> WORD<1-1536> <0-3>

**Example**

```
Switch:1> enable
Switch:1# dump ar 1 vlan 1
```

**Variable Definitions**

The following table defines parameters for the **dump ar** command.

| Variable     | Value                                                                                                                  |
|--------------|------------------------------------------------------------------------------------------------------------------------|
| <1>          | Specifies the slot number.                                                                                             |
| WORD<1-1536> | Specifies a record type in the AR table. Options include vlan, ip_subnet, mac_vlan, mac, arp, ip, ipmc, protocol, all. |
| <0-3>        | Specifies the verbosity from 0–3. Higher numbers specify more verbosity.                                               |

*Use Trace to Diagnose Problems*

Use trace to observe the status of a software module at a given time.

**About This Task**

For example, if you notice a CPU utilization issue (generally a sustained spike above 90%) perform a trace of the control plane activity.

**Procedure**

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Clear the trace:  
clear trace
3. Identify the module ID for which you want to use the trace tool:  
show trace modid-list
4. Begin the trace operation:  
trace level [<Module\_ID>] [<0-4>]

5. Wait approximately 30 seconds.

The default trace settings for CPU utilization are:

- High CPU Utilization: 90%
- High Track Duration: 5 seconds
- Low CPU Utilization: 75%
- Low Track Duration: 5 seconds

6. Stop tracing:

```
trace shutdown
```

7. View the trace results:

```
show trace file [tail]
```

8. Search trace results for a specific string value, for example, the word error:

```
trace grep [WORD<0-128>]
```

If you use this command and do not specify a string value, you clear the results of a previous search.

9. Stop tracing:

```
trace shutdown
```

### Example

```
Switch:1> enable
```

Clear the trace:

```
Switch:1# clear trace
```

Identify the module ID for which you want to use the trace tool:

```
Switch:1# show trace modid-list
```

```
0 - COMMON
1 - SNMP
2 - RMON
3 - PORT_MGR
4 - CHAS_MGR
5 - BRIDGE
6 - HWIF
7 - SIM
8 - CPP
9 - NETDRV
10 - VLAN_MGR
11 - CLI
12 - MAIN
12 - P2IP
12 - RCIP
15 - WEBSRV
16 - ACIF
17 - GBIF
18 - WDT
19 - TDP
20 - MAN_DIAG
21 - MAN_TEST

--More-- (q = quit)
```

Begin the trace operation:

```
Switch:1# trace level 2 3
```

Stop tracing:

```
Switch:1# trace shutdown
```

Save the trace file to the internal flash card for retrieval:

```
Switch:1# save trace
```

Search trace results for a specific string value, for example, the word error:

```
Switch:1# trace grep error
```

Search trace results for a specific string value, for example, MAC address 00-1A-4B-8A-FB-6B:

```
Switch:1# trace grep 00-1A-4B-8A-FB-6B
```

### Variable Definitions

The following table defines parameters for the **trace** command.

| Variable                                                         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>grep</i> [ <i>WORD</i> <0-128>]                               | Search trace results for a specific string value, for example, the word error. Performs a comparison of trace messages.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>level</i> [ <i>&lt;Module_ID&gt;</i> ] [ <i>&lt;0-4&gt;</i> ] | Starts the trace by specifying the module ID and level. <ul style="list-style-type: none"> <li><i>&lt;Module_ID&gt;</i> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the <b>show trace modid-list</b> command or CLI command completion Help.</li> <li><i>&lt;0-4&gt;</i> specifies the trace level from 0–4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.</li> </ul> |
| <i>shutdown</i>                                                  | Stops the trace operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>screen</i> { <i>disable</i>   <i>enable</i> }                 | Enables the display of trace output to the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

The following table defines parameters for the **save trace** command.

| Variable                       | Value                                                                                                                           |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <i>file</i> <i>WORD</i> <1-99> | Specifies the file name in one of the following formats: <ul style="list-style-type: none"> <li>a.b.c.d:&lt;file&gt;</li> </ul> |

### Use Trace to Diagnose IPv6 Problems

Use trace to observe the status of IPv6 at a certain time.

## Before You Begin

- Confirm that trace level 99 is set to a value of 1 before you use trace to diagnose IPv6 problems. Trace level 1 is very terse.

### Caution

#### Risk of traffic loss

Using the trace tool inappropriately can cause CPU lockup conditions, loss of access to the device, loss of protocols, and service degradation.

## Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Activate or deactivate the trace for the IPv6 base:

```
trace ipv6 base <disable|enable> <all|debug|error|icmp|info|ipclient|
nbr|pkt|warn> [vrf WORD <1-16>]
```

3. Activate or deactivate the trace for IPv6 forwarding:

```
trace ipv6 forwarding <disable|enable> <all|debug|error|info|pkt|warn>
[vrf WORD <1-16>]
```

4. Activate or deactivate the trace for IPv6 neighbor discovery:

```
trace ipv6 nd <disable|enable> <all|debug|error|info|nbr|pkt|redirect|
warn> [vrf WORD <1-16>]
```

5. Activate or deactivate the trace for IPv6 OSPF:

```
trace ipv6 ospf <disable|enable> <adj|all|config|error|import|info|
lsa|pkt|spf|warn> [vrf WORD <1-16>]
```

6. Activate or deactivate the trace for the IPv6 routing table manager:

```
trace ipv6 rtm <disable|enable> <all|change-list|debug|error|fib|info|
redist|update|warn> [vrf WORD <1-16>]
```

7. Activate or deactivate the trace for IPv6 transport:

```
trace ipv6 transport <disable|enable> <all|common|tcp|udp> [vrf WORD
<1-16>]
```

8. Deactivate the trace to prevent service degradation:

```
trace shutdown
```

```
clear trace
```

## Examples

```
Switch:1>enable
```

Activate the trace for all the IPv6 base categories on the Management Router:

```
Switch:1#trace ipv6 base enable all vrf MgmtRouter
```

Activate the trace for all the IPv6 forwarding categories:

```
Switch:1#trace ipv6 forwarding enable all
```

Activate the trace for all the IPv6 neighbor discovery categories:

```
Switch:1#trace ipv6 nd enable all
```

Activate the trace for the all IPv6 routing table manager categories:

```
Switch:1#trace ipv6 rtm enable all
```

Activate the trace for all the IPv6 transport categories:

```
Switch:1#trace ipv6 transport enable all
```

Deactivate the trace:

```
Switch:1#trace shutdown
```

```
Switch:1#clear trace
```

```
Removed 5 files.
```

### Variable Definitions

The following table defines parameters for the **trace ipv6** command.

| Variable                                                                                          | Value                                                                         |
|---------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------|
| <i>base</i> <disable enable><br><all debug error icmp info <br>ipclient nbr pkt warn>             | Enables or disables a specific trace category for IPv6 base.                  |
| <i>forwarding</i> <disable <br>enable> <all debug error <br>info pkt warn>                        | Enables or disables a specific trace category for IPv6 forwarding.            |
| <i>nd</i> <disable <br>enable> <all debug error <br>info nbr pkt redirect warn>                   | Enables or disables a specific trace category for IPv6 neighbor discovery.    |
| <i>ospf</i> <disable <br>enable> <adj all config <br>error import info lsa pkt <br>spf warn>      | Enables or disables a specific trace category for IPv6 OSPF.                  |
| <i>rtm</i> <disable <br>enable> <all change-<br>list debug error fib info <br>redist update warn> | Enables or disables a specific trace category for IPv6 routing table manager. |
| <i>transport</i> <disable enable><br><all common tcp udp>                                         | Enables or disables a specific trace category for IPv6 transport.             |
| <i>vrf</i> WORD<1-16>                                                                             | Specifies the VRF name.                                                       |

### View and Delete Debug Files

Use this procedure to view and delete debug files.

Delete debug files to free space in the internal flash. As a best practice, delete these files to ensure enough space exists in intflash. New debug files do not overwrite old debug files. You must remove the file; otherwise, enough free space might not exist in

the intflash to store the core dump if the switch fails or enough space might not exist for you to transfer a new release to the intflash of the switch to upgrade your switch.

The **debug-file remove** command can delete the following types of files:

- core
- archive
- PMEM
- dmalloc
- flrec
- wd\_stats

If you want to delete a specific file, you must use the **remove** command. For more information, see [VOSS CLI Commands Reference](#).

### Procedure

1. To enter User EXEC mode, log on to the switch.

2. View debug files:

```
show debug-file [all] [{slot[-slot]][,...]]
```

3. Delete debug files:

```
debug-file remove [all]
```

4. Enter Privileged EXEC mode:

```
enable
```

5. View core files:

```
show core-files {slot[-slot]][,...]]
```

### Example

The following example shows how you view all debug files for all slots.

```
Switch>show debug-file

=====
                          Core Files
=====
Directory: /intflash/coreFiles/1

### Variable Definitions

The following table defines parameters for the **show core-files** command.

| Variable                          | Value                                                 |
|-----------------------------------|-------------------------------------------------------|
| <code>{slot[-slot][, ...]}</code> | Displays the core files for the slot that you select. |

The following table defines parameters for the **show debug-file** command.

| Variable                          | Value                                                                                                                                                                                                                                                                           |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>all</code>                  | Displays all types of debug files                                                                                                                                                                                                                                               |
| <code>{slot[-slot][, ...]}</code> | Displays debug files for the slot that you select. If you do not select a slot number, the device displays all types of the archived debug files present in a slot by slot basis. If you select a slot number, the device only displays archived files for the slot you select. |

The following table defines parameters for the **debug-file remove** command.

| Variable         | Value                                                                                                                                                                                                             |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>all</code> | Removes all types of debug files in all slots.<br>If you use the option <b>all</b> with the <b>remove debug-file</b> command, then the device deletes all types of debug files, including the latest debug files. |

### Configuring Port Mirroring

Use port mirroring to aid in diagnostic and security operations.

#### About This Task

Use port mirroring to make a copy of a traffic flow and send that copy to a device for analysis, for example, for diagnostic sniffing. Use the mirror to see the packets in the flow without breaking into the physical connection to place a packet onto the sniffer inline. You can also use port mirroring for security. You can send flows to inspection engines for post processing.

Connect the sniffer (or other traffic analyzer) to the output port you specify in this procedure.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```

## 2. Create a port mirroring instance:

```
mirror-by-port <1-479> in-port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} {monitor-mlt <1-512>| out-port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

## 3. Create an I-SID mirroring instance:

```
mirror-by-port <1-479> [in-port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} monitor-isid-offset <1-1000> [mode <rx|tx|both>] [qos <qos-level>]]
```

## 4. Configure the mode:

```
mirror-by-port <1-479> mode <both|rx|tx>
```

**Note**

- When you configure `tx` mode port mirroring on T-UNI and SPBM NNI ports, unknown unicast, broadcast and multicast traffic packets that ingress these ports and the system displays it on the mirror destination port, although they do not egress the mirror source port. This is because `tx` mode port mirroring happens on the mirror source port before the source port squelching logic drops the packets at the egress port.
- The available four mirroring resources are shared between Fabric RSPAN and regular port mirroring, and are allocated based on the mode configured, Ingress (`rx`) or Egress (`tx`). Each configured mode occupies one mirroring resource, but when you configure the mode as `both`, it occupies two mirroring resources (one for Rx and one for Tx).
- Do not configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.

## 5. Enable the mirroring instance:

```
mirror-by-port <1-479> enable
```

## 6. Modify existing mirroring entries as required:

```
mirror-by-port mirror-port <1-479> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

OR

```
mirror-by-port monitor-mlt <1-479> <1-512>
```

OR

```
mirror-by-port monitor-port <1-479> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

**Note**

Before you can modify an existing entry, you must disable the entry: `no mirror-by-port <1-479> enable`.

## 7. Modify QoS value for Fabric RSPAN mirroring session:

```
mirror-by-port <1-479> qos <0-5>
```

## 8. Verify the configuration:

```
show mirror-by-port
```

**Example**

## Port mirroring configuration:

```
Switch:1> enable
Switch:1# configure terminal
```

## Create the port mirroring instance:

```
Switch:1(config)# mirror-by-port 8 in-port 1/15 out-port 1/1
```

The analyzer connects to port 1/1.

## Disable the entry:

```
Switch:1(config)# no mirror-by-port 8 enable
```

## Mirror both ingress and egress traffic passing through port 1/16:

```
Switch:1(config)# mirror-by-port 8 mode both
```

## Enable mirroring for the instance:

```
Switch:1(config)# mirror-by-port 8 enable
```

## Fabric RSPAN configuration:

```
Switch:1> enable
Switch:1# configure terminal
```

## Create the Fabric RSPAN mirroring instance:

```
Switch:1(config)#mirror-by-port 3 in-port 1/3 monitor-isid-offset 3 mode both qos 3
```

Disable the entry:

```
Switch:1(config)# no mirror-by-port 3 enable
```

Mirror the egress traffic passing through port 1/3:

```
Switch:1(config)# mirror-by-port 3 mode tx
```

Enable Fabric RSPAN for the instance:

```
Switch:1(config)# mirror-by-port 3 enable
```

The sample command output in the following example does not necessarily reflect the preceding examples.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#show mirror-by-port

| <i>enable</i>                                                                                                                                                   | Enables or disables a mirroring instance already created in the mirror-by-port table.                                                                                                                                                                                                                                                                                                           |
| <i>in-port</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}<br>{ monitor-mlt <1-512>  out-port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} } | Creates a new mirror-by-port table entry. <ul style="list-style-type: none"> <li><i>in-port</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} specifies the mirrored port.</li> <li><i>monitor-mlt</i> &lt;1-512&gt; specifies the mirroring MLT ID from 1-512.</li> <li><i>out-port</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} specifies the mirroring port.</li> </ul> |
| <i>mirror-port</i> <1-479> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} }                                                                              | Modifies the mirrored port. Before you can modify an existing entry, you must disable the entry: no mirror-by-port <1-479> enable.                                                                                                                                                                                                                                                              |

| Variable                                                                                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>monitor-ip &lt;1-479&gt; {A.B.C.D} [dscp &lt;0-63&gt;] [ttl &lt;2-255&gt;]</code>       | Creates a mirroring instance for Layer 3 mirroring. The destination must be an IP address {A.B.C.D}. The default DSCP is 0 and the default TTL is 255.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>monitor-mlt &lt;1-479&gt; &lt;1-512&gt;</code>                                          | Modifies the monitoring MLT.<1-512> specifies the mirroring MLT ID. Before you can modify an existing entry, you must disable the entry: <code>no mirror-by-port &lt;1-479&gt; enable</code> .                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>monitor-port &lt;1-479&gt; {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Modifies the monitoring ports. Before you can modify an existing entry, you must disable the entry: <code>no mirror-by-port &lt;1-479&gt; enable</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>monitor-vlan &lt;1-479&gt; &lt;1-4059&gt;</code>                                        | Modifies the monitoring VLAN. Before you can modify an existing entry, you must disable the entry: <code>no mirror-by-port &lt;1-479&gt; enable</code> . Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spsbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>mode &lt;both rx tx&gt;</code>                                                          | Configures the mirroring mode. The default is rx. <ul style="list-style-type: none"> <li>• <code>both</code> mirrors both egress and ingress packets.</li> <li>• <code>rx</code> mirrors ingress packets.</li> <li>• <code>tx</code> mirrors egress packets.</li> </ul>                                                                                                                                                                                                                                                                                                                          |
| <code>monitor-isid-offset &lt;1-1000&gt;</code>                                               | Specifies the offset ID that is mapped to the actual monitor I-SID where packets are mirrored. Monitor I-SID = base monitor I-SID + offset ID. The base monitor I-SID is 16776000.                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>qos &lt;0-5&gt;</code>                                                                  | Specifies the Quality of Service (QoS) profiles for the system. Monitoring I-SID supports six different QoS levels, each QoS level can be configured individually. Default value is 1.                                                                                                                                                                                                                                                                                                                                                                                                           |

*Displaying Mirror Resource Usage***About This Task**

Mirror resources can be consumed by internal processes that are not easily identified, which can lead to unexpected resource shortages. Use the following procedure to display mirror resource usage.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display mirror resource usage:

```
show mirror-resources
```

**Example**

```
Switch:1#show mirror-resources
<Switch> Mirror Resource Manager stats:
      2 unique mirror destinations allocated, system max is 4
-----
Mirror      | Mirror    | Total | Mirror
Destination| Direction| Refs  | Users
-----
Port 1/2    | Egress   | 1     | MBP ID 1
Port 1/2    | Ingress  | 1     | MBP ID 1
-----
Function execution completed successfully
```

*Configuring Global Mirroring Actions with an ACL*

Configure the global action to mirror packets that match an access control list (ACL).

**Before You Begin**

- The ACL exists.

**Procedure**

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the global action for an ACL:
 

```
filter acl set <1-2048> global-action {monitor-dst-mlt <1-512>|
monitor-dst-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

**Example**

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

Configure the global action for an ACL:

```
Switch:1(config)# filter acl set 200 global-action monitor-dst-mlt 20
```

### Variable Definitions

The following table defines parameters for the **filter acl set** command.

| Variable                                                                                                                                                                                | Value                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-2048>                                                                                                                                                                                | Specifies an ACL ID from 1-2048.                                                                                                                                                                                                                                                                                 |
| <i>default-action</i> <deny permit>                                                                                                                                                     | Specifies the global action to take for packets that do not match an ACL.                                                                                                                                                                                                                                        |
| <i>global-action</i> { <i>monitor-dst-mlt</i> <i>PT_MLT</i> <1-512>  <i>monitor-dst-ports</i> { <i>slot/port</i> [/ <i>sub-port</i> ] [- <i>slot/port</i> [/ <i>sub-port</i> ]] [,...]} | Specifies the global action to take for matching ACLs: <ul style="list-style-type: none"> <li>• <i>monitor destination MLT</i>—Configures mirroring to a destination MultiLink Trunking (MLT) group.</li> <li>• <i>monitor destination ports</i>—Configures mirroring to a destination port or ports.</li> </ul> |

### Configure ACE Actions to Mirror

#### Important

Product Notice: VSP 8600 Series supports Policy Based Routing (Redirect Next Hop) Per VRF as a demo feature. Do not use this feature in production environments.

Configure actions to use filters for flow-based mirroring.

#### Before You Begin

- The access control entry (ACE) exists.

#### About This Task

If you use the mirror action, ensure that you specify the mirroring destination: MLTs or ports.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure actions for an ACE:
 

```
filter acl ace action <1-2048> <1-2000> {permit|deny} monitor-dst-mlt
<1-512>
```

OR

```
filter acl ace action <1-2048> <1-2000> {permit|deny} monitor-dst-
ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```
3. Ensure the configuration is correct:
 

```
show filter acl action [<1-2048>] [<1-2000>]
```

#### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# filter acl ace action 901 1 permit monitor-dst-mlt 5
```

### Variable Definitions

The following table defines parameters for the **filter acl ace action** command.

| Variable                                                                       | Value                                                                      |
|--------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| <i>1-2048</i>                                                                  | Specifies the ACL ID from 1–2048                                           |
| <i>1-2000</i>                                                                  | Specifies the ACE ID from 1–2000.                                          |
| <i>monitor-dst-mlt &lt;1-512&gt;</i>                                           | Configures mirroring to a destination MLT group.                           |
| <i>monitor-dst-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Configures mirroring to a destination port or ports.                       |
| <i>{permit deny}</i>                                                           | Configures the action mode for security ACEs. The default value is permit. |

### Clearing ARP Information for an Interface

Clear the Address Resolution Protocol (ARP) cache as part of ARP problem resolution procedures.

#### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Clear ARP information:

```
clear ip arp interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

OR

```
clear ip arp interface vlan <1-4059>
```

#### Example

```
Switch:1> enable
```

```
Switch:1# clear ip arp interface gigabitethernet 1/1
```

### Variable Definitions

The following table defines parameters for the `clear ip arp interface` command.

| Variable                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                              | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |

### Flush Routing, MAC, and ARP Tables for a Port

Flush or clear the routing tables for administrative and troubleshooting purposes. The clear and flush commands perform the same function; they remove the contents of the table.

#### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Flush IP routing tables by port:

```
action flushIp
```

3. Flush the MAC address tables by port:

```
action flushMacFdb
```

#### Note

Flushing MAC address tables multiple times in a very short period of time can cause undefined errors. Wait at least 10 seconds between MAC flushes on VSP 8600 Series.

4. Flush ARP tables by port:

```
action flushArp
```

5. Flush all tables with one command:

```
action flushAll
```

6. Exit to Global Configuration mode:

```
exit
```

7. Clear a routing table for a port:

```
clear ip route gigabitEthernet {slot/port[sub-port]}
```

#### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config-if)#action flushAll
Switch:1(config-if)#exit
Switch:1(config)#clear ip route gigabitEthernet 1/1
```

#### Variable Definitions

The following table defines parameters for the **clear ip route gigabitEthernet** command.

| Variable                            | Value                                                                                                                                                                        |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port]}</code> | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

#### *Flush Routing, MAC, and ARP Tables for a VLAN*

Flush or clear the routing tables for administrative and troubleshooting purposes. The clear and flush commands perform the same function; they remove the contents of the table.

#### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Flush IP routing tables by VLAN:

```
vlan action <1-4059> flushIp
```

3. Flush the MAC address tables by VLAN:

```
vlan action <1-4059> flushMacFdb
```

**Note**

Flushing MAC address tables multiple times in a very short period of time can cause undefined errors. Wait at least 10 seconds between MAC flushes on VSP 8600 Series.

4. Flush ARP tables by VLAN:

```
vlan action <1-4059> flushArp
```

5. Flush all tables with one command:

```
vlan action <1-4059> all
```

6. Clear a routing table for a VLAN:

```
clear ip route vlan <1-4059>
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config-if)#vlan action 123 all
Switch:1(config)#clear ip route vlan 123
```

**Variable Definitions**

The following table defines parameters for the **vlan action** and **clear ip route vlan** commands.

| Variable | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

*Ping an IP Device*

**About This Task**

Ping a device to test the connection between the switch and another network device. After you ping a device, the switch sends an Internet Control Message Protocol (ICMP) packet to the target device. If the device receives the packet, it sends a ping reply. After the switch receives the reply, a message displays that indicates traffic can reach the specified IP address. If the switch does not receive a reply, the message indicates the address does not respond.

Ping and traceroute can fail for VRF routes if you use large packet sizes for the operation. Do not use packet sizes larger than the following:

- Ping for VRF: 1480 bytes
- Traceroute for VRF: 1444 bytes

#### Note

Exception: large packets for VRF routes are supported on the CLIP Segmented Management Instance.

You can specify a management instance ID to use the correct source for the outgoing ICMP ECHO request packet.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Ping an IP network connection:

```
ping WORD<0-256> [-d] [-I <1-60>] [-s] [-t <1-120>] [count <1-9999>]
[datasize <28-9216|28-51200>] [grt] [interface gigabitEthernet {slot/
port[sub-port]}| tunnel <1-2000> | vlan <1-4059>] [scopeid <1-9999>]
[source WORD<1-256>] [vrf WORD<1-16>]
```

3. Ping an IP network connection using a Global Routing Table (GRT):

```
ping WORD<0-256> [-d] [-I <1-60>] [-s] [-t <1-120>] [count <1-9999>]
[datasize <28-9216|28-51200>] grt [interface gigabitEthernet {slot/
port[sub-port]}| tunnel <1-2000> | vlan <1-4059>] [source WORD<1-246>]
```

4. Ping a network connection using a Segmented Management Instance:

```
ping WORD<0-256> [-s] [-t <1-120>] [count <1-9999>] [datasize
<28-9216|28-51200>] mgmt [clip | oob | vlan]
```

#### Note

If you do not use the *mgmt* parameter, the **ping** command uses the IP routing stack to initiate the ping request.

If you ping a device using a management CLIP, the ping source IP address is configured as the management CLIP IP address. If you ping a device using a management VLAN, the ping source IP address is configured as the management VLAN IP address.

#### Examples

Ping an IP device from a GRT VLAN IP interface:

```
Switch:1#ping 192.0.2.16 grt interface vlan 1
192.0.2.16 is alive
```

Ping a device using the management routing table:

```
Switch:1#ping 192.0.2.12 mgmt
```

Ping a device using a management CLIP:

```
Switch:1#ping 192.0.2.12 mgmt clip
```

Ping an IP device using a management VLAN:

```
Switch:1#ping 192.0.2.12 mgmt vlan
```

### Variable Definitions

The following table defines parameters for the **ping** command.

| Variable                                                                                                   | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>count &lt;1-9999&gt;</code>                                                                          | Specifies the number of times to ping. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>-d</code>                                                                                            | Configures the ping debug mode. This variable detects local software failures (ping related threads creation or write to sending socket) and receiving issues (icmp packet too short or wrong icmp packet type). This parameter does not apply if you use the <code>mgmt [clip   oob   vlan]</code> parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>datasize &lt;28-9216 28-51200&gt;</code>                                                             | Specifies the size of ping data sent in bytes. The <code>datasize</code> for IPv4 addresses is 28-9216. The <code>datasize</code> for IPv6 addresses is 28-51200. The default is 64.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>grt</code>                                                                                           | Specifies the ping in Global Routing Table context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>-I &lt;1-60&gt;</code>                                                                               | Specifies the interval between transmissions in seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>interface gigabitEthernet {slot/port[sub-port]}   tunnel &lt;1-2000&gt;   vlan &lt;1-4059&gt;</code> | <p>Specifies the outgoing interface. Additional ping interface parameters:</p> <ul style="list-style-type: none"> <li><code>gigabitEthernet {slot/port[sub-port]}</code>: gigabitethernet port</li> <li><code>tunnel</code>: tunnel ID as a value from 1 to 2000</li> <li><code>vlan</code>:</li> </ul> <p>Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.</p> <p>This parameter does not apply if you use the <code>mgmt [clip   oob   vlan]</code> parameter.</p> |

| Variable                                                                                                           | Value                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mgmt [clip   oob   vlan]</code><br><b>Note:</b><br>Exception: <code>oob</code> not supported on 5320 Series. | Specifies the Segmented Management Instance as the source for the outgoing ICMP ECHO packet. The packet goes out this specific interface only.<br>If you do not specify the management interface type, the <b>ping</b> command uses the management routing table to determine the best management interface and selects the source IP based on the egress management interface. |
| <code>-s</code>                                                                                                    | Configures the continuous ping at the interval rate defined by the <code>[-I]</code> parameter or until you enter a <b>Ctrl + C</b> keystroke.                                                                                                                                                                                                                                  |
| <code>scopeid &lt;1-9999&gt;</code>                                                                                | Specifies the circuit ID for IPv6. The default is 5.                                                                                                                                                                                                                                                                                                             |
| <code>WORD&lt;0-256&gt;</code>                                                                                     | Specifies the host name or IPv4 (a.b.c.d) or IPv6 (x:x:x:x:x:x) address.                                                                                                                                                                                                                                                                                                        |
| <code>vrf WORD&lt;1-16&gt;</code>                                                                                  | Specifies the virtual router and forwarder (VRF) name. This parameter does not apply if you use the <code>mgmt [clip   oob   vlan]</code> parameter.                                                                                                                                                                                                                            |

### Run a Traceroute Test

Use traceroute to determine the route packets take through a network to a destination.

### About This Task

Ping and traceroute can fail for VRF routes if you use large packet sizes for the operation. Do not use packet sizes larger than the following:

- Ping for VRF: 1480 bytes
- Traceroute for VRF: 1444 bytes

#### Note

Exception: large packet sizes are supported when running ping and traceroute on the Segmented Management Instance.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`

## 2. Run a traceroute test:

```
traceroute WORD<0-256> [<1-1176>] [-m <1-255>] [-p <1-65535>] [-q  
<1-255>] [-v] [-w <1-255>] [grt [source]] [mgmt [clip | oob | vlan]]  
[source <WORD 1-256>] [vrf <WORD 1-16>]
```

## 3. Run a traceroute test using a Segmented Management Instance:

```
traceroute WORD<0-256> [<1-1176>] [-m <1-255>] [-p <1-65535>] [-q  
<1-255>] [-w <1-255>] [grt [source]] mgmt [<clip | oob | vlan>]
```

### Note

If you do not use the *mgmt* parameter, the **traceroute** command uses the IP routing stack to initiate the traceroute request.

## Examples

Run a traceroute test with a probe packet size of 200 and a max time to live of 60:

```
Switch:1>enable  
Switch:1#traceroute 192.0.2.33 200 -m 60
```

Run a traceroute test for an IPv6 address:

```
Switch:1#traceroute 2001:db8::1
```

Run a traceroute test using the management routing table:

```
Switch:1#traceroute 192.0.2.12 mgmt
```

Run a traceroute test using a management CLIP:

```
Switch:1#traceroute 192.0.2.12 mgmt clip
```

Run a traceroute test using a management VLAN:

```
Switch:1#traceroute 192.0.2.12 mgmt vlan
```

## Variable Definitions

The following table defines parameters for the **tracert** command.

| Variable                                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-m &lt;1-255&gt;</code>                 | Specifies the maximum time-to-live (TTL).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>-p &lt;1-65535&gt;</code>               | <p>Specifies the base UDP port number. The default is 33434.</p> <p><b>Note:</b><br/>If the tracert action is directed to an IPv6 host address, Linux increments the UDP port on a per-TTL basis. For an IPv4 host address, Linux increments the UDP port on a per-probe basis. Because the <b>tracert</b> command sends a default of three probes, three incrementing ports will be sent for an IPv4 host address. If you use the <code>-p</code> parameter with a value greater than 65533, the <b>tracert</b> command fails for an IPv4 host address because the maximum port number, 65535, is exceeded.</p> <p>If you send a tracert probe into the device through the Segmented Management Instance or any routing interface, you must use the default UDP port range of 33434 to 33534. Using other ports will fail.</p> |
| <code>-q &lt;1-255&gt;</code>                 | Specifies the number of probes per TTL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>-v</code>                               | Specifies verbose mode (detailed output). This parameter does not apply if you use the <code>mgmt [clip   oob   vlan]</code> parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>-w &lt;1-255&gt;</code>                 | Specifies the wait time for each probe.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>&lt;1-1176&gt;</code>                   | Specifies the size of the probe packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>grt</code>                              | Specifies the <b>tracert</b> command is executed in <code>grt</code> context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>mgmt [&lt;clip   oob   vlan&gt;]</code> | <p>Specifies the Segmented Management Instance as the source for the outgoing packet. The packet goes out this specific interface only.</p> <p><b>Note:</b><br/>Exception: <code>oob</code> not supported on VSP 4450 Series or XA1400 Series</p> <p>If you do not specify the management interface type, the <b>tracert</b> command uses the management routing table to determine the best management interface and selects the source IP based on the egress management interface.</p>                                                                                                                                                                                                                                                                                                                                       |
| <code>source &lt;WORD 1-256&gt;</code>        | Specifies the source IP address. This parameter does not apply if you use the <code>mgmt [clip   oob   vlan]</code> parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Variable                       | Value                                                                                                                           |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <0-256>            | Specifies the destination IPv4 or IPv6 address, or hostname.                                                                    |
| <i>vrf</i> < <i>WORD</i> 1-16> | Specifies the VRF instance by VRF name. This parameter does not apply if you use the <i>mgmt [clip   oob   vlan]</i> parameter. |

*Showing SNMP Logs*

Show the full SNMP logs. SNMP logs display the alarms and events that have been registered on the device.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Show the logs:  

```
show fulltech file WORD<1-99>
```

**Variable Definitions**

The following table defines parameters for the **show fulltech** command.

| Variable                       | Value                                                                                                                                                                                           |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>file</i> <i>WORD</i> <1-99> | This variable represents the log file to be opened and displayed. It is displayed in the following format:<br><ul style="list-style-type: none"> <li>• <i>/intflash/&lt;file&gt;</i></li> </ul> |

*Using Trace to Examine IS-IS Control Packets*

Use trace as a debug tool to examine the code flow and Intermediate-System-to-Intermediate-System (IS-IS) control packets. When you enable IS-IS trace flags, the system displays only trace information about the set flag.

**Before You Begin**

- You must know what you want to trace before you enable trace.

**Procedure**

1. Enter Privileged EXEC mode:  

```
enable
```
2. Enable the Intermediate-System-to-Intermediate-System trace flags:  

```
trace flags isis set { none | tx-hello | rx-hello | tx-pkt | rx-pkt | adj | opt | tx-lsack | rx-lsack | tx-lsp | rx-lsp | pkt-err | nbr-mismatch | flood | prefix | nbr-change | intf-change | decide | fdb | dr | dd-masterslave | auth-fail | config | purge | policy | redist | tx-snp | rx-snp | timer | global | perf | ucast-fib | node | mcast-fib | isid | ip-shortcut }
```

3. Identify the module ID for which you want to use the trace tool:

```
show trace modid-list
```

4. Clear the trace:

```
clear trace
```

5. Begin the trace operation:

```
trace level [<Module_ID>] [<0-4>]
```

OR

```
trace spbm isis level [<0-4>]
```

OR

```
trace cfm level [<0-4>]
```

**Note**

- Module ID 119 represents the IS-IS module.

6. Wait approximately 30 seconds.

The default trace settings for CPU utilization are:

- High CPU Utilization: 90%
- High Track Duration: 5 seconds
- Low CPU Utilization: 75%
- Low Track Duration: 5 seconds

7. Stop tracing:

```
trace shutdown
```

8. View the trace results:

```
trace screen enable
```

**Important**

If you use trace level 3 (verbose) or trace level 4 (very verbose), do not use the screen to view commands due to the volume of information the system generates and the effect on the system.

9. Save the trace file.

```
save trace [file WORD<1-99>]
```

If you do not specify a file name, the file name is systrace.txt.

10. Display trace lines saved to a file:

```
show trace file [tail]
```

11. Search trace results for a specific string value:

```
trace grep [WORD<0-128>]
```

If you use this command and do not specify a string value, you clear the results of a previous search.

## 12. Stop tracing:

```
trace shutdown
```

## 13. Disable the Intermediate-System-to-Intermediate-System trace flags:

```
trace flags isis remove { none | tx-hello | rx-hello | tx-pkt | rx-  
pkt | adj | opt | tx-lsack | rx-lsack | tx-lsp | rx-lsp | pkt-err |  
nbr-mismatch | flood | spf-intra | spf-inter | spf-extern | prefix |  
nbr-change | intf-change | decide | fdb | dr | dd-masterslave | auth-  
fail | config | purge | policy | redist | tx-snp | rx-snp | timer |  
spbm-decide | global | perf | ucast-fib | node | mcast-fib | isid |  
ip-shortcut }
```

### Example

```
Switch:1> enable
```

### Clear prior trace information:

```
Switch:1# clear trace
```

### Enable IS-IS trace flags for received IS-IS hello packets:

```
Switch:1# trace flags isis set rx-hello
```

### Enable IS-IS trace flags for transmitted IS-IS hello packets:

```
Switch:1# trace flags isis set tx-hello
```

### Configure the module ID to 119 (IS-IS module) and the trace to 4 (very verbose):

```
Switch:1# trace level 119 4
```

### Enable the display of trace output to the screen:

```
Switch:1# trace screen enable  
Switch:1# Screen tracing is on
```

### Disable the display of trace output to the screen:

```
Switch:1# trace screen disable  
Switch:1# Screen tracing is off
```

## Variable Definitions

The following table defines parameters for the **trace flags isis** command.

| Variable                                                                                                                                                                                                                                                                                                                                         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Variable | Value                                                                                                                                                                                   |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          | <ul style="list-style-type: none"> <li>• ucast-fib — Unicast Forwarding Information Base</li> <li>• node — Node</li> <li>• isid — I-SID</li> <li>• ip-shortcut — IP Shortcut</li> </ul> |

The following table defines parameters for the **show trace** command.

| Variable           | Value                                                                |
|--------------------|----------------------------------------------------------------------|
| <i>auto</i>        | Displays the current configuration for the automatic trace function. |
| <i>file [tail]</i> | Displays the trace results saved to a file.                          |
| <i>level</i>       | Displays the current trace level for all modules.                    |
| <i>modid-list</i>  | Specifies the module ID list.                                        |

The following table defines parameters for the **trace** command.

| Variable                                       | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>grep [WORD&lt;0-128&gt;]</i>                | Specifies the search keyword. You can use a specific MAC address. You can search for errors, using the command, <b>trace grep error</b> .                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>cfm level [&lt;0-4&gt;]</i>                 | Starts tracing by CFM. <ul style="list-style-type: none"> <li>• &lt;0-4&gt; specifies the trace level from 0–4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.</li> </ul>                                                                                                                                                                                                                                                                                                                                      |
| <i>spbm isis level [&lt;0-4&gt;]</i>           | Specifies exactly which IS-IS component to display. <ul style="list-style-type: none"> <li>• &lt;0-4&gt; specifies the trace level from 0–4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.</li> </ul>                                                                                                                                                                                                                                                                                                         |
| <i>level [&lt;Module_ID&gt;] [&lt;0-4&gt;]</i> | Starts the trace by specifying the module ID and level.<br><Module_ID> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the <b>show trace modid-list</b> command or CLI command completion Help.<br>0–4 specifies the trace level: <ul style="list-style-type: none"> <li>• 0 — Disabled</li> <li>• 1 — Very terse</li> <li>• 2 — Terse</li> <li>• 3 — Verbose</li> <li>• 4 — Very verbose</li> </ul> |

| Variable                             | Value                                                                                                                                                                                                                                                                          |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>shutdown</code>                | Stops the trace operation.                                                                                                                                                                                                                                                     |
| <code>screen {disable enable}</code> | Enables or disables the display of trace output to the screen.<br><br><b>Important:</b><br>Avoid using the screen to view commands if you use trace level 3 (verbose) or trace level 4 (very verbose) due to the volume of information generated and the effect on the system. |

The following table defines parameters for the **save trace** command.

| Variable                           | Value                                                                                                                                                                                                                                                                     |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file WORD&lt;1-99&gt;</code> | Specifies the file name in one of the following formats:<br><ul style="list-style-type: none"> <li>· a.b.c.d: &lt;file&gt;</li> </ul> WORD<1-99> is a string of 1-99 characters.<br><br><b>Note:</b><br>If you do not specify a file name, the file name is systrace.txt. |

### Viewing the Metric Type of IS-IS Route in TLVs – Detailed

#### About This Task

Use the following procedure to view the detailed information about metric type of IS-IS routes in TLVs in Link State Packets (LSP).

#### Procedure

1. Display the detail view of TLV 135:  

```
show isis lsdb tlv 135 detail
```
2. Display the detail view of TLV 184:  

```
show isis lsdb tlv 184 detail
```

#### Example

##### Viewing the metric type of IS-IS route in TLV 135

```
Switch:1#show isis lsdb tlv 135 detail
```

```

=====
                        ISIS LSDB (DETAIL)
=====
Level-1 LspID: 4072.0000.0000.00-02      SeqNum: 0x00000009      Lifetime: 1110

### Viewing the Metric Type of IS-IS Route in TLVs – Summarized

#### About This Task

Use the following procedure to view the summarized information about metric type of IS-IS routes in TLVs. You can also view the metric type of the prefix.

#### Procedure

Display the summarized view of TLVs 135 and 184:

```
show isis lsdb ip-unicast
```

#### Example

Display the summarized view of TLVs.

```

evp4k:1#show isis lsdb ip-unicast

=====

### Configuring I-SID Monitoring

Use the following procedure to configure Fabric RSPAN (Mirror to I-SID) on the Backbone Edge Bridge (BEB) connected to the monitor station.

#### Note

Do not configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.

#### Note

If you change the egress port or egress MLT for a particular session using a separate CLI command, it overwrites the existing egress port list or egress MLT.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a monitor by I-SID entry:

#### Note

If you use the Extreme Integrated Application Hosting (IAH) port 1/s1 as the analyzer port on the monitoring BEB for remote mirroring, you must associate it to VLAN ID 4091.

```
monitor-by-isid <1-1000> [monitor-isid-offset <1-1000> {egress-mlt
<1-512> | egress-ports {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}] [map-to-vid <1-4093>]]
```

3. Configure map to VLAN ID:

```
monitor-by-isid <1-1000> map-to-vid <1-4093>
```

4. Configure egress MLT:

```
monitor-by-isid <1-1000> egress-mlt <1-512>
```

5. Configure egress port:

```
monitor-by-isid <1-1000> egress-ports {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]}
```

6. Enable monitoring by I-SID entry:

```
monitor-by-isid <1-1000> enable
```

#### Note

Disable the entries (egress ports, MLT, and VLAN ID) to modify or remove parameters in the existing configuration.

**Example**

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# monitor-by-isid 1 monitor-isid-offset 1 egress-port 1/6
Switch:1(config)# monitor-by-isid 2 monitor-isid-offset 2 egress-port 1/7 map-to-vid 200
Switch:1(config)# monitor-by-isid 3 monitor-isid-offset 3 egress-port 1/7 map-to-vid 201
Switch:1(config)# monitor-by-isid 2 egress-port 1/8
Switch:1(config)# monitor-by-isid 1 monitor-isid-offset 1000 egress-ports 1/1 egress-mlt
16 map-to-vid 1000
Switch:1(config)# monitor-by-isid 7 monitor-isid-offset 7 egress-mlt 2 map-to-vid 203
Switch:1(config)# monitor-by-isid 2 egress-mlt 3
```

**Variable Definitions**

The following table defines parameters for the **monitor-by-isid** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                          |
|--------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-1000>                                                           | Specifies the monitoring session.                                                                                                                                                                                                                                                              |
| monitor-isid-offset <1-1000>                                       | Specifies the offset ID that is mapped to the actual monitor I-SID where packets are mirrored.<br>Monitor I-SID = Base monitor I-SID + Offset ID.<br>The base monitor I-SID is 16776000.                                                                                                       |
| egress-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Specifies the port to which the analyzers connect.                                                                                                                                                                                                                                             |
| egress-mlt <1-512>                                                 | Specifies the MLT to which the analyzers connect.                                                                                                                                                                                                                                              |
| map-to-vid <1-4093>                                                | Maps the mirrored packet to a specified VLAN ID for analysis. This parameter is optional.<br><br><b>Note:</b><br>If you use the Extreme Integrated Application Hosting (IAH) port 1/s1 as the analyzer port on the monitoring BEB for remote mirroring, you must associate it to VLAN ID 4091. |

*Displaying I-SID Monitoring Diagnostics*

Use the following procedure to display the **monitor-by-isid** entries on the monitoring BEB.

**Procedure**

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Enter the following command:  
show monitor-by-isid WORD<1-1024>

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)# show monitor-by-isid 3
=====
                Diag Monitor-By-ISID
=====
ID MONITOR_ISID ISID_OFFSET  EGRESS_PORTS  EGRESS_MLT  MAP_TO_VLAN  ENABLE
-----
3    16776000     1             1/4, 1/5     1           999          true
-----
```

**Variable Definitions**

The following table defines parameters for the **show monitor-by-isid** command.

| Variable                  | Value                                                 |
|---------------------------|-------------------------------------------------------|
| <i>WORD&lt;1-1024&gt;</i> | Specifies the session ID list ranging from 1 to 1000. |

*Displaying I-SID Mirroring Statistics*

Use the following procedure to display the statistics of the number of packets mirrored into I-SID on the mirroring BEB.

**Procedure**

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enter the following command:
 

```
show isid-mirroring stats [monitor-isid-offset WORD<1-1024>]
```

**Example**

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# show isid-mirroring stats monitor-isid-offset 1
=====
                Mirror Statistics Info
=====
ISID          ISID_OFFSET  PACKETS
-----
16776000     1            100
-----
```

**Variable Definitions**

The following table defines parameters for the **show isid-mirroring stats** command.

| Variable                                      | Value                                                                                        |
|-----------------------------------------------|----------------------------------------------------------------------------------------------|
| <i>monitor-isid-offset WORD&lt;1-1024&gt;</i> | Specifies the offset ID mapped to monitor the I-SID.<br>The offset ID ranges from 1 to 1000. |

### Clearing Fabric RSPAN (Mirror to I-SID) Statistics

Use the following procedure to clear Fabric RSPAN (Mirror to I-SID) statistics of packets mirrored into the specified mirroring I-SID or all mirroring I-SIDs on the BEB.

#### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enter the following command:

```
clear isid-mirroring stats monitor-isid-offset WORD<1-1024>
```

#### Note

You must use this command on the Mirroring BEB to clear the statistics of packets mirrored into I-SID.

#### Example

```
Switch:1>enable
Switch:1#configure terminal
```

Clear all Fabric RSPAN statistics:

```
Switch:1(config)# clear isid-mirroring stats
```

Clear all Fabric RSPAN (Mirror to I-SID) statistics of packets mirrored into the specified mirroring I-SID

```
Switch:1(config)# clear isid-mirroring stats monitor-isid-offset 1
```

#### Variable Definitions

The following table defines parameters for the **clear isid-mirroring stats** command.

| Variable                                      | Value                                                                                                                                                                                                                                                 |
|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>monitor-isid-offset WORD&lt;1-1024&gt;</i> | Specifies the offset ID that is mapped to the actual monitor I-SID where packets are mirrored.<br>Monitor I-SID = base monitor I-SID + offset ID.<br>The range of the <i>monitor-isid-offset</i> is 1 to 1000.<br>The base monitor I-SID is 16776000. |

## Software Troubleshooting Tool Configuration Using EDM

Use the tools described in this section to perform troubleshooting procedures using Enterprise Device Manager (EDM).

### *Flush Routing Tables by VLAN*

#### **About This Task**

For administrative and troubleshooting purposes, sometimes you must flush the routing tables. You can use EDM to flush the routing tables by VLAN or flush them by port. Perform this procedure to flush the IP routing table for a VLAN.

#### **Procedure**

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Advanced** tab.
4. In the **Vlan Operation Action** box for the VLAN you want to flush, double-click, and then select a flush option from the list.

In a VLAN context, all entries associated with the VLAN are flushed. You can also flush the Address Resolution Protocol (ARP) entries and IP routes for the VLAN.

5. Click **Apply**.

### *Flush Routing Tables by Port*

#### **About This Task**

For administrative and troubleshooting purposes, sometimes you must flush the routing tables. You can use EDM to flush the routing tables by VLAN or flush them by port. Perform this procedure to flush the IP routing table for a port.

#### **Procedure**

1. On the Device Physical View, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **General**.
4. Click the Interface tab.
5. In the **Action** section, select **flushAll**.

In a port context, all entries associated with the port are flushed. You can flush the ARP entries and IP routes for a port. After you flush a routing table, it is not automatically repopulated. The repopulation time delay depends on the routing protocols in use.

6. Click **Apply**.

### *Configure Port Mirroring*

#### **Before You Begin**

- To change a port mirroring configuration, first disable mirroring.

#### **About This Task**

Use port mirroring to aid in diagnostic and security operations.

Use port mirroring to make a copy of a traffic flow and send that copy to a device for analysis, for example, for diagnostic sniffing. Use the mirror to see the packets in the flow without breaking into the physical connection to place a packet onto the sniffer

inline. You can also use port mirroring for security. You can send flows to inspection engines for post processing.

Connect the sniffer (or other traffic analyzer) to the output port you specify in this procedure.

**Procedure**

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **General**.
3. Select the **Port Mirrors** tab.
4. Select **Insert**.
5. To enable port mirroring for the instance, select the **Enable** check box.
6. Configure mirroring as required.

**Note**

- When you configure `tx` mode port mirroring on T-UNI and SPBM NNI ports, unknown unicast, broadcast and multicast traffic packets that ingress these ports and the system displays on the mirror destination port, although they do not egress the mirror source port. This is because `tx` mode port mirroring happens on the mirror source port before the source port squelching logic drops the packets at the egress port.
- The available four mirroring resources are shared between Fabric RSPAN and regular port mirroring, and are allocated based on the mode configured, Ingress (`rx`) or Egress (`tx`). Each configured mode occupies one mirroring resource, but when you configure the mode as `both`, it occupies two mirroring resources (one for Rx and one for Tx).
- Do not configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.

7. Select **Insert**.

**Port Mirrors Field Descriptions**

Use the data in the following table to use the **Port Mirrors** tab.

| Name                    | Description                                                                    |
|-------------------------|--------------------------------------------------------------------------------|
| <b>Id</b>               | Specifies an assigned identifier for the configured port mirroring instance.   |
| <b>MirroredPortList</b> | Specifies a port to be mirrored (the source port).                             |
| <b>Enable</b>           | Enables or disables this port mirroring instance. The default value is Enable. |

| Name                        | Description                                                                                                                                                                                                                                                 |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Mode</b>                 | Specifies the traffic direction of the packet being mirrored: <ul style="list-style-type: none"><li>• tx mirrors egress packets.</li><li>• rx mirrors ingress packets.</li><li>• both mirrors both egress and ingress packets.</li></ul> The default is rx. |
| <b>MirroringPortList</b>    | Specifies a destination port (the port to which the mirrored packets are forwarded). Configures the mirroring port.                                                                                                                                         |
| <b>MirroringMltId</b>       | Specifies the destination MultiLink trunking ID.                                                                                                                                                                                                            |
| <b>MonitoringIsidOffset</b> | Used to configure the monitoring I-SID offset value. The offset ID is mapped to the actual monitor I-SID value to which the packets are mirrored.                                                                                                           |
| <b>MonitoringIsid</b>       | Specifies the actual monitor I-SID value to which the packets are mirrored.                                                                                                                                                                                 |
| <b>MirroringQos</b>         | Used to define the Quality of Service (QoS) profiles for the mirrored packet into monitoring I-SID.                                                                                                                                                         |

### Configure ACLs for Mirroring

Configure the access control list (ACL) to mirror packets for an access control entry (ACE) that matches a particular packet.

#### Before You Begin

- The ACL exists.

#### About This Task

To modify an ACL parameter, double-click the parameter you wish to change. Change the value, and then click Apply. You cannot change a parameter that the system displays it dimmed; in this case, delete the ACL, and then configure a new one.

#### Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Double-click the parameter **MirrorMltId** to configure mirroring to a destination MLT group.
5. Double-click the parameter **MirrorDstPortList** to configure mirroring to a destination port or ports.

**ACL field descriptions**

Use the data in the following table to use the **ACL** tab.

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>              | Specifies a unique identifier for the ACL.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Type</b>              | Specifies the ACL type. Valid options are <ul style="list-style-type: none"> <li>• inVlan</li> <li>• inPort</li> <li>• outPort</li> <li>• inVsn</li> </ul> <p><b>Important:</b><br/>The inVlan ACLs drop packets if you add a VLAN after ACE creation.</p> <p><b>Important:</b><br/>You can insert an inVsn ACL type for a Switched UNI only if the Switched UNI I-SID is associated with a platform VLAN.</p>                                             |
| <b>Name</b>              | Specifies a descriptive user-defined name for the ACL.                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>VlanList</b>          | For inVlan ACL types, specifies all VLANs to associate with the ACL.                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>PortList</b>          | For inPort and outPort ACL types, specifies the ports to associate with the ACL.                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DefaultAction</b>     | Specifies the action taken when no ACEs in the ACL match. Valid options are deny and permit, with permit as the default. Deny means the system drops the packets; permit means the system forwards packets.                                                                                                                                                                                                                                                |
| <b>ControlPktAction</b>  | Specifies the action taken for control packets. Valid options are deny and permit.                                                                                                                                                                                                                                                                                                                                                                         |
| <b>State</b>             | Enables or disables all of the ACEs in the ACL. The default value is enable.                                                                                                                                                                                                                                                                                                                                                                               |
| <b>PktType</b>           | Indicates the packet type to which this ACL applies.                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>MirrorMlId</b>        | Configures mirroring to a destination MLT.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>MirrorDstPortList</b> | Configures mirroring to a destination port or ports.                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>MatchType</b>         | For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <li>• <i>both</i> for traffic ingressing on both UNI ports and NNI ports terminating on this node</li> <li>• <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node</li> <li>• <i>uniOnly</i> for traffic ingressing on UNI ports only</li> </ul> The default value is <i>both</i> |

| Name                                                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Isid</b>                                                                                                  | For inVsn ACL types, specifies the I-SID associated with the customer VLAN (Layer 2 VSN) or the customer VRF (Layer 3 VSN). This I-SID should already be configured on the fabric node.<br>The InVSN Filter supports IP Shortcut traffic if the inVsn ACL match type is <i>both</i> . In this case, the I-SID is zero (0).<br><br><b>Important:</b><br>You can specify a Switched UNI I-SID if the I-SID is associated with a platform VLAN. |
| <b>Origin</b>                                                                                                | Indicates the origin of the ACL: <ul style="list-style-type: none"><li>• config - ACL created by the user.</li><li>• eap - ACL created by Extensible Authentication Protocol (EAP) through Remote Authentication Dial-In User Service (RADIUS) response.</li></ul>                                                                                                                                                                           |
| <b>DefaultSvcRate</b><br><br><b>Note:</b><br>Exception: Only supported on VSP 4900 Series, VSP 7400 Series.  | Specifies the service rate limit in kbps {8-4000000000}.The granularity is 8 kbps.                                                                                                                                                                                                                                                                                                                                                           |
| <b>DefaultPeakRate</b><br><br><b>Note:</b><br>Exception: Only supported on VSP 4900 Series, VSP 7400 Series. | Specifies the value when exceeded causes packets to drop on ingress. Peak rate limit in kbps {8-4000000000}.The granularity is 8 kbps.                                                                                                                                                                                                                                                                                                       |

### Configure ACEs for Mirroring

#### Before You Begin

- The ACL exists.
- The ACE exists.

#### About This Task

Configure actions to use filters for flow mirroring. Use an ACE to define the mirroring actions the filter performs.

If you use the mirror action, ensure that you specify the mirroring destination: IP address, MLTs, ports, or VLANs.

#### Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the ACL for which to modify an ACE.

5. Click **ACE**.
6. Select an ACE, and then click **Action**.
7. Configure one of: **DstPortList**, **DstMltId**, or **DstIpl**.
8. Click **Apply**.

**Action field descriptions**

Use the data in the following table to use the **Action** tab.

**Note**

The table lists the options for both Security ACEs and QoS ACEs. Dependent upon the ACE, the system displays different options on the EDM interface.

| Name                      | Description                                                                                                                                                                                                                                                                       |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>               | Specifies the ACL ID.                                                                                                                                                                                                                                                             |
| <b>AcId</b>               | Specifies the ACE ID.                                                                                                                                                                                                                                                             |
| <b>Mode</b>               | Configures the action mode for security ACEs. The default value is deny.                                                                                                                                                                                                          |
| <b>RemarkDscp</b>         | Specifies the new Per-Hop Behavior (PHB) for matching packets: phbcs0, phbcs1, phbaf11, phbaf12, phbaf13, phbcs2, phbaf21, phbaf22, phbaf23, phbcs3, phbaf31, phbaf32, phbaf33, phbcs4, phbaf41, phbaf42, phbaf43, phbcs5, phbef, phbcs6, phbcs7.<br>This action is a QoS action. |
| <b>RemarkDot1Priority</b> | Specifies the new 802.1 priority bit for matching packets: zero, one, two, three, four, five, six, or seven.<br>This action is a QoS action.<br><br><b>Note:</b><br>This does not apply to IPv6 filtering.                                                                        |
| <b>InternalQoS</b>        | This variable is a QoS action. The default value is 1.<br><br><b>Note:</b><br>This does not apply to IPv6 filtering.                                                                                                                                                              |
| <b>RedirectNextHop</b>    | Specifies the next-hop IPv4 address (a.b.c.d) or IPv6 address (aaaa:bbbb:cccc:dddd:eeee:ffff:gggg:hhhh ) for redirect mode.<br>Applies to ingress ACLs (routed and Layer 2 packets).                                                                                              |
| <b>Count</b>              | Enables the ability to count matching packets. Use this parameter with either a security or QoS ACE. The default is disabled.                                                                                                                                                     |

| Name                        | Description                                                                                                                                |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DstPortList</b>          | Configures mirroring to a destination port or ports. This action is a security action.                                                     |
| <b>DstMlId</b>              | Configures mirroring to a destination MLT. This action is a security action.                                                               |
| <b>MonitoringIsidOffset</b> | Configures the monitoring I-SID offset value. The offset ID is mapped to the actual monitor I-SID value to which the packets are mirrored. |
| <b>MirroringQoS</b>         | Defines the Quality of Service (QoS) profiles for the mirrored packet into monitoring I-SID.                                               |

### Run a Ping Test

#### About This Task

Use ping to determine if an entity is reachable.

#### Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [VOSS Release Notes](#). As an alternative, use CLI.

#### Procedure

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Ping/Trace Route**.
3. Click the **Ping Control** tab.
4. Click **Insert**.
5. In the **OwnerIndex** box, type the owner index.
6. In the **TestName** box, type the name of the test.
7. In the **TargetAddress** box, type the host IP address.
8. From the **AdminStatus** options, select **enabled**.
9. In the remainder of the option boxes, type the desired values.
10. Click **Insert**.
11. Select an entry, and then click **Start**.  
Let the test run for several seconds.
12. Select an entry, and then click **Stop**.
13. View the Ping results.

**Ping Control Field Descriptions**

Use the data in the following table to use the **Ping Control** tab.

| Name                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OwnerIndex</b>             | Provides access control by a security administrator using the View-Based Access Control Model (VACM) for tables in which multiple users need to independently create or modify entries. This is a string of up to 32 characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>TestName</b>               | Specifies the name of the ping test.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>TargetAddress</b>          | Specifies the host address to use at a remote host to perform a ping operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DataSize</b>               | Specifies the size of the data portion (in octets) to transmit in a ping operation. The default is 16.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>TimeOut</b>                | Specifies the timeout value, in seconds, for a remote ping operation. The default is 3 seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ProbeCount</b>             | Specifies the number of times to perform a ping operation at a remote host. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>AdminStatus</b>            | Specifies the state of the ping control entry: enabled or disabled. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DataFill</b>               | Determines the data portion of a probe packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Frequency</b>              | Specifies the number of seconds to wait before repeating a ping test. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>MaxRows</b>                | Specifies the maximum number of entries allowed in the PingProbeHistory table. The default is 50.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>TrapGeneration</b>         | <p>Specifies when to generate a notification. The options are:</p> <ul style="list-style-type: none"> <li>• ProbeFailure—Generates a PingProbeFailed notification subject to the value of TrapProbeFailureFilter. The object TrapProbeFailureFilter can specify the number of successive probe failures that are required before a pingProbeFailed notification is generated.</li> <li>• TestFailure—Generates a PingTestFailed notification. The object TrapTestFailureFilter can determine the number of probe failures that signal when a test fails.</li> <li>• TestCompletion—Generates a PingTestCompleted notification.</li> </ul> <p>The value of this object defaults to zero, indicating that none of the above options have been selected.</p> |
| <b>TrapProbeFailureFilter</b> | Specifies the number of successive probe failures that are required before a pingProbeFailed notification is generated. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>TrapTestFailureFilter</b>  | Determines the number of probe failures that signal when a test fails. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Descr</b>                  | Describes the remote ping test. The default is 0x00.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Name                    | Description                                                                         |
|-------------------------|-------------------------------------------------------------------------------------|
| <b>SourceAddress</b>    | Specifies the IP address (a.b.c.d) as the source address in outgoing probe packets. |
| <b>ByPassRouteTable</b> | Enables (optionally) the bypassing of the route table. The default is disabled.     |

*View Ping Results*

**About This Task**

View ping results to view performance-related data.

**Note**

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [VOSS Release Notes](#). As an alternative, use CLI.

**Procedure**

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Ping/Trace Route**.
3. Click the **Ping Control** tab.
4. Select a ping test entry.
5. Click **Ping Result**.

**Ping Result Field Descriptions**

Use the data in the following table to use the **Ping Result** tab.

| Name                       | Description                                                                                            |
|----------------------------|--------------------------------------------------------------------------------------------------------|
| <b>OwnerIndex</b>          | Specifies the ping test owner.                                                                         |
| <b>TestName</b>            | Specifies the test name.                                                                               |
| <b>OperStatus</b>          | Indicates the operational status of the test. The default is disabled.                                 |
| <b>IpTargetAddressType</b> | Specifies the IP address type of the target. The default is unknown.                                   |
| <b>IpTargetAddress</b>     | Specifies the IP address of the target.                                                                |
| <b>MinRtt</b>              | Specifies the minimum ping round-trip-time (RTT) received. A value of 0 means that no RTT is received. |
| <b>MaxRtt</b>              | Specifies the maximum ping RTT received. A value of 0 means that no RTT is received.                   |
| <b>AverageRtt</b>          | Specifies the current average ping RTT.                                                                |
| <b>ProbeResponses</b>      | Specifies the number of responses to probes.                                                           |
| <b>SentProbes</b>          | Specifies the number of sent probes.                                                                   |

| Name                   | Description                                                                 |
|------------------------|-----------------------------------------------------------------------------|
| <b>RttSumOfSquares</b> | Specifies the sum of squares of RTT for all probes received.                |
| <b>LastGoodProbe</b>   | Specifies the date and time when the last response is received for a probe. |

*View Ping Probe History*

**About This Task**

View the ping probe history to view the history of ping tests performed by the switch.

**Note**

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [VOSS Release Notes](#). As an alternative, use CLI.

**Procedure**

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Ping/Trace Route**.
3. Select a ping entry.
4. Click **Ping Probe History**.

**Ping Probe History Field Descriptions**

Use the data in the following table to use the **Ping Probe History** tab.

| Name              | Description                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OwnerIndex</b> | Specifies the owner index                                                                                                                                                                                  |
| <b>TestName</b>   | Indicates the name given to the test.                                                                                                                                                                      |
| <b>Index</b>      | Specifies the index number.                                                                                                                                                                                |
| <b>Response</b>   | Indicates the amount of time, measured in milliseconds, between request (probe) and response, or when the request timed out. Response is reported as 0 when it is not possible to transmit a probe.        |
| <b>Status</b>     | Indicates the status of the response; the result of a particular probe done by a remote host.                                                                                                              |
| <b>LastRC</b>     | Indicates the last implementation-method-specific reply code (RC) received. If ICMP Echo is used, then a successful probe ends when an ICMP response is received that contains the code ICMP_ECHOREPLY(0). |
| <b>Time</b>       | Indicates the timestamp for this probe result.                                                                                                                                                             |

*Run a Traceroute Test***About This Task**

Run a traceroute test to determine the route packets take through a network to a destination.

**Note**

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [VOSS Release Notes](#). As an alternative, use CLI.

**Procedure**

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Ping/Trace Route**.
3. Click the **Trace Route Control** tab.
4. Click **Insert**.
5. Configure the instance as required.
6. Click **Insert**.
7. Select an entry, and then click **Start**.  
Let the test run for several seconds.
8. Select an entry, and then click **Stop**.
9. View the traceroute test results.

**Trace Route Control Field Descriptions**

Use the data in the following table to use the **Trace Route Control** tab.

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OwnerIndex</b>        | Provides access control by a security administrator using the VACM for tables in which multiple users need to independently create or modify entries.                                                                                                                                                                                                                                                      |
| <b>TestName</b>          | Specifies the name of the traceroute test.                                                                                                                                                                                                                                                                                                                                                                 |
| <b>TargetAddressType</b> | Specifies the type of host address to use on the traceroute request at the remote host. The default is IPv4.                                                                                                                                                                                                                                                                                               |
| <b>TargetAddress</b>     | Specifies the host address used on the traceroute request at the remote host.                                                                                                                                                                                                                                                                                                                              |
| <b>ByPassRouteTable</b>  | Enables bypassing of the route table. If you enable this variable, the remote host bypasses the normal routing tables and sends directly to a host on an attached network. If the host is not on a directly-attached network, an error is returned. You can use this variable to perform the traceroute operation to a local host through an interface that has no route defined. The default is disabled. |
| <b>DataSize</b>          | Specifies the size of the data portion of a traceroute request in octets. The default is 1.                                                                                                                                                                                                                                                                                                                |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TimeOut</b>           | Specifies the timeout value, in seconds, for a traceroute request. The default is 3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>ProbesPerHop</b>      | Specifies the number of times to reissue a traceroute request with the same time-to-live (TTL) value. The default is 3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Port</b>              | <p>Specifies the UDP port to which to send the traceroute request. Specify a port that is not in use at the destination (target) host. The default is the IANA assigned port 33434.</p> <p><b>Note:</b><br/>If the traceroute action is directed to an IPv6 host address, Linux increments the UDP port on a per-TTL basis. For an IPv4 host address, Linux increments the UDP port on a per-probe basis.</p> <p>Because the <b>traceroute</b> command sends a default of three probes, three incrementing ports will be sent for an IPv4 host address. If you use the <b>-p</b> parameter with a value greater than 65533, the <b>traceroute</b> command fails for an IPv4 host address because the maximum port number, 65535, is exceeded.</p> |
| <b>MaxTtl</b>            | Specifies the maximum time-to-live from 1–255. The default is 30.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DSField</b>           | Specifies the value to store in the Differentiated Services (DS) field in the IP packet used to encapsulate the traceroute probe. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>SourceAddressType</b> | Specifies the type of the source address to use at a remote host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SourceAddress</b>     | Uses the specified IP address (which must be an IP number, not a hostname) as the source address in outgoing probe packets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>IfIndex</b>           | Directs the traceroute probes to be transmitted over the specified interface. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>MiscOptions</b>       | Enables an application to specify implementation-dependent options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>MaxFailures</b>       | Indicates the maximum number of consecutive timeouts allowed before terminating a remote traceroute request. The default is 5.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DontFragment</b>      | Enables setting of the do not fragment (DF) flag in the IP header for a probe. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>InitialTtl</b>        | Specifies the initial time-to-live (TTL) value to use. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Frequency</b>         | Specifies the number of seconds to wait before repeating a traceroute test as defined by the value of the various objects in the corresponding row. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>StorageType</b>       | Specifies the storage type for this row.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>AdminStatus</b>       | Specifies the desired state for TraceRouteCtlEntry. The options are enabled or disabled. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>MaxRows</b>           | Specifies the maximum number of entries allowed in the TraceRouteProbeHistoryTable. The default is 50.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>TrapGeneration</b>    | Determines when to generate a notification for this entry. The options are <ul style="list-style-type: none"><li>• <b>pathChange</b> —Generates a TraceRoutePathChange notification after the current path varies from a previously determined path.</li><li>• <b>testFailure</b> —Generates a TraceRouteTestFailed notification after the full path to a target cannot be determined.</li><li>• <b>testCompletion</b> —Generates a TraceRouteTestCompleted notification after the path to a target has been determined.</li></ul> |
| <b>Descr</b>             | Describes the remote traceroute test.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>CreateHopsEntries</b> | Stores the current path for a traceroute test in the TraceRouteHopsTable on an individual hop basis when the value of this object is true. The default is false.                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Type</b>              | Reports or selects the implementation method to use for performing a traceroute operation.                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### View Traceroute Results

#### About This Task

View traceroute results to view performance-related data.

#### Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [VOSS Release Notes](#). As an alternative, use CLI.

#### Procedure

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Ping/Trace Route**.
3. Click the **Trace Route Control** tab.
4. Select a traceroute entry.
5. Click **Trace Route Result**.

### Trace Route Result Field Descriptions

Use the data in the following table to use the **Trace Route Result** tab.

| Name                    | Description                                                                 |
|-------------------------|-----------------------------------------------------------------------------|
| <b>OwnerIndex</b>       | Specifies the index of the owner.                                           |
| <b>TestName</b>         | Specifies the name of the test.                                             |
| <b>OperStatus</b>       | Specifies the operational status of the test. The default is disabled.      |
| <b>CurHopCount</b>      | Specifies the current count of hops.                                        |
| <b>CurProbeCount</b>    | Specifies the current count of probes.                                      |
| <b>IpTgtAddressType</b> | Specifies the IP target address type                                        |
| <b>IpTgtAddr</b>        | Specifies the IP target address.                                            |
| <b>TestAttempts</b>     | Specifies the number of test attempts.                                      |
| <b>TestSuccesses</b>    | Specifies the number of successful test attempts.                           |
| <b>LastGoodPath</b>     | Specifies the date and time when the last response is received for a probe. |

*View the Traceroute History*

#### About This Task

View the traceroute history to view the history of traceroute tests performed by the switch.

The traceroute probe history contains probe information for the hops in the routing path.

#### Note

Troubleshooting using ping and traceroute is not supported on EDM. For more information, see [VOSS Release Notes](#). As an alternative, use CLI.

#### Procedure

1. From the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **Ping/Trace Route**.
3. Click the **Trace Route Control** tab.
4. Select an entry.
5. Click **Trace Route Probe History**.

### Route Probe History Field Descriptions

Use the data in the following table to use the **Trace Route Probe History** tab.

| Name              | Description                                                                                                                                                   |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OwnerIndex</b> | Identifies the Trace Route entry to which a probe result belongs.                                                                                             |
| <b>TestName</b>   | Specifies the test name.                                                                                                                                      |
| <b>Index</b>      | Specifies the Index.                                                                                                                                          |
| <b>HopIndex</b>   | Indicates for which hop in a traceroute path the probe results are intended.                                                                                  |
| <b>ProbeIndex</b> | Specifies the index of a probe for a particular hop in a traceroute path.                                                                                     |
| <b>HAddrType</b>  | Specifies the IP address type of the hop to which this probe belongs.                                                                                         |
| <b>HAddr</b>      | Specifies the IP address of the hop to which this probe belongs.                                                                                              |
| <b>Response</b>   | Specifies the cumulative results at any time.                                                                                                                 |
| <b>Status</b>     | Specifies the status of the probe.                                                                                                                            |
| <b>LastRC</b>     | When a new entry is added, the old entry is purged if the total number of entries exceeds the specified maximum number of entries in the Control Table Entry. |
| <b>Time</b>       | Specifies the response time of the probe.                                                                                                                     |

### Configure I-SID Monitoring

Use the following procedure to configure Fabric RSPAN on the Backbone Edge Bridge (BEB) connected to the monitor station.

**Note**

Do not configure the source of mirrored traffic (mirroring to an I-SID) and the analyzer (monitoring an I-SID) on the same local device with the same I-SID offset. If you require mirroring and monitoring on the same local device, use standard port-based mirroring instead of Fabric RSPAN. Fabric RSPAN mirrors traffic into an I-SID of the SPB Fabric network and monitors traffic on the remote device; the network analyzer resides on the remote monitoring device and not on the same local device.

**Note**

If you change the egress port or egress MLT for a particular session using a CLI command, it overwrites the existing egress port list or egress MLT.

### Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **General**.

3. Click the **Monitor-By-ISID** tab.
4. Click **Insert**.
5. Configure the parameters as required.
6. Click **Insert**.
7. To modify mappings, double-click a parameter to view a list of options.
8. Click **Apply**.

**Monitor-By-ISID Field Descriptions**

Use the data in the following table to use the **Monitor-By-ISID** tab.

| Name                     | Description                                                                                                                                |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Index</b>             | Specifies the entry that contains monitor by I-SID information.                                                                            |
| <b>MonitorIsidOffset</b> | Configures the monitoring I-SID offset value. The offset ID is mapped to the actual monitor I-SID value to which the packets are mirrored. |
| <b>MonitorIsid</b>       | Specifies the actual monitor I-SID value to which packets are mirrored.                                                                    |
| <b>EgressPortList</b>    | Specifies the egress ports to which traffic analyzers connect.                                                                             |
| <b>EgressMlId</b>        | Specifies the egress MLT ID to which traffic analyzers connect.                                                                            |
| <b>MapToVlanId</b>       | Specifies the VLAN ID to map with mirrored traffic on the monitoring node.                                                                 |
| <b>Enable</b>            | Enables or disables monitoring by I-SID.                                                                                                   |

*View and Clear Fabric RSPAN (Mirror to I-SID) Statistics*

Use the following procedure to view or clear statistics of the number of packets mirrored into I-SID on the mirroring BEB.

**Procedure**

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Click **General**.
3. Click the **Isid-Mirroring Stats** tab.

**Isid-Mirroring Stats Field Descriptions**

Use the data in the following table to use the **Isid-Mirroring Stats** tab.

| Name               | Description                                                                 |
|--------------------|-----------------------------------------------------------------------------|
| <b>Index</b>       | Specifies the entry that contains Fabric RSPAN statistics information.      |
| <b>MonitorIsid</b> | Specifies the actual monitor I-SID value to which the packets are mirrored. |

| Name                   | Description                                                               |
|------------------------|---------------------------------------------------------------------------|
| <b>MirroredPackets</b> | Specifies the number of packets mirrored into I-SID on the mirroring BEB. |
| <b>ClearStats</b>      | Clears the Fabric RSPAN statistics.                                       |

## General Troubleshooting

This section provides troubleshooting information for common hardware and software problems.

### Hardware Troubleshooting

The following sections provide troubleshooting information for common hardware problems.

#### *Using Trace to Diagnose Hardware Problems*

Use trace to observe the status of a hardware module at a given time.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Begin the trace operation:  
line-card 1 trace level [*<Module\_ID>*]{<0-4>}
3. Search the trace for a specific string value:  
line-card 1 trace grep {*WORD<0-1024>*}

#### Example

```
Switch:1>enable
```

Begin the trace operation:

```
Switch:1#line-card 1 trace level 67 1
```

Search the trace for a specific string value:

```
Switch:1#line-card 1 trace grep 00-1A-4B-8A-FB-6B
```

### Variable Definitions

The following table defines parameters for the **line-card 1** command.

| Variable                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;Module_ID&gt; {&lt;0-4&gt;}</code> | Starts the trace by specifying the module ID and level.<br><Module_ID> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the <b>show trace modid-list</b> command or CLI command completion Help.<br><0-4> specifies the trace level from 0-4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose. |
| <code>WORD&lt;0-1024&gt;</code>              | Performs a string search in the trace.                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### Troubleshooting USB Viewing Problems

After you insert a USB device in the USB slot, the Linux system automatically detects and mounts the device. If you cannot view files on the device, perform this procedure.

**Note**

Not all hardware platforms can use the USB device for additional file storage. Some platforms use the USB as part of the system operation and must never be removed. For more information, see your hardware documentation.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Check the file system:  
`ls /usb/`
3. Remove a USB device:
  - a. Unmount the USB device:  
`usb-stop`
  - b. Wait for the response that indicates it is safe to remove the device.
  - c. Physically remove the device.
4. Remove and then reinsert the device.

## 5. Check the device for errors:

```
dos-chkdsk /usb
```

Run the **dos-chkdsk /usb repair** command, if at the end of the **dos-chkdsk /usb** command output you see:

1) Correct

2) Don't correct

## 6. If errors are detected, then you can reformat the device:

```
dos-format /usb
```

**Caution**

If you format the device, you erase all data on the device.

**Example**

Check the file system:

```
Switch:1>enable
Switch:1#ls /usb/
Listing Directory /usb/:
drwxr-xr-x 4 0 0 4096 Jan 1 1970 ./
drwxrwxr-x
22 0 0 0 Sep 9 20:22 ../
drwxr-xr-x 2 0 0 4096 Mar 17 16:03 Photos-of-Flash-
drwxr-xr-x 2 0 0 4096 Jun 13 20:56 intflash/
```

Check the device for errors:

```
Switch:1#usb-stop
It is now safe to remove the USB device.
Switch:1#dos-chkdsk /usb
/usr/sbin/fsck.vfat /dev/usb1 -v >& /dev/console dosfsck 2.11a
(05 Mar 2010)
dosfsck 2.11a, 05 Mar 2010, FAT32, LFN
Checking we can access the last sector of the filesystem
Boot sector contents:
System ID "mkdosfs"
Media byte 0xf8 (hard disk)
512 bytes per logical sector
4096 bytes per cluster
32 reserved sectors
First FAT starts at byte 16384 (sector 32)
2 FATs, 32 bit entries
3897344 bytes per FAT (= 7612 sectors)
Root directory start at cluster 2 (arbitrary size)
Data area starts at byte 7811072 (sector 15256)
974240 data clusters (3990487040 bytes)
62 sectors/track, 124 heads
0 hidden sectors
7809178 sectors total
Checking for unused clusters.
Checking free cluster summary.
/dev/usb1: 17 files, 174804/974240 clusters
```

If errors are detected, reformat the disk:

```
Switch:1#dos-format /usb
```

## Software Troubleshooting

This section contains general troubleshooting information for the switch software.

### *Failure to Read Failed Configuration File*

The device can fail to read and load a saved configuration file after it starts. This situation occurs if you enable the factorydefaults boot configuration flag. Configure the flag to false: `no boot config flags factorydefaults`.

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# no boot config flags factorydefaults
```

### *No Web Management Interface Access to a Device*

If the device and the PC that runs the web browser are in the same network, you can find that even though other applications, for example, Telnet, can access a particular switch, the web management interface cannot. This situation can occur if the web browser has a proxy server that resolves the www path and returns the reachable IP address to the browser. If no route exists from the proxy server to the device, the HTTP query does not reach the device, and does not receive a response.

To prevent this problem, ensure that if the web browser uses a proxy server, you specify a route from the proxy server to the device.

### *Configuration in EDM is not applied using CLI*

In EDM, if you apply configuration that disrupts the connection to the web server, and you do not close the EDM session, you cannot apply the same configuration using CLI. This situation occurs if you, for example, delete the Segmented Management Instance, or the management IP address or the route used to access EDM, and you do not close the EDM session afterwards.

To prevent this issue, you must close the EDM session before you can apply the same configuration using CLI.

## Layer 1 Troubleshooting

Use the information in this section to troubleshoot Layer 1 (physical layer) problems.

## Troubleshooting Fiber Optic Links

### About This Task

You can troubleshoot fiber optic links to ensure that the optical transmitters and receivers operate correctly, and to determine if a receiver is saturated, or does not receive enough power.

To troubleshoot optical links and devices, you can use Digital Diagnostic Monitoring (DDM), as well as published optical specifications.

For more information about transceivers, see [Extreme Optics](#) website.

### Important

As a best practice, use transceivers documented in [Extreme Optics](#) website, as they have been through extensive qualification and testing. Extreme Networks is not responsible for issues related to third party transceivers.

### Procedure

1. Measure the transmit power.
2. Compare the measured transmit power with the specified launch power.  
The values are similar. If the measured power is far below the specified value, a faulty transmitter is a possible cause.
3. Compare the measured transmit power for the near-end optical device to the measured transmit power for the far-end device.  
Large differences can mean that the optical devices are mismatched (that is, -SX versus -LX).
4. Measure the receive power at each end of the link.
5. Compare the receive power to the transmit power.
  - For short fiber links, the transmit and received power are similar (after taking into consideration connection losses).
  - For long fiber links, the transmit and received power are similar (after taking into consideration connection losses and fiber attenuation).

Large differences can mean a damaged fiber or dirty or faulty connectors. Large differences can also mean that the link does not use the right type of fiber (single mode or multimode). If the receiver power is measured to be zero, and the link worked previously, it is probable that the far-end transmitter is not operating or the fiber is broken.

6. Compare the measured receive power for the near-end optical device to the measured receive power for the far-end device.

Large differences could mean that the optical devices are mismatched (that is, -SX versus -LX). If optical devices are mismatched, the receiver can be saturated (overdriven).

7. If a receiver is saturated but still operable, install a suitable attenuator.

For long-haul optical devices, the receive power must be significantly less than the transmit power.

- To help debug the link, loop back the local transmit and receive ports, and use the DDM parameters to help determine the fault.

## Reset a QSFP+ or QSFP28 Transceiver

Reset a transceiver to simulate removal and reinsertion of the transceiver, which can be helpful in troubleshooting. For example, if authentication of the transceiver fails but you believe the transceiver is a qualified Extreme Networks part, you can reset the transceiver to begin the authentication process again.

### About This Task

Resetting the transceiver stops traffic and triggers log messages similar to the removal and insertion of the transceiver.

### Before You Begin

- Before you use the **pluggable-optical-module reset** command, ensure the port is administratively down to avoid link flaps.

### Procedure

- Enter Global Configuration mode:  
enable  
  
configure terminal
- Reset the transceiver:  
pluggable-optical-module reset {slot/port[/sub-port]}

### Important

Not all hardware platforms support these port types. For more information, see your hardware documentation.

### Examples

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#pluggable-optical-module reset 1/41
Switch:1(config)#

### Variable Definitions

The following table defines parameters for the **pluggable-optical-module reset** command.

| Variable                            | Value                                                                                                                                                                                                                        |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port]}</code> | Specifies location of the transceiver to reset. Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Layer 2 and 3 Troubleshooting

Use the information in this section to troubleshoot Layer 2 and 3 problems.

### Troubleshooting BPDU Guard

The following procedures provide information to troubleshoot issues with Bridge Protocol Data Unit (BPDU) Guard.

#### No Packets Received on the Port

For BPDU Guard to work on a port, the port must receive BPDU packets. Perform the following procedure to troubleshoot cases when the port does not receive packets.

#### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Show the BPDU Guard status for the port:
 

```
show spanning-tree bpduguard {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```
3. Use the following command to verify that the port receives packets:
 

```
show interface gigabitEthernet statistics verbose {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```
4. Verify that the remote port is sending packets:
 

```
show spanning-tree {mstp|rstp} port role [{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

```
show spanning-tree {mstp|rstp} port statistics [{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

#### Example

Port 1/8 receives packets. The remote port is disabled and does not send BPDU packets.

The following example shows that BPDU Guard is enabled for port 1/8. The BPDU Guard administrative state for the port is enabled but the timer counter is 0.

```
Switch:1>enable
Switch:1#show spanning-tree bpduguard 1/8

**Variable Definitions**

Use the data in the following table to use the **show spanning-tree bpduguard** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

Use the data in the following table to use the **show interface gigabitEthernet statistics verbose** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

Use the data in the following table to use the **show spanning-tree** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{mstp rstp}</code>                                           | Specifies the spanning tree protocol.                                                                                                                                                                                                                                                                                                                         |
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Troubleshooting IPv6 VRRP

The following sections describe troubleshooting information for IPv6 Virtual Router Redundancy Protocol (VRRP).

### VRRP Transitions

When a VRRP transition takes place with the backup taking over as the master, look for the following message in the syslog on the new master, as well as the old master. This message provides information to allow you to determine the cause of the transition.

```
IPv6 Vrrp State Transition Trap(Port/Vlan=200, Type=masterToInitialize, Cause=shutdownReceived, VrId=20,VrIpAddr=fe80:0:0:0:0:0:0:200, Addr=fe80:0:0:0:224:7fff:fe9d:1a03)
```

In this message, see the Type and Cause fields.

**Note**

Although all of the possible causes and types are listed below, the system does not display all of the listed causes and types in the trap/log message.

The following table describes the VRRP transition types.

**Table 283: Transition type**

| Type value | Type definition         |
|------------|-------------------------|
| 1          | None                    |
| 2          | Master to backup        |
| 3          | Backup to master        |
| 4          | Initialize to master    |
| 5          | Master to initialize    |
| 6          | Initialize to backup    |
| 7          | Backup to initialize    |
| 8          | Backup to backup master |
| 9          | Backup master to backup |

The following table describes the VRRP transition causes.

**Table 284: Transition cause**

| Cause value | Cause definition                                                            |
|-------------|-----------------------------------------------------------------------------|
| 1           | None                                                                        |
| 2           | Higher priority advertisement received                                      |
| 3           | Shutdown received                                                           |
| 4           | VRRP address and physical address match                                     |
| 5           | Master down interval                                                        |
| 6           | Preemption                                                                  |
| 7           | Critical IP goes down                                                       |
| 8           | User disabling VRRP                                                         |
| 9           | VRRP status synced from primary                                             |
| 10          | IPv6 interface on which VRRP is configured goes down                        |
| 11          | Lower priority advertisement received                                       |
| 12          | Advertisement received from higher interface IP address with equal priority |
| 13          | Advertisement received from lower interface IP address with equal priority  |

**Table 284: Transition cause (continued)**

| Cause value | Cause definition                      |
|-------------|---------------------------------------|
| 14          | User enabled VRRP                     |
| 15          | Transition because of any other cause |

*Enabling Trace Messages for IPv6 VRRP Troubleshooting*

Use this procedure to enable trace messages for IPv6 VRRP.

When VRRP is enabled on two routing switches, the master-backup relationship forms with one router taking the responsibility of routing. If the master-backup relationship is not formed between the VRRP virtual routers, look for the following trace messages to ensure that the master is sending the advertisements correctly and the backup is processing them.

**Procedure**

1. Enter Privileged EXEC mode:  
`enable`
2. To troubleshoot IPv6 VRRP, you can enable RCIP6 trace messages with the command:  
`trace level 66 3`
3. And to provide additional trace information, you can also enable the following traces:  
`trace ipv6 nd enable`  
`trace ipv6 base enable all`  
`trace ipv6 forwarding enable all`  
`trace ipv6 rtm enable all`  
`trace ipv6 transport enable all`

4. When VRRP is enabled on two routing switches, the master-backup relationship forms with one router taking the responsibility of routing. If the master-backup relationship is not formed between the VRRP virtual routers, look for the following trace messages to ensure that the master is sending the advertisements correctly and the backup is processing them. On the master router, look for the following RCIP6 trace messages.

- tMainTask RCIP6: rcip6\_vrrp.c: 5118: VRF name: GlobalRouter (VRF id 0): ipv6VrrpTic: Am Master for Vrid 200 on IfIndex 2053 Timer 1

If VRRP is enabled on the interface, this timer kicks off every second and shows the state for the VRID.

- [11/18/09 15:08:20:383] tMainTask RCIP6: rcip6\_vrrp.c: 5924: ipv6VrrpSendAdvertisement: for Vrid 200 on IfIndex 2053

```
[11/18/09 15:08:20:583] tMainTask RCIP6: rcip6_vrrp.c:
5175: VRF name: GlobalRouter (VRF id 0): ipv6VrrpTic:
ipv6VrrpSendAdvertisement
```

The preceding trace messages show that the VRRP master is sending the advertisements correctly at the end of advertisement interval for a VRID.

5. On the backup router, look for the following RCIP6 trace messages.

- tMainTask RCIP6: rcip6\_vrrp.c: 5236: VRF name: GlobalRouter (VRF id 0): ipv6VrrpTic: Am Backup for Vrid 200 on IfIndex 2052 Timer 1
- tMainTask RCIP6: rcip6\_vrrp.c: 4854: ipv6VrrpIn: Vrid 200 on IfIndex 2052
- tMainTask RCIP6: rcip6\_vrrp.c: 5545: VRF name: GlobalRouter (VRF id 0): rcIpVrrpProcessAdvt: Am backup for Vrid 200 on IfIndex 2052

The preceding trace messages show that the backup router is receiving the advertisements sent by the master and correctly processing them.

#### *Risks Associated with Enabling Trace Messages*

When traces are enabled on VRRP master, VrrpTic messages are logged for every second and any other configured traces keep displaying, so there is no guarantee that the backup will receive the advertisement from the master within 3 seconds, so it can transit to master also. There is also the risk of toggling of VRRP states (from backup to master and back again).

Enable the limited traces based on whichever is required.

#### *VRRP with Higher Priority Running as Backup*

The VRRP router with the higher priority can display as the backup for the following reasons

- Hold-down timer is running.
- The configured Critical IP is not reachable or does not exist.

If the critical-IP is configured for VRRP master, and the critical interface goes down or is deleted, the master transitions to the backup state. In this case, the log shows the transition cause as 1 like many other cases.

If the holddown timer is configured for VRRP master, the holddown timer delays the preemption, giving the device, which is becoming the master enough time to construct routing tables.

### Procedure

1. To determine that the issue is with the critical interface, look for the following trace message.

```
tMainTask RCIP6: rcip6_vrrp.c: 5152: VRF name: GlobalRouter (VRF id
0): ipv6VrrpTic: Becoming backup for Vrid 200 on IfIndex 2052 because
of invalid critical IP
```

2. If the holddown Timer is configured for VRRP master, the holddown timer delays the preemption, giving the device, which is becoming the master enough time to construct routing tables.

```
tMainTask RCIP6: rcip6_vrrp.c: Enter in HoldDown processing,Vrid 200
LastRecvd 0 MasterDown 3, Holddown time remaining 970, Holddownstate 2
```

## Troubleshooting RSMLT

The following sections provide information for troubleshooting IPv4 Split Multi-Link Trunking (RSMLT).

### *RSMLT Peers Not Up*

If, after a series of reconfigurations, RSMLT peers do not transition to the up state, use the following procedure to troubleshoot the issue. You can observe this issue on dual-stack VLANs after multiple delete and re-adds of IPv4 interfaces.

### Procedure

1. Display the RSMLT configuration. This command shows whether the peers are up:
 

```
show ip rsmlt peer
```
2. Enter VLAN Interface Configuration mode:
 

```
enable

configure terminal

interface vlan <1-4059>
```
3. To recover the peers if they are down, disable and reenables RSMLT on both IST peers:
 

```
no ip rsmlt

ip rsmlt
```
4. If the problem persists, boot from a saved configuration.

### Example

Display the RSMLT configuration:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 1
Switch:1(config-if)#show ip rsmlt peer
```

```
=====
                          Ip Rsmlt Peer Info - GlobalRouter
                          =====
```

| VID | IP           | MAC               | ADMIN  | OPER | HDTMR | HUTMR  |
|-----|--------------|-------------------|--------|------|-------|--------|
| 1   | 192.0.2.1    | 00:1f:ca:1e:d3:1e | Enable |      | Up    | 60 180 |
| 2   | 198.51.100.1 | 00:1b:ca:1d:e3:1d | Enable |      | Up    | 60 180 |

```
-----
```

| VID | HDT REMAIN | HUT REMAIN | SMLT ID |
|-----|------------|------------|---------|
| 1   | 60         | 180        | 10      |
| 2   | 60         | 180        | 10, 16  |

```
-----
```

| VID | IPv6 | MAC | ADMIN | OPER | HDTMR | HUTMR |
|-----|------|-----|-------|------|-------|-------|
|-----|------|-----|-------|------|-------|-------|

```
-----
```

| VID | HDT REMAIN | HUT REMAIN | SMLT ID |
|-----|------------|------------|---------|
|-----|------------|------------|---------|

```
-----
Switch:1(config-if)#no ip rsmlt
Switch:1(config-if)#ip rsmlt
```

#### Enabling Trace Messages for RSMLT Troubleshooting

Use the following procedure to obtain additional RSMLT-related information.

#### Procedure

If the preceding information does not resolve the issue, you can use the following command to obtain additional RSMLT-related information:

```
trace level 173 4
```

#### Important

Enabling this trace on a loaded system can slow down the CPU, especially if executed through the console. Use Telnet if possible.

## Troubleshooting IPv6 Connectivity Loss

If the switch experiences loss of IPv6 connectivity, use the following procedure to troubleshoot the issue.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Through the command line interface, make sure the required routes are in place and the corresponding neighbor entries are resolved (that is, in REACHABLE, PROBE, DELAY or STALE state).
3. INCOMPLETE neighbor state indicates a problem if the corresponding neighbor is used by some of the IPv6 routes. This applies to neighbor entries with link-local addresses.

### Note

Global addresses are not normally used as next hops. Having a global IPv6 neighbor entry as INCOMPLETE does not usually lead to a connectivity issue.

4. If the corresponding route is not in place then this is a routing issue. If the neighbor is not present or is INCOMPLETE, then further debugging is needed on the network level (that is, the state of other nodes needs to be examined).
5. Disabling and re-enabling IPv6 on the VLAN often recovers connectivity.
6. Display the RSMLT and MLT status:

```
show ip rsmlt
```

```
show mlt
```

Make sure the RSMLT peer MAC is learned and the IST state is `ist`.

## Troubleshooting vIST Failure

### About This Task

When you use Virtual Inter-Switch Trunk (vIST), all critical network traffic runs on this link. If vIST fails, network protocols such as RIP, VRRP, OSPF, and VLACP go down and eventually cause a network outage.

vIST uses an SPBM tunnel to virtually connect two nodes that can be anywhere in the SPBM cloud. Even if the two vIST nodes are directly connected by an MLT link, the vIST VLAN does not have MLT ports as members. Instead, it is configured to be an SPBM C-VLAN.

### Note

For more information on vIST and a configuration example, see [MultiLink Trunking and Split MultiLink Trunking](#) on page 2571.

The vIST tunnel is up as long as there is SPBM connectivity between the IST peers. If there is a vIST failure, check the following procedure for some possible reasons:

**Procedure**

1. Enter Global Configuration mode:  

```
enable

configure terminal
```
2. Verify that the vIST VLAN is configured on the vIST switch:  

```
show virtual-ist
```
3. Verify that an I-SID is associated with the vIST VLAN:  

```
show isis spbm i-sid discover
```

**Important**

The I-SID associated with the vIST VLAN should be the same on the vIST peer, and this I-SID should not be used anywhere else in the network.

4. Verify that the vIST peers are on the same subnet.
5. If peer ARP is not resolved, enable **trace level 14** to see if ARP request/response are being sent/received.
6. If vIST is not up, check the **mac fdb table** and verify that the peer MAC is synchronized:  

```
show vlan mac-address-entry <1-4059>
```
7. If the vIST peer MAC is learned, check to see if the peer IP address is reachable.
  - a. Use **show virtual-ist** to obtain the vIST peer IP address.
  - b. Ping the peer IP address.
8. If unable to **ping** the peer IP address, check to see if ARP is resolved.  

```
show ip arp vlan <vid>
```

## Multicast Troubleshooting

Use the following information to troubleshoot multicast features and multicast routing.

### *Multicast Feature Troubleshooting*

Use the information in this section to troubleshoot multicast feature problems.

#### **Troubleshooting IGMP Layer 2 Querier**

The following sections provide troubleshooting information for the IGMP Layer 2 Querier feature.

##### Querier Not Elected

If a Querier is not elected, use the following procedure to troubleshoot the issue.

**Procedure**

1. Enter Privileged EXEC mode:  

```
enable
```

- As the IGMP Layer 2 Querier is based on IGMP snoop, check whether IGMP snoop is enabled on the VLAN:

```
show ip igmp interface vlan
```

If IGMP snoop is disabled, the Layer 2 Querier cannot work until IGMP snoop and IGMP Layer 2 Querier are reenabled.

### Example

Check whether IGMP snoop is enabled on the VLAN:

```
Switch:1>enable
Switch:1#show ip igmp interface vlan
```

```

### Enable Trace Messages for IGMP Layer 2 Querier Troubleshooting

If the preceding information does not address your issue, you can also use the following trace command to view additional information related to Layer 2 querier.

**Caution**

Using the trace tool inappropriately can cause CPU lockup conditions, loss of access to the device, loss of protocols, and service degradation. If you use trace level 3 (verbose) or trace level 4 (very verbose), do not use the screen to view commands due to the volume of information the system generates and the effect on the system.

**Procedure**

1. Enter Privileged EXEC mode:  
`enable`
2. Use the following trace command to begin the trace operation for additional information related to Layer 2 querier:  
`trace level 23 <1-4>`
3. Stop tracing:  
`trace shutdown`
4. View the trace results:  
`trace screen enable`
5. View trace saved to a file:  
`show trace file [tail]`

**Variable Definitions**

Use the data in the following table to use the **trace** command.

| Variable                                | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>level</i><br>[<Module_ID><br>[<1-4>] | Starts the trace by specifying the module ID and level. Module ID 23 represents the IGMP module<br><Module_ID> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the <b>show trace modid-list</b> command or CLI command completion Help.<br><0-4> specifies the trace level: <ul style="list-style-type: none"> <li>• 0 — Disabled</li> <li>• 1 — Very terse</li> <li>• 2 — Terse</li> <li>• 3 — Verbose</li> <li>• 4 — Very verbose</li> </ul> |
| <i>shutdown</i>                         | Stops the trace operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>screen {disable enable}</i>          | Enables or disables the display of trace output to the screen.<br><br><b>Important:</b><br>Avoid using the screen to view commands if you use trace level 3 (verbose) or trace level 4 (very verbose) due to the volume of information generated and the effect on the system.                                                                                                                                                                                                                                                                                                               |

Use the data in the following table to use the **show trace** command.

| Variable           | Value                                             |
|--------------------|---------------------------------------------------|
| <i>file [tail]</i> | Displays the trace results saved to a file.       |
| <i>level</i>       | Displays the current trace level for all modules. |
| <i>modid-list</i>  | Specifies the module ID list.                     |

### Troubleshoot IGMPv3 Backwards Compatibility

If you configure the switch to operate in v2-v3 compatibility mode, the switch supports all IGMPv2 and v3 messages. The switch parses the group address of the messages. If the group address is out of SSM range and it is a v3 message, the switch drops the message. If it is a v2 message, IGMP snoop processes handle the message.

To troubleshoot issues with the IGMPv3 backwards compatibility feature, perform the following procedure.

#### Procedure

1. Enter Privileged EXEC mode:

```
enable
```
2. Verify that the SSM static channel is configured for the v1/v2 joins received. Display the configured SSM static channels:

```
show ip igmp ssm-map
```

- Verify that the SSM group range is configured for the v1/v2 joins received. Display the configured SSM group range:

```
show ip igmp ssm
```

### Example

Display the configured SSM static channels and display the configured SSM group range:

```
Switch:1#show ip igmp ssm-map
=====
                                Igmp Ssm Channel - GlobalRouter
=====
GROUP          SOURCE          MODE          ACTIVE          STATUS

## Multicast Routing Troubleshooting Using CLI

### View IGMP Interface Information

Perform this procedure to view the IGMP interface table.

#### About This Task

If an interface does not use an IP address, the system does not display it in the IGMP table. One exception is an IGMP snooping interface, which does not require an interface IP address.

If an interface uses an IP address, but neither IGMP snoop or PIM is enabled, the system displays the interface as inactive in the Status field.

#### Procedure

- Enter Privileged EXEC mode:

```
enable
```

- View IGMP interfaces:

```
show ip igmp interface [gigabitethernet {slot/port[/sub-port]}[-slot/
port[/sub-port]][,...]}[vlan <1-4059>] [vrf WORD<1-16>] [vrfids WORD<0-
512>]
```

### Example

View IGMP interfaces:

```
Switch:1#show ip igmp interface

=====
=====
                        Icmp Interface - GlobalRouter
=====

### Variable Definitions

The following table defines parameters for the **show ip igmp interface** command.

| Variable                                                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. If you do not specify a slot and port, the command output includes all IGMP interfaces.                                                        |
| vlan <1-4059>                                                                | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. If you do not specify a VLAN ID, the command output includes all IGMP interfaces. |
| vrf WORD <1-16>                                                              | Optionally, identifies the VRF name. If you do not specify a VRF name, the results display information for the Global Router. If you specify a VRF name, the results display information only for the VRF you specify.                                                                                                                                                                                                                                                                                       |
| vrfids WORD <0-512>                                                          | Optionally, identifies the VRF ID. If you do not specify a range of VRF IDs, the results display information for the Global Router. If you specify a VRF ID or range of VRF IDs, the results display information only for the VRF you specify.                                                                                                                                                                                                                                                               |

### View Multicast Group Trace Information for IGMP Snoop

### About This Task

Multicast group trace tracks the data flow path of the multicast streams.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display the multicast group trace for an IGMP snoop-enabled interface:  
show ip igmp snoop-trace [source {A.B.C.D}] [group {A.B.C.D}]

### Example

Display the multicast group trace for an IGMP snoop-enabled interface:

```
Switch:1# show ip igmp snoop-trace
```

```
=====
                        Snoop Trace - GlobalRouter
=====
```

| GROUP ADDRESS | SOURCE ADDRESS | IN VLAN | IN PORT | OUT VLAN | OUT PORT | TYPE   |
|---------------|----------------|---------|---------|----------|----------|--------|
| 233.252.0.1   | 192.0.2.6      | 500     | 1/1     | 500      | 1/5      | ACCESS |
| 233.252.0.10  | 192.0.2.7      | 500     | 1/1     | 500      | 1/10     | ACCESS |

### Variable Definitions

The following table defines parameters for the **show ip igmp snoop-trace** command.

| Variable                | Value                                                  |
|-------------------------|--------------------------------------------------------|
| <i>group {A.B.C.D}</i>  | Specifies the group IP address in the format a.b.c.d.  |
| <i>source {A.B.C.D}</i> | Specifies the source IP address in the format a.b.c.d. |

### View IGMP Group Information

View information about IGMP groups to see the current group operation on the switch.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View IGMP group information:  
show ip igmp group group <A.B.C.D> detail [port {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] [vlan <1-4059>] [vrf WORD <1-16>] [vrfids WORD <0-512>]  
  
show ip igmp group group <A.B.C.D> tracked-members [member-subnet <A.B.C.D./X>] [port {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] [source-subnet <A.B.C.D./X>] [vlan <1-4059>] [vrf WORD <1-16>] [vrfids WORD <0-512>]

## Example

View IGMP group information:

```
Switch:1>enable
Switch:1#show ip igmp group group 232.0.0.0

=====
                          Icmp Group - GlobalRouter

## Variable Definitions

The following table defines parameters for the **show ip igmp group** command.

| Variable                                  | Value                                                 |
|-------------------------------------------|-------------------------------------------------------|
| <i>count</i>                              | Displays the number of entries in the IGMP group.     |
| <i>group</i> <A.B.C.D>                    | Specifies the address of the IGMP group.              |
| <i>member-subnet</i> {default <A.B.C.D>}] | Specifies the IP address and mask of the IGMP member. |
| <i>vrf</i> WORD<1-16>                     | Specifies the VRF name.                               |
| <i>vrfids</i> WORD<0-512>                 | Specifies the VRF ID.                                 |

The following table defines parameters for the **show ip igmp group group** command.

| Variable                                                                                                                                                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <code>vrfids WORD&lt;0-512&gt;</code>                                                                                                                    | Specifies the VRF ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

The following table defines parameters for the **show ip igmp group group <A.B.C.D> tracked-members** command.

| Variable                                                                | Value                                                 |
|-------------------------------------------------------------------------|-------------------------------------------------------|
| <code>member-subnet {default   &lt;A.B.C.D&gt;}]</code>                 | Specifies the IP address and mask of the IGMP member. |
| <code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Specifies the port list.                              |
| <code>source-subnet &lt;A.B.C.D/X&gt;</code>                            | Specifies the source IP address and the subnet mask.  |

| Variable                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>vlan &lt;1-4059&gt;</code>      | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies the VRF name.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies the VRF ID.                                                                                                                                                                                                                                                                                                                                                                                                                  |

### Determine the Data Stream Learned with IP Multicast over Fabric Connect on the VLAN

Use this procedure to determine the data stream learned when IP Multicast over Fabric Connect is configured on the VLAN.

#### About This Task

The following section shows sample output for the `show ip mroute route` command.

In this table, every stream uses one (\*,G) entry and x (S,G) entries, depending on how many servers forward traffic to the same group.

The 0.0.0.0 mask is always tied to a (\*,G) entry.

If you do not specify a VRF name or range of VRF IDs, the results display information for the Global Router. If you do specify a VRF name or range of VRF IDs, the results display information only for the VRFs you specify.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Determine the data stream learned:

```
show ip mroute route [vrf WORD <0-32>] [vrfids <0-255>]
```

#### Example

Determine the data stream learned:

```
Switch:1>show ip mroute route

=====
                        Mroute Route - GlobalRouter
=====
GROUP          SOURCE          SRCMASK          UPSTREAM_NBR    IF      EXPIR   PROT
-----
233.252.0.1    0.0.0.0          0.0.0.0          0.0.0.0         V3      30      spb-access
233.252.0.1    192.0.2.102     255.255.255.0   0.0.0.0         -       0       spb-network
233.252.0.2    0.0.0.0          0.0.0.0          0.0.0.0         V2      30      pimsm
225.1.1.1      198.51.100.99   255.255.255.0   0.0.0.0         V3      173     spb-pim-gw

Total 4
```

#### Variable Definitions

The following table defines parameters for the `show ip mroute route` command.

| Variable                          | Value                   |
|-----------------------------------|-------------------------|
| <code>vrf WORD&lt;0-32&gt;</code> | Specifies the VRF name. |
| <code>vrfids &lt;0-255&gt;</code> | Specifies the VRF ID.   |

### Display the SPBM Multicast Database

You can determine the database used by the SPBM multicast module by using the following procedure.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the SPBM multicast database:

```
show isis spbm ip-multicast-route [all][detail][group {A.B.C.D}][vlan <2-4059>][vrf WORD<0-16>][vsn-isid <1-16777215>]
```

#### Important

When you use this command without parameters or use the detail or group optional parameters without specifying a VLAN ID or VSN I-SID, the command output displays Layer 3 context only. No Layer 2 context is displayed.

### Example

Show the SPBM multicast database:

```
Switch(config)#show isis spbm ip-multicast-route

=====
                        SPBM IP-MULTICAST FIB ENTRY INFO
=====
Source          Group          Data ISID  BVLAN Source-BEB
-----
192.2.0.1       233.252.0.246    16000001  101    EVP
-----
Total Number of SPBM IP MULTICAST ROUTE Entries: 1
=====
```

### Variable Definitions

The following table defines parameters for the `show isis spbm ip-multicast-route` command.

| Variable            | Value                                                                 |
|---------------------|-----------------------------------------------------------------------|
| <code>all</code>    | Displays all IP Multicast over Fabric Connect route information.      |
| <code>detail</code> | Displays detailed IP Multicast over Fabric Connect route information. |

| Variable                                          | Value                                                                                                                                                         |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>group {A.B.C.D}</i><br><i>source {A.B.C.D}</i> | Displays information on the group IP address for the IP Multicast over Fabric Connect route. If you select source it will also display the source IP address. |
| <i>vlan &lt;2-4059&gt;</i>                        | Displays IP Multicast over Fabric Connect route information by VLAN.                                                                                          |
| <i>vrf WORD&lt;0-16&gt;</i>                       | Displays IP Multicast over Fabric Connect route information by VRF.                                                                                           |
| <i>vsn-isis &lt;1-16777215&gt;</i>                | Displays IP Multicast over Fabric Connect route information by I-SID.                                                                                         |

### Troubleshoot IP Multicast over Fabric Connect for Layer 2 VSNs

If traffic is not moving properly, use the following procedure to determine the issue.

#### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Ensure that all switch nodes in the network operate with the most recent software release to support IP Multicast over Fabric Connect:
 

```
show software
```
3. Ensure that you create and enable SPBM infrastructure globally.
  - a. Ensure that SPBM is enabled globally:
 

```
show spbm
```
  - b. Ensure that IS-IS is enabled globally:
 

```
show isis
```
  - c. Ensure an SPBM instance exists with at least one Backbone VLAN (B-VID). Also ensure multicast is enabled:
 

```
show isis spbm
```
4. Ensure that you enable the CFM configuration.
  - a. Ensure a CFM maintenance-association exists:
 

```
show cfm maintenance-association
```
  - b. Ensure a CFM maintenance-domain exists:
 

```
show cfm maintenance-domain
```
  - c. Ensure a maintenance-endpoint exists in the MEP ID column and is enabled in the ADMIN column:
 

```
show cfm maintenance-endpoint
```
5. Ensure a Customer VLAN (C-VLAN) exists and ensure you add UNI ports to the C-VLAN.
  - a. Display C-VLAN information:
 

```
show vlan i-sid
```
  - b. Display ports for the C-VLAN:
 

```
show vlan members port {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

- c. Display NNI and UNI receivers:

```
show isis spbm ip-multicast-route detail
```

6. Ensure that you assign the same I-SID to the C-VLAN on all of the BEBs where you configure the C-VLAN:

```
show vlan i-sid
```

7. Ensure that you enable IP Multicast over Fabric Connect globally:

```
show isis spbm
```

8. Ensure that you enable IGMP Snooping on the C-VLAN on all of the Backbone Edge Bridges (BEBs). Ensure the protocol configured on the VLAN added is snoop-spb in the MODE column, which indicates IGMP is enabled on a VLAN with an associated I-SID (IP Multicast over Fabric Connect for a Layer 2 VSN):

```
show ip igmp interface
```

9. Ensure that you enable IGMP Snooping on access Layer 2 switches to prevent flooding of multicast traffic to non-receiver ports:

```
show ip igmp snoop-trace
```

```
show ip igmp interface
```

10. Ensure that the IGMP version used by the multicast hosts and the Layer 2 switches outside the SPBM network is the same as the IGMP version configured on the C-VLAN:

```
show ip igmp interface
```

### Troubleshoot IP Multicast over Fabric Connect for Layer 3 VSNs

If traffic is not moving properly, use the following procedure to determine the issue.

#### Procedure

1. Ensure that all switch nodes in the network operate with the most recent software release to support IP Multicast over Fabric Connect:

```
show software
```

2. Ensure that you create and enable SPBM infrastructure globally.

- a. Ensure that SPBM is enabled globally:

```
show spbm
```

- b. Ensure that IS-IS is enabled globally:

```
show isis
```

- c. Ensure an SPBM instance exists with at least one Backbone VLAN (B-VID). Also ensure multicast is enabled:

```
show isis spbm
```

3. Ensure that you enable the CFM configuration.

- a. Ensure a CFM maintenance-association exists:

```
show cfm maintenance-association
```

- b. Ensure a CFM maintenance-domain exists:

```
show cfm maintenance-domain
```

- c. Ensure a maintenance-endpoint exists in the MEP ID column and is enabled in the ADMIN column:  

```
show cfm maintenance-endpoint
```
4. Ensure the following on all the Backbone Edge Bridges (BEBs) where the Layer 3 VSN is present.
  - a. Ensure that you enable IP multicast globally:  

```
show isis spbm
```
  - b. Ensure that you create an IPVPN for the VRF:  

```
show ip ipvpn [vrf WORD<1-16>][vrfids WORD<0-512>]
```
  - c. Ensure that you assign an I-SID to the VRF:  

```
show isis spbm ip-multicast-route all
```
  - d. Ensure that you enable the MVPN:  

```
show ip vrf mvpn
```
5. On the VLANs that need Layer 3 VSN IP Multicast over Fabric Connect routing, create an IP interface on the VLAN if one does not exist. The address should be on the same subnet as the IGMP hosts connected to the VLAN. Also, ensure that you enable IP Multicast over Fabric Connect.
6. Enter VLAN Interface Configuration mode:  

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```
7. Create an IP interface on the VLAN and enable IP Multicast over Fabric Connect:  

```
ip address <A.B.C.D>
```

```
ip spb-multicast enable
```
8. Ensure that you enable IGMP Snooping on access Layer 2 switches to prevent flooding of multicast traffic to non-receiver ports:  

```
show ip igmp snoop-trace
```

```
show ip igmp interface
```
9. Ensure that the IGMP version used by the multicast hosts and the Layer 2 switches outside the SPBM network is the same as the IGMP version configured on the C-VLAN:  

```
show ip igmp interface
```

### Troubleshoot IP Multicast over Fabric Connect for IP Shortcuts

If traffic is not moving properly, use the following procedure to determine the issue.

#### Procedure

1. Ensure that all switch nodes in the network operate with the most recent software release to support IP Multicast over Fabric Connect:  

```
show software
```

2. Ensure that you create and enable SPBM infrastructure globally.
  - a. Ensure that SPBM is enabled globally:

```
show spbm
```
  - b. Ensure that IS-IS is enabled globally:

```
show isis
```
  - c. Ensure an SPBM instance exists and at least one Backbone VLAN exists (B-VID). Also ensure multicast is enabled:

```
show isis spbm
```
3. Ensure that you enable the CFM configuration.
  - a. Ensure a CFM maintenance-association exists:

```
show cfm maintenance-association
```
  - b. Ensure a CFM maintenance-domain exists:

```
show cfm maintenance-domain
```
  - c. Ensure a maintenance-endpoint exists in the MEP ID column and is enabled in the ADMIN column:

```
show cfm maintenance-endpoint
```
4. Ensure the following on all BEBs where you want IP Multicast over Fabric Connect. Ensure that you enable IP Multicast over Fabric Connect globally:

```
show isis spbm
```
5. On the VLANs that need Layer 3 VSN IP Multicast over Fabric Connect routing, create an IP interface on the VLAN if one does not exist. The address should be on the same subnet as the IGMP hosts connected to the VLAN. Also, ensure that you enable IP Multicast over Fabric Connect. Create an IP interface on the VLAN and enable IP Multicast over Fabric Connect.
6. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```
7. Create an IP interface on the VLAN and enable IP Multicast over Fabric Connect:

```
ip address <A.B.C.D>
```

```
ip spb-multicast enable
```
8. Ensure that you enable IGMP Snooping on access Layer 2 switches to prevent flooding of multicast traffic to non-receiver ports:

```
show ip igmp snoop-trace
```

```
show ip igmp interface
```
9. Ensure that the IGMP version used by the multicast hosts and the Layer 2 switches outside the SPBM network is the same as the IGMP version configured on the C-VLAN:

```
show ip igmp interface
```

## View the Hardware Resource Usage

## About This Task

The switch can query the number of ingress and egress IP multicast streams traversing the switch. After you configure the thresholds for ingress and egress records, if the record-usage goes beyond the threshold, the device notifies you by way of a trap on the console, logged message, or both.

If you do not configure the thresholds, the switch displays only the ingress and egress records currently in use.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the hardware resource usage:

```
show ip mroute hw-resource-usage
```

## Example

Show the hardware resource usage:

```
Switch:1>show ip mroute hw-resource-usage
=====
                          Multicast Hardware Resource Usage
=====
EGRESS      INGRESS      EGRESS      INGRESS      LOG MSG      SEND TRAP      SEND TRAP
REC IN-USE  REC IN-USE  THRESHOLD   THRESHOLD   ONLY         ONLY          AND LOG
-----
0           0           0           0           false       false        false
```

## Using PIM Debugging Commands

Use Protocol Independent Multicast (PIM) traces to aid in PIM troubleshooting.

## Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Start debug trace message output:
 

```
debug ip pim pimdbgtrace
```
3. Stop debug trace message output:
 

```
no debug ip pim pimdbgtrace

default debug ip pim pimdbgtrace
```
4. Configure the system to display trace messages forwarded by the device:
 

```
debug ip pim send-dbg-trace
```
5. Stop the system from displaying trace messages forwarded by the device:
 

```
no debug ip pim send-dbg-trace

default debug ip pim send-dbg-trace
```

6. Configure the system to display trace messages received by the device:  

```
debug ip pim rcv-dbg-trace
```
7. Stop the system from displaying trace messages received by the device:  

```
no debug ip pim rcv-dbg-trace
```

```
default debug ip pim rcv-dbg-trace
```
8. Configure the system to display hello messages forwarded or received by the device:  

```
debug ip pim hello
```
9. Stop the system from displaying hello messages forwarded or received by the device:  

```
no debug ip pim hello
```

```
default debug ip pim hello
```
10. Configure the system to display and log debug trace messages:  

```
debug ip pim pimdbglog
```
11. Stop the system from displaying and logging debug trace messages:  

```
no debug ip pim pimdbglog
```

```
default debug ip pim pimdbglog
```
12. Configure the system to display register messages forwarded or received by the device:  

```
debug ip pim register
```
13. Stop the system from displaying register messages forwarded or received by the device:  

```
no debug ip pim register
```

```
default debug ip pim register
```
14. Configure the system to display debug trace messages after an enabled message type, for example, hello or register, is received from a specific sender IP address:  

```
debug ip pim source {A.B.C.D}
```

### Variable Definitions

The following table defines parameters for the **debug ip pim** command.

| Variable               | Value                                                                                      |
|------------------------|--------------------------------------------------------------------------------------------|
| <i>assert</i>          | Displays the assert debug traces. The default is false (disabled).                         |
| <i>bstrap</i>          | Displays bootstrap debug traces. The default is false (disabled).                          |
| <i>group {A.B.C.D}</i> | Displays debug traces from a specific group IP address. The default is 0.0.0.0 (disabled). |
| <i>hello</i>           | Displays hello debug traces. The default is false (disabled).                              |

| Variable                | Value                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------|
| <i>joinprune</i>        | Displays join and prune debug traces. The default is false (disabled).                      |
| <i>pimdbglog</i>        | Logs debug traces. The default is false (disabled).                                         |
| <i>pimdbgtrace</i>      | Displays PIM debug traces. The default is false (disabled).                                 |
| <i>rcv-dbg-trace</i>    | Displays trace messages received by the switch. The default is false (disabled).            |
| <i>register</i>         | If enabled, the system displays register debug traces. The default is false (disabled).     |
| <i>regstop</i>          | Displays register stop debug traces. The default is false (disabled).                       |
| <i>rp-adv</i>           | Displays RP advertisement debug traces. The default is false (disabled).                    |
| <i>send-dbg-trace</i>   | Displays trace messages forwarded by the switch. The default is false (disabled).           |
| <i>source {A.B.C.D}</i> | Displays debug traces from a specific source IP address. The default is 0.0.0.0 (disabled). |

### Determine the Protocol Configured on the Added VLAN

Use this procedure to determine the protocol configured on the added VLAN.

The protocol configured on the added VLAN can be one of the following values:

- snoop
- snoop-spb
- route-spb
- pim

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Determine the protocol configured on the added VLAN:  
show ip igmp interface [gigabitethernet {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] [vlan <1-4059>] [vrf WORD<1-16>] [vrfids WORD<0-512>]

The protocol displays under the Mode column of the command output.

### Example

Determine the protocol configured on the added VLAN:

```
Switch:1#show ip igmp interface
```

```
=====
=====
```

```
                  Igmp Interface - GlobalRouter
```

```

=====
=====
=====
QUERY          OPER          QUERY  WRONG          LASTMEM          SCOPE
IF  INTVL  STATUS  VERS.  VERS  QUERIER  MAXRSPT  QUERY  JOINS  ROBUST  QUERY  MODE          L2ISID  ISID

```

Variable Definitions

The following table defines parameters for the **show ip igmp interface** command.

| Variable                                                                     | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <i>vlan</i> <1-4059>                                                         | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <i>vrf</i> WORD<1-16>                                                        | Specifies the VRF instance by the VRF name.                                                                                                                                                                                                                                                                                                                                                                                |
| <i>vrfids</i> WORD<0-512>                                                    | Specifies the VRF ID for which to display statistics.                                                                                                                                                                                                                                                                                                                                                                      |

Multicast routing troubleshooting using EDM

Use the information in this section to help you troubleshoot multicast routing problems using Enterprise Device Manager (EDM).

View IGMP Interface Information

Use the Interface tab to view the IGMP interface table. You can use this procedure to determine the protocol configured on the added VLAN.

The protocol configured on the added VLAN can be one of the following values:

- snoop
- pim

About This Task

If an interface does not use an IP address, the system does not display it in the IGMP table. If an interface uses an IP address, but neither IGMP snoop or PIM is enabled, the system displays the interface as inactive in the Status field.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **IGMP**.
3. Select the **Interface** tab.

### Interface Field Descriptions

Use the data in the following table to use the **Interface** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>              | Shows the interface where IGMP is enabled.                                                                                                                                                                                                                                                                                                                                           |
| <b>QueryInterval</b>        | Configures the frequency (in seconds) at which the interface transmits IGMP host query packets. The default is 125.                                                                                                                                                                                                                                                                  |
| <b>Status</b>               | Shows the IGMP row status. If an interface uses an IP address and PIM-SM is enabled, the status is active. Otherwise, it is notInService.                                                                                                                                                                                                                                            |
| <b>Version</b>              | Configures the version of IGMP (1, 2, or 3) that you want to configure on this interface. For IGMP to function correctly, all routers on a LAN must use the same version. The default is version 2.                                                                                                                                                                                  |
| <b>OperVersion</b>          | Shows the version of IGMP that currently runs on this interface.                                                                                                                                                                                                                                                                                                                     |
| <b>Querier</b>              | Shows the address of the IGMP querier on the IP subnet to which this interface attaches.                                                                                                                                                                                                                                                                                             |
| <b>QueryMaxResponseTime</b> | <p>Configures the maximum response time (in tenths of a second) advertised in IGMPv2 general queries on this interface. You cannot configure this value for IGMPv1. Smaller values enable a router to prune groups faster. The default is 100 tenths of a second (equal to 10 seconds.)</p> <p><b>Important:</b><br/>You must configure this value lower than the QueryInterval.</p> |
| <b>WrongVersionQueries</b>  | Shows the number of queries received with an IGMP version that does not match the interface. You must configure all routers on a LAN to run the same version of IGMP. If the interface receives queries with the wrong version, this value indicates a version mismatch.                                                                                                             |
| <b>Joins</b>                | Shows the number of times this interface added a group membership, which is the same as the number of times an entry for this interface is added to the cache table. This number gives an indication of the amount of IGMP activity over time.                                                                                                                                       |

| Name                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Robustness</b>                  | Tunes for the expected packet loss of a network. This value is equal to the number of expected query packet losses for each serial query interval, plus 1. If you expect a network to lose query packets, increase the robustness value.<br>The default value of 2 means that the switch drops one query for each query interval without the querier aging out.                                                                                                                                                                                                                                                                                    |
| <b>LastMembQueryIntvl</b>          | Configures the maximum response time (in tenths of a second) inserted into group-specific queries sent in response to leave group messages. This value is also the time between group-specific query messages. You cannot configure this value for IGMPv1.<br>Decrease the value to reduce the time to detect the loss of the last member of a group. The range is from 0–255 and the default is 10 tenths of second. As a best practice, configure this parameter to values greater than 3. If you do not need a fast leave process, you can configure values greater than 10. (The value 3 is equal to 0.3 seconds and 10 is equal to 1 second.) |
| <b>OtherQuerierPresent Timeout</b> | Shows the length of time that must pass before a multicast router determines that no other querier exists. If the local router is the querier, the value is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>FlushAction</b>                 | Configures the flush action to one of the following: <ul style="list-style-type: none"> <li>• none</li> <li>• flushGrpMem</li> <li>• flushMrouter</li> <li>• flushSender</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>RouterAlertEnable</b>           | Instructs the router to ignore IGMP packets that do not contain the router alert IP option. If you disable this variable (default configuration), the router processes IGMP packets regardless of the status of the router alert IP option.<br><br><b>Important:</b><br>To maximize network performance, configure this parameter according to the version of IGMP currently in use. <ul style="list-style-type: none"> <li>• IGMPv1—Disable</li> <li>• IGMPv2—Enable</li> <li>• IGMPv3—Enable</li> </ul>                                                                                                                                          |
| <b>SsmSnoopEnable</b>              | Enables SSM snoop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SnoopQuerierEnable</b>          | Enables IGMP Layer 2 Querier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SnoopQuerierAddr</b>            | Specifies the pseudo address of the IGMP snoop querier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>ExplicitHostTrackingEnable</b>  | Enables or disables IGMPv3 to track hosts for each channel or group. The default is disabled. You must select this field if you want to use fast leave for IGMPv3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Name                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>McastMode</b>                 | Indicates the protocol configured on the VLAN. <ul style="list-style-type: none"> <li>snoop — Indicates IGMP snooping is enabled on a VLAN.</li> <li>snoop-spb — Indicates IGMP is enabled on a VLAN with an associated I-SID (IP multicast over Fabric Connect for a Layer 2 VSN).</li> <li>pim — Indicates PIM is enabled.</li> <li>routed-spb — Indicates IP multicast over Fabric Connect is enabled on the Layer 3 VSN or for IP Shortcuts.</li> </ul> |
| <b>ExtnUpnpFilterEnable</b>      | Enables Universal Plug and Play (uPnP) Filtering to filter multicast packets destined for a specific range. The default is disabled.                                                                                                                                                                                                                                                                                                                        |
| <b>ExtnUpnpFilterAddress</b>     | Indicates the multicast destination IP address to filter on an IGMP-enabled interface. The default is 239.255.255.250/32.                                                                                                                                                                                                                                                                                                                                   |
| <b>ExtnUpnpFilterAddressMask</b> | Indicates the IGMP uPnP Filtering IP subnet to which this interface is attached.                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SnoopOrigin</b>               | Specifies the origin of IGMP Snooping configuration on the port. The supported values are: <ul style="list-style-type: none"> <li>config - Set by the user.</li> <li>radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.</li> </ul>                                                                                                                                                                                          |
| <b>ExtnRoutedSpbQuerierAddr</b>  | Specifies the IP address of the SPB querier.                                                                                                                                                                                                                                                                                                                                                                                                                |

#### Determine the Data Stream Learned when IP Multicast over Fabric Connect is Configured on the VLAN

Use the following procedure to determine the data stream learned when IP multicast is configured on the VLAN.

##### Procedure

1. In the navigation pane, expand **Configuration > IP > Multicast**.
2. Click the **Routes** tab.

#### Routes field descriptions

Use the data in the following table to use the **Routes** tab.

| Name              | Description                                                                                                                                                        |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Group</b>      | Displays the IP multicast group address for this entry that contains multicast routing information.                                                                |
| <b>Source</b>     | Displays the network address that, when combined with the corresponding route SourceMask value, identifies the source that contains multicast routing information. |
| <b>SourceMask</b> | Displays the network mask that, when combined with the corresponding route Source value, identifies the multicast source.                                          |

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>UpstreamNeighbor</b> | Shows the address of the upstream neighbor from which the IP datagrams from these sources are received. The address is 0.0.0.0 if the network is local.                                                                                                                                                                                                                            |
| <b>Interface</b>        | Displays the interface, slot and portnumber, or VLAN ID where IP datagrams sent by these multicast sources to this multicast address are received.                                                                                                                                                                                                                                 |
| <b>ExpiryTime</b>       | Displays the amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging.                                                                                                                                                                                                                                                 |
| <b>Protocol</b>         | Displays the protocol as one of the following: <ul style="list-style-type: none"> <li>• other(1): none of the following</li> <li>• local(2): manually configured</li> <li>• netmgmt(3): configured by a network management protocol</li> <li>• pimSparseMode(8): PIM-SMv2</li> <li>• igmpOnly(10)</li> <li>• pimSsmMode(11)</li> <li>• spb (12)</li> <li>• spbpimgw(13)</li> </ul> |

**Show the SPBM Multicast Database**

Determine the database used by the SPBM multicast module.

**Procedure**

1. In the navigation pane, expand **Configuration > ISIS > SPBM**.
2. Click the **IpMcastRoutes** tab.

**IpMcastRoutes field descriptions**

Use the data in the following table to use the **IpMcastRoutes** tab.

| Name             | Description                                                                           |
|------------------|---------------------------------------------------------------------------------------|
| <b>VsnIsid</b>   | Specifies the VSN I-SID. Layer 2 VSN and Layer 3 VSN each require a VSN I-SID.        |
| <b>Group</b>     | Specifies the group IP address for the IP Multicast over Fabric Connect route.        |
| <b>Source</b>    | Specifies the IP address where the IP Multicast over Fabric Connect route originated. |
| <b>NickName</b>  | Specifies the nick name used to filter criteria.                                      |
| <b>SourceBeb</b> | Specifies the source BEB for the IP multicast route.                                  |
| <b>VlanID</b>    | Specifies the ID for the C-VLAN.                                                      |
| <b>VrfName</b>   | Specifies the VRF name.                                                               |

| Name                 | Description                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Datalsid</b>      | Specifies the data I-SID for the IP Multicast over Fabric Connect route. A BEB receives IP multicast data from a sender, a BEB allocates a data I-SID in the range of 16,000,000 to 16,512,000 for the stream. The stream is identified by the source IP address, group IP address, and the local VLAN the stream is received on. The data I-SID is a child of the scope or VSN I-SID. |
| <b>Type</b>          | Specifies the type for the IP Multicast over Fabric Connect route.                                                                                                                                                                                                                                                                                                                     |
| <b>Bvlan</b>         | Specifies the B-VLAN for the IP Multicast over Fabric Connect route.                                                                                                                                                                                                                                                                                                                   |
| <b>NniInterfaces</b> | Specifies the NNI ports for the IP multicast route. SPBM runs in the core on the ports that connect to the core. These ports are NNI ports. Ports that face a customer VLAN are user-to-network interface (UNI) ports.                                                                                                                                                                 |

## Troubleshooting Fabric Attach

The following sections help you troubleshoot problems with Fabric Attach (FA) using either the Command Line Interface (CLI) or the Enterprise Device Manager (EDM).

### *Troubleshooting workflow*

Troubleshoot FA in the following sequence:

- **Verify FA configuration:**

As a first step, for proper operation, verify that FA is enabled properly at both the global and interface levels. Use the procedures in this section to verify FA configuration.

- **Verify LLDP port-level transmission and reception:**

LLDP operates at the interface level. Enabling FA at the port level automatically enables LLDP transmission and reception at the port level. Similarly, enabling FA at the MLT level automatically enables LLDP transmission and reception for all ports in that MLT. Use the procedures in this section to verify LLDP interface (port or MLT) statistics.

- **Verify FA discovery, I-SID-to-VLAN mapping assignments and Switched UNI I-SID creation:**

After you verify LLDP transmission, verify that FA element discovery completed successfully. After a successful FA discovery, FA clients can send I-SID-to-VLAN mapping assignments to the FA Server on an FA-enabled port or MLT. The FA server accepts or rejects these mapping assignments. A prerequisite to successful mapping assignments is that IS-IS and SPBM are properly configured on the FA

server. Successful FA mappings result in the creation of ELAN I-SIDs with end-points of type Switched UNI on the FA Server switch.

### *Troubleshoot Fabric Attach using CLI*

#### View Fabric Attach Configuration

To operate properly, Fabric Attach (FA) must be configured properly at both the global and interface level on the switch. Use this procedure to verify FA configuration.

#### Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. To verify that FA is enabled globally, enter one of the following commands:
  - `show fa`
  - `show fa agent`
3. To view all FA interfaces (ports and MLTs), enter:  

```
show fa interface
```
4. To view FA interface configuration on ports, use one of the following commands:
  - To view FA configuration on all ports, enter:  

```
show fa interface port
```
  - To view FA configuration on a specific port, enter:  

```
show fa interface port [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```
5. To view FA interface configuration on MLTs, use one of the following commands:
  - To view FA configuration on all MLTs, enter:  

```
show fa interface mlt
```
  - To view FA configuration on a specific MLT, enter:  

```
show fa interface mlt [<1-512>]
```
  - To view FA interface configuration based on the authentication status, enter:  

```
show fa interface [enabled-auth] [disabled-auth]
```

#### Example

Verify that FA is configured globally.

```
Switch:1>show fa

=====
Fabric Attach Configuration
=====

FA Service : enabled
FA Element Type : server
FA Assignment Timeout : 240
FA Discovery Timeout : 240
FA Provision Mode : spbm
```

Verify FA configuration at the interface (port or MLT) level, on all interfaces.

In the following example output, note that:

- FA is enabled on interfaces 2/10, 4/11 and Mlt2.
- Both FA and message authentication are disabled on port 4/6.
- Both FA and message authentication are enabled on port 4/11.

```
Switch:1#show fa interface
=====
Fabric Attach Interfaces
=====

*Troubleshoot Fabric Attach using EDM*

**Graph LLDP Reception Statistics**

Use this procedure to graphically view the LLDP reception statistics.

**About This Task**

LLDP operates at the port interface level. Enabling FA on a port automatically enables LLDP transmission and reception on that port. It also enables traffic tagging and disables spanning tree on that port.

Enabling FA on an MLT enables LLDP transmission and reception on all ports in that MLT.

**Note**

When a port is removed from an MLT, LLDP transmission on that port stops and spanning tree is enabled. Any I-SID-to-VLAN mappings on that port are removed, if not already learned on any other port in the MLT. This also causes the Switched UNI I-SID to be deleted from the MLT. However, if the mappings are learned on another port on the MLT, the Switched UNI I-SID continues to exist for that MLT.

For ports in an LACP MLT, when FA is enabled, tagging is enabled on all ports in the LACP MLT. The consistency check for FA is based on key membership. If all ports with the same key do not support FA, FA is not successfully enabled on those ports.

**Note**

If a slot is removed from the switch chassis, the statistics are not displayed on the slot ports. When the slot is inserted back again, the statistics counters are reset.

**Procedure**

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > 802\_1ab.LLDP**.
2. Click the **RX Stats** tab.
3. To view the reception statistics graphically for a port:
  - a. Select a row, and click **Graph**.  
The system displays the **RX Stats-Graph,<port-number>** tab.
  - b. Select one of the parameters, and click the appropriate icon in the upper-left corner of the menu bar to draw a line chart, area chart, bar chart or a pie chart.
4. To clear the existing counters, and fix a reference point in time to restart the counters, click **Clear Counters**.
5. To export the statistical data to a file, click **Export**.
6. To configure a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

RX Stats Field Descriptions

Use the data in the following table to use the **RX Stats** tab.

| Name                         | Description                                                                                                                                                                                                                                                                                               |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FramesDiscardedTotal</b>  | Specifies the number of LLDP frames received on the port, but discarded, for any reason.<br>This counter provides an indication of possible LLDP header formatting problems in the sending system, or LLDP PDU validation problems in the receiving system.                                               |
| <b>FramesErrors</b>          | Specifies the number of invalid LLDP frames received on the port.                                                                                                                                                                                                                                         |
| <b>FramesTotal</b>           | Specifies the total number of LLDP frames received on the port.                                                                                                                                                                                                                                           |
| <b>TLVsDiscardedTotal</b>    | Specifies the number of LLDP TLVs discarded on the port, for any reason.                                                                                                                                                                                                                                  |
| <b>TLVsUnrecognizedTotal</b> | Specifies the number of LLDP TLVs on the port, that are unrecognized on that port. An unrecognized TLV is referred to as the TLV whose type value is in the range of reserved TLV types (000 1001–111 1110). An unrecognized TLV could be, for example, a basic management TLV from a later LLDP version. |

## Graph LLDP Transmission Statistics

Use this procedure to view the LLDP transmission (TX) statistics. You can also view the statistics graphically.

### About This Task

LLDP operates at the port interface level. Enabling FA on a port automatically enables LLDP transmission and reception on that port. It also enables traffic tagging and disables spanning tree on that port.

Enabling FA on an MLT enables LLDP transmission and reception on all ports in that MLT.

#### Note

When a port is removed from an MLT, LLDP transmission on that port stops and spanning tree is enabled. Any I-SID-to-VLAN mappings on that port are removed, if not already learned on any other port in the MLT. This also causes the Switched UNI I-SID to be deleted from the MLT. However, if the mappings are learned on another port on the MLT, the Switched UNI I-SID continues to exist for that MLT.

For ports in an LACP MLT, when FA is enabled, tagging is enabled on all ports in the LACP MLT. The consistency check for FA is based on key membership. If all ports with the same key do not support FA, FA is not successfully enabled on those ports.

#### Note

If a slot is removed from the switch chassis, the statistics are not displayed on the slot ports. When the slot is inserted back again, the statistics counters are reset.

### Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics > 802\_1ab.LLDP**.
2. Click the **TX Stats** tab.  
The system displays the transmission statistics.
3. To view the transmission statistics graphically for a port:
  - a. Select a row, and click **Graph**.  
The system displays the **TX Stats-Graph,<port-number>** tab.
  - b. To view the graph, select one of the parameters, and click the appropriate icon on the upper-left corner of the menu bar to draw a line chart, area chart, bar chart or a pie chart.
4. To clear the existing counters, and fix a reference point in time to restart the counters, click **Clear Counters**.
5. To export the statistical data to a file, click **Export**.
6. To fix a poll interval, select an appropriate value from the **Poll Interval** drop-down list.

### TX Stats Field Descriptions

Use the data in the following table to use the **TX Stats** tab.

| Name               | Description                                            |
|--------------------|--------------------------------------------------------|
| <b>FramesTotal</b> | Specifies the total number of LLDP frames transmitted. |

*Troubleshooting FA Server Rejection of I-SID-to-VLAN Assignments Using Trace*

Consider an FA solution where the FA Server receives I-SID-to-VLAN assignment requests from a proxy device and some of these assignment requests are rejected by the FA Server. Use this procedure to help you troubleshoot the cause of the rejection.

**Note**

When the FA Server rejects an I-SID-to-VLAN assignment request, the error message in the log file lists a generic reason for the failure, such as `rejected due to application error (status 9)`. To troubleshoot further, you must use trace.

This procedure also demonstrates how you can configure trace for enhanced troubleshooting.

**Procedure**

**Begin troubleshooting on the FA Server**

1. Enter Privileged EXEC mode:  
`enable`
2. Verify that router IS-IS is enabled. This is required for proper FA operation.  
`show isis`

**Note**

I-SID-to-VLAN assignments are always rejected if router IS-IS is disabled.

3. Verify that FA is enabled on the interface on which I-SID-to-VLAN assignments are expected.  
`show fa interface [disabled-auth] [enabled-auth] [mlt <1-512>] [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`
4. Verify the discovery and authentication status of the proxy device, on the interface.  
`show fa elements [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`
5. Determine the I-SID-to-VLAN assignments received on the interface and which ones are rejected.  
`show fa assignment [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`

6. View the log file to determine the cause of the assignment rejection.

```
show log file module fa
```

#### Note

When the FA Server rejects an I-SID-to-VLAN assignment request, only a generic reason for the rejection is logged.

### Enhanced troubleshooting using trace

7. Configure trace:

- a. Enable keyword search in the trace output:

```
trace grep WORD<0-128>
```

- b. Set the trace level for FA:

```
trace level <Module_ID>
```

#### Note

- <Module\_ID> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the **show trace modid-list** command or CLI command completion Help.
- FA uses the trace level 221.

- c. Turn on trace:

```
trace screen [enable] |[disable]
```

#### Example:

The following example simulates a configuration error on the FA Server as a result of which the FA Server rejects I-SID-to-VLAN assignments from the proxy device. When the FA Server rejects an I-SID-to-VLAN assignment, the error message listed in the log file is a generic reason for the rejection, as demonstrated in this example. To troubleshoot further, set up trace.

On the FA Server, assume that the interface MLT 1 consists of ports 1/5 and 1/6. Assume that a proxy device sends I-SID-to-VLAN assignment mapping requests with I-SID 9005 and CVID 400, on this interface.

#### Simulate a configuration error on the FA Server:

Configure a management I-SID with a C-VID value that is different from that of the C-VID in the I-SID-to-VLAN assignment request from the proxy. So, for example, configure a management I-SID with C-VID 999, which is different from the C-VID advertised by the proxy, which is 400. This causes rejection of I-SID-to-VLAN assignment requests on the interface.

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface mlt 1
Switch:1(config-mlt)#no fa enable
```

```
Switch:1(config-mlt)#fa management i-sid 9005 c-vid 999
Switch:1(config-mlt)#fa enable
Switch:1(config-mlt)#exit
Switch:1(config)#exit
```

At this stage, the FA Server rejects I-SID-to-VLAN assignments as shown below.

```
Switch:1#show fa assignment

## Troubleshooting FAN Transit

Use the following section to troubleshoot Fabric Area Network (FAN) Transit information on a switch.

*View FAN Transit information - Detailed*

### About This Task

Use this procedure to verify detailed FAN Transit information of a switch acting as a transit node in a FAN. Transit nodes are not members of the FAN and only forward FAN traffic.

This procedure also includes verification on the FAN member nodes.

### Procedure

**Verification on FAN member nodes:**

1. Verify that the node is a FAN member:  

```
show isis
```
2. Verify that the node signals FAN membership on TLV 147:  

```
show isis lsdb local tlv 147 detail
```
3. Verify that the node creates FAN multicast FIB entries for itself and the other member nodes:  

```
show isis spbm multicast-fib
```
4. Verify that the transit node is a part of the FAN tree:  

```
12 tracetree-fan
```
5. Verify that the transit node is in the SPB path between the FAN member nodes:  

```
show isis spbm unicast-tree <2-4059>
```

#### Verification on the transit node:

6. Verify that the transit node is not a member of the FAN and does not signal FAN membership on TLV 147:  

```
show isis
```

```
show isis lsdb local tlv 147 detail
```
7. Verify that the transit node creates FAN multicast FIB entries for the FAN member nodes:  

```
show isis spbm multicast-fib
```

#### Example

Use the following example to verify FAN Transit information on a transit node between two end-point SPB nodes, BEB-A and BEB-B.

**Verification on BEB-A:**

**Note**

You can execute the following commands on either BEB-A or BEB-B. The following example displays the sample outputs for BEB-A.

Verify that BEB-A is a member of the FAN. The FAN Member attribute displays as Yes.

```

BEB-A:1#show isis
=====
                        ISIS General Info
=====
AdminState      : enabled
RouterType     : Level 1

## Upper Layer Troubleshooting

Use the information in this section to troubleshoot upper layer problems.

### Troubleshooting SNMP

#### About This Task

Troubleshoot Simple Network Management Protocol (SNMP) if the network management station (NMS) does not receive traps.

Verify the management configurations for the management station. Also verify the management station setup. If the management station can reach a device but not receive traps, verify the trap configurations (that is, the trap destination address and the traps to be sent).

If you enable enhanced secure mode, the switch does not support the default SNMPv1 and default SNMPv2 community strings, and default SNMPv3 user name. The individual in the administrator access level role can configure a non-default value for the community strings, and the switch can continue to support SNMPv1 and SNMPv2. The individual in the administrator access level role can also configure a non-default value for the SNMPv3 user name and the switch can continue to support SNMPv3. If you disable enhanced secure mode, the SNMPv1 and SNMPv2 support for community strings remains the same, and the default SNMPv3 user name remains the same. Enhanced secure mode is disabled by default.

### Procedure

1. From the NMS, ping the IP address for the switch. If you can ping successfully, the IP address is valid and you may have a problem with the SNMP setup.  
If you cannot ping the switch, you have a problem with either the path or the IP address.
2. Telnet to the switch.  
If you can Telnet, the switch IP address is correct.
3. If Telnet does not work, connect to the console port using a serial line connection and ensure that the IP address configuration is correct.
4. If the management station is on a separate subnet, make sure that the gateway address and subnet mask are correct.
5. Using a management application, perform an SNMP Get request and an SNMP Set request (that is, try to poll the device or change a configuration using management software).
6. If you cannot reach the device using SNMP, access the console port, and then ensure that the SNMP community strings and traps are correct.
7. Use sniffer traces to verify that the switch receives the poll.
8. Use sniffer traces to verify that the NMS receives the response.
9. Verify that the data in the response is the data that was requested.

### *SNMP Trap not Received*

Perform the following procedure to troubleshoot issues in which an SNMP trap is not received.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Show the BPDU Guard status for the port:  
`show spanning-tree bpduguard {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}`

3. Configure the correct SNMP target information:

```
snmp-server host WORD<1-256> [port <1-65535>] v3 {noAuthNoPriv|
authNoPriv|authPriv WORD<1-32> [inform [timeout <1-2147483647>]
[retries <0-255>]] [filter WORD<1-32>]
```

**Example**

In the following example, BPDU guard is enabled on port 1/8, BPDU packets are received, port 1/8 is disabled, and the TimerCount is incrementing, but no SNMP trap is ever received.

```
Switch:1>enable
Switch:1#show spanning-tree bpduguard 1/8

=====
                        Bpdu Guard
=====
Port          PORT      PORT      TIMER  BPDUGUARD  BPDUGUARD
NUM          MLTID  ADMIN_STATE  OPER_STATE  TIMEOUT  COUNT  ADMIN_STATE  ORIGIN
-----
1/8          Down    Down        120        0        Disabled  CONFIG
```

**Variable Definitions**

The following table defines parameters for the **show spanning-tree** command.

| Variable                                                    | Value                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]][,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

The following table defines parameters for the **snmp-server host** command.

| Variable                                                 | Value                                                                                                                                                                                                       |
|----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>filter WORD&lt;1-32&gt;</i>                           | Specifies a filter profile name.                                                                                                                                                                            |
| <i>host WORD&lt;1-256&gt;</i>                            | Specifies the IPv4 or IPv6 host address                                                                                                                                                                     |
| <i>inform [timeout &lt;1-2147483647&gt;]</i>             | Specifies the notify type. The optional timeout parameter configures the timeout value, which specifies the time to wait for a reply before resending the inform message. Time is specified in centiseconds |
| <i>noAuthNoPriv authNoPriv authPriv WORD&lt;1-32&gt;</i> | Specifies the security level.                                                                                                                                                                               |
| <i>port &lt;1-65535&gt;</i>                              | Specifies the port number that will be set as the destination port at the UDP level in the trap packet.                                                                                                     |

| Variable                                                                        | Value                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>retries</i> <0-255>                                                          | Specifies the number of packets to be sent if no reply is received.                                                                                                                                                                                                                                                                                           |
| <i>{slot/port[/sub-port]</i><br><i>[-slot/port[/sub-port]]</i><br><i>[,...]</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Troubleshooting DHCP

### About This Task

Perform this procedure to troubleshoot the following Dynamic Host Configuration Protocol (DHCP) scenarios:

- The client cannot obtain a DHCP address when in the same subnet.
- The client cannot obtain a DHCP address when in a different subnet.

When the DHCP server and client are on the different subnets or VLANs, you must configure the device as a DHCP relay agent. The device must forward DHCP requests to the DHCP server. You must perform extra troubleshooting steps to troubleshoot the DHCP relay agent.

### Procedure

1. Check the physical connectivity between the DHCP client and server.
2. Verify network connectivity by configuring a static IP address on a client workstation.  
If the workstation still cannot reach the network, the problem is not DHCP. Start troubleshooting network connectivity.
3. Attempt to obtain an IP address from the DHCP server by manually forcing the client to send a DHCP request.  
If the client obtains an IP address after the PC startup is complete, the issue is not the DHCP server.
4. Obtain an IP address on the same subnet or VLAN as the DHCP server.  
If the issue persists, the problem may be with the DHCP server. If DHCP is working on the same subnet or VLAN as the DHCP server, the DHCP issue can be with the DHCP relay agent.
5. Confirm the DHCP relay agent configuration is correct.
6. Obtain sniffer traces where the traffic ingresses and egresses the switch and also on the client side of the network.
7. Check the logs on the switch for errors such as size exceeded or incorrect packet format.

## Troubleshooting DHCP Relay

### Before You Begin

- Configure the server to reply to the client subnet. Check the server configuration file to verify the configuration.
- Configure a route on the server for the client subnet to create a path on which to send replies.

### About This Task

Perform this procedure to troubleshoot the DHCP relay agent.

### Procedure

1. Verify that the interfaces that link the client and server are up, and that the ports are in the forwarding state.

- a. To verify client availability, you can configure a temporary static IP address on the client, and then use the `ping` command.

```
ping WORD<0-256>
```

- b. To verify the port is in the forwarding state, use the following command for the slot and port number:

```
show spanning-tree [rstp|mstp] port role [{slot/port[/sub-port]}[-slot/port[/sub-port]][, ...]]
```

#### Note

Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

If STP detects loops in the configuration, it blocks ports to avoid flooding in the network. In this situation, the port is not in the forwarding state.

2. Ensure that DHCP is enabled on the client interface and that a valid forwarding path exists and is enabled. Ensure the server is reachable.
3. View the statistics counters for the relay.
4. If request or reply counters do not increase, use a sniffer tool to ensure that the client sends the packets, and that the interface module receives the packets.

You can configure mirroring for the ingress port to verify if the packets reach the module.

- a. If the client sends the packets, check that the packets reach the CPP and search the trace results for the ingress port:

```
trace level 9 3
```

```
trace grep WORD<0-128>
```

- b. If the packets reach the CPP, check that they reach the DHCP protocol; check for errors or packet drop messages:

```
trace level 170 3
```

```
trace grep WORD<0-128>
```

- 5. If Option 82 is enabled, check the statistic counters for dropped packets, and perform a trace for the DHCP protocol:

```
trace level 170 3
```

**Example**

```
Switch:1# ping 192.0.2.31
```

```
Switch:1#show spanning-tree mstp port role

**Variable Definitions**

Use the data in the following table to use the troubleshooting commands in this procedure.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>WORD&lt;0-128&gt;</i>                                     | Specifies the text string to use as the search criterion.                                                                                                                                                                                                                                                                                                     |
| <i>WORD&lt;0-256&gt;</i>                                     | Specifies the IP address.                                                                                                                                                                                                                                                                                                                                     |

### *Troubleshooting Client Connection to the DHCP Server*

#### **About This Task**

Perform this procedure if the client cannot reach the DHCP server.

#### **Procedure**

1. Check that the DHCP relay agent in the network switch is correctly configured.
2. Check that the DHCP server configuration is correct.
3. Check for routing issues.

The routing in the network may not be configured so that DHCP request and reply packets are propagated. You can use ping and traceroute.

4. Check that the DHCP pools are correctly configured.
5. If the client cannot reach the server because the link is down, enable auto-negotiation on the link.

### *Troubleshooting IPv6 DHCP Relay*

The following sections provide troubleshooting information for IPv6 DHCP Relay.

#### *IPv6 DHCP Relay Switch Side Troubleshooting*

With DHCP Relay, the switch only participates in forwarding the requests and replies to and from the client and the DHCP server. The switch always acts as the relay agent, on which you configure the forward path to the server.

To troubleshoot DHCP Relay issues on the switch, use the following procedure.

#### **Procedure**

1. Verify that the DHCP server is reachable using ping. If ping is working and the DHCP server is reachable, DHCP should work.
2. Verify that the relay agents and the forward path configured are reachable. Ping the server and the gateway to the server.
3. Check that the relay agent configurations are correct. Also verify that DHCP is enabled on the switch:

```
show ipv6 dhcp-relay interface {gigabitEthernet {slot/port[/sub-port]}
[-slot/port[/sub-port]][,...]}|vlan <1-4059>
```

4. Verify that IPv6 forwarding is enabled globally:  

```
show ipv6 global
```
5. Verify that the IPv6 based VLAN where the DHCP relay agent is configured is enabled:  

```
show ipv6 interface vlan <1-4059>
```
6. In a scenario with VRRP and SMLT, configure VRRP IP as the DHCP relay agent.
7. When using the VRRP VRID as the relay agent, make sure the VRRP configurations are proper.

8. To verify that relay forward and relay receive are working, enable trace for DHCP with IPv6, and grep trace for relay:

```
trace level 66 3
```

```
trace grep relay
```

```
trace screen enable
```

9. Display the count of DHCP Relay requests and replies to verify the system received requests and replies:

```
show ipv6 dhcp-relay counters
```

### *IPv6 DHCP Relay Server Side Troubleshooting*

Use the following procedure to troubleshoot IPv6 DHCP Relay on the server side.

#### **Procedure**

1. Enable the services on the server side, and then create an IP pool.

The IP pool must contain the range of addresses that you want to assign to the clients.

Configure the IP pool with the same network subnet as that of the relay agent.

2. When the configuration is complete, initiate a DHCP request from a client.
3. Check the log file available on the server to verify the reason for packet drop.
4. Capture the packets on the server side using Ethereal.
5. From the server side, use ping to verify that the relay agent address is reachable. Ensure that a route to the relay is configured.
6. For more configuration aspects, see the Microsoft webpage for troubleshooting and configuration issues.

#### **Note**

You can receive some log messages that indicate the system cannot forward packets. However, certain situations are not DHCP failures.

Example 1: if you receive the message `0x00108796 (relayMsgSend) : cannot find route entry for destination on the console`, you must ping the server. If the server is not reachable, the system cannot forward the packet. This is not a DHCP issue.

Example 2: if you receive the message `0x00108705` this indicates a problem at the transmission level. Check the server reachability and ensure that MAC learning is correct before you pursue DHCP issues.

### *IPv6 DHCP Relay Client Side Troubleshooting*

You can collect a client console dump, which can be used to analyze why the received packet cannot be processed and the allocated address cannot be used by the client.

In addition, restarting the client can also fix the issue in some cases.

Make sure the client supports IPv6 requests.

Connect the server directly to the client. If the IP is assigned, then the problem is with the relay.

#### *Enabling Trace Messages for IPv6 DHCP Relay*

Use this procedure to enable trace for IPv6 DHCP Relay and enable IPv6 forwarding trace.

#### **Procedure**

1. Enter Privileged EXEC mode:  
`enable`
2. To troubleshoot IPv6 DHCP Relay, you can enable rcip6 trace messages using the following command:  
`trace level 66 3`
3. You can also enable IPv6 forwarding trace using the following command:  
`trace ipv6 forwarding enable <all|debug|error|info|pkt|warn>`

#### **Example**

Enable rcip6 trace messages and enable IPv6 forwarding trace:

```
Switch:1>enable
Switch:1#trace level 66 3
Switch:1#trace ipv6 forwarding
```

## Troubleshooting TACACS+

The switch supports the Terminal Access Controller Access Control System plus (TACACS+) client. TACACS+ is a remote authentication protocol that provides centralized validation of users who attempt to gain access to a router or network access server (NAS). The TACACS+ feature is disabled by default.

The switch implementation of TACACS+ does not support:

- Earlier versions of TACACS
- Point-to-Point Protocol (PPP) authentication and accounting
- IPv6 addresses

See the following sections to troubleshoot TACACS+.

#### *Unable to Log On Using Telnet*

If you cannot log on using Telnet, perform the following steps.

#### **Procedure**

1. Check whether the TACACS+ server is available or unreachable.
2. On the TACACS+ server, check whether you configured the privilege level correctly. On successful authorization, the TACACS+ server returns an access level to the switch for the current user, which determines the user access privileges. The switch supports access levels 1 to 6 and access level 15.

The following table maps user accounts to TACACS+ privilege level.

| Switch access level | TACACS+ privilege level | Description                                                                                                                                                                                                                    |
|---------------------|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NONE                | 0                       | If the TACACS+ server returns an access level of 0, the user is denied access. You cannot log into the device if you have an access level of 0.                                                                                |
| READ ONLY           | 1                       | Permits you to view only configuration and status information.                                                                                                                                                                 |
| LAYER 1 READ WRITE  | 2                       | Permits you to view most of the switch configuration and status information and change physical port settings.                                                                                                                 |
| LAYER 2 READ WRITE  | 3                       | Permits you to view and change configuration and status information for Layer 2 (bridging and switching) functions.                                                                                                            |
| LAYER 3 READ WRITE  | 4                       | Permits you to view and change configuration and status information for Layer 2 and Layer 3 (routing) functions.                                                                                                               |
| READ WRITE          | 5                       | Permits you to view and change configuration and status information across the switch. This level does not allow you to change security and password settings.                                                                 |
| READ WRITE ALL      | 6                       | Permits you to have all the rights of read-write access and the ability to change security settings, including command line interface (CLI) and web-based management user names and passwords, and the SNMP community strings. |

| Switch access level | TACACS+ privilege level | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NONE                | 7 to 14                 | If the TACACS+ server returns an access level of 7 to 14, the user is denied access. You cannot log into the device if you have an access level of 7 to 14.                                                                                                                                                                                                                                                                                                          |
| READ WRITE ALL      | 15                      | Permits you to have all the rights of read-write access and the ability to change security settings, including command line interface (CLI) and web-based management user names and passwords, and the SNMP community strings.<br><br><b>Note:</b><br>Access level 15 is internally mapped to access level 6, which ensures consistency with other vendor implementations. The switch does not differentiate between an access level of 6 and an access level of 15. |

After you enable TACACS+ authorization, the current privilege-level to command mapping on the switch is no longer relevant because the TACACS+ server has complete responsibility for command authorization. TACACS+ authorization provides access to the system based on username, not based on privilege level.

**Note**

If you want to switch to a privilege level 'X' using `tacacs switch level <1-15>` command, you must create a user "\$enabX\$" on the TACACS+ server. X is the privilege level that you want to change.

3. On the TACACS+ server, check whether you configured the password and user name correctly.
4. On the TACACS+ server, check whether you configured the switch IP address in the trust list.
5. Check whether you configured the encryption key, connection mode (single connection or per-session connection), and TCP port number the same on the TACACS+ server and switch.
6. If you can log on to the switch, check whether the TACACS+ server configured on the platform has the correct IP address:

```
show tacacs
```

7. Use the output from the **show tacacs** command to verify whether you configured the single connection option on the platform, and whether the TACACS+ server supports the single connection.

### Example

Check whether the TACACS+ server configured on the platform has the correct IP address:

```
Switch:1>enable
Switch:1(config)#show tacacs

Global Status:

    global enable : false

    authentication enabled for : cli

    accounting enabled for : none

    authorization : disabled

    User privilege levels set for command authorization : None

Server:

    create :

Prio  Status  Key      Port  IP address  Timeout  Single  Source  SourceEnabled
-----
Primary NotConn ***** 3    192.0.2.254  30    true  5.5.5.5  true
Backup  NotConn ***** 47   198.51.100.1  10   false 0.0.0.0  false
```

### Unable to Log On Using SSH

If you cannot log on using Secure Shell (SSH), perform the following steps.

### Procedure

1. Verify that the network, the switch, and the TACACS+ server is reachable.
2. Verify whether you configured the SSH client correctly.
3. Verify whether you enabled and configured the SSH function correctly on the switch:  
`show ssh global`

### Example

Verify whether you enabled and configured SSH function correctly on the switch:

```
Switch:1>enable
Switch:1#show ssh global

Total Active Sessions : 0
    version           : v2only
    port              : 22
    max-sessions      : 4
    timeout           : 60
    action rsa-keygen : rsa-keysize 2048
    action dsa-keygen : dsa-keysize 2048
    rsa-auth          : true
    dsa-auth          : true
    pass-auth         : false
    enable            : true
```

## Job Aid

The following table describes the fields in the output for the **show ssh global** command.

| Parameter             | Description                                                                                                                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Total active sessions | Specifies the number of active SSH sessions underway.                                                                                                                                         |
| version               | Specifies if SSH is version 1 or version 2. The default is v2. As a best practice, configure the version to v2 only.                                                                          |
| port                  | Specifies the SSH connection port. The default is 22. You cannot configure the following TCP ports as SSH connection ports: 0 to 1024 (except port 22), 1100, 4095, 5000, 5111, 6000, or 999. |
| max-sessions          | Specifies the maximum number of SSH sessions allowed. The default is 4.                                                                                                                       |
| timeout               | Specifies the SSH connection authentication timeout in seconds. The default is 60 seconds.                                                                                                    |
| action rsa-keygen     | Specifies the SSH RSA key size.                                                                                                                                                               |
| action dsa-keygen     | Specifies the SSH DSA key size.                                                                                                                                                               |
| rsa-auth              | Specifies if RSA authentication is enabled or disabled. The default is enabled.                                                                                                               |
| dsa-auth              | Specifies if DSA authentication is enabled or disabled. The default is enabled.                                                                                                               |
| pass-auth             | Specifies if password authentication is enabled or disabled. The default is enabled.                                                                                                          |
| enable                | Specifies if SSH secure mode is enabled. False is disabled. Secure is enabled.                                                                                                                |

*Unable to Log On by any Means*

If you cannot log on by any means, perform the following steps.

**Procedure**

1. Check whether the TACACS+ server runs properly and try to restart the TACACS+ server.
2. Check whether you enabled both TACACS+ and RADIUS on the switch.

```
show radius
```

```
show tacacs
```

If TACACS+ fails, RADIUS can take over the authentication, authorization, and accounting (AAA) process.

3. Check whether you configured the TACACS+ server to unencrypted mode, as the switch always sends encrypted TACACS+ messages.

4. Check whether you configured the switch properly.

#### Note

In particular, check the IP address and key.

```
show tacacs
```

5. Check whether you configured the encryption key, connection mode (single connection or per-session connection), and TCP port number the same on the TACACS+ server and switch.
6. If the server connects directly, check whether the administrative and operation status of the port is up:

```
show interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}
```

7. If the server is connected in a network, check whether the switch has a route configured to the server network:

```
show ip route
```

8. If the server is connected in a network, check whether the switch has a route configured to the server network:

```
show ip route
```

```
show ipv6 route
```

9. For the Out-of-Band (OOB) or VLAN Segmented Management Instance, check whether the switch has a route configured to the server network:

```
show mgmt ip route
```

```
show mgmt ipv6 route
```

```
show mgmt ip route static
```

10. For Segmented Management Instance troubleshooting, check the management network statistics:

```
show mgmt ip arp
```

```
show khi mgmt statistics
```

```
show mgmt ip ip-statistics
```

```
show mgmt ip icmp-statistics
```

### Examples

Check if you enabled both TACACS+ and RADIUS on the switch:

```
Switch:1>enable
Switch:1(config)#show tacacs

Global Status:

  global enable : false

  authentication enabled for : cli

  accounting enabled for : none
```

```

authorization : disabled

User privilege levels set for command authorization : None

Server:
        create :

Prio   Status Key      Port  IP address  Timeout Single Source SourceEnabled
Primary NotConn ***** 3     192.0.2.254 30    true 5.5.5.5 true
Backup NotConn ***** 47    198.51.100.1 10   false 0.0.0.0 false

Switch:1>show radius
        acct-attribute-value : 193
                acct-enable : false
        acct-include-cli-commands : false
        access-priority-attribute : 192
                auth-info-attr-value : 91
        command-access-attribute : 194
        cli-commands-attribute : 195
                cli-cmd-count : 40
                cli-profile-enable : false
                enable : false
        igap-passwd-attr : standard
        igap-timeout-log-fsize : 512
                maxserver : 10
        mcast-addr-attr-value : 90
        supported-vendor-ids : 1584, 562, 1916
                secure-flag : false
    
```

Check if the administrative and operation status of the port is up:

```

Switch:1#show interface gigabitethernet 1/2

=====
                        Port Interface

*Administrator Unable to Obtain Accounting Information from the TACACS+ Server*

If the administrator is unable to obtain accounting information from the TACACS+ server, perform the following steps.

**Procedure**

1. Check whether you enabled accounting on the switch:  

```
show tacacs
```
2. Check whether you enabled accounting on the TACACS+ server.

### Example

Check whether accounting is enabled on the switch:

```
Switch:1>enable
Switch:1(config)#show tacacs

Global Status:

    global enable : false

    authentication enabled for : cli

    accounting enabled for : none

    authorization : disabled

    User privilege levels set for command authorization : None

Server:

        create :

Prio   Status  Key      Port  IP address  Timeout  Single Source  SourceEnabled
Primary NotConn *****  3     192.0.2.254   30    true 5.5.5.5  true
Backup  NotConn *****  47    198.51.100.1  10    false 0.0.0.0  false
```

### Trap Server Cannot Receive Trap Packets from the Switch

If the trap server cannot receive trap packets from the switch, perform the following steps.

#### Procedure

1. Check whether you configured the trap server correctly on the switch:  

```
show snmp-server host
```
2. Check whether a firewall exists between the switch and the trap server.

### Example

Check whether you configured the trap server correctly on the switch:

```
Switch:1>enable
Switch:1#show snmp-server host

*Troubleshoot TACACS+ Problems*

Use the **trace level** command to check traps and log files to see any TACACS+ failure. If TACACS+ experiences failure conditions, the TACACS+ module sends SNMP traps to notify the user. The TACACS+ module also logs the failure information into the system log file.

**About This Task**

**Caution**

Using the trace tool inappropriately can cause CPU lockup conditions, loss of access to the device, loss of protocols, and service degradation. If you use trace level 3 (verbose) or trace level 4 (very verbose), do not use the screen to view commands due to the volume of information the system generates and the effect on the system.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Configure the trace level for the TACACS+ module:  
`trace level 109 <1-4>`  
  
The TACACS+ module ID is 109.
3. Stop trace:  
`trace shutdown`
4. View the trace results on screen:  
`trace screen enable`
5. View trace saved to a file:  
`show trace file [tail]`
6. Save the trace file to the Compact Flash card for retrieval:  
`save trace [file WORD<1-99>]`

If you do not specify a file name, the file name is `systrace.txt`. By default, the system saves the file to the external flash.

7. Save the trace file for retrieval:  
`save trace [file WORD<1-99>]`

If you do not specify a file name, the file name is `systrace.txt`.

### Variable Definitions

The following table defines parameters for the **trace** command.

| Variable                                 | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>level</i><br>[<Module_ID>]<br>[<1-4>] | Starts the trace by specifying the module ID and level. Module ID 23 represents the IGMP module<br><Module_ID> specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the <b>show trace modid-list</b> command or CLI command completion Help.<br><0-4> specifies the trace level: <ul style="list-style-type: none"> <li>• 0 — Disabled</li> <li>• 1 — Very terse</li> <li>• 2 — Terse</li> <li>• 3 — Verbose</li> <li>• 4 — Very verbose</li> </ul> |
| <i>shutdown</i>                          | Stops the trace operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>screen {disable enable}</i>           | Enables or disables the display of trace output to the screen.<br><br><b>Important:</b><br>As a best practice, avoid using the screen to view commands if you use trace level 3 (verbose) or trace level 4 (very verbose) due to the volume of information generated and the effect on the system.                                                                                                                                                                                                                                                                                           |

The following table defines parameters for the **show trace** command.

| Variable           | Value                                             |
|--------------------|---------------------------------------------------|
| <i>file [tail]</i> | Displays the trace results saved to a file.       |
| <i>level</i>       | Displays the current trace level for all modules. |
| <i>modid-list</i>  | Specifies the module ID list.                     |

## Using BGP Debugging Commands

Use global and peer debug commands to display specific debug messages for the global and peer Border Gateway Protocol (BGP) configuration, including the BGP neighbors.

You can use these commands to troubleshoot the BGP configuration.

### Procedure

1. Enter BGP Router Configuration mode:

```
enable

configure terminal

router bgp
```
2. Show specific debug messages for the global BGP configuration:

```
global-debug mask WORD<1-100>
```

3. Display specific debug messages for the global BGP neighbors:  
`neighbor-debug-all mask WORD<1-100>`
4. Display specific debug messages for BGP peers or peer groups:  
`neighbor <nbr_ipaddr|peer-group-name> neighbor-debug-mask WORD<1-100>`
5. Display debug messages on the console:  
`debug-screen <on|off>`

### Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# router bgp
```

Display the global debug messages for error and packet:

```
Switch:1(router-bgp)#global-debug mask error,packet
```

End (disable) the display of global debug messages:

```
Switch:1(router-bgp)#global-debug mask none
```

Display specific debug messages for the global BGP neighbors:

```
Switch:1(router-bgp)#neighbor-debug-all mask packet,event
```

Display specific debug messages for BGP peers or peer groups:

```
Switch:1(router-bgp)#neighbor 192.0.2.10 neighbor-debug-mask event,trace
```

Display debug messages on the console:

```
Switch:1(router-bgp)#debug-screen on
```

### Variable Definitions

The following table defines parameters for the **global-debug mask** and **neighbor-debug-all mask** commands.

| Variable                 | Value                                                                                                                                                                                                                                                                                     |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD&lt;1-100&gt;</i> | Specifies one or more mask choices that you enter, separated by commas with no space between choices. For example: [ <i>&lt;mask&gt;</i> , <i>&lt;mask&gt;</i> , <i>&lt;mask&gt;</i> ...]. Options include: none, all, error, packet, event, trace, warning, state, init, filter, update. |

The following table defines parameters for the **neighbor** command.

| Variable                                        | Value                                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;nbr_ipaddr peer-group-name&gt;</code> | Specifies the IP address or the group name of the peer.                                                                                                                                                                                                                                                     |
| <code>WORD&lt;1-100&gt;</code>                  | Specifies one or more mask choices that you enter, separated by commas with no space between choices. For example: [ <code>&lt;mask&gt;</code> , <code>&lt;mask&gt;</code> , <code>&lt;mask&gt;</code> ...]. Options include: none, all, error, packet, event, trace, warning, state, init, filter, update. |

*Job Aid*

Use debug command values to control debug messages for global BGP message types, and for message types associated with a specified BGP peer or peer group. The following table identifies mask categories and messages.

**Table 285: Mask categories and messages**

| Mask category | Message                                                             |
|---------------|---------------------------------------------------------------------|
| none          | None disables the display of all debug messages.                    |
| all           | All configures the device to show all categories of debug messages. |
| error         | Error configures the device to show error debug messages.           |
| packet        | Packet configures the device to show packet debug messages.         |
| event         | Event configures the device to show event debug messages.           |
| warning       | Warning configures the device to show warning debug messages.       |
| init          | Init configures the device to show initialization debug messages.   |
| filter        | Filter configures the device to show filter-related debug messages. |
| update        | Update configures the device to show update-related debug messages. |

## Traps Reference

The switch generates alarms, traps, and logs. This section provides information about traps.

### Note

The OID values of the rclsisTrap (OID 1.3.6.1.4.1.2272.1.63.9) table are populated only when the Duplicate ISIS Sys-id & Nickname condition is present. This MIB table captures this specific condition only. Use other tables such as rclsisAdjTable (OID 1.3.6.1.4.1.2272.1.63.10) or isisISAdjTable (OID 1.3.6.1.3.37.1.6.1) to gather IS-IS information.

## Proprietary Traps

The following tables describe proprietary traps for the switch. All of the following traps have a status of current.

**Table 286: 1.3.6.1.4.1.45.4.8.0.xx series**

| OID                    | Notification type                | Objects                          | Description                                                                                                                          |
|------------------------|----------------------------------|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| 1.3.6.1.4.1.45.4.8.0.1 | slaMonitorAgentExceptionDetected | slaMonitorAgentExceptionDetected | The SLA Monitor (SLA Mon) agent process has terminated unexpectedly. You must reenable SLA Monitor to restart the SLA Monitor agent. |

**Table 287: 1.3.6.1.4.1.45.5.17.0.xx series**

| OID                     | Notification type                    | Objects                                                                                                                                                                                                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.3.6.1.4.1.45.5.17.0.1 | bsDhcpSnoopingBindingTableFull       | bsDhcpSnoopingNotificationClientMACAddr                                                                                                                                                                                                                    | A bsDhcpSnoopingBindingTableFull notification is generated when you try adding a new DHCP binding entry, and the binding table is full. The value of bsDhcpSnoopingNotificationClientMACAddr gives the MAC address that cannot be added to the binding table. This notification also indicates that additional untrusted DHCP packets will not be added to the binding table, and will be dropped. |
| 1.3.6.1.4.1.45.5.17.0.2 | bsDhcpSnoopingTrap                   | <ul style="list-style-type: none"> <li>bsDhcpSnoopingNotificationSourcePort</li> <li>bsDhcpSnoopingNotificationMsgTypebsDhcpSnoopingNotificationSourceMACAddr</li> <li>bsDhcpSnoopingNotificationClientMACAddr</li> <li>bsDhcpSnoopingIfTrusted</li> </ul> | A bsDhcpSnoopingTrap notification is generated when a DHCP packet is dropped.                                                                                                                                                                                                                                                                                                                      |
| 1.3.6.1.4.1.45.5.17.0.4 | bsDhcpSnoopingStaticEntryMACConflict | bsDhcpSnoopingNotificationSourceMACAddr bsDhcpSnoopingIfIndex                                                                                                                                                                                              | A bsDhcpSnoopingStaticEntryMACConflict notification is generated when a DHCP packet is dropped, because a static entry with the same MAC address was found in the binding table.                                                                                                                                                                                                                   |

**Table 288: 1.3.6.1.4.1.45.5.18.0.xx series**

| OID                     | Notification type                   | Objects                                                                                                                         | Description                                                                                                                                                                                                                                     |
|-------------------------|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.3.6.1.4.1.45.5.18.0.1 | bsaiArpPacketDroppedOnUntrustedPort | <ul style="list-style-type: none"> <li>bsArpInspectionIfTrusted</li> <li>bsArpInspectionNotificationSourceMACAddress</li> </ul> | A bsaiArpPacketDroppedOnUntrustedPort trap signifies that an ARP packet is dropped on an untrusted port, due to an invalid IP or MAC address binding. The port is identified by the instance of bsArpInspectionIfTrusted generated by the trap. |

**Table 289: 1.3.6.1.4.1.45.5.20.0.xx series**

| OID                     | Notification type                | Objects                 | Description                                                                                                                                                                                                                                                                                                   |
|-------------------------|----------------------------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.3.6.1.4.1.45.5.20.0.2 | bsSourceGuardCannotEnablePort    | bsSourceGuardConfigMode | A bsSourceGuardCannotEnablePort trap signifies that there are insufficient resources to enable IP Source Guard checking on a port because of internal state changes within the system such as system initialization. The port is identified by the instance of bsSourceGuardConfigMode generated by the trap. |
| 1.3.6.1.4.1.45.5.20.0.1 | bsSourceGuardReachedMaxIpEntries | bsSourceGuardConfigMode | A bsSourceGuardReachedMaxIpEntries trap signifies that the maximum number of IP address entries on a port has been reached. The port is identified by the instance of bssourceGuardConfigMode generated by the trap.                                                                                          |

**Table 290: 1.3.6.1.4.1.45.5.34.0.xx series**

| OID                     | Notification type        | Objects | Description                                                                                                |
|-------------------------|--------------------------|---------|------------------------------------------------------------------------------------------------------------|
| 1.3.6.1.4.1.45.5.34.0.1 | bsnesGloballyEnabled     |         | A bsnesGloballyEnabled trap signifies that the Energy Saver feature was enabled globally.                  |
| 1.3.6.1.4.1.45.5.34.0.2 | bsnesGloballyDisabled    |         | A bsnesGloballyDisabled trap signifies that the Energy Saver feature was disabled globally.                |
| 1.3.6.1.4.1.45.5.34.0.3 | bsnesManuallyActivated   |         | A bsnesManuallyActivated trap signifies that the Energy Saver was activated manually.                      |
| 1.3.6.1.4.1.45.5.34.0.4 | bsnesManuallyDeactivated |         | A bsnesManuallyDeactivated trap signifies that the Energy Saver feature was deactivated manually.          |
| 1.3.6.1.4.1.45.5.34.0.5 | bsnesScheduleNotApplied  |         | A bsnesScheduleNotApplied trap signifies that a schedule was not applied because SNTP is not synchronized. |
| 1.3.6.1.4.1.45.5.34.0.6 | bsnesScheduleApplied     |         | A bsnesScheduleApplied trap signifies that SNTP is synchronized and the schedule is being applied.         |
| 1.3.6.1.4.1.45.5.34.0.7 | bsnesActivated           |         | A bsnesActivated trap signifies that the Energy Saver feature was activated by the schedule.               |
| 1.3.6.1.4.1.45.5.34.0.8 | bsnesDeactivated         |         | A bsnesDeactivated trap signifies that the Energy Saver feature was deactivated by the schedule.           |

**Table 291: 1.3.6.1.4.1.45.5.43.0.xx series**

| ODID                    | Notification type               | Objects                                                                                                                | Description                                                                                                                                                                                                                                                    |
|-------------------------|---------------------------------|------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.3.6.1.4.1.45.5.43.0.1 | bsLstInterfaceStatus Changed    | <ul style="list-style-type: none"> <li>• ifIndex</li> <li>• bsLstInterfaceStatus</li> <li>• bsLstGroupIndex</li> </ul> | A bsLstInterfaceStatus Changed trap signifies that a physical or logical interface changed status in a Link-state tracking (LST) tracking group.                                                                                                               |
| 1.3.6.1.4.1.45.5.43.0.2 | bsLstInterfaceOperState Changed | <ul style="list-style-type: none"> <li>• ifIndex</li> <li>• bsLstInterfaceStatus</li> <li>• bsLstGroupIndex</li> </ul> | A bsLstInterfaceOperState Changed trap signifies that the operational status of an LST group changed due to an interface status change. For example, when the last interface in an LST group is down, the operational status of the LST group changes to down. |

**Table 292: 1.3.6.1.4.1.2272.1.4.10.1.1.xxx series**

| OID                             | Notification type    | Objects                                                                                                                                                        | Description                                                                                                                       |
|---------------------------------|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| 1.3.6.1.4.1.2272.1.4.10.1.1.114 | rcPortShutdownReason | <ul style="list-style-type: none"> <li>• rcPortVlAcPTotalFlapCount</li> <li>• rcPortVlAcPFirstFlapTimeStamp</li> <li>• rcPortVlAcPLastFlapTimeStamp</li> </ul> | An rcPortShutdownReason trap signifies that the specific VLACP link port status is down as VLACP flaps are detected on that port. |

**Table 293: 1.3.6.1.4.1.2272.1.21.0.xx series**

| OID                        | Notification type      | Objects                                                                                                        | Description                                                                                                                                                                                                                      |
|----------------------------|------------------------|----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.3.6.1.4.1.2272.1.21.0.3  | rcnErrorNotification   | rcErrorLevel<br>rcErrorCode<br>rcErrorText                                                                     | An rcnErrorNotification trap signifies that the SNMPv2 entity, acting in an agent role, has detected an error condition.                                                                                                         |
| 1.3.6.1.4.1.2272.1.21.0.4  | rcnStpNewRoot          | rcStgId                                                                                                        | An rcnStpNewRoot trap signifies that the SNMPv2 entity, acting in an agent role, has detected that the Spanning Tree Protocol declared the device to be the new root of the spanning tree.                                       |

## Standard Traps

The following table describes standard traps that the switch can generate.

**Table 295: Standard traps**

| OID                | Notification type | Objects                                                                               | Description                                                                                                                                                                |
|--------------------|-------------------|---------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.3.6.1.2.1.16.0.1 | risingAlarm       | alarmIndex<br>alarmVariable<br>alarmSampleType<br>alarmValue<br>alarmRisingThreshold  | The SNMP trap that is generated after an alarm entry crosses the rising threshold and generates an event that is configured to send SNMP traps. TRAP TYPE ENTERPRISE rmon  |
| 1.3.6.1.2.1.16.0.2 | fallingAlarm      | alarmIndex<br>alarmVariable<br>alarmSampleType<br>alarmValue<br>alarmFallingThreshold | The SNMP trap that is generated after an alarm entry crosses the falling threshold and generates an event that is configured to send SNMP traps. TRAP TYPE ENTERPRISE rmon |

**Table 295: Standard traps (continued)**

| OID                    | Notification type       | Objects                                                                                                                                                                                                                                                                                                                     | Description                                                                                                                                                                                                                                                                                                                                           |
|------------------------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.3.6.1.2.1.46.1.3.0.3 | vrrpTrapStateTransition | ifIndex<br>vrrpTrapStateTransitionType<br>vrrpTrapStateTransitionCause<br>vrrpOperVrld<br>vrrpOperIpAddr<br>ipAdEntAddr                                                                                                                                                                                                     | A vrrpTrapStateTransition trap signifies a state transition has occurred on a particular Virtual Router Redundancy Protocol (VRRP) interface. Implementation of this trap is optional. vrrpOperIpAddr contains the IP address of the VRRP interface while ipAdEntAddr contains the IP address assigned to the physical interface.                     |
| 1.3.6.1.2.1.68.0.1     | vrrpTrapNewMaster       | vrrpOperMasterIpAddr                                                                                                                                                                                                                                                                                                        | The newMaster trap indicates that the sending agent has transitioned to Master state.                                                                                                                                                                                                                                                                 |
| 1.3.6.1.2.1.68.0.2     | vrrpTrapAuthFailure     | vrrpTrapPacketSrc<br>vrrpTrapAuthErrorType                                                                                                                                                                                                                                                                                  | A vrrpAuthFailure trap signifies that a packet has been received from a router whose authentication key or authentication type conflicts with the authentication key or authentication type of this router.                                                                                                                                           |
| 1.3.6.1.2.1.80.0.1     | pingProbeFailed         | pingCtlTargetAddressType<br>pingCtlTargetAddress<br>pingResultsOperStatus<br>pingResultsIpTargetAddressType<br>pingResultsIpTargetAddress<br>pingResultsMinRtt<br>pingResultsMaxRtt<br>pingResultsAverageRtt<br>pingResultsProbeResponse<br>pingResultsSentProbes<br>pingResultsRttSumOfSquares<br>pingResultsLastGoodProbe | This trap is generated after a probe failure is detected when the corresponding pingCtlTrapGeneration object is configured to probeFailure(0) subject to the value of pingCtlTrapProbeFailureFilter. The object pingCtlTrapProbeFailureFilter can specify the number of successive probe failures required before this notification can be generated. |

**Table 295: Standard traps (continued)**

| OID                | Notification type    | Objects                                                                                                                                                                                                                                                                                                                      | Description                                                                                                                                                                                                                                                                 |
|--------------------|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Virtual Link Aggregation Control Protocol

Use Virtual Link Aggregation Control Protocol (VLACP) as an extension to LACP for end-to-end failure detection. VLACP is not a link aggregation protocol, it is a mechanism to periodically check the end-to-end health of a point-to-point connection. VLACP uses the Hello mechanism of LACP to periodically send Hello packets to ensure end-to-end communication. After Hello packets are not received, VLACP transitions to a failure state, which indicates a service provider failure and that the port is disabled.

The VLACP only works for port-to-port communications where there is a guarantee for a logical port-to-port match through the service provider. VLACP does not work for port-to-multiport communications where there is no guarantee for a point-to-point match through the service provider. You can configure VLACP on a port.

You can also use VLACP with MLT to complement its capabilities and provide quick failure detection.

VLACP trap messages are sent to the management stations if the VLACP state changes. If the failure is local, the only traps that are generated are port linkdown or port linkup.

The Ethernet cannot detect end-to-end failures. Functions such as remote fault indication or far-end fault indication extend the Ethernet to detect remote link failures. A major limitation of these functions is that they terminate at the next Ethernet hop. They cannot determine failures on an end-to-end basis.

For example, in [Figure 258](#), after the Enterprise networks connect the aggregated Ethernet trunk groups through a service provider network connection (for example, through a VPN), far-end failures cannot be signaled with Ethernet-based functions that operate end-to-end through the service provider network. The multilink trunk (between Enterprise switches S1 and S2) extends through the Service Provider (SP) network.

The following illustration shows an MLT running with VLACP. VLACP can operate end-to-end, but you can also use it as a point-to-point link.

**Figure 258: Problem description (1 of 2)**

In the following illustration, if the Layer 2 link on S1 (S1/L2) fails, the link-down failure is not propagated over the SP network to S2 and S2 continues to send traffic over the failed S2/L2 link.

**Figure 259: Problem description (2 of 2)**

Use VLACP to detect far-end failures, which causes MLT to failover if end-to-end connectivity is not guaranteed for links in an aggregation group. VLACP prevents the failure scenario.

The switch software uses the following VLACP timers:

- fast periodic timer—100 to 20 000 ms; default 200 ms
- slow periodic timer—10 000 to 30 000 ms; default 30 000 ms

## VLACP considerations

Use the information in this section to understand the considerations while configuring VLACP into your network.

- If a VLACP-enabled port does not receive a VLACP Data Unit (VLACPDU), it must enter the disabled state. There are occasions where a VLACP-enabled port does not receive a VLACPDU but remains in the forwarding state. To avoid this situation, ensure that the VLACP configuration at the port level is consistent. You must either enable or disable both sides of the point-to-point connection.
- If VLACP is enabled on a MACsec Key Agreement-enabled link, it takes approximately 30 seconds for the VLACP session to begin.

You can configure VLACP on each port. The port can be either an individual port or an MLT member. VLACPDUs can be sent periodically on each port where VLACP is enabled to exchange VLACPDUs from an end-to-end perspective. If VLACPDUs are not received on a particular link, that link is taken down after the expiry timeout occurs (timeout scale x periodic time).

## VLACP Flap Detect and Damping

When there is instability or packet loss in a connection, the Virtual Link Aggregation Control Protocol (VLACP) state of the port flaps, causing services such as IP multicast to stop and start rapidly. This behavior causes system-wide instability, including high CPU utilization. In such cases, VLACP Flap Detect and Damping provides link flap detection capability, by configuring a specific time interval and frequency to count the number of VLACP flaps. After the system detects excessive VLACP flaps, it disables the specific VLACP port until the root cause is resolved.

For example, VLACP Flap Detect and Damping detects 3 VLACP flaps within 60 seconds, by default. After the system detects the first VLACP flap, the flap timer starts to count the number of VLACP flaps occurring within 60 seconds. If the flap count reaches 3 before the timer ends, the system disables the specific VLACP port, and generates a Simple Network Management Protocol (SNMP) trap. For more information about SNMP traps, see [Logs and Traps Fundamentals](#) on page 2465.

If you view the port state information, the port displays as operationally down and the reason provided is VLACP\_FLAP. The following example shows a port that is disabled because of VLACP flapping; only the relevant sections of the show command output is included.

```
Switch:1#show interface gigabitethernet 1/1
=====
                        Port Interface
=====
PORT          LINK   PORT   PHYSICAL   STATUS
NUM          INDEX DESCRIPTION TRAP  LOCK    MTU   ADDRESS   ADMIN OPERATE
-----
1/1          192   1000BaseTX  true false   1950 e4:5d:52:3c:64:00  up   down
=====
                        Port State
=====
PORT NUM   ADMINSTATUS  PORTSTATE  REASON      DATE
```

---

1/1      up      down      **VLACP\_FLAP**      09/19/19 02:22:58

**Note**

VLACP Flap Detect and Damping does not support auto-recovery of VLACP ports; you must reenble the ports manually.

*VLACP Flap Detect and Damping Considerations*

Use the following information when configuring VLACP Flap Detect and Damping.

- Do not enable VLACP Flap Detect and Damping on Link Aggregation Control Protocol (LACP) enabled ports.

**Note**

Link flap detection takes priority if you enable both VLACP Flap Detect and Damping and link flap detection on the same port.

## VLACP Configuration using CLI

---

Configure Virtual LACP (VLACP) to implement link status control protocol at the port level. VLACP detects end-to-end failures in the switch. Virtual LACP cannot interoperate with Link Aggregation Control Protocol (LACP).

### Configure VLACP on a port

Configure VLACP on a port to ensure there is end-to-end reachability. VLACP uses the Hello mechanism of LACP to periodically send Hello packets to ensure there is an end-to-end approach. After Hello packets are not received, VLACP transitions to a failure state and disables the port.

**Important**

Changes made at the global level override and reset all port level settings.

**About This Task**

Use the following information to prevent flooding VLACP packets across a defaulted switch:

- Use the default MAC address, 01:80:c2:00:11:00, for end-to-end connections that traverse an intermediate network.
- Use the reserved multicast MAC address 01-80-c2-00-00-0f for directly-connected, peer-to-peer links.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure optional parameters for the port. If you do not configure these parameters, the system uses the default values.

- a. Configure the protocol identification for the port:

```
vlacp ethertype <1536-65535 | 0x600-0xffff> [funcmac-addr  
0x00:0x00:0x00:0x00:0x00:0x00]
```

- b. Configure the fast or slow periodic times:

```
vlacp fast-periodic-time <100-20000> | slow-periodic-time  
<10000-30000>
```

You can configure both parameters in the same command entry.

- c. Configure the timeout parameters:

```
vlacp timeout <long|short> timeout-scale <2-10>
```

You can configure both parameters in the same command entry.

3. Enable VLACP on a port:

```
vlacp enable
```

## Example

Configure VLACP on port 1/1:

```
Switch:1# configure terminal
```

```
Switch:1# interface GigabitEthernet 1/2
```

```
Switch:1# vlacp fast-periodic-time 400 timeout short
```

```
Switch:1# vlacp enable
```

### Variable Definitions

Use the data in the following table to help you use the **vlACP** command.

| Variable                                                        | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>enable</code>                                             | Enables VLACP for this port. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>ethertype &lt;1536-65535   0x600-0xffff&gt;</code>        | Configures the VLACP protocol identification for this port. Enter the type in decimal or hexadecimal format. The default is 0x8103.                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>fast-periodic-time &lt;100-20000&gt;</code>               | Configures the fast periodic time (in milliseconds) for this port. The default is 200.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>funcmac-addr &lt;0x00:0x00:0x00:0x00:0x00:0x00&gt;</code> | Configures the multicast MAC address used for the VLACPDU. Specify a MAC address in the format 0x00:0x00:0x00:0x00:0x00:0x00. The default is 01:80:c2:00:11:00.                                                                                                                                                                                                                                                                                                                                                        |
| <code>slow-periodic-time &lt;10000-30000&gt;</code>             | Configures the slow periodic time (in milliseconds) for a specific port type. The default is 30,000.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>timeout {long short}</code>                               | Configures the port to use the long or short timeout: <ul style="list-style-type: none"> <li><code>long</code> sets the port to use the timeout-scale value multiplied by the slow periodic time.</li> <li><code>short</code> sets the port to use the timeout-scale value multiplied by the fast periodic time.</li> </ul> <p>For example, if you specify a short timeout, set the timeout-scale value to 3, and the fast periodic time to 400 ms, the timer expires within 1000 to 1200 ms. The default is long.</p> |
| <code>timeout-scale &lt;2-10&gt;</code>                         | Configures a timeout scale for this port used to calculate the timeout. The default value is 3.                                                                                                                                                                                                                                                                                                                                                                                                                        |

### View the VLACP Port Configuration

View the VLACP port configuration to show the port VLACP configuration.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the VLACP port configuration for all interfaces:

```
show vlACP interface gigabitEthernet [vid <1-4059>] [{slot/port[/sub-port]} [-slot/port[/sub-port]] [,...]]
```

## Example

```
Switch:1>show vlacp interface gigabitethernet
=====
                                VLACP Information

*Variable definitions*

Use the data in the following table to use the **show vlacp interface gigabitethernet** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>vid &lt;1-4059&gt;</code>                                    | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.<br>The VLAN ID is in one of the following formats: A single VLAN ID (vlan-id), a range of VLAN IDs [(vlan-id)-(vlan-id)] or a series of VLAN IDs (vlan-id, vlan-id, vlan-id). |
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Specifies a port or list of ports to show only the VLACP information for those ports. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                                                                      |

## Displaying VLACP Statistics for Specific Ports

Display VLACP statistics for specific ports to manage network performance.

### Note

Slot and port information can differ depending on hardware platform.

### About This Task

You can enable sequence numbers for each VLACPDU to assist in monitoring performance. The switch counts mismatched PDU sequence numbers to determine packet loss information. By default, sequence numbers are enabled.

You can use the show commands from Privileged EXEC mode but must enter Global Configuration mode to enable or disable the sequence numbers.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Confirm sequence numbers are enabled:  

```
show vlacp
```
3. (Optional) Enable sequence numbers for VLACPDUs:  

```
vlacp sequence-num
```
4. View VLACP statistics:  

```
show interfaces gigabitEthernet statistics vlacp [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] ]
```
5. (Optional) View VLACP statistics history:  

```
show interfaces gigabitEthernet statistics vlacp history [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]] ]
```
6. (Optional) Clear VLACP statistics:  

```
clear vlacp stats [port {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]]
```
7. (Optional) Disable sequence numbers for VLACPDUs:  

```
no vlacp sequence-num
```

## Example

Determine if sequence numbers are enabled, and then view port statistics. Port numbering may differ depending on your product and configuration.

```
Switch:1(config)#show vlacp
```

```
=====
```

```
                        VlACP Global Information
```

```
=====
```

```
SystemId: 32:11:9f:20:00:00
```

```
      VlACP: enable
```

```
VlACP Sequence Number: enable
```

```
Switch:1(config)#show interfaces gigabitEthernet statistics vlacp
```

```
=====
```

```
                        Port Stats VlACP
```

```
=====
```

| PORT<br>NUM | TX<br>VLACPDU | RX<br>VLACPDU | SEQNUM<br>MISMATCH |
|-------------|---------------|---------------|--------------------|
| 8/1         | 106058        | 105554        | 0                  |
| 12/11       | 15            | 12            | 0                  |
| 12/23       | 0             | 0             | 0                  |

```
=====
```

### Variable Definitions

Use the data in the following table to use the commands in this procedure.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Enabling or disabling VLACP globally

Use VLACP as an extension to LACP for end-to-end failure detection. Enable or disable VLACP globally to reset the port level configuration. The default is disabled.

### About This Task

#### Important

Changes you make at the global level override and reset all port level settings.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable VLACP globally:

```
vlACP enable
```

3. Disable VLACP globally:

```
no vlACP enable
```

### Example

Enable VLACP globally:

```
Switch:1(config)# vlACP enable
```

## Configure VLACP Flap Detect and Damping on a Port

### About This Task

Perform the following procedure to control link state changes on VLACP ports. By default, VLACP Flap Detect and Damping is disabled on all VLACP ports.

#### Important

Do not enable VLACP Flap Detect and Damping on Link Aggregation Control Protocol (LACP) enabled ports.

## Before You Begin

- To configure VLACP Flap Detect and Damping on sub-ports, enable channelization. For more information about channelization, see [Channelization](#) on page 585.
- As a best practice, to modify an existing VLACP Flap Detect and Damping configuration, first disable VLACP on the interface.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable VLACP Flap Detect and Damping on the specified port:

```
vlacp flap-detect enable
```

3. Configure the time interval (in seconds) to record VLACP flaps:

```
vlacp flap-interval <10-600>
```

4. Configure the VLACP flap frequency:

```
vlacp flap-frequency <3-30>
```

5. View VLACP Flap Detect and Damping configuration on the specific port:

```
show vlapc interface gigabitethernet {slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]}
```

## Example

Configure VLACP Flap Detect and Damping on port 1/3:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/3
Switch:1(config-if)#vlacp flap-detect enable
Switch:1(config-if)#vlacp flap-interval 120
Switch:1(config-if)#vlacp flap-frequency 6
Switch:1(config-if)#show vlapc interface gigabitethernet 1/3
```

```

### Variable Definitions

Use data in the following table to use the **vlacp** command.

| Variable                           | Value                                                                                                                            |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <i>flap-detect enable</i>          | Enables VLACP Flap Detect and Damping on the specified port. By default, VLACP Flap Detect and Damping is disabled on all ports. |
| <i>flap-interval&lt;10-600&gt;</i> | Configures VLACP Flap Detect and Damping time interval in seconds. The default value is 60 seconds.                              |
| <i>flap-frequency&lt;3-30&gt;</i>  | Configures the VLACP Flap count permitted during the configured time interval. The default value is 3.                           |

## Clear VLACP Flap Detect and Damping Statistics for a Port

Perform the following procedure to clear the VLACP Flap Detect and Damping statistics for a specific VLACP port or all VLACP ports on the switch.

### Procedure

- Enter Privileged EXEC mode:
 

```
enable
```
- Clear VLACP Flap Detect and Damping statistics:
 

```
clear vlapc flap-stats port [{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]]
```

### Example

```
Switch:1>enable
Switch:1#clear vlapc flap-stats port 2/11
```

### Variable Definitions

Use data in the following table to use the **clear vlapc flap-stats** command.

| Variable                                                        | Value                                                                                                                                                                        |
|-----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>port{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]]</i> | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## VLACP Configuration using EDM

Configure Virtual LACP (VLACP) to implement link status control protocol at the port level. VLACP cannot interoperate with Link Aggregation Control Protocol (LACP).

## Enabling VLACP globally

Enable VLACP globally to detect for end-to-end failure. VLACP uses the Hello mechanism of LACP to periodically send Hello packets to ensure there is an end-to-end approach. After Hello packets are not received, the VLACP transitions to a failure state and the port is disabled.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **MLT/LACP**.
3. Click the **VLACP Global** tab.
4. Select the **VlACPEnable** check box.
5. Click **Apply**.

### *VLACP Global* field descriptions

Use the data in the following table to use the **VLACP Global** tab.

| Name               | Description                                      |
|--------------------|--------------------------------------------------|
| <b>VlACPEnable</b> | Enables VLACP globally. The default is disabled. |

## Configure VLACP on a Port

Perform the following procedure to enable VLACP on a port. VLACP periodically checks the end-to-end condition of a point-to-point connection. You can also configure VLACP Flap Detect and Damping to control link state changes on VLACP ports. By default, VLACP Flap Detect and Damping is disabled on all VLACP ports.

### Important

Changes made at the global level override and reset all port level settings.

### Before You Begin

- To configure VLACP Flap Detect and Damping on sub-ports, enable channelization.
- As a best practice, to modify an existing VLACP or VLACP Flap Detect and Damping configuration, first disable VLACP on the interface.

### About This Task

Use the following information to prevent flooding VLACP packets across a defaulted switch:

- Use the default MAC address, 01:80:c2:00:11:00, for end-to-end connections that traverse an intermediate network.
- Use the reserved multicast MAC address 01-80-c2-00-00-0f for directly-connected, peer-to-peer links.

### Procedure

1. On the Device Physical View tab, select a port.

2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **VLACP** tab.
5. Configure the parameters, as required.
6. Select **Apply**.

### **VLACP** Field Descriptions

Use data in the following table to use the **VLACP** tab.

| Name                     | Description                                                                                                                                                                                 |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdminEnable</b>       | Enables VLACP for the port. The default is disabled.                                                                                                                                        |
| <b>OperEnable</b>        | Specifies the VLACP operational status for the port. The default is false.                                                                                                                  |
| <b>FastPeriodicTimer</b> | Specifies the number of milliseconds between periodic transmissions using short timeouts. Use the same value for all LACP-enabled ports. The default value is 200.                          |
| <b>SlowPeriodicTimer</b> | Specifies the number of milliseconds between periodic transmissions using long timeouts. Use the same value for all LACP-enabled ports. The default value is 30000.                         |
| <b>Timeout</b>           | Specifies the timeout control value. Specify long or short timeout. The default value is long.                                                                                              |
| <b>TimeoutScale</b>      | Assigns the value used to calculate timeout from the periodic time for all VLACP-enabled ports. $\text{Timeout} = \text{PeriodicTime} \times \text{TimeoutScale}$ . The default value is 3. |
| <b>EtherType</b>         | Specifies the VLACP identification. The ID is in hexadecimal format. The default value is 0x8103.                                                                                           |
| <b>EtherMacAddress</b>   | Specifies the multicast MAC address exclusively used for VLACPDUs. The default is 01:80:c2:00:11:00.                                                                                        |
| <b>PortState</b>         | Specifies the VLACP port state.                                                                                                                                                             |
| <b>FlapDetectEnable</b>  | Enables VLACP Flap Detect and Damping on the port. By default, VLACP Flap Detect and Damping is disabled on all ports.                                                                      |
| <b>FlapFrequency</b>     | Specifies the number of VLACP flaps detected on the port. The port is shut down if the recorded flaps are within the configured time interval. The default value is 3.                      |

| Name                      | Description                                                                                                                                           |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FlapInterval</b>       | Specifies the time interval (in seconds) during which the VLACP flaps on the port are monitored. The default value is 60 seconds.                     |
| <b>TotalFlapCount</b>     | Shows the total number of VLACP flaps detected on the port since you enabled VLACP Flap Detect and Damping or cleared the counters and timers.        |
| <b>FirstFlapTimeStamp</b> | Shows the timestamp of the first VLACP flap detected on the port since you enabled VLACP Flap Detect and Damping or cleared the counters and timers.  |
| <b>LastFlapTimeStamp</b>  | Shows the timestamp of the latest VLACP flap detected on the port since you enabled VLACP Flap Detect and Damping or cleared the counters and timers. |
| <b>FlapClearStats</b>     | Clears all VLACP Flap Detect and Damping counters and timers.                                                                                         |

## Configuring VLACP on an Extreme Integrated Application Hosting Port

### Note

This procedure only applies to VSP 4900 Series and VSP 7400 Series.

### About This Task

Perform this procedure to enable Virtual Link Aggregation Control Protocol (VLACP) on an Extreme Integrated Application Hosting (IAH) port. VLACP periodically checks the end-to-end health of a point-to-point connection.

### Procedure

1. In the navigation tree, expand **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **VLACP** tab.
4. Select **AdminEnable**.
5. Configure the other parameters as required.
6. Select **Apply**.

**VLACP** Field Descriptions

Use data in the following table to configure the **VLACP** tab.

| Name                     | Description                                                                                                                                                                         |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdminEnable</b>       | Enables VLACP on the Extreme Integrated Application Hosting (IAH) port. The default is disabled.                                                                                    |
| <b>OperEnable</b>        | Specifies the VLACP operational status for the IAH port. The default is false.                                                                                                      |
| <b>FastPeriodicTimer</b> | Specifies the number of milliseconds between periodic transmissions using short timeouts. Set the same value for all LACP enabled IAH ports. The default value is 200.              |
| <b>SlowPeriodicTimer</b> | Specifies the number of milliseconds between periodic transmissions using long timeouts. Set the same value for all LACP enabled IAH ports. The default value is 30000.             |
| <b>Timeout</b>           | Specifies the timeout control value. The default value is long.                                                                                                                     |
| <b>TimeoutScale</b>      | Specifies the value used to calculate timeout duration from the periodic time for all VLACP enabled IAH ports.<br>Timeout = PeriodicTime x TimeoutScale.<br>The default value is 3. |
| <b>EtherType</b>         | Specifies the VLACP protocol identification. The ID is in hexadecimal format.<br>The default value is 0x8103.                                                                       |
| <b>EtherMacAddress</b>   | Specifies the multicast MAC address exclusively used for VLACPDUs.                                                                                                                  |
| <b>PortState</b>         | Specifies the VLACP port state.                                                                                                                                                     |

# VLAN Configuration

---

- [VLAN Fundamentals](#) on page 4082
- [VLAN Configuration Using CLI](#) on page 4109
- [VLAN Configuration using EDM](#) on page 4145

A VLAN is a switched network that is logically segmented by functions, project teams, or applications without regard to the physical location of users. By using a VLAN, you can divide the Local Area Network into smaller groups without interfering with the physical network.

The following topics provide necessary concepts and procedures to configure VLANs.

## VLAN Fundamentals

---

The practical applications of a VLAN include the following:

- You can create VLANs, or workgroups, for common interest groups.
- You can create VLANs, or workgroups, for specific types of network traffic.
- You can add, move, or delete members from these workgroups without making physical changes to the network.

By dividing the network into separate VLANs, you can create separate broadcast domains. This arrangement conserves bandwidth, especially in networks supporting broadcast and multicast applications that flood the network with traffic. A VLAN workgroup can include members from a number of dispersed physical segments on the network, improving traffic flow between them.

The switch performs the Layer 2 switching functions necessary to transmit information within VLANs, as well as the Layer 3 routing functions necessary for VLANs to communicate with one another. You can define a VLAN for a single switch or spanning multiple switches. A port can be a member of multiple VLANs. A VLAN is associated with a spanning tree group.

A VLAN packet is classified before it is forwarded. If the packet matches a classification rule, the port membership is checked. If the port is not an allowed member (potential, static, or active), the system drops the packet.

## Port-Based VLANs

A port-based VLAN is a VLAN in which you explicitly configure the ports to be in the VLAN. When you create a port-based VLAN on a device, you assign a VLAN

identification number (VLAN ID) and specify the ports that belong to the VLAN. These port members are always active port members. The VLAN ID is used to coordinate VLANs across multiple switches. Any type of frame can be classified to a port-based VLAN.

The example in the following figure shows two port-based VLANs: one for the marketing department, and one for the sales department. Ports are assigned to each port-based VLAN. A change in the sales area can move the sales representative at port 1/1 to the marketing department without moving cables. With a port-based VLAN, you only need to indicate in the Command Line Interface (CLI) that port 1/1 in the sales VLAN now is a member of the marketing VLAN.

**Figure 260: Port-based VLAN**

## Private VLANs

**Table 297: E-Tree and Private VLANs product support**

| Feature                  | Product         | Release introduced |
|--------------------------|-----------------|--------------------|
| E-Tree and Private VLANs | 5320 Series     | Fabric Engine 8.6  |
|                          | 5420 Series     | VOSS 8.4           |
|                          | 5520 Series     | VOSS 8.2.5         |
|                          | 5720 Series     | Fabric Engine 8.7  |
|                          | 7520 Series     | Fabric Engine 8.10 |
|                          | 7720 Series     | Fabric Engine 8.10 |
|                          | VSP 4450 Series | VSP 4000 4.0       |
|                          | VSP 4900 Series | VOSS 8.1           |
|                          | VSP 7200 Series | VOSS 4.2.1         |
|                          | VSP 7400 Series | VOSS 8.0           |
|                          | VSP 8200 Series | VOSS 4.1           |
|                          | VSP 8400 Series | VOSS 4.2           |
|                          | VSP 8600 Series | Not Supported      |
|                          | XA1400 Series   | Not Supported      |
| Routing on Private VLANs | 5320 Series     | Fabric Engine 8.6  |
|                          | 5420 Series     | VOSS 8.5           |
|                          | 5520 Series     | VOSS 8.5           |
|                          | 5720 Series     | Fabric Engine 8.7  |
|                          | 7520 Series     | Fabric Engine 8.10 |
|                          | 7720 Series     | Fabric Engine 8.10 |
|                          | VSP 4450 Series | Not Supported      |
|                          | VSP 4900 Series | VOSS 8.5           |
|                          | VSP 7200 Series | VOSS 8.5           |
|                          | VSP 7400 Series | VOSS 8.5           |
|                          | VSP 8200 Series | VOSS 8.5           |
|                          | VSP 8400 Series | VOSS 8.5           |
|                          | VSP 8600 Series | Not Supported      |
|                          | XA1400 Series   | Not Supported      |

Private VLANs provide isolation between ports within a Layer-2 service.

The primary and secondary VLAN make the private VLAN. Standard VLAN configuration takes place on the primary VLAN. The secondary VLAN is used to label traffic ingressing isolated ports.

Ports in the private VLAN are configured as isolated, promiscuous, or trunk. The default value is None.

#### Port Types

#### Note

Layer 2 and Layer 3 services based on port types also apply in any routing scenario between two private VLANs or E-trees.

**Table 298: Layer 2 services based on port types**

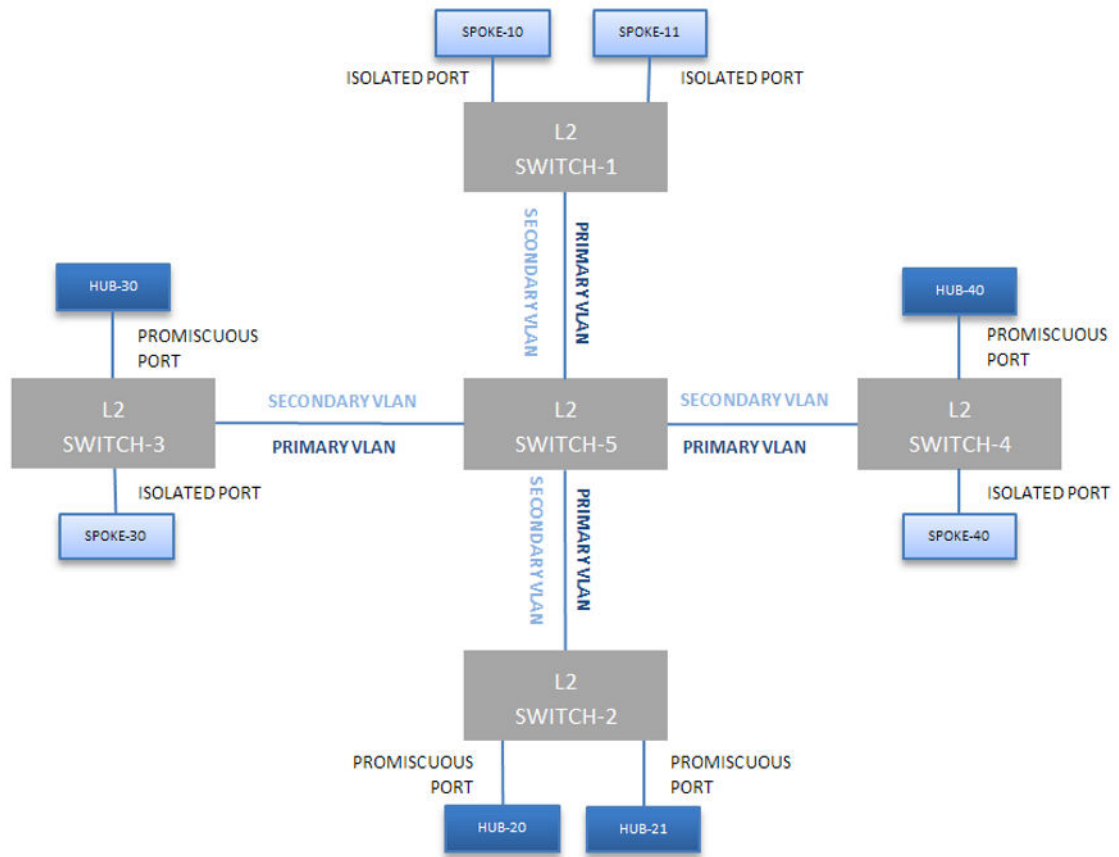

| Port type                              | Description                                                                                                              |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| Promiscuous (tagged or untagged ports) | Promiscuous ports communicate with all other ports within the private VLAN. Uses the primary VLAN.                       |
| Isolated (tagged or untagged ports)    | Isolated ports communicate with the promiscuous ports, but not with any other isolated port. Uses the secondary VLAN.    |
| Trunk (tagged ports)                   | Trunk ports carry traffic between other port members within the private VLANs. Accepts either primary or secondary VLAN. |

**Table 299: Layer 3 services based on port types**

| Port type                              | Description                                                                                              |
|----------------------------------------|----------------------------------------------------------------------------------------------------------|
| Promiscuous (tagged or untagged ports) | Promiscuous ports communicate with all other ports of any Layer 3 VLAN.                                  |
| Isolated (tagged or untagged ports)    | Isolated ports communicate with any promiscuous or regular VLAN ports but not with other isolated ports. |
| Trunk (tagged ports)                   | Trunk ports carry traffic between other port members within the private VLANs.                           |

Trunk ports must have VLAN encapsulation enabled. A port can be a single port or can belong to an MLT.

The following figure shows a basic private VLAN topology with private VLAN configured on five switches. All ports connecting to other switches are trunk type ports and all other ports are either promiscuous or isolated ports. On the secondary VLAN, spokes can communicate with hubs, and hubs can communicate with all spokes in the same private VLAN using the primary VLAN, however, spokes cannot communicate with other spokes.

**Figure 261: Private VLAN Topology**

#### *E-Tree*

The E-Tree allows private VLANs to traverse the Shortest Path Bridging MAC (SPBM) network.

For more information about E-Tree and SPBM configuration, see [E-Tree and Private VLAN topology](#) on page 1010.

#### *Routing on Private VLANs*

You can route traffic out of a private VLAN (PVLAN) by applying an IP address to a PVLAN. IP routing is supported on private VLANs for edge switches. With PVLAN packet routing, two hosts located in different private VLANs can communicate over the network.

Packets can be routed over the network between the following:

- regular VLAN and a private VLAN
- different private VLANs

- different I-SIDs (E-tree)

**Note**

Routed private VLANs support Secondary IP Interfaces. For more information, see [Secondary IP Interfaces](#) on page 4094.

The number of private VLANs that you configure with an IP address influences the IPv4 Egress ACE count. For information about scaling information, see [VOSS Release Notes](#). Limits are not enforced; either number of private VLANs or number of private VLAN trunk ports can go beyond the recommended values. As a best practice, use the **show io resources filter** command to monitor allocated resources.

**Note**

You cannot enable IP Multicast on a private VLAN interface. **ip spb-multicast enable** and **ip pim enable** commands are not available on a private VLAN.

### Private VLAN Configuration Rules

The following are private VLAN rules for the switch:

- Use private VLANs for Layer 2 and Layer 3 services.
- You cannot configure IP Source Guard (IPSG) on ports that are members of private VLANs.
- Do not use the `untag-port default vlan` parameter on private VLAN interfaces that are operating as trunk ports, because it impacts the private VLAN functionality.

## Policy-Based VLANs

Received frames are classified into a policy-based VLAN based on certain fields of the frame that matches the associated VLAN policy.

### Port Membership Types

In a policy-based VLAN, a port can be designated as a potential member, a static member, or one not allowed to be a member of the VLAN.

If a port is designated as a potential member of the VLAN, and the incoming traffic matches the policy, the system dynamically adds the port to the active port list of the VLAN, making the port an active member of the VLAN. After the system adds a port to the active list, it can remove the port from the active list due to time-out. Potential member ports that join the VLAN are removed (timed out) from the active port list of the VLAN after the timeout (aging time) period expires.

All members of the Spanning Tree Group associated with a protocol-based VLAN are automatically considered potential members of the VLAN. In addition, all tagged ports (trunk ports) become static ports. If you do not want all the tagged ports to be static members of a protocol-based VLAN, put the port in the disallowed list.

Static port members are always members of the VLAN. Static port members are not aged out due to inactivity and they are not removed from the active list. If a server

or router connects to a port, designate that port as a static member of a VLAN. If a server connects to a port that is only a potential member and the server sends very little traffic, a client fails to reach the server if the server port is timed out of the VLAN. As a best practice, make these ports static members of the VLAN.

A disallowed port can never become a member of the VLAN until you add it as a port-member. After you remove a port from the VLAN, the system adds the port to the disallowed list.

On any single spanning-tree instance, an access (untagged) port can belong to one port-based VLAN and many policy-based VLANs. A trunk (tagged) port can belong to many port-based and policy-based VLANs.

The following table describes port membership types for policy-based VLANs.

**Table 300: Port membership types for policy-based VLANs**

| Membership type                      | Description                                                                                                                                                                                 |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Potential                            | Potential members of a VLAN become active members upon receiving data matching the policy defined for the VLAN (a packet tagged with that VLAN, or an untagged packet matching the policy). |
| Static (always a member)             | Static members are always active members of the VLAN after you configure them as belonging to that VLAN.                                                                                    |
| Not allowed to join (never a member) | Ports of this type cannot join the VLAN.                                                                                                                                                    |

The following table lists supported policy-based VLANs.

**Table 301: Supported policy-based VLAN types**

| VLAN type      | Support   |
|----------------|-----------|
| Protocol-based | supported |

#### *Protocol-Based VLANs*

Protocol-based VLANs are an effective way to segment your network into broadcast domains according to the network protocols in use.

A port member of a port-based VLAN can belong to multiple protocol-based VLANs. Port tagging is not required for a port to be a member of multiple protocol-based VLANs.

The switch supports IPv6 protocol-based VLAN only.

## SPBM B-VLAN

Each SPBM network instance is associated with at least one backbone VLAN (B-VLAN) in the core SPBM network.

This VLAN is used for both control plane traffic and dataplane traffic.

**Note**

Always configure two B-VLANs in the core to allow load distribution over both B-VLANs.

SPBM alters the behavior of the VLAN. When a B-VLAN is associated with an SPBM network the following VLAN attributes and behaviors are modified for the B-VLAN:

- Flooding is disabled
- Broadcasting is disabled
- Source MAC address learning is disabled
- Unknown MAC discard is enabled

Ports cannot be added to a B-VLAN manually, IS-IS takes care of adding ports to the B-VLAN.

Essentially the B-MAC addresses are programmed into the B-VLAN Forwarding Information Bases (FIBs) by IS-IS instead of the traditional VLANs flooding and learning approach.

Modification of the VLAN behavior is necessary to ensure proper control over the SPBM traffic.

### VLAN Tagging and Port Types

The switch supports the IEEE 802.1Q specification for tagging frames and coordinating VLANs across multiple switches.

Figure 262 shows how an additional four octet (tag) header is inserted in a frame after the source address and before the frame type. The tag contains the VLAN ID associated with the frame.

**Figure 262: VLAN tag insertion**

### *802.1Q Tagged Ports*

Tagging a frame adds four octets to a frame, possibly making it bigger than the traditional maximum frame size. If a device does not support IEEE 802.1Q tagging, it can have problems interpreting tagged frames that it receives.

Whether tagged frames are sent depends on what you configure at the port level. Tagging is configured as true or false for the port, and is applied to all VLANs on that port.

A port with tagging enabled applies the VLAN ID tag to all packets sent on the port. Tagged ports are typically used to multiplex traffic belonging to multiple VLANs to other IEEE 802.1Q-compliant devices.

If you disable tagging on a port, it does not send tagged frames. A nontagged port connects a switch to devices that do not support IEEE 802.1Q tagging. If a tagged frame is forwarded to a port with tagging configured to false, the switch removes the tag from the frame before sending it to the port.

### *Treatment of Tagged and Untagged Frames*

The switch associates a frame with a VLAN based on the data content of the frame and the configuration of the receiving port. The treatment of the frame depends on whether the frame is tagged or untagged.

If a tagged frame is received on a port, if the port is a static or potential member of the VLAN ID specified in the tag, the switch directs it to that VLAN. If the port is not a member of the VLAN that is identified by the tag in the packet, the switch discards the packet. If a port is untagged, you can configure it to discard tagged frames received on the port. In this case the tagged frame is discarded.

For untagged frames, VLAN membership is implied from the content of the frame itself. You can configure a tagged port to accept or discard untagged frames received on the port.

The default VLAN of a port is the VLAN to which untagged frames are classified if they do not match the criteria of any policy-based VLAN of which the port is a member. The default VLAN of the port can be any port-based VLAN a port belongs to, or the unassigned VLAN (1). Frames classified to the unassigned VLAN are discarded.

The frame is forwarded based on the VLAN on which the frame is received, and on the forwarding options available for that VLAN. The switch tries to associate untagged frames with a VLAN in the following order:

- Does the frame belong to a protocol-based VLAN?
- What is the default VLAN for the receiving port?
- Is the default VLAN for the port not the unassigned VLAN?

If the frame meets none of these criteria, it is discarded.

### *Untagging Default VLAN on a Tagged Port Feature*

This feature provides the ability to connect two devices such as an IP phone and a PC to a single port of the switch. Most IP phones ship with an embedded three port switch, and traffic coming from the phone is generally tagged (VLAN ID configured statically or remotely). However, the traffic originating from a PC is usually untagged traffic and must be separated from the IP phone traffic. This separation ensures that broadcast traffic from the PC does not impact voice quality.

After an IP phone is attached to an untagged port, it can fail to register with a remote Internet Telephony Gateway (or equivalent device) dependent on the netmask of the destination IP address (Call Server subnet).

For more information about the Network with IP phone and PC, see the following figure.

**Figure 263: Network with IP phone and PC**

IP phones and PCs coexist on the same port due to the use of an embedded IP Phone Layer 2 switch. In this scenario if you configure the port as untagged, the egress traffic on this port is untagged and no separation exists between the traffic to the IP phone and the PC. To avoid this condition, the port that connects to the IP phone must be tagged. If the port is tagged, the traffic for the PC is tagged with the default VLAN ID for the port. This configuration creates a problem because the PC does not expect tagged packets. Untag the default VLAN on a tagged port (in this example, port 1/1 that connects to the IP phone) to ensure that the traffic to the PC is sent untagged.

## VLAN Router Interfaces

When you configure routing on a VLAN, you assign an IP address to the VLAN, which acts as a virtual router interface address for the VLAN. This IP address is not associated with a physical port. You can reach the VLAN IP address through any of the VLAN port

members. Frames are routed to another VLAN IP address within the device. A port can belong to multiple VLANs; some, all, or none can perform routing.

## IP routing and VLANs

The switch supports IP routing on the following types of VLANs:

- Port-based VLANs
- IP protocol-based VLANs

## VLAN Implementation

This section describes how to implement VLANs and describes default VLANs, the unassigned (NULL) VLAN, and brouter ports. This section also summarizes the defaults and rules regarding VLAN creation on the switch.

- [Default VLAN](#) on page 4092
- [NULL VLAN](#) on page 4092
- [Brouter Ports](#) on page 4092

### *Default VLAN*

Devices are factory-configured so that all ports are in a port-based VLAN called the default VLAN. Because all ports are in the default VLAN, the device behaves like a Layer 2 device. The VLAN ID of this default VLAN is always 1, and it is always a port-based VLAN. You cannot delete the default VLAN.

### *NULL VLAN*

Internally, the switch creates a special port-based VLAN called NULL VLAN or unassigned VLAN. This is a place holder VLAN for ports that are not members of any port-based VLAN. When a port is removed from all port-based VLANs, it is added to the NULL VLAN as a port member. Ports can belong to policy-based VLANs as well as to the NULL VLAN. If a frame does not meet the policy criteria and no underlying port-based VLAN exists, the port belongs to the NULL VLAN and the frame is dropped.

Because it is an internal construct, the NULL VLAN cannot be deleted.

### *Brouter Ports*

A brouter port is actually a one-port VLAN with an IP interface. The difference between a brouter port and a standard IP protocol-based VLAN configured to perform routing is that the routing interface of the brouter port is not subject to the spanning tree state of the port. A brouter port can be in the blocking state for nonroutable traffic and still route IP traffic. Because a brouter port is a single-port VLAN, it uses one VLAN ID. Each brouter port decreases the number of available VLANs by one.

## VLAN Configuration Rules

The following are VLAN rules for the switch:

- The switch supports configurable VLANs in the range of 1 to 4059. VLAN 0 is invalid. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. VLAN IDs on the switch range from 2 to 4094 but, by default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the *vrf-scaling* and *spbm-config-mode* boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998.
- A tagged port can belong to multiple VLANs in multiple Spanning Tree Groups.
- Under the default configuration, the default Spanning Tree Group is number 1 if the chassis configuration permits multiple STGs.
- An untagged port can belong to only one port-based VLAN.
- You can configure only one protocol-based VLAN for a given protocol.
- The VLAN membership of a frame is determined by the following order of precedence, if applicable:
  1. IEEE 802.1Q tagged VLAN ID
  2. protocol-based VLAN
  3. port-based VLAN default VLAN of the receiving port
- You cannot configure a VLAN name that uses all numbers, for example, 222.

## VLAN Feature Support

The following table summarizes supported features.

For the latest scalability information, see [VOSS Release Notes](#).

**Table 302: VLAN support**

| Feature                                                                                                                                              | Description |
|------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| Number of VLANs                                                                                                                                      | 4059        |
| Port-based VLANs                                                                                                                                     | Supported   |

|                         | VSP 8200 Series | VOSS 8.10                                                                                                 |
|                         | VSP 8400        | VOSS 8.10                                                                                                 |
|                         | XA1400 Series   | VOSS 8.10                                                                                                 |

The ability to add Secondary IP Interfaces on a Layer 2 VLAN means that you can have both primary and secondary IP subnets as local routes and increase the number of connected hosts. This feature is useful for subnets that have used all available host IP addresses.

You can configure Secondary IP Interfaces on VLAN interfaces only; you cannot configure a Secondary IP Interface for a brouter port or CLIP interface. Both the Global Router (VRF 0) and user-defined VRFs support Secondary IP Interfaces on associated VLANs. The secondary addresses share the same routeable MAC with the primary IP address.

A VLAN interface can support up to 32 secondary IP addresses. The total number of secondary IP addresses you can create on the same switch depends on available resources. For scaling information, see [VOSS Release Notes](#).

DHCP Smart Relay makes DHCP Relay aware of Secondary IP Interfaces. DHCP Smart Relay can also work with a subset of VRRP addresses. For more information, see [DHCP Smart Relay for Secondary IP Interfaces](#) on page 688.

### Configuration Rules

- You must configure a primary IP address on the VLAN before you can add secondary addresses.
- You cannot remove a primary IP address if a secondary address exists.
- Primary and secondary subnets must be unique across all VLANs, including within the same VLAN. Subnets cannot overlap, meaning you cannot configure a subnet range that would be included within another subnet range.
- When the command originates on the switch, the **ping** and **traceroute** commands both support secondary IP addresses as the source IP address. If you do not specify a source address as part of the command, the switch automatically uses the a secondary address in the subnet.
- Protocol exchange, both unicast and multicast, occurs only on the primary subnet. Control packets use the primary IP address, including neighbor or peer relationships, and election processes.

#### Note

IGMP interfaces accept and process all IGMP reports received for subnets that belong to that interface, either primary or secondary.

- Routing protocols do not advertise secondary subnets; you must configure redistribution of direct routes to announce secondary subnets.
- The switch sends all broadcast packets within the VLAN to all hosts regardless of subnet.
- You cannot configure the following features on a secondary subnet:
  - BFD
  - IP security features
  - LLDP
  - Proxy ARP
  - UDP
  - Virtual Inter-Switch Trunk (vIST) peers
- The following feature restrictions exist for Secondary IP Interfaces:
  - You cannot configure a MAC offset for secondary IP addresses.
  - You cannot configure RSMLT on a VLAN with secondary IP addresses.
  - You cannot configure a DvR Gateway IP address that exists in a secondary subnet. DvR-One-IP always selects the primary IP address.
  - You cannot configure a secondary IP address as the source IP for a Fabric Extend tunnel.

For more information, see the following tasks:

- [Assign an IP Address to a VLAN](#) on page 4115 (CLI)
- [Configure a Secondary IP Interface for a VLAN](#) on page 4158 (EDM)

## Network Load Balancing

**Table 304: Network Load Balancing product support**

| Feature                                            | Product         | Release introduced |
|----------------------------------------------------|-----------------|--------------------|
| Network Load Balancing (NLB) - multicast operation | 5320 Series     | Not Supported      |
|                                                    | 5420 Series     | Not Supported      |
|                                                    | 5520 Series     | VOSS 8.2.5         |
|                                                    | 5720 Series     | Fabric Engine 8.7  |
|                                                    | 7520 Series     | Fabric Engine 8.10 |
|                                                    | 7720 Series     | Fabric Engine 8.10 |
|                                                    | VSP 4450 Series | Not Supported      |
|                                                    | VSP 4900 Series | VOSS 8.1           |
|                                                    | VSP 7200 Series | VOSS 6.0           |
|                                                    | VSP 7400 Series | VOSS 8.0           |
|                                                    | VSP 8200 Series | VOSS 6.0           |
|                                                    | VSP 8400 Series | VOSS 6.0           |
|                                                    | VSP 8600 Series | Not Supported      |
| XA1400 Series                                      | Not Supported   |                    |
| Network Load Balancing (NLB) - unicast operation   | 5320 Series     | Not Supported      |
|                                                    | 5420 Series     | Not Supported      |
|                                                    | 5520 Series     | VOSS 8.2.5         |
|                                                    | 5720 Series     | Fabric Engine 8.7  |
|                                                    | 7520 Series     | Fabric Engine 8.10 |
|                                                    | 7720 Series     | Fabric Engine 8.10 |
|                                                    | VSP 4450 Series | Not Supported      |
|                                                    | VSP 4900 Series | VOSS 8.1           |
|                                                    | VSP 7200 Series | VOSS 4.2.1         |
|                                                    | VSP 7400 Series | VOSS 8.0           |
|                                                    | VSP 8200 Series | VOSS 4.0           |
|                                                    | VSP 8400 Series | VOSS 4.2           |
|                                                    | VSP 8600 Series | VSP 8600 4.5       |
| XA1400 Series                                      | Not Supported   |                    |

Microsoft Network Load Balancing (NLB) is a clustering technology available with the Microsoft Windows 2000, Microsoft Windows 2003, Microsoft Windows 2008, and Microsoft Windows 2012 Server family of operating systems. You can use NLB to share the workload among multiple clustering servers. NLB uses a distributed algorithm to

load balance TCP/IP network traffic across a number of hosts, enhancing the scalability and availability of the following mission critical, IP-based services:

- web
- VPN
- Streaming media
- Firewalls

NLB also provides high availability by detecting host failures and automatically redistributing traffic to remaining operational hosts.

#### *NLB Considerations and Restrictions*

Although the switch interoperates with NLB clusters that operate in Unicast mode and Multicast mode, the following restrictions apply:

- True egress mirroring is not supported on all VOSS hardware platforms. Because packets are mirrored prior to the completion of packet processing, egress mirrored packets can differ from the packets egressing the port. Therefore, NLB Unicast traffic and NLB Multicast traffic destined to the NLB Virtual Mac Address are not mirrored correctly.

#### **Note**

To mirror the egress traffic of VOSS hardware platforms, you can use the NEXT-hop device ingress mirroring to capture the egress packets of the switch.

Of the VOSS hardware platforms, only VSP 4450 Series supports true egress mirroring.

- Inter-VRF routing is not supported between an NLB client and an NLB cluster VLAN in Unicast mode or Multicast mode.
- You must configure NLB to use the same mode as the NLB Server.
- Static ARP entries are not supported for NLB Unicast or NLB Multicast.
- For interoperability with NLB, the switch provides configuration options at the VLAN level.
- ARP entries for NLB server IP addresses do not age out when there is still client traffic coming to the NLB servers, even after the NLB servers are no longer reachable.

#### *NLB Clustering in Unicast Mode*

When the cluster is running in NLB unicast mode, all servers in the cluster share a common virtual MAC address, which is 02-bf-x-x-x-x (where x-x-x-x is the cluster IP address in hexadecimal form). All traffic destined to this MAC address is sent to all the servers in the cluster. The virtual MAC address is specified in the Sender MAC Address field of the Address Resolution Protocol (ARP) reply from the cluster to the switch. ARP responses from the switch are sent to the virtual MAC address (rather than to the hardware MAC address).

You can configure the switch for NLB unicast mode support. After you enable the NLB unicast option, the switch floods traffic destined to the cluster IP address to all ports

on the VLAN. Unicast mode supports connectivity to a secondary virtual IP address. For information about software scaling capabilities in unicast mode, see [VOSS Release Notes](#).

#### *NLB Clustering in Multicast Mode*

When the cluster is running in NLB multicast mode, a multicast virtual MAC address with the format 03-bf-x-x-x-x (where x-x-x-x is the cluster IP address in hexadecimal form) is bound to all cluster hosts but the real MAC address of the network adapter is retained. The multicast MAC address is used for client-to-cluster traffic, and the real MAC address of the adapter is used for network traffic specific to the host server.

You can configure the switch for NLB multicast mode support. When you enable NLB multicast mode on a VLAN, the routed traffic destined to the NLB cluster is flooded by default on all ports of the VLAN. All VLANs support multiple cluster IPs by default. You can connect up to 200 NLB clusters to a single VLAN. For information about software scaling capabilities, see [VOSS Release Notes](#).

#### **Note**

Shortest Path Bridging MAC (SPBM) supports NLB Unicast and Multicast modes. For more information on SPBM, see [Fabric Basics and Layer 2 Services](#) on page 1001.

#### *Supported NLB Topologies*

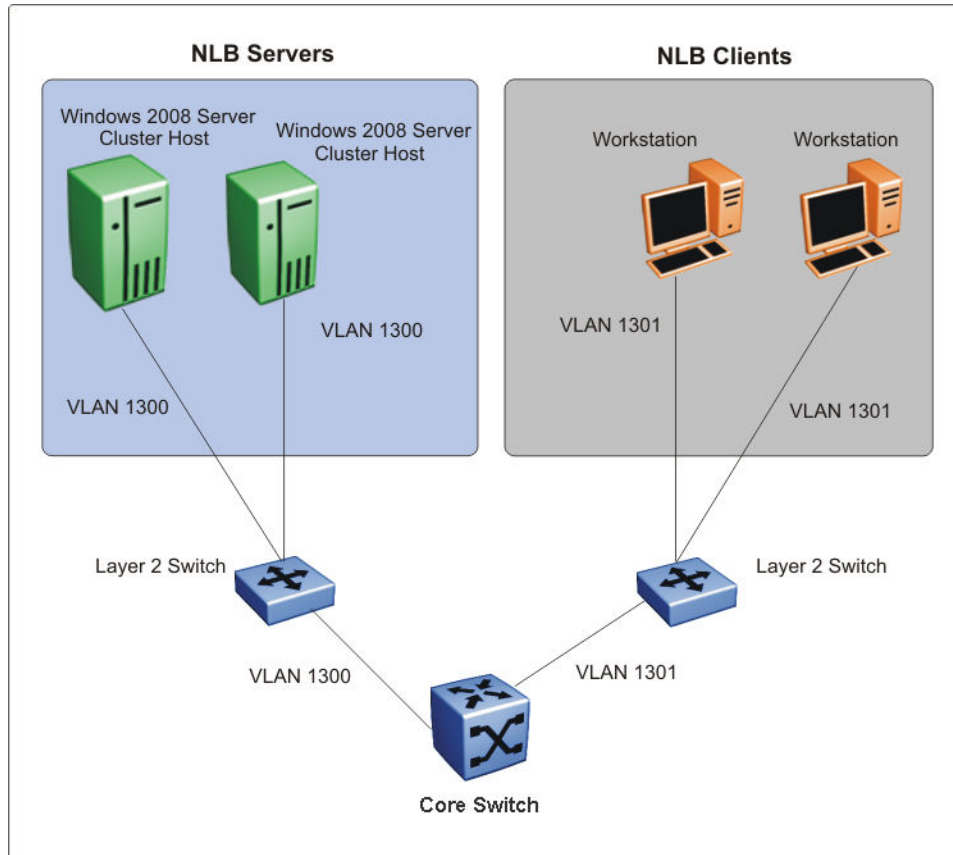

The switch supports Network Load Balancing (NLB) in the following topologies.

##### **Supported NLB topology—example 1**

The switch supports NLB when the NLB Cluster connections use a different physical port on the switch than the NLB clients.

The following figure illustrates this configuration where the NLB Server and the NLB Client workstations connect to different aggregation switches, which connect to the switch using different VLANs and different ports.

**Figure 264: Supported NLB topology—example 1**

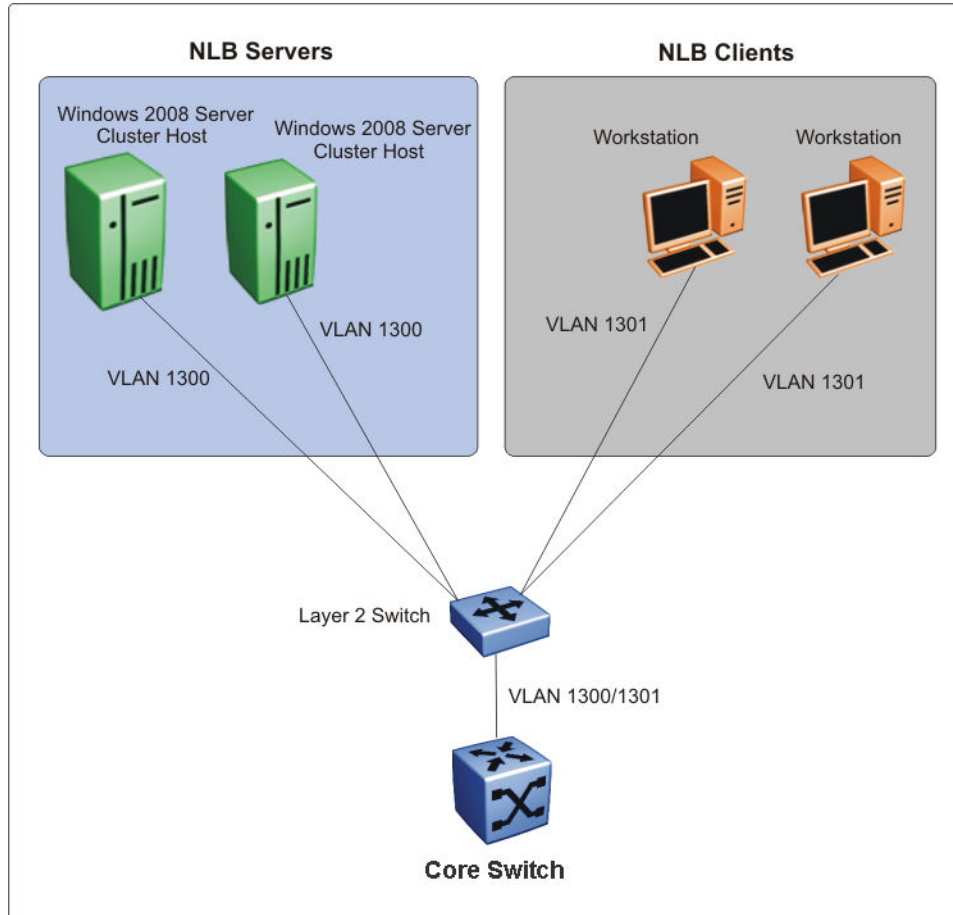

#### Supported NLB topology—example 2

The switch also supports the following topology where the NLB Server and the NLB Client workstations connect to the same aggregation switch and then connect to the switch using the same port.

#### Note

The switch supports Layer 3 routing between an NLB-enabled VLAN and another VLAN on the same port.

**Figure 265: Supported NLB topology—example 2**

#### Other supported NLB topologies

The switch supports NLB in the following other topologies:

- NLB cluster hosts and clients are connected to Layer 2 Ethernet switches that are SMLT connected to the SMLT cluster.
- NLB cluster hosts are directly connected and distributed between the switches and the clients are connected to Layer 2 Ethernet switch that is SMLT connected to the SMLT cluster.
- NLB cluster hosts and clients are directly connected and distributed between the switches in the SMLT cluster.
- NLB cluster hosts and clients are connected to Layer 2 Ethernet switches that are SMLT connected to the SMLT cluster core.

#### Note

For more information on the above topologies, see *Technical Configuration Guide for Microsoft Network Load Balancing*.

## NLB and Directed Broadcast Resource Limits

NLB and Directed Broadcast consume resources from the same pool of 200 resources. When you configure either NLB or Directed Broadcast, the switch uses one resource. If you configure both NLB and Directed Broadcast, the switch uses two resources.

To avoid a situation where there is a lack of resources, adhere to the following limits:

- The number of NLB cluster IP interfaces multiplied by the number of configured clusters must be equal to, or less than, 200. The number of NLB cluster IP interfaces is the key, not the number of VLANs. You can configure 1 VLAN with up to 200 NLB cluster IP interfaces or configure up to 200 VLANs with 1 NLB cluster IP interface per VLAN.

For example: 1 NLB cluster IP interface x 200 clusters = 200 or 2 NLB cluster IP interfaces x 100 clusters = 200

- If you configure VLANs with Directed Broadcast only, you can scale up to 200 VLANs.
- If you configure VLANs with both **NLB** and **Directed Broadcast**, you can only scale up to 100 VLANs assuming there is only 1 NLB cluster IP interface per VLAN.

For information on Directed Broadcast, see [Denial-of-Service Attack Prevention](#) on page 3273.

## VLAN MAC-layer Filtering Database and MAC Security

**Table 305: FDB Protected by Port product support**

| Feature                                             | Product         | Release introduced |
|-----------------------------------------------------|-----------------|--------------------|
| FDB protected by port (MAC security limit-learning) | 5320 Series     | Fabric Engine 8.6  |
|                                                     | 5420 Series     | VOSS 8.4           |
|                                                     | 5520 Series     | VOSS 8.3           |
|                                                     | 5720 Series     | Fabric Engine 8.7  |
|                                                     | 7520 Series     | Not Supported      |
|                                                     | 7720 Series     | Not Supported      |
|                                                     | VSP 4450 Series | VSP 4000 4.0       |
|                                                     | VSP 4900 Series | VOSS 8.3           |
|                                                     | VSP 7200 Series | Not Supported      |
|                                                     | VSP 7400 Series | Not Supported      |
|                                                     | VSP 8200 Series | Not Supported      |
|                                                     | VSP 8400 Series | Not Supported      |
|                                                     | VSP 8600 Series | Not Supported      |
|                                                     | XA1400 Series   | Not Supported      |

To perform MAC-layer bridging, the device must know the destination MAC-layer address of each device on each attached network to forward packets to the appropriate

destination. The system stores MAC-layer addresses in the bridge forwarding database (FDB) table, and can forward packet traffic based on the destination MAC-layer address information.

### *MAC Security*

Use MAC security to control traffic from specific number of MAC addresses. You can also limit the number of allowed MAC addresses. You can enable this feature at the port level.

Port-level security applies to traffic for all VLANs received on that port.

Port-level MAC security provides limit—learning option:

- **limit-learning:** This option protects the FDB from traffic from too many MAC addresses, which fill the FDB table.

This option limits the number of MAC addresses a port learns. You can specify a maximum number of addresses. After the number of addresses reaches the maximum, learning stops. The port disables packet forwarding and drops packets from new source MAC address. MAC address learning resumes after enough existing addresses age out and there is room to learn new MAC addresses.

#### **Note**

If you configure a limit on a port that has already learned more than the new limit, packet forwarding for those additional MAC addresses continues to work until the port flaps, you flush the MAC address, or the MAC address disappears.

### *Restrictions*

The following list identifies restrictions to MAC security limit-learning:

- This feature is not supported on:
  - MLT ports members
  - NNI ports
  - Transparent Port UNI or Switched UNI
- The switch supports MAC learning only in the VLAN domain; it is not supported in the I-SID domain.
- The port MAC limit does not count static MAC addresses.
- The switch supports the maximum number of MAC addresses a port can learn for non-SPBM configurations.

## Prevention of IP Spoofing within a VLAN

### *VLAN IP as the default gateway*

You can prevent VLAN logical IP spoofing by blocking the external use of the device IP address. A configurable option is provided, for each port, which detects a duplicate IP address (that is, an address that is the same as the device VLAN IP address) and blocks all packets with a source or destination address equal to that address.

If an ARP packet is received that has the same source IP address as the logical VLAN IP address of the receiving port, all traffic coming to that port (with this MAC address as source/destination address) is discarded by the hardware. After detecting a duplicate IP address, the device sends a gratuitous ARP packet to inform devices on the VLAN about the correct MAC address for that IP address. You can specify a time on a configurable global timer after which the MAC discard record is deleted, and the device resumes accepting packets from that MAC address.

#### *VRRP IP as the default gateway*

Similarly, you can prevent VRRP IP spoofing by blocking the external use of the virtual IP address. A configurable option is provided, for each port, which detects a duplicate IP address (that is, an address that is the same as the device virtual IP address) and blocks all packets with a source or destination address equal to that address.

If an ARP packet is received that has the same source IP address as the virtual IP address of the receiving port, all traffic coming to that port (with this MAC address as source/destination address) is discarded by the hardware. After detecting a duplicate IP address, the device sends a gratuitous ARP packet to inform devices on the VRRP subnet about the correct virtual router MAC address for that IP address. You can specify a time on a configurable global timer after which the MAC discard record is deleted, and the device resumes accepting packets from that MAC address.

#### *Packet spoofing*

You can stop spoofed IP packets by configuring the switch to forward only IP packets that contain the correct source IP address of your network. By denying all invalid source IP addresses, you minimize the chance that your network is the source of a spoofed DoS attack.

A spoofed packet is one that comes from the Internet into your network with a source address equal to one of the subnet addresses on your network. The source address belongs to one of the address blocks or subnets on your network. To provide spoofing protection, you can use a filter that examines the source address of all outside packets. If that address belongs to an internal network or a firewall, the packet is dropped.

To prevent DoS attack packets that come from your network with valid source addresses, you need to know the IP network blocks in use. You can create a generic filter that:

- Permits valid source addresses
- Denies all other source addresses

To do so, configure an ingress filter that drops all traffic based on the source address that belongs to your network.

If you do not know the address space completely, it is important that you at least deny private (see RFC1918) and reserved source IP addresses. The following table lists the source addresses to filter.

**Table 306: Source addresses to filter**

| Address            | Description                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0.0.0.0/8          | Historical broadcast. High Secure mode blocks addresses 0.0.0.0/8 and 255.255.255.255/16. If you enable this mode, you do not need to filter these addresses. |
| 10.0.0.0/8         | RFC1918 private network                                                                                                                                       |
| 127.0.0.0/8        | Loopback                                                                                                                                                      |
| 169.254.0.0/16     | Link-local networks                                                                                                                                           |
| 172.16.0.0/12      | RFC1918 private network                                                                                                                                       |
| 192.0.2.0/24       | TEST-NET                                                                                                                                                      |
| 192.168.0.0/16     | RFC1918 private network                                                                                                                                       |
| 224.0.0.0/4        | Class D multicast                                                                                                                                             |
| 240.0.0.0/5        | Class E reserved                                                                                                                                              |
| 248.0.0.0/5        | Unallocated                                                                                                                                                   |
| 255.255.255.255/32 | Broadcast1                                                                                                                                                    |

You can also enable the spoof-detect feature on a port.

## VLAN loop prevention

**Table 307: Simple Loop Prevention Protocol product support**

| Feature                                | Product         | Release introduced |
|----------------------------------------|-----------------|--------------------|
| Simple Loop Prevention Protocol (SLPP) | 5320 Series     | Fabric Engine 8.6  |
|                                        | 5420 Series     | VOSS 8.4           |
|                                        | 5520 Series     | VOSS 8.2.5         |
|                                        | 5720 Series     | Fabric Engine      |
|                                        | 7520 Series     | Fabric Engine 8.10 |
|                                        | 7720 Series     | Fabric Engine 8.10 |
|                                        | VSP 4450 Series | VSP 4000 4.0       |
|                                        | VSP 4900 Series | VOSS 8.1           |
|                                        | VSP 7200 Series | VOSS 4.2.1         |
|                                        | VSP 7400 Series | VOSS 8.0           |
|                                        | VSP 8200 Series | VSP 8200 4.0       |
|                                        | VSP 8400 Series | VOSS 4.2           |
|                                        | VSP 8600 Series | VSP 8600 4.5       |
|                                        | XA1400 Series   | VOSS 8.0.50        |

### Loop Prevention

Under certain conditions, such as incorrect configurations or cabling, loops can form. This is true mainly for layer 2 bridged domains, such as VLANs.

Simple Loop Prevention Protocol (SLPP) provides active protection against Layer 2 network loops on a per-VLAN basis. SLPP uses a lightweight hello packet mechanism to detect network loops. Sending hello packets on a per VLAN basis allows SLPP to detect VLAN based network loops for untagged as well as tagged IEEE 802.1Q VLAN link configurations. After SLPP detects a loop, the port is shutdown.

#### Note

If SLPP is used in a vIST environment, it must be enabled on both the vIST peers. Because, when an SLPP packet of a vIST peer is looped through UNI ports to the other device, that device will shut down its UNI port due to receiving SLPP packets from its peer. A device's own SLPP packets will go over a vIST connection but will not be forwarded by its vIST peer back onto its UNI ports.

Configure the SLPP functionality with the following criteria:

- SLPP TX Process – You decide on which VLANs a switch can send SLPP hello packets. The packets are then replicated out all ports which are members of the SLPP-enabled VLAN. As a best practice, enable SLPP on all VLANs.
- SLPP RX Process – You decide on which ports the switch can act when receiving an SLPP packet that is sent by the same switch or by its SMLT peer. You must enable

this process only on Access SMLT ports. You can enable this process only when the design permits on SMLT CORE ports in the case of a square/full mesh core design.

- SLPP Action – The action operationally disables the ports receiving the SLPP packet. You can also tune the network failure behavior. You can choose how many SLPP packets a port needs to receive before a switch takes an action. You need to stagger these values to avoid edge switch isolation – see the best practices at the end of this section.

Loops can be introduced into the network in many ways. One way is through the loss of an MLT/link aggregation configuration caused by user error or malfunctioning equipment. This scenario does not always introduce a broadcast storm, but because all MAC addresses are learned through the looping ports, does significantly impact Layer 2 MAC learning. Spanning Tree cannot in all cases detect such a configuration issue, whereas SLPP reacts and disables the malfunctioning links and limits network impact to a minimum.

The desire is to prevent a loop from causing network problems, while also attempting not to isolate totally the edge where the loop was detected. Total edge closet isolation is the last resort to protect the rest of the network from the loop. With this in mind, some administrators adopt the concept of an SLPP primary switch and SLPP secondary switch. These are strictly design terms and are not configuration parameters. The Rx thresholds are staggered between the primary and secondary switch. Therefore, the primary switch disables an uplink immediately upon a loop occurring. If this resolves the loop issue, then the edge closet still has connectivity back through the SLPP secondary switch. If the loop is not resolved, then the SLPP secondary switch disables the uplink and isolates the closet to protect the rest of the network from the loop.

As the number of VLANs running SLPP scale off of a specific uplink port, the Rx-threshold value may need to be increased to prevent complete isolation of the offending edge. The primary goal of SLPP is to protect the core at all costs. In certain loop conditions, what can occur is the secondary switch also detects the loop and SLPP Rx-threshold of the secondary switch is reached before the primary can stop the loop by taking its port down. Therefore, both switches eventually take their ports down and the edge is isolated. The larger the number of VLANs associated with the port, the more likely this can occur, especially for loop conditions that affect all VLANs.

The loop detection functionality of the device must not be used under normal operating conditions. Only use it if directed by the technical support personnel.

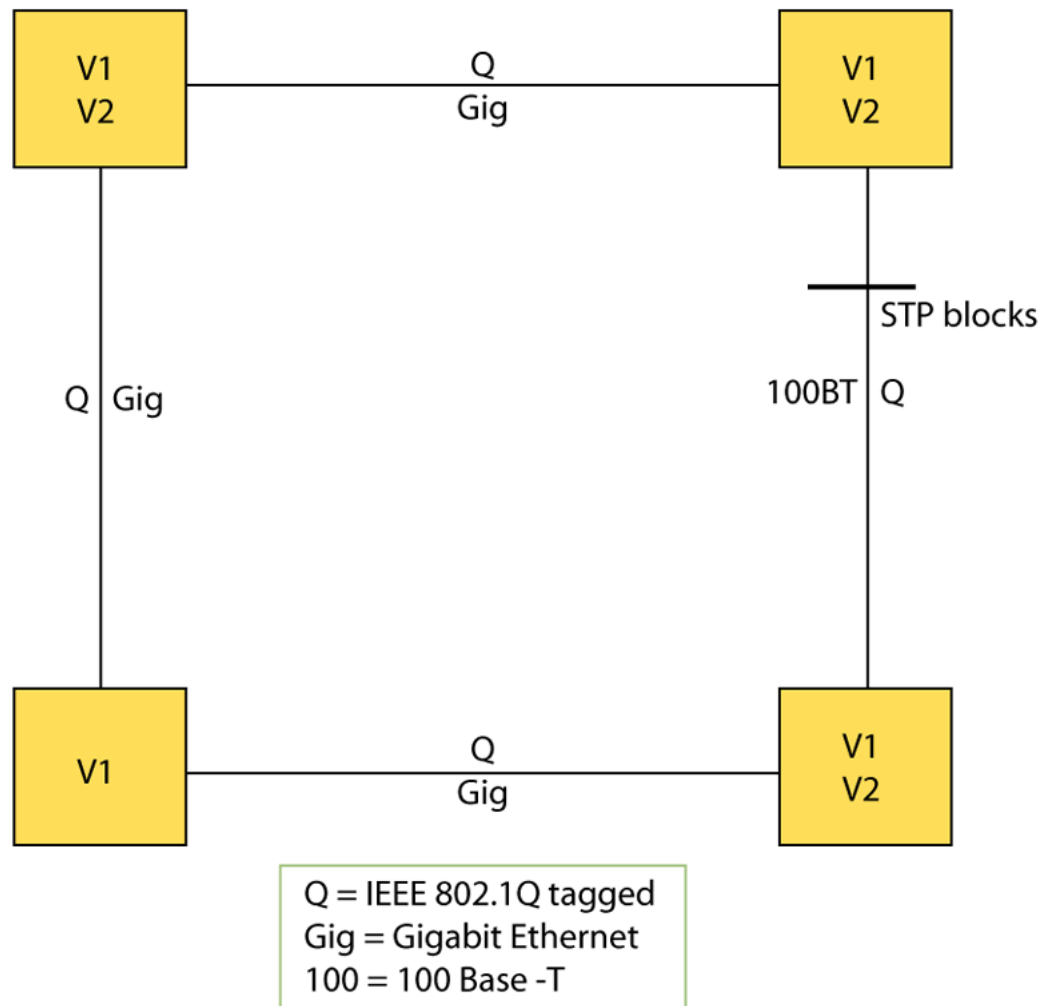

You cannot configure the EtherType for SLPP. The switch uses an EtherType of 0x8102 .

## Spanning Tree and Protection against Isolated VLANs

Virtual Local Area Network (VLAN) isolation disrupts packet forwarding. The following figure illustrates the problem. Two VLANs (V1 and V2) connect four devices, and both VLANs are in the same spanning tree group. V2 includes three of the four devices, whereas V1 includes all four devices. After a spanning tree protocol detects a loop, it blocks the link with the highest link cost. In this case, the 100 Mbps link is blocked, which isolates a device in V2. To avoid this problem, either configure V2 on all four

devices or use MSTP with a different Multiple Spanning Tree Instance (MSTI) for each VLAN.

**Figure 266: VLAN isolation**

## IGMP Layer 2 Querier

In a Layer 2 multicast network, you can enable Layer 2 querier on one of the switches in the VLAN. IGMP Layer 2 querier provides the IGMP querier function so that the switch can provide the recurring queries that maintain IGMP groups when you do not use multicast routing for multicast traffic.

### *IGMP Layer 2 Querier Overview*

In a multicast network, if you only need to use Layer 2 switching for the multicast traffic, you do not need multicast routing. However, you must have an IGMP querier on the network for multicast traffic to flow from sources to receivers. A multicast router provides the IGMP querier function. You can also use the IGMP Layer 2 Querier feature to provide a querier on a Layer 2 network without a multicast router.

The Layer 2 querier function originates queries for multicast receivers, and processes the responses accordingly. On the connected Layer 2 VLANs, IGMP snoop continues to provide services as normal. IGMP snoop responds to queries and identifies receivers for the multicast traffic.

You must enable Layer 2 querier and configure an IP address for the querier before it can originate IGMP query messages. If a multicast router exists on the network, the switch automatically disables the Layer 2 querier.

In a Layer 2 multicast network, enable Layer 2 querier on only one of the switches in the VLAN. A Layer 2 multicast domain supports only one Layer 2 querier. No querier election exists.

### *IGMP Snooping*

IGMP Snooping enables Layer 2 switches in the network to examine IGMP control protocol packets exchanged between downstream hosts and upstream routers.

When Layer 2 switches examine the IGMP control protocol packets, they:

### *IGMP Layer 2 Querier and IGMP Interaction*

IGMP Layer 2 Querier uses IGMP to learn which groups have members on each of the attached physical networks, and it maintains a list of multicast group memberships for each attached network and a timer for each membership. In this case, multicast group memberships means the presence of at least one member of a multicast group on a given attached network, not a list of all of the members.

IGMP Layer 2 Querier can assume one of two roles for each of the attached networks:

- Querier
- Non-Querier

After you enable IGMP Layer 2 Querier, the system assumes it is a multicast router, so it sends the General Query, Group Specific/Group, and Source Specific Query when Leave/BLOCK messages are received. IGMP queries are required to maintain an IGMP group.

For more information about how to configure IGMP Layer 2 Querier, see [IP Multicast](#) on page 1586.

## Switched UNI Layer 3

Create a platform VLAN using the command `vlan create <vlan-id> type port-mstprsp <msti-instance>`. Enable Layer 3 services on the platform VLAN and is associated with the Switched UNI (S-UNI) Service Instance Identifier (I-SID). All S-UNI ports are added to the platform VLAN.

You must associate the S-UNI I-SID to the platform VLAN. After you associate the platform VLAN with the I-SID, it becomes a CVLAN.

The switch performs MAC and ARP learning on the platform VLAN.

#### Note

You cannot add S-UNI ports or MLT to the S-UNI platform VLANs directly. Add the ports to the I-SID and assign the I-SID to the platform VLAN.  
You can associate only port based VLAN with S-UNI I-SID.

## VLAN Configuration Using CLI

This section provides procedures to configure and to manage Virtual Local Area Networks (VLANs) using the command line interface (CLI).

### Create a VLAN

Create a VLAN by port, protocol, or an SPBM B-VLAN. Optionally, you can choose to assign the VLAN a name and color.

Assign an IP address to the VLAN. You can also assign a MAC-offset value that allows you to manually change the default MAC address.

#### About This Task

If you configure the SLA Mon agent address under an IP interface or VLAN, you must remove the SLA Mon address before you can remove the IP address or VLAN.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Create a VLAN by specifying one of the following VLAN types:
  - a. Create a VLAN by port:
 

```
vlan create <2-4059> [name WORD<0-64>] type port-mstprstp <0-63>
[color <0-32>]
```
  - b. Create a VLAN using a user-defined protocol and specify the frame encapsulation header type:
 

```
vlan create <2-4059> [name WORD<0-64>] type protocol-mstprstp <0-63>
ipv6 [color <0-32>]
```
  - c. Create an SPBM B-VLAN:
 

```
vlan create <2-4059> [name WORD<0-64>] type spbm-bvlan [color <0-32>]
```
3. (Optional) Associate a CVLAN I-SID to the platform VLAN.
 

```
vlan i-sid <1-4059> <1-16777215> [force]
```
4. Log on to the VLAN Interface Configuration mode for the VLAN ID:
 

```
interface VLAN <1-4059>
```

## 5. Assign an IP address to a VLAN:

```
ip address {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>} [dvr-one-ip] [state-disabled]
```

## 6. (Optional) Assign a Secondary IP Interface to a VLAN:

```
ip address {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>} secondary
```

## 7. (Optional) Specify the MAC-offset value:

```
ip address <A.B.C.D/X>|<A.B.C.D> <A.B.C.D> dvr-one-ip <MAC-offset>
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#vlan create 2 type port-mstprstp 0 color 4
Switch:1(config)#vlan i-sid 2 100
Switch:1(config)#interface vlan 2
Switch:1(config-if)#ip address 192.0.2.0/24 dvr-one-ip
```

*Variable Definitions*

The following table defines parameters for the **vlan create** command.

| Variable                                  | Value                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <2-4059>                                  | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| name WORD<0-64>                           | Specifies the VLAN name. The name attribute is optional.                                                                                                                                                                                                                                                                                                                           |
| type port-mstprstp <0-63> [color <0-32>]  | Creates a VLAN by port: <ul style="list-style-type: none"> <li>&lt;0-63&gt; is the STP instance ID from 0 to 63.</li> <li>color &lt;0-32&gt; is the color of the VLAN in the range of 0 to 32.</li> </ul> <b>Note:</b><br>MSTI instance 62 is reserved for SPBM if SPBM is enabled on the switch.                                                                                  |
| type pvlan-mstprstp <0-63> [color <0-32>] | Creates a private VLAN by port: <ul style="list-style-type: none"> <li>&lt;0-63&gt; is the STP instance ID from 0 to 63.</li> <li>color &lt;0-32&gt; is the color of the VLAN in the range of 0 to 32.</li> </ul>                                                                                                                                                                  |

| Variable                                              | Value                                                                                                                                                                                                                          |
|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>type protocol-mstprstp &lt;0-63&gt; ipv6</code> | Creates a VLAN by protocol: <ul style="list-style-type: none"> <li>• <code>&lt;0-63&gt;</code> is the STP instance ID.</li> <li>• <code>color &lt;0-32&gt;</code> is the color of the VLAN in the range of 0 to 32.</li> </ul> |
| <code>type spbm-bvlan</code>                          | Creates a SPBM B-VLAN.                                                                                                                                                                                                         |

The following table defines parameters for the **ip address** command.

| Variable                                                         | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;A.B.C.D/X&gt;   &lt;A.B.C.D&gt; &lt;A.B.C.D&gt;</code> | Specifies the IP address and subnet mask in the format A.B.C.D/X or A.B.C.D A.B.C.D.                                                                                                                                                                                                                                                                                                                                                                        |
| <code>dvr-one-ip</code>                                          | Specifies that the IP address will be used as the DvR gateway IP address and will be used by all other DvR Controllers for the DvR VLAN subnet.                                                                                                                                                                                                                                                                                                             |
| <code>&lt;MAC-offset&gt;</code>                                  | Specifies a number by which to offset the MAC address from the chassis MAC address. This ensures that each IP address has a different MAC address. If you omit this variable, a unique MAC offset is automatically generated. Different hardware platforms support different ranges. To see which range is available on the switch, use the CLI command completion Help.<br><br><b>Note:</b><br>You cannot specify the mac-offset for a given secondary IP. |
| <code>secondary</code>                                           | Identifies the IP address as a Secondary IP Interface.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>state-disabled</code>                                      | Creates the IP interface in an administratively disabled state. This parameter is useful if you want to preconfigure an IP interface, including the routing protocol configuration for that interface, and enable it later during a maintenance window. This parameter applies only to the primary IP address. By default, the switch enables an IP interface after you configure the primary IP address.                                                   |

The following table defines parameters for the `vlan i-sid` command.

| Variable                        | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;1-4059&gt;</code>     | Specifies the VLAN ID. Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>&lt;0-16777215&gt;</code> | Specifies the service instance identifier (I-SID). You cannot use I-SID 0x00ffffff. The system reserves this I-SID to advertise the virtual BMAC in an SMLT dual-homing environment. This value is the same for the primary and secondary VLANs.                                                                                                                                                                                                              |
| <code>force</code>              | Specifies the software must replace the existing VLAN-to-I-SID mapping, if one exists.                                                                                                                                                                                                                                                                                                                                                                        |

## Create a Private VLAN

### About This Task

You can create a private VLAN and set the port type. The primary and secondary VLAN IDs are associated with the same MTSI, the secondary VLAN inherits the primary VLAN configuration. You cannot create another VLAN with the same VLAN ID as the secondary VLAN. The secondary VLAN cannot be any other type of VLAN other than a secondary VLAN.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Create a private VLAN:
 

```
vlan create <2-4059> type pvlan-mstprstp secondary <2-4059>
```
3. Specify a name for the VLAN:
 

```
vlan create <2-4059> name
```

## 4. Enter GigabitEthernet Interface Configuration mode:

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## 5. Set the port type:

```
private-vlan <isolated|promiscuous|trunk>
```

**Note**

If the port is a member of an MLT, the port inherits the private VLAN port type of the MLT.

## 6. Exit to Global Configuration mode:

```
exit
```

## 7. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

## 8. Add ports to the primary VLAN:

```
vlan members add <1-4059> {slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]}
```

**Example**

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# vlan create 2 type pvlan-mstprstp 6 secondary 5
```

```
Switch:1(config)# interface gigabitethernet 1/36
```

```
Switch:1(config-if)# private-vlan isolated
```

```
Switch:1(config-if)# exit
```

```
Switch:1(config)# interface vlan 2
```

```
Switch:1(config-if)# vlan members add 2 1/36
```

*Variable Definitions*

Use the data in the following table to use the **vlan create** command.

| Variable                                      | Value                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;2-4059&gt;</code>                   | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| <code>name WORD&lt;0-64&gt;</code>            | Specifies the VLAN name. The name attribute is optional.                                                                                                                                                                                                                                                                                                                           |
| <code>type pvlan-mstprstp &lt;0-63&gt;</code> | Creates a private VLAN by port. The variable <code>&lt;0-63&gt;</code> is the STP instance ID from 0 to 63.<br><br><b>Note:</b><br>MSTI instance 62 is reserved for SPBM if SPBM is enabled on the switch.                                                                                                                                                                         |
| <code>secondary&lt;2-4059&gt;</code>          | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |

Use the data in the following table to use the `private vlan port type` command.

| Variable                                        | Value                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;isolated promiscuous trunk&gt;</code> | Specifies the port type. If not specified, the port type defaults to None. <ul style="list-style-type: none"> <li>Isolated: An Isolated port can belong only to one private VLAN</li> <li>Promiscuous: A Promiscuous port can belong to many private VLANs</li> <li>Trunk: A Trunk port can belong to many private VLANs, is tagged, and can also belong to non-private VLANs</li> </ul> |
| <code>no private-vlan</code>                    | Port defaults to type None.                                                                                                                                                                                                                                                                                                                                                              |
| <code>default private-vlan</code>               | Port defaults to type None.                                                                                                                                                                                                                                                                                                                                                              |

#### Note

If there are other non-private VLANs using the defined port, the following message is displayed: All non private VLANs using this interface will be removed once this port becomes a member of a private VLAN. Ports with private-vlan type of isolated or promiscuous may only contain private VLANs. Do you wish to continue (y/n) ?

Use the data in the following table to use the `interface vlan` and `vlan members add` commands.

| Variable                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;1-4059&gt;</code> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

## Assign an IP Address to a VLAN

Assign an IP address to a VLAN so that it supports routing operations.

### Before You Begin

- You must create the VLAN.
- Activate IP forwarding globally.
- If you use this procedure to create a Secondary IP Interface, you must first create the primary IP address.

## About This Task

If an IP interface is configured without specifying the VRF instance, it maps to VRF 0 by default.

## Procedure

1. Enter VLAN Interface Configuration mode:
 

```
enable

configure terminal

interface vlan <1-4059>
```
2. Assign a primary IP address to a VLAN:
 

```
ip address {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>} [dvr-one-ip] [name WORD
<0-64>] [state-disabled]
```
3. (Optional) Assign a Secondary IP Interface to a VLAN:
 

```
ip address {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>} secondary
```
4. (Optional) If required, associate the VLAN with a VRF:
 

```
vrf WORD<1-16>
```

## Example

Add a primary IP address to the VLAN and configure it as the DvR-One-IP interface. Give the address a name.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface vlan 2
Switch:1(config-if)#ip address 192.0.2.5 255.255.255.0 dvr-one-ip name Boston
```

## Variable Definitions

The following table defines parameters for the **ip address** command.

| Variable                        | Value                                                                                                                                           |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <A.B.C.D/X> <A.B.C.D> <A.B.C.D> | Specifies the IP address and subnet mask in the format A.B.C.D/X or A.B.C.D A.B.C.D.                                                            |
| <i>dvr-one-ip</i>               | Specifies that the IP address will be used as the DvR gateway IP address and will be used by all other DvR Controllers for the DvR VLAN subnet. |
| <i>name WORD &lt;0-64&gt;</i>   | Specifies the name associated with the IP address on a VLAN. This parameter does not apply to all hardware platforms.                           |

| Variable              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>secondary</i>      | Identifies the IP address as a Secondary IP Interface.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>state-disabled</i> | Creates the IP interface in an administratively disabled state. This parameter is useful if you want to preconfigure an IP interface, including the routing protocol configuration for that interface, and enable it later during a maintenance window. This parameter applies only to the primary IP address. By default, the switch enables an IP interface after you configure the primary IP address.<br><br><b>Note:</b> This parameter is not saved in the configuration file. |

The following table defines parameters for the **vrf** command.

| Variable                | Value                          |
|-------------------------|--------------------------------|
| <i>WORD&lt;0-16&gt;</i> | Specifies the VRF of the VLAN. |

## **NEW!** Display All Configured IP Addresses

### About This Task

Use this procedure to verify the configuration of all IP addresses, including Secondary IP Interfaces on VLANs. You cannot create Secondary IP Interfaces on brouter ports.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display all configured IP addresses:  
`show ip address`
3. Display all primary IP addresses:  
`show ip address primary`
4. Display all secondary IP addresses:  
`show ip address secondary`
5. Display IP addresses associated with a VLAN:  
`show ip address vlan [vlan-id[-vlan-id] [, ...]]<1-4059>`
6. Display IP addresses associated with a VRF name:  
`show ip address vrf WORD<1-16>`
7. Display IP addresses associated with a VRF ID:  
`show ip address vrfids WORD<0-512>`

## View the IPv4 and IPv6 Interface Configuration on a VLAN

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Verify the interface configuration on the VLAN:

For IPv4, enter: `show interfaces vlan ip`

For IPv6, enter: `show ipv6 interface vlan`

## Example

Verify the IPv4 interface configuration on the VLAN:

```
Switch:1(config-if)# show interfaces vlan ip
```

```
=====
```

```
                                Vlan Ip
```

```
=====

## **NEW!** Remove All Secondary IP Interfaces From a VLAN

Perform this procedure to remove all secondary IP addresses on a VLAN simultaneously.

### About This Task

To remove specific secondary IP addresses from a VLAN, use the **no** operator with the **ip address {A.B.C.D} secondary** command on the VLAN.

### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Remove all Secondary IP Interfaces from a VLAN:
 

```
clear secondary-ips vlan <1-4059>
```

## Performing a general VLAN action

Perform a general VLAN action to initiate a specific function on a VLAN, such as clearing learned MAC addresses or ARP entries from the forwarding database by performing this procedure.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Perform a general VLAN action:
 

```
vlan action <1-4059> {none|flushMacFdb|flushArp|flushIp|flushDynMemb|triggerRipUpdate|all}
```

### Example

Perform a general VLAN action:

```
Switch(config)# vlan action 1 none

Switch(config)# vlan action 1 flushMacFdb

Switch(config)# vlan action 1 flushIp
```

```
Switch(config)# vlan action 1 flushDynMemb
```

### Variable Definitions

Use the data in the following table to use the **vlan action** command.

| Variable                | Value                                                                                                                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>none</i>             | Configures action to none. This action performs no updates.                                                                                                                                                               |
| <i>flushMacFdb</i>      | Configures action to flushMacFdb. This action removes the learned MAC addresses from the forwarding database for the selected VLAN.                                                                                       |
| <i>flushArp</i>         | Configures action to flushArp. This action removes the ARP entries from the address table for the selected VLAN.                                                                                                          |
| <i>flushIp</i>          | Configures action to flushIp. This action removes the learned IP addresses from the forwarding table for the selected VLAN.                                                                                               |
| <i>flushDynMemb</i>     | Configures action to flushDynMemb. This action removes port members not configured as static from the list of active port members of a policy-based VLAN, and removes MAC addresses learned on those ports for this VLAN. |
| <i>flushDynMemb</i>     | Configures action to flushDynMemb. This action removes port members not configured as static from the list of active port members of a policy-based VLAN, and removes MAC addresses learned on those ports for this VLAN. |
| <i>triggerRipUpdate</i> | Configures action to triggerRipUpdate.                                                                                                                                                                                    |
| <i>all</i>              | Configures action to all and performs all preceding actions.                                                                                                                                                              |

## Configuring static MAC addresses for a VLAN

Configure the static MAC address parameters.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure a static MAC address of a VLAN:

```
vlan mac-address-static <1-4059> <0x00:0x00:0x00:0x00:0x00:0x00>
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

## Example

Configure a static MAC address of a VLAN:

```
Switch(config)# vlan mac-address-static 1 0x00:0x00:0x00:0x00:0x00:0x01
1/1
```

### Variable Definitions

Use the data in the following table to use the **vlan mac-address-static** command.

| Variable                                               | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                               | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <0x00:0x00:0x00:0x00:0x00:0x00>                        | Indicates the MAC address.                                                                                                                                                                                                                                                                                                                                                                                                 |
| {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |

## Limit MAC Address Learning

Configure the MAC security feature to control traffic from specific number of MAC addresses. The total number of MAC addresses that you can configure are fixed. The switch help text shows the maximum MAC addresses a port can learn in non-SPBM configurations. In an SPBM configuration, the maximum value is reduced by half.

### About This Task

This feature limits the number of forwarding database (FDB) entries learned on a particular port to a user-specified value. After the number of learned forwarding database entries reaches the maximum limit, MAC learning stops on that port.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface mlt <1-512>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Protect the FDB from hits by too many MAC addresses:

```
mac-security [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] limit-learning enable [max-addr <max-addr>]
```

## Example

Protect the FDB from hits by too many MAC addresses:

```
Switch:1(config)#interface gigabitethernet 1/1
Switch:1(config-if)#mac-security limit-learning enable
Switch:1(config-if)#mac-security limit-learning max-addr 5000
```

## Variable Definitions

Use the data in the following table to use the **mac-security limit-learning** command.

| Variable                                                                                                                                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>enable</i>                                                                                                                                        | Limits the MAC learning for the port. After the number of addresses reaches the maximum, the port disables packet forwarding and drops packets.<br>If you enable <i>limit-learning</i> , the FDB entry for each port is limited to the number you specify in <i>max-addr</i> .                                                                                                                                                                        |
| <i>max-addr</i><br><max-addr>                                                                                                                        | Specifies the maximum number of MAC addresses to learn. After the number of addresses reaches the maximum, the port disables packet forwarding and drops packets. The default is 1024. Depending on the hardware platform, the parameter range can vary. Use the CLI Help to see the available range for the switch.                                                                                                                                  |
| <i>port</i> { <i>slot/</i><br><i>port</i> [/ <i>sub-</i><br><i>port</i> ] [ <i>-slot/</i><br><i>port</i> [/ <i>sub-</i><br><i>port</i> ]]<br>[,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.<br>Use this parameter to apply the change to multiple ports without changing CLI modes. |

## Configuring the forwarding database timeout globally

Use the following procedure to configure the aging time globally for the forwarding database.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enter the following command:
 

```
mac-address-table aging-time <10-1000000>
```

### Variable Definitions

Use the data in the following table to use the **mac-address-table** command.

| Variable                  | Value                                                                                                     |
|---------------------------|-----------------------------------------------------------------------------------------------------------|
| <i>aging-time</i>         | Specifies the timeout period for dynamically learned mac addresses on the vlan. The default value is 300. |
| <i>&lt;10-1000000&gt;</i> | Specifies the range for the aging time.                                                                   |

## Adding or removing ports in a VLAN

Add or remove the ports in a VLAN to configure the ports in the VLAN.

### Procedure

1. Enter Interface Configuration mode:
 

```
enable

configure terminal

interface GigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...] } or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Add ports in a VLAN:
 

```
vlan members add <1-4059> {slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...] } [{portmember|static|notallowed}]
```
3. Remove ports in a VLAN:
 

```
vlan members remove <1-4059> {slot/port[/sub-port]} [-slot/port[/sub-
port]] [,...] } [{portmember|static|notallowed}]
```

## Example

Add ports in a VLAN:

```
Switch(config-if)#vlan members add 1 1/2 static
```

Remove ports in a VLAN:

```
Switch(config-if)#vlan members remove 1 1/2 notallowed
```

## Variable Definitions

Use the data in the following table to use the **vlan members add** and **vlan members remove** commands.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;1-4059&gt;</code>                                        | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |
| <code>portmember</code>                                            | Configures the port type as port member.                                                                                                                                                                                                                                                                                                                                                                                   |

## Add a Source MAC Addresses for a VLAN

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Add a VLAN source MAC address:

```
vlan srcmac <1-4059> <0x00:0x00:0x00:0x00:0x00:0x00>
```

### Example

Add a VLAN source MAC address:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#vlan srcmac 10 0x00:0x00:0x00:0x00:0x00:0x11
```

## Configure NLB support

Use Microsoft Network Load Balancing (NLB) to share the workload among multiple clustering servers. For information about software scaling capabilities, see [VOSS Release Notes](#).

### Before You Begin

- For all modes, configure an IP address on the VLAN enabled with NLB.
- To switch between Unicast NLB and Multicast NLB, you must first disable the NLB support.

### About This Task

Use the following procedure to configure NLB support on an IP interface to enable or disable NLB support.

The default value is NLB support disabled.

#### Note

SPBM supports Network Load Balancing (NLB) Unicast and Multicast modes.

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```

2. Enable NLB support on an interface:

```
nlb-mode unicast
```

Or,

```
nlb-mode multicast
```

To switch from one nlb-mode to another, you must first disable the NLB support, and then enter the new nlb-mode.

3. (Optional) Disable NLB support on an interface:

```
no nlb-mode
```

### Example

Configure unicast mode for VLAN 2, and then switch to multicast mode.

```
Switch:1(config)#interface vlan 2
Switch:1(config-if)#nlb-mode unicast
Switch:1(config-if)#no nlb-mode
Switch:1(config-if)#nlb-mode multicast
```

## Configuring a tagged port to discard untagged frames

Configure a tagged port to discard all untagged packets so that the frame is not classified into the default VLAN for the port.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure a tagged port to discard untagged frames:

```
untagged-frames-discard [port {slot/port[/sub-port] [-slot/port[/sub-  
port]][,...]}
```

3. Discard a tagged frame on an untagged port:

```
tagged-frames-discard [port {slot/port[/sub-port] [-slot/port[/sub-  
port]][,...]] enable
```

4. Untag the default VLAN on a tagged port:

```
untag-port-default-vlan [port {slot/port[/sub-port] [-slot/port[/sub-  
port]][,...]] enable
```

### Example

Configure a tagged port to discard untagged frames:

```
Switch(config-if)#untagged-frames-discard port 1/1
```

Discard a tagged frame on an untagged port:

```
Switch(config-if)#tagged-frames-discard port 1/1 enable
```

Untag the default VLAN on a tagged port:

```
Switch(config-if)#untag-port-default-vlan port 1/2 enable
```

### Variable Definitions

Use the data in the following table to use optional parameters with the **untagged-frames-discard** command.

| Variable                                                         | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port][-slot/port[/sub-port]][,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Configuring SLPP

Enable the Simple Loop Prevention Protocol (SLPP) globally and for a VLAN to detect a loop and automatically stop it. The VLAN configuration controls the boundary of SLPP-PDU transmission.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable SLPP:  

```
slpp enable
```
3. Configure the transmission interval:  

```
slpp tx-interval <500-5000>
```
4. Add a VLAN to the transmission list:  

```
slpp vid <1-4059>
```

### Example

Enable SLPP:

```
Switch(config)# slpp enable
```

Configure the transmission interval to 5000 milliseconds:

```
Switch(config)# slpp tx-interval 5000
```

Add a VLAN, with the VLAN ID 2, to the transmission list:

```
Switch(config)# slpp vid 1
```

### Variable Definitions

Use the data in the following table to use the **slpp** command.

| Variable              | Value                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>enable</i>         | Enables or disables the SLPP operation. You must enable the SLPP operation to enable the SLPP packet transmit and receive process.<br>If you disable the SLPP operation, the system sends no SLPP packets and discards received SLPP packets.<br>To set this option to the default value, use the <b>default</b> operator with the command. The default is disabled. |
| <i>500-5000</i>       | Configures the SLPP packet transmit interval, expressed in milliseconds in a range from 500-5000. The default value is 500. To set this option to the default value, use the <b>default</b> operator with the command.                                                                                                                                               |
| <i>&lt;1-4059&gt;</i> | Adds a VLAN, by VLAN ID, to a SLPP transmission list. Use the <b>no</b> operator to remove this configuration.                                                                                                                                                                                                                                                       |

### Job aid

The following table provides SLPP values.

**Table 308: SLPP values**

| Enable SLPP           | Setting                         |
|-----------------------|---------------------------------|
| Access SMLT           | Yes                             |
| Core SMLT             | No                              |
| Primary switch        |                                 |
| Packet Rx threshold   | 5                               |
| Transmission interval | 500 milliseconds (ms) (default) |
| Secondary switch      |                                 |
| Packet Rx threshold   | 50                              |
| Transmission interval | 500 ms (default)                |

## Configuring SLPP packet-rx on a port

Enable SLPP by port to detect a loop and automatically stop it.

### Important

To provide protection against broadcast and multicast storms, as a best practice, enable Rate Limiting for broadcast traffic and multicast traffic.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure SLPP on a port:

```
slpp port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} packet-  
rx [packet-rx-threshold <1-500>]
```

## Example

```
Switch(config-if)# slpp port 1/1 packet-rx-threshold 5
```

Variable Definitions

Use the data in the following table to use the **slpp port** command.

| Variable                                               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-500>                                                | <p>Specifies the SLPP reception threshold on the ports, expressed as an integer. The packet reception threshold specifies how many SLPP packets the port receives before it is administratively disabled. To set this option to the default value, use the <b>default</b> operator with the command. The default value is 1.</p> <p><b>Note:</b><br/>As a best practice, configure the rx-threshold above 50 slpp packets only on lightly loaded switches. If you configure the rx-threshold to a value greater than 50 on a heavily loaded switch and a loop occurs, the system can experience high CPU utilization.</p> |
| {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]} | <p>Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.</p>                                                                                                                                                                                                                                                      |

Job aid

The following table provides the SLPP values.

**Table 309: SLPP values**

| Enable SLPP           | Setting                         |
|-----------------------|---------------------------------|
| Access SMLT           | Yes                             |
| Core SMLT             | No                              |
| Primary switch        |                                 |
| Packet Rx threshold   | 5                               |
| Transmission interval | 500 milliseconds (ms) (default) |
| Secondary switch      |                                 |
| Packet Rx threshold   | 50                              |
| Transmission interval | 500 ms (default)                |

## Configuring SLPP packet-tx on a VLAN

Enable SLPP by VLAN to detect a loop and automatically stop it. This configuration controls the boundary of SLPP-PDU transmission.

### Important

To provide protection against broadcast and multicast storms, as a best practice, enable Rate Limiting for broadcast traffic and multicast traffic.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable SLPP:

```
slpp enable
```

3. Configure the transmission interval:

```
slpp tx-interval <500-5000>
```

4. Add a VLAN to the transmission list:

```
slpp vid <1-4059>
```

### Example

Log on to the VLAN Interface Configuration mode:

```
Switch(config)# interface vlan 2
```

Enable SLPP:

```
Switch(config-if)# slpp enable
```

Configure the transmission interval to 500 milliseconds:

```
Switch(config-if)# slpp tx-interval 500
```

Add a VLAN, with the VLAN ID of 2, to the transmission list:

```
Switch(config-if)# slpp vid 2
```

### Variable Definitions

Use the data in the following table to use the **slpp** command.

| Variable              | Value                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>enable</i>         | Activates or disables the SLPP operation. You must enable the SLPP operation to enable the SLPP packet transmit and receive process.<br>If you disable the SLPP operation, the system sends no SLPP packets and discards received SLPP packets.<br>To set this option to the default value, use the <b>default</b> operator with the command. The default is disabled. |
| <i>500-5000</i>       | Configures the SLPP packet transmit interval, expressed in milliseconds in a range from 500-5000. The default value is 500. To set this option to the default value, use the <b>default</b> operator with the command.                                                                                                                                                 |
| <i>&lt;1-4059&gt;</i> | Adds a VLAN, by VLAN ID, to a SLPP transmission list. Use the <b>no</b> operator to remove this configuration.                                                                                                                                                                                                                                                         |

### Viewing SLPP information

Use SLPP information to view loop information.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View SLPP information:  
show slpp

#### Example

```
Switch# show slpp
```

```
=====
                        SLPP Info
=====
      operation : enabled
      tx-interval : 500
      vlan : 2
```

### Viewing SLPP information for a port

Show SLPP information for a port so that you can view the loop information for a port.

## Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View SLPP information for a port:

```
show slpp interface GigabitEthernet [{slot/port[/sub-port]}[-slot/
port[/sub-port]][,...]]
```

3. Clear SLPP packet RX counters:

```
clear slpp stats port [{slot/port[/sub-port]}[-slot/port[/sub-port]]
[,...]]
```

## Example

```
Switch# show slpp interface GigabitEthernet 1/7
```

```

=====
                                Port Interface
=====
PORT          PKT-RX      PKT-RX      INCOMING      SLPP PDU
NUM           COUNT      THRESHOLD   VLAN ID       ORIGINATOR
-----
1/7           enabled    5
-----
PORT          PKT-RX      TIME LEFT
NUM           COUNT      TO CLEAR RX COUNT
-----
1/7           29         21600
=====

```

### Variable Definitions

Use the data in the following table to use the **show slpp interface GigabitEthernet** command.

| Variable                                                         | Value                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Configuring spoof detection

Configure spoof detection to prevent IP spoofing.

For more information about this feature, see [Prevention of IP Spoofing within a VLAN](#) on page 4102.

**Procedure**

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable or disable spoof detection:

```
spoof-detect [port {slot/port[-slot/port] [,...]}] [enable]
```

```
no spoof-detect [port {slot/port[-slot/port] [,...]}] [enable]
```

3. Enable or disable auto-recovery on a port:

```
auto-recover-port [port {slot/port[-slot/port] [,...]}] [enable]
```

```
no auto-recover-port [port {slot/port[-slot/port] [,...]}] [enable]
```

**Example**

Enable spoof detection:

```
Switch(config-if)# spoof-detect port 1/1 enable
```

Enable autorecovery on a port:

```
Switch(config-if)# auto-recover-port port 1/1 enable
```

**View VLAN Information**

View the VLAN information to display the basic configuration for all VLANs or a specified VLAN.

**Procedure**

1. To enter User EXEC mode, log on to the switch.

2. View VLAN information:

```
show vlan basic <1-4059>
```

3. View advanced parameters:

```
show vlan advance <1-4059>
```

**Example**

View VLAN information for VLAN 2:

```
Switch:1>show vlan basic 2
```

```
=====
```

```

=====
                        Vlan Basic
=====
VLAN
ID   NAME           TYPE           INST
                                ID  PROTOCOLID  SUBNETADDR  SUBNETMASK  VRFID  ORIGIN
-----
2    VLAN-2          byPort         0   none        N/A         N/A         0      CONFIG

```

## View VLAN information:

```

Switch:1>show vlan basic

### Variable Definitions

Use the data in the following table to use optional parameters with the **show vlan basic** and **show vlan advance** commands.

| Variable | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

### View Private VLAN Information

You can view the private VLAN information to display the primary and secondary VLANs and I-SIDs, and also view the private VLAN port types.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View private VLAN information:  
show vlan private-vlan <1-4059>
3. View private VLAN port information:  
show interfaces gigabitethernet private-vlan

#### Example

View VLAN information for private VLAN :

```
Switch:1(config)# show vlan private-vlan
```

```

All 1 out of 1 Total Num displayed

## Viewing router port information

View the router port information to display the router port VLAN information for all VLANs on the device or for the specified VLAN.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View router port information:

```
show vlan router-port
```

### Example

View router port information:

```
Switch:1> show vlan router-port
```

| Vlan Id | Port | VrfId |
|---------|------|-------|
| 2202    | 1/11 | 0     |

All 1 out of 1 Total Num of Vlan Router Port Entries displayed

## Viewing VLAN port member status

View the VLAN port member status to display the port member status for all VLANs on the device or for the specified VLAN.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View VLAN port member status:

```
show vlan members [<1-4059>][null-vlan][port {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]]
```

### Example

View VLAN port member status:

```
Switch:1> show vlan members port 1/2
```

| Vlan Port |             |               |                  |
|-----------|-------------|---------------|------------------|
| VLAN ID   | PORT MEMBER | ACTIVE MEMBER | STATIC MEMBER    |
|           |             |               | NOT_ALLOW MEMBER |

```
-----  
2    1/2,1/5-1/8,1/11,  1/2,1/5-1/8,1/11,  
     1/14,1/26,1/38    1/14,1/26,1/38  
  
3    1/2,1/5-1/8,1/14,  1/2,1/5-1/8,1/14,  
     1/26,1/38          1/26,1/38  
  
4    1/1-1/2,1/5-1/8,  1/1-1/2,1/5-1/8,  
     1/13-1/14,1/25-   1/13-1/14,1/25-  
     1/26,1/37-1/38    1/26,1/37-1/38  
  
100  1/2,1/14,1/23-     1/2,1/14,1/23-  
     1/24,1/26-1/28,   1/24,1/26-1/28,  
     1/38               1/38  
  
300  1/2,1/5-1/8,1/14,  1/2,1/5-1/8,1/14,  
     1/26,1/38          1/26,1/38
```

### Variable definitions

Use the data in the following table to use optional parameters with the **show vlan members** command.

| Variable                                                          | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>null-vlan</code>                                            | Displays port members of the NULL VLAN. This is a place holder VLAN for ports that are not members of any port-based VLAN. When a port is removed from all port-based VLANs, it is added to the NULL VLAN as a port member. The NULL VLAN is an internal construct and cannot be deleted.                                                                                                                                                                                                                                                                                                                                                                          |
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]][,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. If you do not specify a port, the command shows information for all the ports.                                                                                                                                                                                                                       |
| <code>&lt;1-4059&gt;</code>                                       | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <code>vrf-scaling</code> and <code>spbm-config-mode</code> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.<br><br><b>Note:</b><br>Entering a VLAN ID is optional. If you enter a VLAN ID the command shows information for the specified VLAN or port. Without the VLAN ID the command shows information for all the configured VLANs. |

## Viewing VLAN source MAC addresses

View the VLAN source MAC addresses to display the source MAC address for a source MAC-based VLAN on the device or for the specified VLAN.

### Procedure

View VLAN source MAC addresses:

```
show vlan src-mac [<1-4059>]
```

## Example

View VLAN source MAC addresses:

```
Switch(config)# show vlan src-mac
```

```
=====
                        Vlan Srcmac
=====
VLAN_ID   MAC_ADDRESS
-----
10        00:00:00:00:00:11

All 1 out of 1 Total Num of Vlan Srcmac Entries displayed
```

## Viewing VLAN forwarding database information

Use this procedure to display the MAC addresses that are learned or statically configured for a VLAN. In order to learn you have to be connected to another switch or host and receive some traffic.

### Note

The VSP 4450 Series does not display a log message when MAC learning maximum limit is reached.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. View VLAN forwarding database information:

```
show vlan mac-address-entry [<1-4059>]
```

## Example

View VLAN forwarding database information:

```
Switch:1> show vlan mac-address-entry
```

```
=====
                        Vlan Fdb
=====

1    learned   f8:15:47:e1:80:0c  Port-1/2   false  -
2    learned   32:20:d3:81:00:77  Port-1/9   false  -
4    learned   b4:a9:5a:2b:78:31  Port-2/1   false  -

3 out of 3 entries in all fdb(s) displayed.

```

### Variable Definitions

Use the data in the following table to use optional parameters with the **show vlan mac-address-entry** command.

| Variable                            | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                            | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| mac <0x00:0x00:0x00:0x00:0x00:0x00> | Specifies the MAC address.                                                                                                                                                                                                                                                                                                                                                                                                 |
| port {slot/port[-slot/port][,...]}  | Specifies the port or port list.                                                                                                                                                                                                                                                                                                                                                                                           |
| spbm-tunnel-as-mac                  | Displays where entries are learned. The TUNNEL column indicates where in the SPBM network an entry is learned.                                                                                                                                                                                                                                                                                                             |

## Viewing manual edit MAC addresses

Use the procedure to view the list of manual edit MAC addresses and the associated ports configured as allow-mac for MAC security.

### Procedure

View manual edit MAC addresses:

```
show vlan manual-edit-mac
```

### Example

View manual edit MAC addresses:

```
Switch(config)# show vlan manual-edit-mac
```

```

=====
Manual Edit Mac
=====
MAC ADDRESS      PORTS
-----

```

```
00:00:00:00:00:55 1/3
00:00:00:00:00:66 1/3

All 2 out of 2 Total Num of Manual Edit Mac Entries displayed
```

## View Port-Level MAC Security

### Note

This procedure only applies to VSP 4450 Series, and VSP 4900 Series.

View port-level MAC security to review the configuration.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View port-level MAC security for limit-learning:  
show interfaces gigabitethernet limit-fdb-learning [{slot/port[-slot/  
port][,...]]

### Example

View port-level MAC security for limit-learning:

```
Switch:1# show interfaces gigabitethernet limit-fdb-learning 1/4-1/5
```

```
=====
                        Port limit-fdb-learning
=====

2          unicast      disable
22         multicast    multicast 1/19-1/21  2 3
Total Entries: 2

```

## Enable DvR on a Layer 2 VSN (VLAN)

### Before You Begin

- Ensure that the VLAN on which to enable DvR exists and is associated with an I-SID.

### About This Task

On a Controller, DvR must be manually enabled at the Layer 2 VSN (VLAN) level.

Use this procedure to configure a gateway IPv4 address for a Layer 2 VSN (VLAN) subnet and then enable DvR on it. This address is pushed, along with other Layer 3 configuration information, from the Controllers to the Leaf nodes within the domain, so that the Leaf nodes can create a gateway IP service for each DvR-enabled Layer 2 VSN.

#### Note

Optionally, you can now use a single IP address in the subnet for every Controller by configuring the DvR VLAN IP to be the same as the DvR GW IP.

### Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Configure a gateway IPv4 address for the VLAN.

```
dvr gw-ipv4 {A.B.C.D}
```

#### Important

Ensure that you configure the same gateway IPv4 address on all Controllers in the domain that belong to a Layer 2 VSN (VLAN).

3. Enable DvR.

```
dvr enable
```

By default, DvR is disabled.

### Example

Enable DvR on the Global Router VLAN.

```

Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config-if)#vlan create 200 type port-mstprstp 0

```

```
Switch:1(config-if)#vlan i-sid 200 20200
Switch:1(config-if)#interface vlan 200
Switch:1(config-if)#dvr gw-ipv4 192.0.2.1
Switch:1(config-if)#dvr enable
Switch:1(config-if)#ip address 192.0.2.2 255.255.0.0
```

**Enable DvR on a VLAN associated to a VRF:**

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config-if)#vlan create 400 type port-mstprstp 0
Switch:1(config-if)#vlan i-sid 400 20200
Switch:1(config-if)#interface vlan 400
Switch:1(config-if)#vrf vrf500
Switch:1(config-if)#dvr gw-ipv4 198.51.100.1
Switch:1(config-if)#dvr enable
Switch:1(config-if)#ip address 198.51.100.2 255.255.0.0
```

*Variable definitions*

Use the data in the following table to use the **dvr gw-ipv4** command.

| Variable  | Value                                            |
|-----------|--------------------------------------------------|
| {A.B.C.D} | Specifies the gateway IPv4 address for the VLAN. |

Configure a Single IP Address for All DvR Controllers on a VLAN Subnet

**Before You Begin**

- Ensure that the VLAN on which to enable DvR exists and is associated with an I-SID.

**About This Task**

On a Controller, DvR must be manually enabled at the Layer 2 VSN (VLAN) level.

Use this procedure to configure a single IP address to be used for both the DvR GW IP and the VLAN IP in the DvR VLAN. This IP address represents the DvR GW IP address used by all DvR Controllers for the same DvR VLAN. When you configure a DvR VLAN in this way, the Controllers no longer have a unique VLAN IP address.

**Note**

Optionally, you can use two different IP address for the DvR VLAN and the DvR GW IP.

**Procedure**

1. Enter VLAN Interface Configuration mode:

```
enable

configure terminal

interface vlan <1-4059>
```

2. Configure a single IP address for both the DvR GW IP and the VLAN IP in the DvR VLAN.

```
ip address {<A.B.C.D/X>|<A.B.C.D> <A.B.C.D>} dvr-one-ip
```

3. Enable DvR.

```
dvr enable
```

By default, DvR is disabled.

### Example

Enable DvR.

```
Switch:1>en
Switch:1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config-if)#vlan create 200 type port-mstprstp 0
Switch:1(config-if)#vlan i-sid 200 20200
Switch:1(config-if)#interface vlan 200
Switch:1(config-if)#ip address 192.0.2.1 255.255.0.0 dvr-one-ip
Switch:1(config-if)#dvr enable
```

### Variable Definitions

The following table defines parameters for the **ip address** command.

| Variable                        | Value                                                                                         |
|---------------------------------|-----------------------------------------------------------------------------------------------|
| <A.B.C.D/X> <A.B.C.D> <A.B.C.D> | Specifies the IP address and subnet mask in the format A.B.C.D/X or A.B.C.D A.B.C.D.          |
| <i>dvr-one-ip</i>               | Specifies the IP address used for the DvR gateway IP address and the VLAN IP in the DvR VLAN. |

## VLAN Configuration using EDM

This section describes how to configure and manage Virtual Local Area Networks (VLAN) using Enterprise Device Manager (EDM).

### Configure a VLAN on a Port

Configure a VLAN on a port.

#### Procedure

1. In the Device Physical View tab, select a port or multiple ports.
2. In the Navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **VLAN** tab.
5. To perform tagging, select **PerformTagging**.
6. To discard tagged frames, select **DiscardTaggedFrames**.
7. To discard untagged frames, select **DiscardUntaggedFrames**.

8. To use the Untag Default VLAN feature, select **UntagDefaultVlan**.

**Important**

Enable tagging on the port before you configure UntagDefaultVlans.

9. Enter a default VLAN ID.  
 10. To enable spoof detect, select **SpoofDetect**.  
 11. In the Classification area, select the types of VLAN to enable.  
 12. In the **Classification** area, select the Private VLAN port type.  
 See [Create a Private VLAN](#) on page 4151 for more information.  
 13. Select **Apply**.  
 14. Select **Close**.

**VLAN** field descriptions

Use the data in the following table to use the **VLAN** tab.

| Name                         | Description                                                                                                                                                                                                                              |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PerformTagging</b>        | If checked, this port is a tagged (Trunk) Port. It can belong to multiple port-based VLANs and a VLAN tag is inserted in every frame it transmits. If it is not checked, the port is an untagged (Access) port. The default is disabled. |
| <b>VlanIdList</b>            | Identifies which VLANs this port is assigned.                                                                                                                                                                                            |
| <b>DiscardTaggedFrames</b>   | If selected, and the port is untagged (an access port), tagged frames received on the port are discarded by the forwarding process. If clear, tagged frames are processed normally. The default is disabled.                             |
| <b>DiscardUntaggedFrames</b> | If selected and the port is tagged (a trunk port), untagged frames received on the port are discarded by the forwarding process. If clear, untagged frames are processed normally. The default is disabled.                              |
| <b>UntagDefaultVLAN</b>      | If selected, even if the port is tagged (a trunk port), frames forwarded to the default VLAN for the port are not tagged. The default is disabled.                                                                                       |
| <b>UntaggedVlanIds</b>       | Identifies which VLANs this port is associated with as untagged.                                                                                                                                                                         |
| <b>DefaultVlanId</b>         | Specifies the VLAN ID assigned to untagged frames received on this trunk port that match no policy-based VLAN to which the port belongs.                                                                                                 |
| <b>SpoofDetect</b>           | Enables or disables spoof detection on the specified port.                                                                                                                                                                               |

| Name                                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Protocol</b>                                                                                 | Enables protocol-based VLAN on the port. This feature is always enabled.                                                                                                                                                                                                                                                                                                                                      |
| <b>PrivateVlanPortType</b>                                                                      | Specifies the port type for a Private VLAN. If not specified, the port type defaults to None. <ul style="list-style-type: none"> <li>Isolated: An Isolated port can belong only to one private VLAN</li> <li>Promiscuous: A Promiscuous port can belong to many private VLANs.</li> <li>Trunk: A Trunk port can belong to many private VLANs, is tagged, and can also belong to non-private VLANs.</li> </ul> |
| <b>Origin</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series and XA1400 Series. | Specifies the origin of VLAN configuration on the port, either manually configured through CLI or EDM, or dynamically configured through Auto-sense.                                                                                                                                                                                                                                                          |

## Configure the VLAN Feature on an Extreme Integrated Application Hosting Port

### Note

This procedure only applies to VSP 4900 Series and VSP 7400 Series.

### About This Task

Perform this procedure to configure the VLAN feature on an Extreme Integrated Application Hosting (IAH) port.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **VLAN** tab.
4. Select **PerformTagging**, to enable tagging.
5. Select **DiscardTaggedFrames**, to discard tagged frames.
6. Select **DiscardUntaggedFrames**, to discard untagged frames.
7. Select **UntagDefaultVlan**, to enable the Untag Default VLAN feature.

### Important

You must enable tagging on the IAH port before you enable the Untagging Default VLANs feature.

8. In the **DefaultVlanId** field, enter a default VLAN ID.
9. Select **SpoofDetect**, to enable spoof detection.
10. In the **PrivateVlanPortType** field, select a type.
11. Select **Apply**.

**VLAN** Field Descriptions

Use data in the following table to use the **VLAN** tab.

| Name                         | Description                                                                                                                                                                                                                                                                                                                      |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PerformTagging</b>        | Enables tagging (trunking) on the Extreme Integrated Application Hosting (IAH) port. It can belong to multiple port-based VLANs and a VLAN tag is inserted in every frame it transmits. If it is not checked, the IAH port is an untagged (Access) IAH port. The default value is different for each IAH port.                   |
| <b>VlanIdList</b>            | Shows the VLAN ID to which the IAH port is assigned to.                                                                                                                                                                                                                                                                          |
| <b>DiscardTaggedFrames</b>   | Enables the functionality to discard tagged frames received on the IAH port by the forwarding process, for untagged (access) IAH port. The default is disabled.                                                                                                                                                                  |
| <b>DiscardUntaggedFrames</b> | Enables the functionality to discard untagged frames received on the IAH port by the forwarding process, for tagged (trunk) IAH port. The default is disabled.                                                                                                                                                                   |
| <b>UntagDefaultVLAN</b>      | Enables the functionality to untag the frames forwarded to the default VLAN, even if the IAH port is tagged (trunk port). The default is disabled.                                                                                                                                                                               |
| <b>UntaggedVlanIds</b>       | Shows the untagged VLAN IDs associated with the IAH port.                                                                                                                                                                                                                                                                        |
| <b>DefaultVlanId</b>         | Specifies the VLAN ID assigned to untagged frames received on the IAH port that match no policy-based VLAN to which the IAH port belongs.                                                                                                                                                                                        |
| <b>SpoofDetect</b>           | Enables spoof detection on the specified IAH port.                                                                                                                                                                                                                                                                               |
| <b>PrivateVlanPortType</b>   | Specifies the following: <ul style="list-style-type: none"> <li>• <b>trunk:</b> tagged IAH port.</li> <li>• <b>isolated:</b> Only private VLANs are permitted on isolated IAH ports.</li> <li>• <b>promiscuous:</b> Only private VLANs are permitted on promiscuous IAH ports.</li> <li>• <b>none:</b> default value.</li> </ul> |

## View existing VLANs

View the configuration and current status of all defined VLANs.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration** > **VLAN**.

2. Select **VLANs**.
3. View the configured VLANs in the **Basic** tab.
4. View the configured private VLANs in the **Private VLAN** tab.

## Create a Port-Based VLAN

Create a port-based VLAN. To create a different type of VLAN, see one of the following procedures:

- [Create a Protocol-Based VLAN](#) on page 4159
- [Create a SPBM B-VLAN](#) on page 4160

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Select **VLANs**.
3. In the **Basic** tab, select **Insert**.
4. In the **Id** box, enter an unused VLAN ID, or use the ID provided.
5. In the **Name** box, type the VLAN name, or use the name provided.
6. In the **Color Identifier** box, select the down arrow and choose a color from the list, or use the color provided.
7. In the **MstpInstance** box, select the down arrow and choose an msti instance from the list.
8. In the **Type** box, select **byPort**.
9. In the **PortMembers** box, select **(...)**.
10. Select the ports to add as member ports.  
The ports that are selected are recessed. Nonselected ports are not recessed. You cannot select a Port number that is dimmed as a VLAN port members.
11. Select **OK**.
12. Select **Insert**.

### Basic Field Descriptions

Use the data in the following table to use the **Basic** tab.

| Name           | Description                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>      | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| <b>Name</b>    | Specifies the name of the VLAN.                                                                                                                                                                                                                                                                                                                                                    |
| <b>IfIndex</b> | Specifies the logical interface index assigned to the VLAN.                                                                                                                                                                                                                                                                                                                        |

| Name                    | Description                                                                                                                                                                                                                   |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Color Identifier</b> | Specifies a proprietary color scheme to associate a color with the VLAN. Color does not affect how frames are forwarded.                                                                                                      |
| <b>Type</b>             | Specifies the type of VLAN: <ul style="list-style-type: none"> <li>• byPort</li> <li>• byProtocolId</li> <li>• spbm-bvlan</li> <li>• private</li> </ul>                                                                       |
| <b>MstpInstance</b>     | Identifies the MSTP instance.                                                                                                                                                                                                 |
| <b>VrfId</b>            | Indicates the Virtual Router to which the VLAN belongs.                                                                                                                                                                       |
| <b>VrfName</b>          | Indicates the name of the Virtual Router to which the VLAN belongs.                                                                                                                                                           |
| <b>PortMembers</b>      | Specifies the slot/port of each VLAN member. The system displays the sub-port only for channelized ports.                                                                                                                     |
| <b>ActiveMembers</b>    | Specifies the slot/port of each VLAN member. The system displays the sub-port only for channelized ports.                                                                                                                     |
| <b>StaticMembers</b>    | Specifies the slot/port of each static member of a policy-based VLAN. The system displays the sub-port only for channelized ports.                                                                                            |
| <b>NotAllowToJoin</b>   | Specifies the slot/ports that are never allowed to become a member of the policy-based VLAN. The system displays the sub-port only for channelized ports.                                                                     |
| <b>ProtocolId</b>       | Specifies the network protocol for protocol-based VLANs. This value is taken from the Assigned Numbers of remote function call (RFC).<br>If the VLAN type is port-based, none is displayed in the Basic tab ProtocolId field. |

| Name                       | Description                                                                                                                                                                                                                                                                                                                       |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AgingTime</b>           | Specifies the timeout period, in seconds, to age out dynamic members of this VLAN. This field only applies to policy-based VLANs. The default is 600.                                                                                                                                                                             |
| <b>Clear Secondary IPs</b> | Removes all secondary IP addresses on a VLAN simultaneously. To remove specific secondary IP addresses from a VLAN, use the <b>Secondary IP Addresses</b> tab ( <b>Configuration &gt; VLAN &gt; VLANs &gt; Basic &gt; IP</b> ). For more information, see <a href="#">Secondary IP Addresses Field Descriptions</a> on page 4158. |

#### Note

If you or another user changes the name of an existing VLAN using the VLAN **Basic** tab (or using CLI), the system does not display the new name initially in EDM. To display the updated name, perform one of the following actions:

- Refresh your browser to reload EDM.
- Log out of EDM and log in again to restart EDM.
- Select **Refresh** in the VLAN **Basic** tab toolbar. If the system displays the old VLAN name in other tabs, select **Refresh** on those tabs as well.

## Create a Private VLAN

### Before You Begin

- To create a private VLAN, you must configure the VLAN type to private and configure the private VLAN port type.
- The ports you add to a private VLAN must have a port type of isolated, promiscuous, or trunk.

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. On the **Basic** tab, select **Insert**.
4. For **Id**, type an unused VLAN ID, or use the ID provided.
5. (Optional) For **Name**, type the VLAN name, or use the name provided.
6. (Optional) For **Color Identifier**, select a color from the list, or use the color provided.
7. (Optional) For **MstpInstance**, select an msti instance from the list.
8. For **Type**, select **private**.
9. For **PortMembers**, select the ellipsis (...).

10. Select the ports to add as member ports.

The ports that are selected are recessed, while the non-selected ports are not recessed. Port numbers that are dimmed cannot be selected as VLAN port members.

11. Select **OK**.

12. For **Secondary Vlan**, type an unused VLAN ID.

13. Select **Insert**.

14. In the Device Physical View, select the Private VLAN port members.

15. In the navigation pane, expand **Configuration > Edit > Port**.

16. Select **General**.

17. Select the **VLAN** tab.

18. For **PrivateVlanPortType**, select the port type.

19. Select **Apply**.

### Basic Field Descriptions

Use the data in the following table to use the **Basic** tab.

| Name                    | Description                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>               | Specifies the VLAN ID in the range of 2 to 4059. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. By default, the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. |
| <b>Name</b>             | Specifies the name of the VLAN.                                                                                                                                                                                                                                                                                                                                                    |
| <b>IfIndex</b>          | Specifies the logical interface index assigned to the VLAN.                                                                                                                                                                                                                                                                                                                        |
| <b>Color Identifier</b> | Specifies a proprietary color scheme to associate a color with the VLAN. Color does not affect how frames are forwarded.                                                                                                                                                                                                                                                           |
| <b>Type</b>             | Specifies the type of VLAN: <ul style="list-style-type: none"> <li>• byPort</li> <li>• byProtocolId</li> <li>• spbm-bvlan</li> <li>• private</li> </ul>                                                                                                                                                                                                                            |
| <b>MstpInstance</b>     | Identifies the MSTP instance.                                                                                                                                                                                                                                                                                                                                                      |
| <b>VrfId</b>            | Indicates the Virtual Router to which the VLAN belongs.                                                                                                                                                                                                                                                                                                                            |
| <b>VrfName</b>          | Indicates the name of the Virtual Router to which the VLAN belongs.                                                                                                                                                                                                                                                                                                                |
| <b>PortMembers</b>      | Specifies the slot/port of each VLAN member. The system displays the sub-port only for channelized ports.                                                                                                                                                                                                                                                                          |

| Name                       | Description                                                                                                                                                                                                                                                                                                                          |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ActiveMembers</b>       | Specifies the slot/port of each VLAN member. The system displays the sub-port only for channelized ports.                                                                                                                                                                                                                            |
| <b>StaticMembers</b>       | Specifies the slot/port of each static member of a policy-based VLAN. The system displays the sub-port only for channelized ports.                                                                                                                                                                                                   |
| <b>NotAllowToJoin</b>      | Specifies the slot/ports that are never allowed to become a member of the policy-based VLAN. The system displays the sub-port only for channelized ports.                                                                                                                                                                            |
| <b>ProtocolId</b>          | Specifies the network protocol for protocol-based VLANs. This value is taken from the Assigned Numbers of remote function call (RFC).<br>If the VLAN type is port-based, none is displayed in the Basic tab ProtocolId field.                                                                                                        |
| <b>AgingTime</b>           | Specifies the timeout period, in seconds, to age out dynamic members of this VLAN. This field only applies to policy-based VLANs.<br>The default is 600.                                                                                                                                                                             |
| <b>Clear Secondary IPs</b> | Removes all secondary IP addresses on a VLAN simultaneously.<br>To remove specific secondary IP addresses from a VLAN, use the <b>Secondary IP Addresses</b> tab ( <b>Configuration &gt; VLAN &gt; VLANs &gt; Basic &gt; IP</b> ). For more information, see <a href="#">Secondary IP Addresses Field Descriptions</a> on page 4158. |

#### Note

If you or another user changes the name of an existing VLAN using the VLAN **Basic** tab (or using CLI), the system does not display the new name initially in EDM. To display the updated name, perform one of the following actions:

- Refresh your browser to reload EDM.
- Log out of EDM and log in again to restart EDM.
- Select **Refresh** in the VLAN **Basic** tab toolbar. If the system displays the old VLAN name in other tabs, select **Refresh** on those tabs as well.

**VLAN** field descriptions

Use the data in the following table to use the **VLAN** tab.

| Name                         | Description                                                                                                                                                                                                                              |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PerformTagging</b>        | If checked, this port is a tagged (Trunk) Port. It can belong to multiple port-based VLANs and a VLAN tag is inserted in every frame it transmits. If it is not checked, the port is an untagged (Access) port. The default is disabled. |
| <b>VlanIdList</b>            | Identifies which VLANs this port is assigned.                                                                                                                                                                                            |
| <b>DiscardTaggedFrames</b>   | If selected, and the port is untagged (an access port), tagged frames received on the port are discarded by the forwarding process. If clear, tagged frames are processed normally. The default is disabled.                             |
| <b>DiscardUntaggedFrames</b> | If selected and the port is tagged (a trunk port), untagged frames received on the port are discarded by the forwarding process. If clear, untagged frames are processed normally. The default is disabled.                              |
| <b>UntagDefaultVLAN</b>      | If selected, even if the port is tagged (a trunk port), frames forwarded to the default VLAN for the port are not tagged. The default is disabled.                                                                                       |
| <b>UntaggedVlanIds</b>       | Identifies which VLANs this port is associated with as untagged.                                                                                                                                                                         |
| <b>DefaultVlanId</b>         | Specifies the VLAN ID assigned to untagged frames received on this trunk port that match no policy-based VLAN to which the port belongs.                                                                                                 |
| <b>SpoofDetect</b>           | Enables or disables spoof detection on the specified port.                                                                                                                                                                               |
| <b>Protocol</b>              | Enables protocol-based VLAN on the port. This feature is always enabled.                                                                                                                                                                 |

| Name                                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PrivateVlanPortType</b>                                                                      | Specifies the port type for a Private VLAN. If not specified, the port type defaults to None. <ul style="list-style-type: none"> <li>• Isolated: An Isolated port can belong only to one private VLAN</li> <li>• Promiscuous: A Promiscuous port can belong to many private VLANs.</li> <li>• Trunk: A Trunk port can belong to many private VLANs, is tagged, and can also belong to non-private VLANs.</li> </ul> |
| <b>Origin</b><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series and XA1400 Series. | Specifies the origin of VLAN configuration on the port, either manually configured through CLI or EDM, or dynamically configured through Auto-sense.                                                                                                                                                                                                                                                                |

## View Private VLAN Information

You can view the private VLAN information for the primary and secondary VLANs, I-SIDs, and private VLAN port types.

### Procedure

1. In the navigation pane, expand the **Configuration > VLAN** folders.
2. Select **VLANs**.
3. Select **Private VLAN**.

### Private VLAN field descriptions

Use the data in the following table to use the **Private VLAN** tab.

| Name                             | Description                               |
|----------------------------------|-------------------------------------------|
| <b>Primary Vlan</b>              | Shows the VLAN ID for the primary VLAN.   |
| <b>Secondary Vlan</b>            | Shows the VLAN ID for the secondary VLAN. |
| <b>Primary / Secondary I-sid</b> | Shows the I-SID for the VLAN.             |

## Configure a Primary IP Address for a VLAN

Assign an IP address to a VLAN to enable routing on the VLAN.

### About This Task

If you configure the SLA Mon agent address under an IP interface or VLAN, you must remove the SLA Mon address before you can remove the IP address or VLAN.

The ability to create an IP interface in a disabled state in one step is available only using CLI.

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. On the **Basic** tab, select the VLAN to configure.
4. Select **IP**.
5. On the **Primary IP Address** tab, select **Insert**.
6. Configure the required parameters.
7. Select **Insert**.

### Primary IP Address Field Descriptions

Use the data in the following table to use the **Primary IP Address** tab.

| Name                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Interface</b>       | Shows the interface to which this entry applies.                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Ip Address</b>      | Specifies the IP address to associate with the VLAN.                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Net Mask</b>        | Specifies the subnet mask associated with the IP address of this entry. The value of the mask is an IP address with all the network bits configured to 1 and all the hosts bits configured to 0.                                                                                                                                                                                                                           |
| <b>Name</b>            | Specifies a name for the interface.                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>BcastAddrFormat</b> | Shows the IP broadcast address format on this interface.                                                                                                                                                                                                                                                                                                                                                                   |
| <b>ReasmMaxSize</b>    | Shows the size of the largest IP datagram which this entity can reassemble from incoming IP fragmented datagrams received on this interface.                                                                                                                                                                                                                                                                               |
| <b>VlanId</b>          | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <b>BrouterPort</b>     | Indicates whether this entry corresponds to a brouter port, as oppose to a routable VLAN.                                                                                                                                                                                                                                                                                                                                  |

| Name             | Description                                                                                                                                                                                                                                                                                                                                                                |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MacOffset</b> | Specifies the MAC offset value. Routable VLANs are assigned MAC addresses arbitrarily or by offset. Their MAC addresses are: <ul style="list-style-type: none"> <li>• 24 bits: Vendor ID</li> <li>• 12 bits: Chassis ID</li> <li>• 12 bits: 0xA00-0xFFFF</li> </ul> If you enter the MAC offset, the lowest 12 bits are 0xA00 plus the offset. If not, they are arbitrary. |
| <b>IfType</b>    | Identifies the type of interface.                                                                                                                                                                                                                                                                                                                                          |
| <b>VrfId</b>     | Associates the VLAN with a VRF. VRF ID 0 is reserved for the administrative VRF.                                                                                                                                                                                                                                                                                           |

## **NEW!** Modify the Administrative State of an IP Interface on a VLAN

By default, the switch enables an IP interface after you configure the primary IP address. You can administratively disable, and then reenable, an IPv4 interface after you create it. For example, if you want to change the routing protocol configuration on the interface.

### About This Task

This procedure applies to the IP Layer and functionality for the VLAN.

The ability to create an IP interface in a disabled state in one step is available only using CLI.

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANs**.
3. On the **Basic** tab, select the VLAN you need to modify.
4. Select **IP**.
5. Select the **IP Interface** tab.
6. Change the **AdminStatus** value to change the administrative state.
7. Select **Apply**.

## **NEW!** IP Interface

Use the data in the following table to help use the **IP Interface** tab.

| Name               | Description                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdminStatus</b> | Modifies the administrative state of the IP Interface. By default, the switch enables an IP interface after you configure the primary IP address. |
| <b>OperState</b>   | Displays the operational state of the IP Interface.                                                                                               |

**NEW!** Configure a Secondary IP Interface for a VLAN

Assign a secondary IP address to a VLAN to increase the number of connected hosts the VLAN can support.

**Before You Begin**

You must configure a primary IP address before you can add a Secondary IP Interface.

**Procedure**

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANS**.
3. On the **Basic** tab, select the VLAN to configure.
4. Select **IP**.
5. On the **Secondary IP Addresses** tab, select **Insert**.
6. Type the IP address.
7. Type the subnet mask.
8. Select **Insert**.

**NEW!** *Secondary IP Addresses Field Descriptions*

Use the data in the following table to use the **Secondary IP Addresses** tab.

| Name              | Description                                      |
|-------------------|--------------------------------------------------|
| <b>Interface</b>  | Identifies the IP interface.                     |
| <b>Ip Address</b> | Specifies the secondary IP address.              |
| <b>Net Mask</b>   | Specifies the subnet mask for the address.       |
| <b>Vlan ID</b>    | Identifies the VLAN ID.                          |
| <b>Vrf ID</b>     | Identifies the associated VRF ID, if applicable. |

## Change VLAN Port Membership

Modify VLAN port members to control access to the VLAN.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Select **VLANS**.
3. Select the **PortMembers** number for the VLAN for which you want to modify port membership.
4. Select the port members you wish to add or remove.
5. Select **Ok**.
6. Select **Apply**.

The VLAN port membership is changed.

## Create a Protocol-Based VLAN

Use a protocol-based VLAN so that the VLAN only carries certain traffic types.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Select **VLANs**.
3. In the **Basic** tab, select **Insert**.
4. In the **Id** box, type the unique VLAN ID or use the ID provided.
5. In the **Name** box, type the VLAN name or use the name provided.
6. In the **Color Identifier** box, select the color or use the color provided.  
This color is used to visually distinguish the VLANs in a network.
7. In the **MstpInstance** box, select the down arrow and choose an MSTI instance from the list.
8. In the **Type** box, select **byProtocolId**.  
This activates additional fields needed to configure protocol-based VLANs.
9. To specify the VLAN port membership, select the button (...) for one of the following fields:

#### Port Members

OR

#### StaticMembers

OR

#### NotAllowToJoin

10. Select each port button to choose the desired membership color.

Yellow: Potential members—dynamic (potential members are treated as always members)

OR

Green: Always members—static

OR

Red: Never members—not allowed to join

#### Important

In a protocol-based VLAN, a potential member becomes an active member of the VLAN after a frame of the specified protocol is received.

11. Select **Insert**.

## Create a SPBM B-VLAN

Create a Shortest Path Bridging MAC (SPBM) Backbone VLAN (B-VLAN). Each SPBM network instance is associated with at least one backbone VLAN (B-VLAN) in the core SPBM network. This VLAN is used for both control plane traffic and dataplane traffic.

### Note

As a best practice, configure two B-VLANs in an SPBM dual-homing environment.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Select **VLANS**.
3. In the **Basic** tab, Select **Insert**.
4. In the **Id** box, enter an unused VLAN ID, or use the ID provided.
5. In the **Name** box, type the VLAN name, or use the name provided.
6. In the **Color Identifier** box, select the down arrow and choose a color from the list, or use the color provided.
7. In the **Type** box, select **spbm-bvlan**.
8. Select **Insert**.
9. Collapse the **VLANS** tab.  
The VLAN is added to the **Basic** tab.

## Configure Advanced VLAN Features

Use advanced VLAN features to configure the VLAN name, aging time, VLAN operation action, and QoS level. The VLAN Operation Action parameter can be useful for troubleshooting.

You can also configure a DvR Gateway IPv4 address on a VLAN, and enable DvR on it.

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Select **VLANS**.
3. Select the **Advanced** tab.
4. Configure the parameters as required by double-clicking fields to make changes.  
You cannot make changes to fields that are dim.
5. Select **Apply**.

**Advanced** Field Descriptions

Use the data in the following table to use the **Advanced** tab.

| Name                                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                                                                                    | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <b>Name</b>                                                                                  | Specifies the name of the VLAN.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>IfIndex</b>                                                                               | Specifies the logical interface index assigned to the VLAN.                                                                                                                                                                                                                                                                                                                                                                |
| <b>Type</b>                                                                                  | Specifies the type of VLAN: <ul style="list-style-type: none"> <li>• byPort</li> <li>• byProtocolId</li> <li>• spbm-bvlan</li> <li>• private</li> </ul>                                                                                                                                                                                                                                                                    |
| <b>Isid</b>                                                                                  | Specifies the Service Instance Identifier (I-SID) number assigned to a customer VLAN (C-VLAN). The default value is 0, which indicates that no I-SID is assigned.                                                                                                                                                                                                                                                          |
| <b>Isid Name</b><br><br><b>Note:</b><br>This field does not apply to all hardware platforms. | Specifies the name of the I-SID.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Origin</b>                                                                                | Specifies the origin of the VLAN configuration, either manually configured through CLI or SNMP, or dynamically configured through RADIUS VSA or Zero Touch Fabric Configuration.                                                                                                                                                                                                                                           |
| <b>ProtocolId</b>                                                                            | Specifies the network protocol for protocol-based VLANs.<br>If the VLAN type is not protocol-based, a value of None displays in the <b>Basic</b> tab <b>ProtocolId</b> field.                                                                                                                                                                                                                                              |
| <b>AgingTime</b>                                                                             | Specifies the timeout period for dynamic VLAN membership. A potential VLAN port is made ACTIVE after it receives a packet that matches the VLAN; if no such packet is received for AgingTime seconds, the port is no longer active. The default is 600.                                                                                                                                                                    |

| Name                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MacAddress</b>             | Specifies the MAC address assigned to the virtual router interface for this VLAN. This field is relevant only after the VLAN is configured for routing. This MAC address is used as the Source MAC in routed frames and ARP replies.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Vlan Operation Action</b>  | <p>Performs an operation on the VLAN. The values are:</p> <ul style="list-style-type: none"> <li>• none</li> <li>• flushMacFdb: Configures action to flushMacFdb. This action removes the learned MAC addresses from the forwarding database for the selected VLAN.</li> <li>• flushArp: Configures action to flushArp. This action removes the ARP entries from the address table for the selected VLAN.</li> <li>• flushIip: Configures action to flushIip. This action removes the learned IP addresses from the forwarding table for the selected VLAN.</li> <li>• flushDynMemb: Configures action to flushDynMemb. This action removes port members not configured as static from the list of active port members of a policy-based VLAN and removes MAC addresses learned on those ports.</li> <li>• all: Configures action to all. This action performs all the supported actions; it does not perform the Snoop-related actions.</li> </ul> <p>The default is none.</p> |
| <b>Result</b>                 | Specifies the result code after you perform an action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>NlbMode</b>                | Enables or disables Microsoft Network Load Balancing (NLB) operations on the VLAN. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SpbMulticast</b>           | Enables or disables IP Multicast over Fabric Connect. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SpbPimGatewayMulticast</b> | Enables or disables SPB-PIM Gateway Multicast on a VLAN. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>RmonEnable</b>             | Enables or disables Remote Monitoring (RMON) on the interface. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Ipv6FhsSnoopDhcpEnable</b> | Enables or disables IPv6 dhcp snooping on a VLAN. The default is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Name                                                                                                                          | Description                                                                                                                                                                                                                                                                          |

The default is disabled.<br><br><b>Note:</b><br>You must enable DvR on every VLAN that is configured on a DvR Controller.                                                  |
| <b>DvrGwIpv4Addr</b>                                                                                                          | Specifies the DvR gateway IPv4 address for a VLAN.<br><br><b>Important:</b><br>Ensure that you configure the same gateway IPv4 address on all Controllers in the DvR domain that belong to a VLAN.                                                                                   |
| <b>DvrGwIpv4Onelp</b>                                                                                                         | Enables or disables the DvR One IP for a VLAN. The default is disabled (false).                                                                                                                                                                                                      |
| <b>DvrVrrpElection</b><br><br><b>Note:</b><br>Exception: not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series. | Identifies the DvR VLAN, and associated I-SID, to become the primary Virtual Router Redundancy Protocol (VRRP) router through the election process. You can identify only one VLAN for election per DvR Controller. By default, no VLAN is configured as the DvR VRRP election VLAN. |
| <b>MvpnIsidValue</b><br><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series or XA1400 Series.                     | Configures the MVPN I-SID value for the VLAN.                                                                                                                                                                                                                                        |
| <b>MvpnIsidStatus</b><br><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series or XA1400 Series.                    | Identifies the MVPN I-SID status. CONFIG indicates that the VRF was created manually and DYNAMIC indicates that the VRF was created by configuring an MVPN I-SID on a VLAN.                                                                                                          |
| <b>MvpnIsidOffset</b><br><br><b>Note:</b><br>Exception: not supported on VSP 8600 Series or XA1400 Series.                    | Allows you to add an offset parameter to the MVPN I-SID. This is an optional value and the range is 0-511.                                                                                                                                                                           |

## Configure NLB Support

Use Microsoft Network Load Balancing (NLB) to share the workload among multiple clustering servers. For more information about software scaling capabilities, see [VOSS Release Notes](#).

### Before You Begin

Ensure that the VLAN exists and has an associated IP address.

### About This Task

Use the following procedure to configure NLB support on an IP interface to enable or disable NLB support. The default value is NLB support disabled.

#### Note

- SPBM supports Network Load Balancing (NLB) Unicast and Multicast modes.
- Static multicast ARP entries are not supported for NLB Unicast or NLB Multicast.
- Multicast MAC flooding is not supported for NLB.
- ARP entries for NLB server IP addresses do not age out when there is still client traffic coming to the NLB servers, even after the NLB servers are no longer reachable.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Select **VLANs**.
3. Select the **Advanced** tab.
4. In the row for the VLAN, double-click the value in the **NlbMode** column.
5. Select the appropriate value.
6. Select **Apply**.

## Configure a Port to Accept Tagged or Untagged Frames

Configure a port to accept tagged or untagged frames.

### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand the following folders: **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **VLAN** tab.

- To configure tagging on the port, select the **PerformTagging** check box.  
This setting applies to all VLANs associated with the port.

**Note**

If the check box is selected, tagging is enabled. All frames sent from this port are tagged.

If the check box is cleared, tagging is disabled. The port does not send tagged frames. The switch removes the tag before sending the frame out of the port.

- To discard tagged frames on a port for which tagging is disabled, select **DiscardTaggedFrames**.
- To discard untagged frames on a port for which tagging is enabled, select **DiscardUntaggedFrames**.
- To designate a default VLAN to associate with a packet that does not match a policy-based VLAN, enter a VLAN ID in the **DefaultVlanId** box or use the default VLAN 1.
- Select **Apply**.
- Select **Close**.

## Configure Untagging Default VLAN on a Tagged Port

Configure an untagged default VLAN on a tagged port to separate untagged packets originating from a PC from the tagged packets originating from an IP phone.

### Procedure

- In the Device Physical View tab, select a port.
- In the navigation tree, expand the following folders: **Configuration > Edit > Port**.
- Select **General**.
- Select the **VLAN** tab.
- Select **UntagDefaultVlan**.
- In the **DefaultVlanId**, enter a default VLAN ID.
- Select **Apply**.
- Select **Close**.

## Configuring SLPP globally

Enable the Simple Loop Prevention Protocol (SLPP) to detect a loop and automatically stop it.

### Procedure

- In the navigation tree, expand the following folders: **Configuration > VLAN**.
- Click **SLPP**.
- Click the **Global** tab.
- Select **GlobalEnable**.
- In the **TransmissionInterval** box, type a value for the time interval for loop detection.

6. Click **Apply**.

### **Global** field descriptions

Use the data in the following table to use the **Global** tab.

| Name                        | Description                                                                                                                                            |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GlobalEnable</b>         | Activates or disables SLPP globally. The default is disabled.                                                                                          |
| <b>TransmissionInterval</b> | Configures the interval for which loop detection occurs. The interval is expressed in milliseconds in a range from 500–5000. The default value is 500. |

### *Job aid*

The following table provides the SLPP values.

**Table 310: SLPP values**

| Enable SLPP           | Setting                         |
|-----------------------|---------------------------------|
| Access SMLT           | Yes                             |
| Core SMLT             | No                              |
| Primary switch        |                                 |
| Packet Rx threshold   | 5                               |
| Transmission interval | 500 milliseconds (ms) (default) |
| Secondary switch      |                                 |
| Packet Rx threshold   | 50                              |
| Transmission interval | 500 ms (default)                |

## Configuring the SLPP by VLAN

Activate SLPP on a VLAN to enable forwarding of the SLPP packet over the VLAN. This configuration controls the boundary of SLPP-PDU transmission.

### **Before You Begin**

- Enable SLPP globally before you configure it on a VLAN.

### **Procedure**

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **SLPP**.
3. Click the **VLANS** tab.
4. Click **Insert**.
5. Click the **VlanId** ellipses (...).
6. Select the desired VLAN ID.
7. Click **Ok**.

8. Select **SlppEnable**.
9. Click **Insert**.

### VLANS Field Descriptions

Use the data in the following table to use the **VLANS** tab.

| Name              | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>     | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <b>SlppEnable</b> | Activates SLPP on the selected VLAN. The SLPP packet transmission and reception process is active only if you enable the SLPP operation. If you disable the SLPP operation, the following occurs: <ul style="list-style-type: none"> <li>• the system sends no SLPP packets</li> <li>• the system discards received SLPP packets</li> </ul> The default is enabled.                                                        |

## Configuring the SLPP by port

Use SLPP on a port to avoid traffic loops on the port.

### Note

To provide protection against broadcast and multicast storms, as a best practice, enable Rate Limiting for broadcast traffic and multicast traffic.

### Before You Begin

- Enable SLPP globally before you configure it on a port.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **VLAN**.
2. Click **SLPP**.
3. Click the **Ports** tab.
4. Double-click the **PktRxThreshold** box for the desired port to edit the threshold value for packet reception.
5. Double-click the **SlppEnable** box for the desired port.
6. Select **true** to enable SLPP.
7. Click **Apply**.

**Ports** field descriptions

Use the data in the following table to use the **Ports** tab.

| Name                                | Description                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>                      | Specifies the interface index number for a port.                                                                                                                                                                                                                                                                                                            |
| <b>PktRxThreshold</b>               | Specifies the threshold for packet reception. Configure the SLPP packet receive threshold to a value (1- 500) that represents the number of received SLPP-PDUs to shut down the port. This variable is a port-level parameter, therefore if the port is tagged, SLPP-PDUs from the various VLANs increment this single threshold counter. The default is 1. |
| <b>SlppEnable</b>                   | Activates SLPP on the selected interface. The default is disabled.                                                                                                                                                                                                                                                                                          |
| <b>IncomingVlanId</b>               | Shows the VLAN ID of the classified packet on a port disabled by SLPP.                                                                                                                                                                                                                                                                                      |
| <b>SrcNodeType</b>                  | Specifies the source node type of the received SLPP packet.                                                                                                                                                                                                                                                                                                 |
| <b>PktRxCount</b>                   | Shows the total number of SLPP packets the port received.                                                                                                                                                                                                                                                                                                   |
| <b>TimeToClrPktRxCount</b>          | Specifies the timer to clear the SLPP receive counter. After you enable SLPP and the port receives SLPP PDUs, the timer starts. After the timer exceeds the configured value, the system resets the count to zero. The default is 21,600 seconds.                                                                                                           |
| <b>RemainingTimeToClrPktRxCount</b> | Shows the time remaining before the SLPP receive counter is reset to zero.                                                                                                                                                                                                                                                                                  |

*Job aid*

The following table provides the SLPP values.

**Table 311: SLPP values**

| Enable SLPP           | Setting                         |
|-----------------------|---------------------------------|
| Access SMLT           | Yes                             |
| Core SMLT             | No                              |
| Primary switch        |                                 |
| Packet Rx threshold   | 5                               |
| Transmission interval | 500 milliseconds (ms) (default) |
| Secondary switch      |                                 |

**Table 311: SLPP values (continued)**

| Enable SLPP           | Setting          |
|-----------------------|------------------|
| Packet Rx threshold   | 50               |
| Transmission interval | 500 ms (default) |

## Configuring the forwarding database timeout globally

Configure the forwarding database global timeout to age out dynamically learned forwarding information.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**
2. Click **VLANS**.
3. Click the **FdbAging** tab.
4. Type an interval, in seconds, for aging out dynamically learned forwarding information, or keep the default.
5. Click **Apply**.

### *FDB Aging* field descriptions

Use the data in the following table to use the **FDB Aging** tab.

| Name            | Description                                                                                               |
|-----------------|-----------------------------------------------------------------------------------------------------------|
| <b>FdbAging</b> | Specifies the timeout period for dynamically learned mac addresses on the vlan. The default value is 300. |

## Viewing VLAN forwarding database information

Perform this procedure to view forwarding database entries for all VLANs on the device.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANS**.
3. In the VLANS tab, click the **Forwarding** tab.

**Forwarding** Field Descriptions

Use the data in the following table to use the **Forwarding** tab.

| Name           | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>  | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <b>Address</b> | Specifies a unicast MAC address for which the VLAN has forwarding or filtering information.                                                                                                                                                                                                                                                                                                                                |
| <b>Status</b>  | Specifies the status of the VLAN. The values are: <ul style="list-style-type: none"> <li>• other</li> <li>• invalid</li> <li>• learned</li> <li>• self</li> <li>• mgmt</li> </ul>                                                                                                                                                                                                                                          |
| <b>Port</b>    | Specifies either a value of zero (0) or the port number of the port on which a frame having the specified MAC address was seen. A value of <b>cpp</b> indicates a self-assigned MAC address.                                                                                                                                                                                                                               |
| <b>BMac</b>    | Shows the backbone MAC address if the entry is learned from a Shortest Path Bridging MAC (SPBM) network.                                                                                                                                                                                                                                                                                                                   |
| <b>Cvid</b>    | Specifies the customer VID.                                                                                                                                                                                                                                                                                                                                                                                                |

## Viewing the Forwarding Database for a Specific VLAN

Use the forwarding database for VLANs to determine how the system forwards a received frame.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration** > **VLAN**
2. Click **VLANs**.
3. Select a VLAN.
4. Click **Bridge**.
5. Click the **Forwarding** tab and the VLAN forwarding database information is displayed.

**Forwarding** Field Descriptions

Use the data in the following table to use the **Forwarding** tab.

| Name           | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b>  | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <b>Address</b> | Specifies a unicast MAC address for which the bridge has forwarding or filtering information.                                                                                                                                                                                                                                                                                                                              |
| <b>Status</b>  | Specifies the status. Values include the following: <ul style="list-style-type: none"> <li>• self—one of the bridge addresses</li> <li>• learned—a learned entry that is being used</li> <li>• mgmt—a static entry</li> </ul>                                                                                                                                                                                              |
| <b>Port</b>    | Specifies either a value of zero (0) or the port number of the port on which a frame having the specified MAC address was seen. A value of <b>cpp</b> indicates a self-assigned MAC address.                                                                                                                                                                                                                               |
| <b>Cvid</b>    | Identifies the customer VID for this interface.                                                                                                                                                                                                                                                                                                                                                                            |

## Clearing learned MAC addresses by VLAN

Use the clear learned MAC addresses feature to flush the bridge forwarding database.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANS**.
3. Click the **Advanced** tab.
4. Double-click in the **VLAN Operation Action** field.
5. Choose **FlushMacFdb** from the list.
6. Click **Apply**.

## Clearing learned MAC addresses for all VLANs by port

Use the following procedure to clear all the forwarding database (FDB) for VLANs associated with this port.

**Procedure**

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand the following folders: **Configuration > Edit > Port**.
3. Click **General**.
4. In the Interface tab **Action** box, select **FlushMacFdb**.
5. Click **Apply**.  
All learned MAC addresses are cleared from the forwarding database (FDB) for VLANs associated with this port.
6. Click **Close**.

## Configuring static forwarding

Configure static forwarding to specify the group of ports that are allowed to forward frames.

**Important**

Entries are valid for unicast and for group/broadcast addresses.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.
2. Click **VLANs**.
3. Select the **Basic** tab.
4. Select a VLAN.
5. Click **Bridge**.
6. In the Bridge, VLAN tab, click the **Static** tab.
7. Click **Insert**.
8. In the **MacAddress** box, enter a forwarding destination MAC address.
9. In the **Port** box, click the ellipsis button (...).
10. Select the port on which the frame is received.
11. Click **Ok**.
12. Click **Insert**.

**Static field descriptions**

Use the data in the following table to use the **Static** tab.

| Name              | Description                                                                                                                                                       |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MacAddress</b> | Specifies the destination MAC address in a frame to which the forwarding information for this entry applies. This object can take the value of a unicast address. |
| <b>Port</b>       | Specifies the port number of the port on which the frame is received.                                                                                             |

| Name          | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanId</b> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <b>Status</b> | Specifies the status of the VLAN.                                                                                                                                                                                                                                                                                                                                                                                          |

## Configure Limit Learning

Limit MAC address learning to limit the number of forwarding database (FDB) entries learned on a particular port to a user-specified value. After the number of learned forwarding database entries reaches the maximum limit, MAC learning stops at that port.

### Procedure

1. On the Device Physical View tab, select one or more ports.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **Limit-Learning** tab.
5. Configure the parameters as required.
6. Select **Apply**.

### *Limit Learning* Field Descriptions

Use the data in the following table to use the **Limit-Learning** tab.

| Name                   | Description                                                                                                       |
|------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>PortNum</b>         | Shows the slot and port number to configure.                                                                      |
| <b>MaxMacCount</b>     | Configures the number of entries in the MAC table for the port that causes learning to stop. The default is 1024. |
| <b>CurrentMacCount</b> | Shows the number of entries currently in the MAC table for the port.                                              |
| <b>Enable</b>          | Enables or disables limit learning for the port. The default is disable.                                          |
| <b>MacLearning</b>     | Shows if MAC learning is enabled or disabled for the port.                                                        |

|                                                                                                                                                                                                                                                                                                                                                                                                                   | VSP 8200 Series | VOSS 8.0                                                                                                 |
|                                                                                                                                                                                                                                                                                                                                                                                                                   | VSP 8400 Series | VOSS 8.0                                                                                                 |
|                                                                                                                                                                                                                                                                                                                                                                                                                   | VSP 8600 Series | VSP 8600 8.0                                                                                             |
| XA1400 Series                                                                                                                                                                                                                                                                                                                                                                                                     | Not Supported   |                                                                                                          |

VRF Lite provides secure customer data isolation.

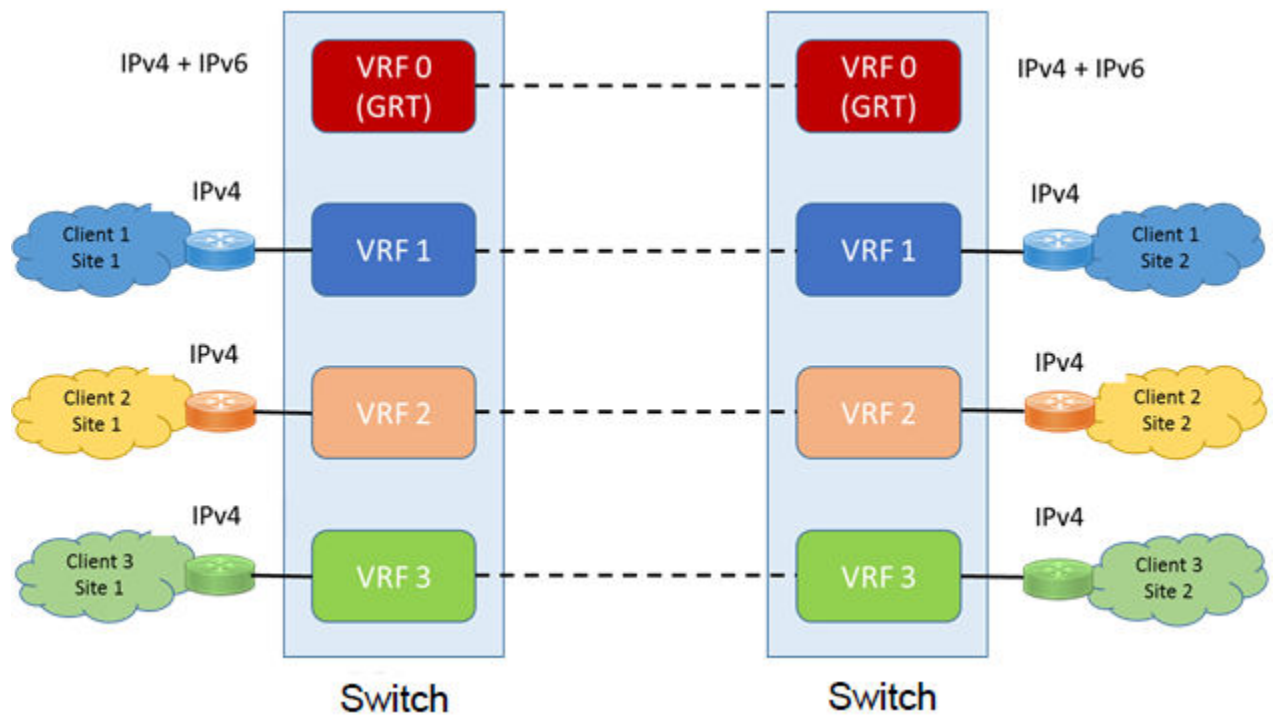

## VRF Lite Fundamentals

The switch supports what is termed as VRF Lite. Lite conveys the fact that the switch does not use Multiprotocol Label Switching (MPLS) for VRF; VRF Lite is a device virtualization feature, not a network-wide virtualization feature.

Use VRF Lite to offer networking capabilities and traffic isolation to customers that operate over the same node (router). Each virtual router emulates the behavior of a dedicated hardware router; the network treats each virtual router as a separate physical router. In effect, you can perform the functions of many routers using a single platform that runs VRF Lite. The result is a substantial reduction in the cost associated with providing routing and traffic isolation for multiple clients.

With multicast virtualization for IPv4, the switch can function as multiple virtual multicast routers.

The following figure shows one platform acting as multiple virtual routers, each serving a different customer network.

**Figure 267: Multiple virtual routers in one system**

A switch can support many virtual routers. Each virtual router instance is called a VRF instance. A VRF represents a single instance of a virtual router. Each instance maintains its own routing table. The term Multiple Virtual Router (MVR) is sometimes used to represent a router that contains many VRF instances.

The IPv6 Virtualization functionality adds IPv6 support on VRFs and Layer 3 VSNs. Each VRF instance has its own IPv6 interfaces, IPv6 address space, IPv6 routing table, and IPv6 global parameters. For more information on Layer 3 VSN, see [Layer 3 VSN Configuration](#) on page 1537.

The Global Router, VRF 0, is the first instance of the router. When the system starts, it creates VRF 0 by default. VRF 0 provides all non-virtual and traditional routing services. You cannot delete this instance. You can create and configure other VRF instances, if required.

VRF 0 is the only VRF that you can log into through CLI. CLI requires you to specify the VRF when you enter commands.

You can associate one VRF instance with many IPv4 or IPv6 interfaces. These interfaces are unique for each VRF instance. An interface is an entity with an IPv4 or IPv6 address that has the following characteristics:

- A unique association with a VLAN.
- A unique association with a router, if not associated with a VLAN
- A unique association with a circuit

A VLAN can only be associated with a single VRF instance.

#### Note

- You cannot associate a VLAN or port and a VRF instance if the VLAN or port has an IPv4 or IPv6 address. You must first associate the port and VRF instance and then you can configure the IPv4 or IPv6 address.
- Use the **boot config flag vrf-scaling** command, on supported switches, to increase the total number of supported VRFs. For more information on route scaling, see [VOSS Release Notes](#).

## VRF Lite Capability and Functionality

VRF Lite supports virtualization of the following IPv4 and IPv6 protocols and features.

- IPv4 protocols or features:
  - ARP
  - BGP
  - Circuitless IP
  - DHCP
  - IGMP
  - RIP
  - Route policies
  - Route preferences
  - Router Discovery
  - Static routes
  - User Datagram Protocol (UDP)
  - VLAN
  - VRRP

- IPv6 protocols or features:
  - BGP
  - IPv6 Interfaces and IPv6 Static Routes
  - ECMP and Alternative Route
  - OSPF
  - Route redistribution for static and direct routes
  - VRRPv3
  - DHCP Relay
  - IPv6 Reverse Path Forwarding
  - ICMP Ping & Traceroute
  - IS-IS Accept Policies

The switch uses VRF Lite to perform the following actions:

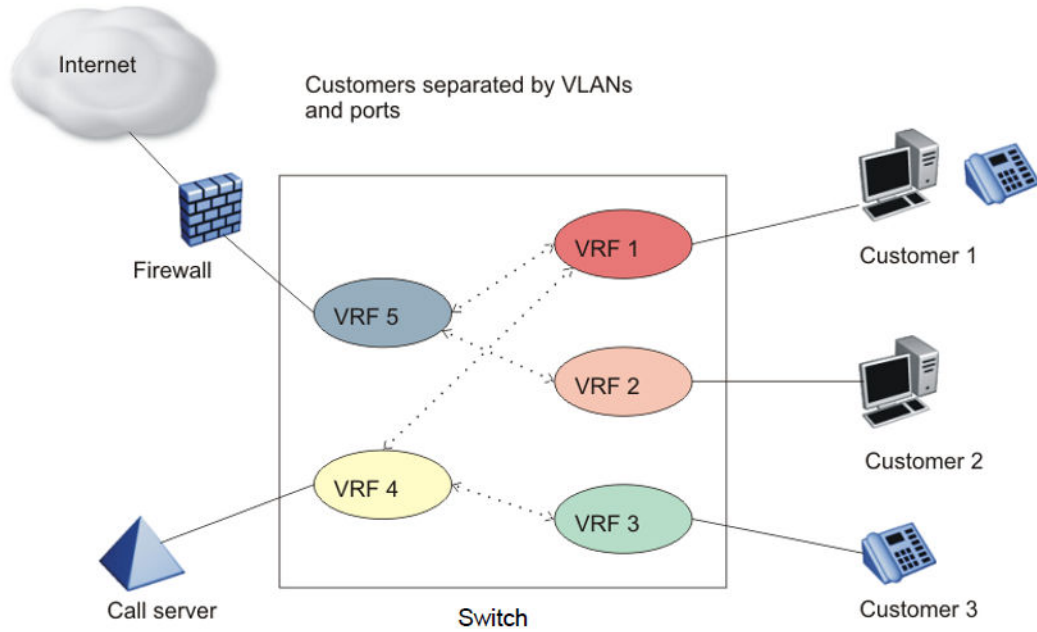

- Partition traffic and data and represent an independent router in the network
- Provide virtual routers that are transparent to end-users
- Support addresses that are not restricted to the assigned address space provided by host Internet Service Providers (ISP)
- Support overlapping IP address spaces in separate VRF instances

**Note**

If you enable multicast route redistribution between two VRFs, the switch does not support IP addresses that overlap within the two VRFs. The device does not generate an error if addresses overlap. You must avoid this situation.

VRF Lite interoperates with RFC 4364, Layer 3 VPNs. Split MultiLink Trunking (SMLT) and Routed SMLT (RSMLT) are also supported for VRF instances.

Although customer data separation into Layer 3 virtual routing domains is usually a requirement, sometimes customers must access a common network infrastructure. For example, they want to access the Internet, data storage, Voice over IP (VoIP)-public switched telephone network (PSTN), or call signaling services. To interconnect VRF instances, you can use an external firewall that supports virtualization, or use inter-VRF forwarding for specific services. With the inter-VRF solution, you can use routing policies and static routes to inject IP subnets from one VRF instance to another, and you can use filters to restrict access to certain protocols. The following figure depicts inter-VRF forwarding by the switch.

**Figure 268: Inter-VRF forwarding**

For more information about the latest VRF Lite scalability, see [VOSS Release Notes](#).

For configuration information about multicast virtualization, see [IP Multicast](#) on page 1586.

## VRF Lite and inter-VRF route redistribution

The switch supports three route redistribution functions:

- Intra-VRF inter-protocol route redistribution (redistribution within the same VRF instance), for example, redistribute RIP to OSPF.
- Inter-VRF inter-protocol redistribution (redistribution between two VRF instances), for example, redistribute RIP in VRF 2 to OSPF in VRF 4.
- Inter-VRF static routes (for example, a static route in a given VRF instance) configured as a typical static route but with the added parameter of a next-hop-vrf (the next-hop IP address is found in the next-hop-vrf instance).

With inter-VRF route redistribution, a user in one VRF instance can access route data in other VRF instances. You can redistribute routes within a VRF instance or between VRF instances; for example, one VRF instance can redistribute routes to all other VRF instances. You can redistribute Local, static, OSPF, RIP, and BGP routes and both dynamic (OSPF, BGP, and RIP) and static route redistribution is supported.

More than one routing protocol can be present in each VRF instance. Route redistribution can occur either between different protocol types, or between the same protocol types on different VRF instances.

An interface uses redistribution to announce routes that are learned by other protocols (OSPF or BGP, for example). Control route redistribution by using route policies. When

you associate routing policies with route redistribution, the policy is checked before the target protocol is updated. Across VRF instances, the policy is checked at the source VRF instance, so only qualified routes are added to the routing table.

You can use static route commands to inject one specific route (including a default route) from one VRF instance to another. The route is added to the target VRF instance, while the next hop is resolved by the next-hop VRF instance.

Static routes are used to direct packets from a given source using a next-hop IP address. The next-hop-vrf option in a static route permits this path to proceed from one VRF to another. Overlapping IP addresses are supported within VRFs, thus it is possible for two VRFs to have identical IP addresses.

The following list describes interVRF route redistribution:

- Redistributed routes are added to the target VRF instance, and their next hop remains in the source VRF instance.
- If either the source or destination VRF instance is deleted, the redistribution configuration is automatically deleted.
- Redistributed routes are not further redistributed to another VRF instance.
- Route redistribution is unidirectional. You must configure route redistribution for the reverse direction if you require it. You can configure different route policies for each direction.
- After you configure interVRF route redistribution between two VRF instances, you must avoid using overlapping IP addresses between these two VRF instances.

Avoid overlapping addresses; the device does not generate an error if addresses overlap.

- Intra-VRF routes take precedence over inter-VRF routes.
- You can physically connect two VRF instances to distribute route across VRF instances (in this case, you do not need to configure route redistribution).

### *Route Redistribution Operation*

To perform redistribution, the device maintains a route change list. The change list contains all the best routes that are either added to or deleted from the forwarding table. When a best route is added to or deleted from the forwarding table, the change list is updated to reflect the change and notify registered protocols. The registered protocols pick up the change from the change list when it becomes available.

An example scenario of interVRF redistribution follows. To redistribute OSPF routes in VRF 1 to RIP in VRF 0:

- Create, enable, and apply a RIP redistribution instance. The source protocol is OSPF and the VRF source is VRF 1.
- When an OSPF route is added in VRF 1, the Routing Table Manager (RTM) in VRF 1 puts the new route into the change list.

- The device notifies RIP in VRF 0, because RIP is registered with the RTM of VRF 1 for OSPF route changes.
- To send OSPF routes from VRF 1 through the RIP interface in VRF 0, the interface uses a route policy with match VRF criterion of VRF 1.

The switch also supports inter-domain multicast routing. For more information, see [IP Multicast](#) on page 1586.

## Port parameters and VRF Lite management

You can configure each VRF instance as a separate router, this means that you can configure different routing protocols and associated parameters for each instance. You can associate non0 VRF instances with ports.

The port parameters that you can edit for a VRF instance depend on whether the port belongs to only one, or more than one, VRF instance. For example, if a port belongs to only one VRF, you can edit the port parameters of the VRF. If a port belongs to more than one VRF instance, you cannot edit the port parameters of that port unless you are accessing the port through the Global Router with read-write-all access. If you do not have read-write-all access, you can only edit the GlobalRouter port parameters. If a port belongs to a single non0 VRF, the port parameters can be changed by this VRF. If a port belongs to multiple VRF instances, only a user with read-write-all access who is accessing the port through the Global Router can change this port configuration.

## Management VRF

The following sections detail Management VRF features.

### *Management Port*

The management port is a 10/100/1000 Mb/s Ethernet port that you can use for an out-of-band management connection to the switch.

#### **Note**

Not all hardware platforms provide a dedicated, physical management interface. For more information, see your hardware documentation.

### *Management Router VRF*

#### **Note**

MgmtRouter is only supported on VSP 8600 Series.

The switch has a separate VRF called Management Router (MgmtRouter) reserved for the management port and the Virtual Management IP address. The configured IP subnet has to be globally unique because the management protocols, for example, SNMP, Telnet, and FTP, can go through in-band or out-of-band ports. The VRF ID for the Management Router is 512.

The switch never switches or routes transit packets between the Management Router VRF port and the Global Router VRF, or between the Management Router VRF and other VRF ports.

The switch honors the VRF of the ingress packet; however, in no circumstance does the switch allow routing between the Management VRF and Global Router VRF. The switch does not support the configuration if you have an out-of-band management network with access to the same networks present in the GRT routing table.

**Note**

IPv6 is not supported on MgmtRouter.

### *Non Virtualized Client Management Applications*

**Note**

This section only applies to VSP 8600 Series.

Ensure that you do not define a default route in the Management Router VRF. A route used for non-virtualized client management applications, such as Telnet, Secure Shell (SSH), and FTP, originating from the switch, will always match a default route defined in the Management Router VRF.

If you want out-of-band management, as a best practice, define a specific static route in the Management Router VRF to the IP subnet where your management application resides.

When you specify a static route in the Management Router VRF, it enables the client management applications originating from the switch to perform out-of-band management without affecting in-band management. This enables in-band management applications to operate in the Global Router VRF.

Non-virtualized client management applications originating from the switch, such as Telnet, SSH, and FTP, follow the behavior listed below:

1. Look at the Management Router VRF route table.
2. If no route is found, the applications will proceed to look in the Global Router VRF table.

Non-virtualized client management applications include:

- DNS
- FTP client with the copy command
- NTP
- rlogin

**Note**

Rlogin is only supported on VSP 8600 Series.

- RADIUS authentication and accounting
- SSH
- SNMP clients in the form of traps

- SYSLOG
- TACACS+
- Telnet
- TFTP client

For management applications that originate outside the switch, the initial incoming packets establish a VRF context that limits the return path to the same VRF context.

### *Virtualized Management Applications*

Virtualized management applications, such as ping and traceroute, operate using the specified VRF context. To operate ping or traceroute you must specify the desired VRF context. If not specified, ping defaults to the Global Router VRF. For example, if you want to ping a device through the out-of-band management port you must select the Management Router VRF. For example, if you want to ping a device through the out-of-band management port you must select the Management Router VRF.

#### **Note**

IPv6 is not supported on MgmtRouter.

```
Switch:1(config)#ping 192.0.2.1 vrf MgmtRouter
192.0.2.1 is alive
```

#### **Ping test for IPv6:**

```
Switch:1(config)#ping 2001:db8::1 vrf vrfRED
2001:db8::1 is alive
```

#### **Traceroute test for IPv4:**

```
Switch:1#traceroute 192.0.2.1 vrf MgmtRouter
```

#### **Traceroute test for IPv6:**

```
Switch:1#traceroute 2001:db8::1 vrf vrfRED
```

## VRF Lite Configuration Rules

You must select the VRF for global IPv4 or IPv6 options before entering commands; not all Global Router parameters are configurable on other VRF instances.

Layer 1 and Layer 2 information (including VLAN information) is global and is not maintained for each VRF instance. However, you can associate a set of VLANs with a VRF instance.

A VLAN cannot belong to more than one VRF instance at a time. When you create a VLAN, more than one physical port can belong to it. You can associate a VRF instance with more than one IPv4 or IPv6 interface (a physical Ethernet port or a VLAN).

Perform physical port assignment at the VLAN and brouter port level. A VRF instance inherits all the ports assigned to its VLANs and brouter ports. You cannot directly assign a physical port to a VRF instance, but it is implicitly assigned when you associate the VRF with VLANs or brouter ports.

For IPv4, after you configure interVRF route redistribution between two VRF instances, avoid overlapping IP addresses between these two VRF instances.

When you configure VRF Lite, remember the following rules:

- You can connect two VRFs from the same system with an external cable.
- An IPv4 or IPv6 routable VLAN can become a member of a VRF.
- An IPv4 or IPv6 interface can belong to only one VRF.
- A VRF can exist even if no interfaces are assigned to it.
- Routing policies apply to VRFs on an individual basis.
- Multiple VRFs on the same node can function in different autonomous systems.

Following rules apply to IPv4 interfaces specifically:

- If you configure an IPv4 interface without specifying the VRF instance, it is mapped to VRF 0 by default.
- VRF Lite supports SMLT and RSMLT.
- VRF Lite supports RIP in and out policies.
- VRF Lite supports OSPF in and out (accept and redistribute) policies.
- Before you delete a VRF instance, disable OSPF. Deleting a VRF instance deletes the OSPF instance if OSPF is disabled.
- When you create a VRF instance, an OSPF instance is not automatically created. To activate OSPF on a VRF instance, first create an OSPF instance, and then enable OSPF.
- You can configure a VRF so it can have IP interfaces with OSPF, RIP, static routes, and policies simultaneously.
- Every IPv4 interface is a member of VRF 0 unless explicitly defined to belong to another VRF.

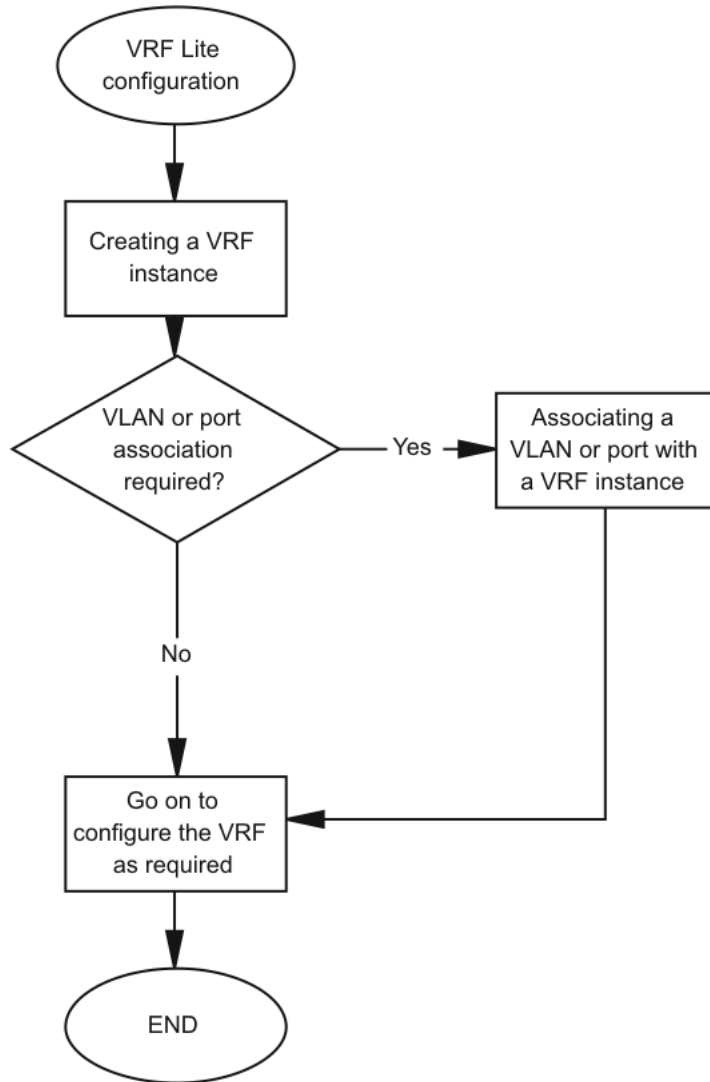

## VRF Lite configuration using the CLI

---

Use Virtual Router and Forwarding (VRF) Lite to provide many virtual routers using one switch.

This section shows you how to configure a VRF instance and how to associate ports and VLANs with VRF instances.

The following task flow shows you the sequence of procedures you perform to configure VRF Lite.

**Figure 269: VRF Lite configuration procedures**

## Create a VRF Instance

### About This Task

Create a VRF instance to provide a virtual routing interface for a user.

For more information on route scaling, see [VOSS Release Notes](#).

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Create a VRF instance and specify a VRF name:  
`ip vrf WORD<1-16>`

3. Configure the maximum number of routes:

- For IPv4:

```
ip vrf WORD<1-16> max-routes <max-routes>
```

- For IPv6:

```
ip vrf WORD<1-16> ipv6-max-routes <max-routes>
```

4. Enable max-routes traps:

- For IPv4:

```
ip vrf WORD<1-16> max-routes-trap enable
```

- For IPv6:

```
ip vrf WORD<1-16> ipv6-max-routes-trap enable
```

**Note**

The maximum number of IPv6 routes for the Global Router are fixed and cannot be changed.

5. Enter VRF Router Configuration mode:

```
router vrf WORD<1-16>
```

6. Configure the IP routing protocol triggers for the VRF:

Use one of the following commands on your switch:

- `ip bgp`

`ip bgp` creates both ipv4 and ipv6 instances.

- `ip ospf`

Use `ipv6 ospf` to create an OSPFv3 instance.

- `ip rip`

RIPng is not virtualized, hence the IPv6 configuration does not apply here.

**Note**

You cannot configure BGP, OSPF, or RIP on a VRF instance unless you first configure the routing protocol trigger.

7. Ensure that the instance is configured correctly:

```
show ip vrf [WORD<1-16>]
```

*Examples*

Create a VRF instance:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip vrf vrfRED
```

Configure the maximum number of IPv4 routes and enable max-routes traps.

```
Switch:1(config)#ip vrf vrfRED max-routes 12000
Switch:1(config)#ip vrf vrfRED max-routes-trap enable
```

Enter Router Configuration mode and configure the routing protocol triggers for the VRF:

```
Switch:1(config)#router vrf vrfRED
Switch:1(router-vrf)#ip bgp
Switch:1(router-vrf)#ip ospf
Switch:1(router-vrf)#ip rip
```

To Configure OSPFv3 instance for the VRF:

```
Switch:1(config)#router vrf vrfRED
Switch:1(router-vrf)#ipv6 ospf
```

Exit to Global configuration mode:

```
Switch:1(router-vrf)#exit
```

Configure the maximum number of IPv6 routes and enable IPv6 max-routes traps.

```
Switch:1(config)#ip vrf vrfRED ipv6-max-routes 7700
Switch:1(config)#ip vrf vrfRED ipv6-max-routes-trap enable
```

Ensure that the instance is configured correctly:

```
Switch:1#show ip vrf vrfRED

### Variable Definitions

The following table defines parameters for the **ip vrf** command.

| Variable                                                               | Value                                                                                                                                                                                                                                                                            |

Depending on the hardware platform, the parameter range and default value can vary. Use the CLI Help to see the available range for the switch. For route scaling information, see <a href="#">VOSS Release Notes</a> . |
| <i>max-routes-trap enable</i>                                          | Enables SNMP traps after the maximum number of IPv4 routes are reached.                                                                                                                                                                                                          |

| Variable                                 | Value                                                                                                       |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <code>ipv6-max-routes-trap enable</code> | Enables SNMP trap generation based on the configured number of maximum IPv6 routes. The default is enabled. |
| <code>name WORD&lt;0-16&gt;</code>       | Renames the VRF instance.                                                                                   |
| <code>vrf-trap</code>                    | Enables the device to send VRF-related traps.                                                               |

The following table defines parameters for the **show ip vrf** command.

| Variable                                                                | Value                                                                                                                                                                                                                                                       |
|-------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>max-routes [vrffids WORD&lt;0-512&gt;] [WORD &lt;1-16&gt;]</code> | Displays the maximum number of routes for the specified VRFs. <ul style="list-style-type: none"> <li><code>vrffids WORD&lt;0-512&gt;</code> specifies a list of VRFs by VRF IDs.</li> <li><code>WORD&lt;1-16&gt;</code> specifies a VRF by name.</li> </ul> |
| <code>vrffids WORD&lt;0-512&gt;</code>                                  | Specifies a list of VRFs by VRF IDs.                                                                                                                                                                                                                        |
| <code>WORD&lt;1-16&gt;</code>                                           | Specifies a VRF by name.                                                                                                                                                                                                                                    |

## Associate a VLAN or Port with a VRF Instance

You can assign a VRF instance to a port or VLAN. You cannot associate a VLAN or port and a VRF instance if the VLAN or port has an IP address. You can configure the IP address after you associate the port and VRF instance.

### Before You Begin

- Ensure the VRF is already configured.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Associate the port or VLAN with a VRF instance:

```
vrf WORD<1-16>
```

### Example

```
Switch:1> enable
Switch:1# configure terminal
```

Create a VRF named Two:

```
Switch:1(config-if)# ip vrf Two
```

Create a VLAN of type byport:

```
Switch:1(config-if)# vlan create 33 name vlan-30 type port-mstprstp 0
```

Enter VLAN Interface Configuration mode:

```
Switch:1(config-if)# interface vlan 33
```

Assign the VLAN to VRF Two:

```
Switch:1(config-if)# vrf Two
```

Assign an IP address to the VLAN:

```
Switch:1(config-if)# ip address 192.0.2.2/24
```

Assign a secondary IP address to the VLAN:

```
Switch:1(config-if)# ip address 192.0.4.2/24
```

Enter VRF configuration mode:

```
Switch:1(config-if)# router vrf Two
```

### Variable Definitions

Use the data in the following table to use the **vrf** command.

| Variable                          | Value                               |
|-----------------------------------|-------------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code> | Specifies the VRF instance by name. |

## Create an IP VPN Instance on a VRF

Create an IP VPN instance to advertise IP routes from one VRF to another across a Shortest Path Bridging MAC (SPBM) network.

### Before You Begin

- The VRF must exist.

### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. Create an IP VPN instance on the VRF:

```
ipvpn
```

3. Assign a service instance identifier (I-SID) to the IP VPN:

```
i-sid <0-16777215>
```

## 4. Enable IP VPN on the VRF:

```
ipvpn enable
```

By default, a new IP VPN instance is disabled.

## 5. Display all IP VPNs:

```
show ip ipvpn [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

**Example**

From Global Configuration mode, log on to Router VRF Configuration mode:

```
Switch:1(config)# router vrf red
```

Create the IP VPN instance:

```
Switch:1(router-vrf)# ipvpn
```

Enable IP VPN:

```
Switch:1(router-vrf)# i-sid 100
```

Enable IP VPN:

```
Switch:1(router-vrf)#ipvpn enable
```

```

=====
                                IPv4  IPVPN
=====
VRF Name          VRF ID   IPv4 IPVPN   IPv6 IPVPN   I-SID   I-SID Name
-----
red                1       enabled    disabled     100     ISID-1
-----
1 out of 1 Total active IPv4 L3 VSN displayed, including 0 active IPv6 L3 VSN.

```

*Variable definitions*

Use the data in the following table to use the **show ip ipvpn** command.

| Variable                              | Value                   |
|---------------------------------------|-------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies the VRF name. |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies the VRF ID.   |

Use the data in the following table to use the **i-sid** command.

| Variable                              | Value                                                                                                                      |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>i-sid &lt;0-16777215&gt;</code> | Assigns an I-SID to the VRF to configure. Use the no or default option to remove the I-SID to VRF allocation for this VRF. |

**Create an IPv6 VPN Instance****Before You Begin**

The VRF must exist.

## About This Task

Create an IPv6 VPN instance to advertise IPv6 routes from a VRF to Shortest Path Bridging MAC (SPBM) network. For more information about Layer 3 Virtual Services Networks (VSNs) and SPBM, see [Layer 3 VSN Configuration](#) on page 1537.

## Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Create an IPv6 VPN instance:

```
ipv6 ipvpn
```

3. Assign a service instance identifier (I-SID) to the IPv6 VPN:

```
i-sid <0-16777215>
```

4. Enable IPv6 VPN:

```
ipv6 ipvpn enable
```

5. Display all IPv6 VPNs:

```
show ipv6 ipvpn [vrf WORD<1-16> | vrfids WORD<0-512>]
```

## Example

Create and enable IPv6 VPN instance:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrf vrfred
Switch:1(router-vrf)#ipv6 ipvpn
Switch:1(router-vrf)#i-sid 100
Switch:1(router-vrf)#ipv6 ipvpn enable
Switch:1(router-vrf)#show ipv6 ipvpn
=====
                                IPv6 IPVPN
=====
VRF Name          VRF ID  IPv6 IPVPN  IPv4 IPVPN  I-SID      I-SID Name
-----
vrfred            2       enabled    disabled    5555      ISID-5555
=====
1 out of 1 Total IPv6 L3 VSN, 1 active IPv6 and 0 active IPv4 displayed.
```

### Variable definitions

Use the data in the following table to configure the **ipv6 ipvpn** command.

| Variable      | Value                                        |
|---------------|----------------------------------------------|
| <i>enable</i> | Enables IPv6 IPVPN. The default is disabled. |

Use the data in the following table to configure the **i-sid** command.

| Variable                        | Value                                         |
|---------------------------------|-----------------------------------------------|
| <code>&lt;0-16777215&gt;</code> | Assigns an I-SID to the VRF being configured. |

Use the data in the following table to configure the **show ipv6 ipvpn** command.

| Variable                              | Value                   |
|---------------------------------------|-------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies the VRF name. |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies the VRF ID.   |

## Configure the Maximum Number of VRFs

Perform this procedure to change the maximum number of VRFs and Layer 3 VSNs that the switch supports. Increasing the number of VRFs or Layer 3 VSNs can be useful in a WAN scenario or other large network.

The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see [VOSS Release Notes](#).

### About This Task

#### Important

If you enable this boot config flag, and the switch operates in SPBM mode (default configuration), the switch reduces the number of configurable VLANs. In such a configuration, the switch reserves VLANs 3500 to 3998 for internal use. You cannot use these VLANs as either platform VLANs or B-VLANs. You can still use the reserved VLAN range for customer VLANs (C-VLAN) on Flex UNI and B-VLANs on FE-VID.

Enabling the boot config flag to use more than 24 VRFs on VSP 8600 Series requires a license.

### Before You Begin

- If the switch operates in SPBM mode, before you enable the boot config flag, perform the following actions:
  - Check in-VLAN filters. If a filter references a VLAN in the 3500 to 3998 range, you must delete the filter or the filter configuration fails when you restart the switch.
  - Delete VLANs in the 3500 to 3998 range.
- Before you disable the boot config flag on VSP 8600 Series, delete additional VRFs if more than 24 exist.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Increase the maximum number of VRFs and Layer 3 VSNs:  

```
boot config flag vrf-scaling
```
3. Verify the configuration:  

```
show boot config flags
```
4. Save the configuration:  

```
save config
```
5. Restart the switch for the change to take effect:  

```
reset
```

## Examples

Enable the boot config flag to increase the maximum number of VRFs and Layer 3 VSNs. In the following example, the switch operates in SPBM mode and reserves the VLAN ID range of 3500 to 3999. If the switch does not operate in SPBM mode, the system does not display the VLAN warning message when you enable VRF scaling.

```
Switch:1>en
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flag vrf-scaling
Warning: Vlan 3500 to 3999 will be reserved for internal use.

Warning: Please save the configuration and reboot the switch
         for this configuration to take effect.
```

### Note

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
flags block-snmp false
flags debug-config false
flags debugmode false
flags dvr-leaf-mode false
flags enhancedsecure-mode false
flags factorydefaults false
flags flow-control-mode true
flags ftpd true
flags hsecure false
flags ipv6-egress-filter true
flags ipv6-mode false
flags linerate-directed-broadcast false
flags logging true
flags nni-mstp false
flags reboot true
flags spanning-tree-mode mstp
flags spbm-config-mode true
flags sshd true
flags syslog-rfc5424-format true
flags telnetd true
flags tftpd true
```

```

flags trace-logging false
flags urpf-mode true
flags verify-config true
flags vrf-scaling true
flags vxlan-gw-full-interworking-mode false

```

The following example shows the message that the system displays if you try to enable the boot config flag and configured VLANs use IDs between 3500 and 3999.

```

Switch:1>en
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flag vrf-scaling

Error: Delete all configured platform vlans between 3500 and 3999 to enable vrf-scaling.

```

## Enabling IPv6 trap notifications

### About This Task

Perform this procedure to enable SNMP traps when maximum number of IPv6 routes are reached.

#### Note

Different hardware platforms support different parameter ranges. Use the CLI Help to see the available range.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enable max-routes trap:
 

```
ip vrf WORD<1-16> ipv6-max-routes-trap enable
```

### Example

```

Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip vrf vrfRED ipv6-max-routes-trap enable

```

### Variable definitions

Use the data in the following table to use the **ipv6-max-routes-trap** command.

| Variable      | Value                                                                                                       |
|---------------|-------------------------------------------------------------------------------------------------------------|
| <i>enable</i> | Enables SNMP trap generation based on the configured number of maximum IPv6 routes. The default is enabled. |

## Display IPv6 max-routes Information

### About This Task

Perform this procedure to display the maximum IPv6 routes configured.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display max-routes information:  
show ip vrf ipv6-max-routes [vrfids WORD<0-512> | WORD<1-16>]

### Example

```
Switch:1#show ip vrf ipv6-max-routes
```

```
=====
                                VRF Specific Configuration
=====
```

| VRF-ID | VRF-NAME     | CONTEXT-NAME | IPV6-MAX-ROUTES | IPV6-MAX-ROUTES-TRAP | VRF-TRAP |
|--------|--------------|--------------|-----------------|----------------------|----------|
| 0      | GlobalRouter |              | 8000            | enable               | NA       |
| 1      | vrfred       | vrf1         | 5000            | enable               | enable   |
| 2      | vrfblue      | vrf2         | 5000            | enable               | enable   |

```
3 out of 3 Total Num of VRF Entries displayed.
```

## VRF Lite configuration using Enterprise Device Manager

Use VRF Lite to provide many virtual routers using a single switch.

### Configuring a VRF instance

#### About This Task

Configure a VRF instance to provide a virtual routing interface for a user.

#### Note

The maximum routes of IPv4 and IPv6 for Global Router (GRT) are non-configurable and fixed at the system limits.

Maximum route traps are not generated on GRT. For non-default VRFs, the permitted maximum routes can be lower than system limits and traps generate when the limit is exceeded.

#### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VRF**.
2. Click **VRF**.
3. Click the **VRF** tab.
4. Click **Insert**.
5. Specify the VRF ID.

6. Name the VRF instance.
7. Configure VRF Lite-related traps.
8. Configure the other parameters as required.
9. Click **Insert**.

### VRF field descriptions

Use the data in the following table to help you use the **VRF** tab.

| Name                           | Description                                                                                                                                                                                                                                                                                                                  |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>                      | Specifies the ID number of the VRF instance. VRF ID 0 is reserved for the GlobalRouter.                                                                                                                                                                                                                                      |
| <b>Name</b>                    | Names the VRF instance.                                                                                                                                                                                                                                                                                                      |
| <b>ContextName</b>             | Identifies the VRF. The SNMPv2 Community String or SNMPv3 contextName denotes the VRF context and is used to logically separate the MIB port management.                                                                                                                                                                     |
| <b>TrapEnable</b>              | Enables the VRF to send VRF Lite-related traps (VrfUp and VrfDown). The default is enabled.                                                                                                                                                                                                                                  |
| <b>MaxRoutes</b>               | Configures the maximum number of routes allowed for the VRF, which varies depending on the hardware. For scaling information, see <a href="#">VOSS Release Notes</a> . The default value varies for the GlobalRouter and non-default VRFs, depending on your hardware platform.                                              |
| <b>RpTrigger</b>               | Specifies the Routing Protocol (RP) triggers for the VRF. The triggers are used to initiate or shutdown routing protocols on a VRF. You can act upon multiple RPs simultaneously. You can also use this option to bring individual RPs up in steps.                                                                          |
| <b>MaxRoutesTrapEnable</b>     | Enables the generation of the VRF Max Routes Exceeded traps. The default is enabled.                                                                                                                                                                                                                                         |
| <b>Ipv6MaxRoutes</b>           | Configures the maximum number of IPv6 routes allowed for the VRF, which varies depending on the hardware. For scaling information, see <a href="#">VOSS Release Notes</a> . The default value varies for the GlobalRouter and non-default VRFs, depending on your hardware platform.                                         |
| <b>Ipv6MaxRoutesTrapEnable</b> | Enables SNMP trap generation after the maximum number of IPv6 routes are reached. The default is enabled.                                                                                                                                                                                                                    |
| <b>Active</b>                  | Displays if the VRF is active (true).                                                                                                                                                                                                                                                                                        |
| <b>Origin</b>                  | Displays the VRF origin (DYNAMIC or CONFIG). CONFIG indicates the VRF was manually created by the user. DYNAMIC indicates the VRF was created configuring an mvpn-isid on a VLAN. The Default VRF and the MGMT VRF are considered DYNAMIC.<br><br><b>Note:</b> Only CONFIG VRFs are saved and visible in the running-config. |

## Associating a port to a VRF instance

### About This Task

Associate a port to a Virtual Router Forwarding (VRF) instance so that the port becomes a member of the VRF instance.

You can assign a VRF instance to a port after you configure the VRF. The system assigns ports to the GlobalRouter, VRF 0, by default.

### Procedure

1. In the **Device Physical** View tab, select a port.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Click **General**.
4. Click the **VRF** tab.
5. To the right of the **BrouterVrfId** box, click the ellipsis (...) button.
6. In the **BrouterVrfId** dialog box, select the required VRF.
7. Click **OK**.
8. Click **Apply**.

### VRF field descriptions

Use the data in the following table to use the **VRF** tab.

| Name                  | Description                                               |
|-----------------------|-----------------------------------------------------------|
| <b>VrfIds</b>         | Shows the VRF ID.                                         |
| <b>VrfNames</b>       | Shows the VRF name.                                       |
| <b>VrfCount</b>       | Shows the number of VRFs to which the port is associated. |
| <b>BrouterVrfId</b>   | Specifies the VRF ID for a brouter port.                  |
| <b>BrouterVrfName</b> | Shows the VRF name for a brouter port.                    |

## Associating an Extreme Integrated Application Hosting Port to a VRF Instance

### Note

This procedure only applies to VSP 4900 Series and VSP 7400 Series.

### About This Task

Perform this procedure to associate an Extreme Integrated Application Hosting (IAH) port to a Virtual Router Forwarding (VRF) instance.

### Note

You can associate a VRF instance to an IAH port after you configure the VRF. By default, the IAH ports are associated to the GlobalRouter.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **VRF** tab.
4. (Optional) In the **VrfNames** field, select the **ShowAll** button to view the VRF instances the IAH Port is associated with.
5. In the **BrouterVrflid** field, select the ellipsis (...) button, and select the required VRF instance(s).
6. Select **Ok**.
7. Select **Apply**.

### VRF Field Descriptions

Use data in the following table to use the **VRF** tab.

| Name                  | Description                                                                                                 |
|-----------------------|-------------------------------------------------------------------------------------------------------------|
| <b>Vrflids</b>        | Shows the VRF ID.                                                                                           |
| <b>VrfNames</b>       | Shows the VRF name.                                                                                         |
| <b>VrfCount</b>       | Shows the number of VRFs to which the Extreme Integrated Application Hosting (IAH) port is associated with. |
| <b>BrouterVrflid</b>  | Specifies the VRF ID for a brouter port.                                                                    |
| <b>BrouterVrfName</b> | Shows the VRF name for a brouter port.                                                                      |

## Configuring interVRF route redistribution policies

Configure interVRF route redistribution so that a VRF interface can announce routes that other protocols learn, for example, OSPF, RIP, or BGP. Use a route policy to control the redistribution of routes.

### Before You Begin

- Ensure VRF instances exist.
- Configure route policies, if required.
- Change the VRF instance as required.

### About This Task

#### Procedure

1. In the navigation tree, expand **Configuration > IP**.
2. Select **Policy**.
3. Select the **Route Redistribution** tab.
4. Select **Insert**.
5. Select the ellipsis (...) button near the **DstVrflid** box to select the source and destination VRF IDs.

6. Select the ellipsis (...) button near the **SrcVrflid** box to select the source and destination VRF IDs.
7. In the **Protocol** option box, select the protocol.
8. In the **RouteSource** option box, select the route source.
9. Select **Enable**.
10. Choose the route policy to apply to the redistributed routes.
11. Configure other parameters as required.
12. Select **Insert**.
13. Select the **Applying Policy** tab.
14. Select **RedistributeApply**.
15. Select **Apply**.

### **Route Redistribution** field descriptions

Use the data in the following table to use the **Route Redistribution** tab.

| Name               | Description                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DstVrflid</b>   | Specifies the destination VRF ID to use in the redistribution.                                                                                                                                                                                                                                                                     |
| <b>Protocol</b>    | Specifies the protocols for which you want to receive external routing information.                                                                                                                                                                                                                                                |
| <b>SrcVrflid</b>   | Specifies the source VRF ID to use in the redistribution.                                                                                                                                                                                                                                                                          |
| <b>RouteSource</b> | Indicates if the protocol receives notification about the routes this source learns. The route source is equivalent to the owner in the routing table.                                                                                                                                                                             |
| <b>Enable</b>      | Enables or disables route redistribution. The default is disabled.                                                                                                                                                                                                                                                                 |
| <b>RoutePolicy</b> | Specifies the route policies to apply to the redistributed routes from the source VRF. Use the route policy to determine whether the system advertises a specific route to the specified protocol.                                                                                                                                 |
| <b>Metric</b>      | Specifies the metric announced in advertisements. The default is 0.                                                                                                                                                                                                                                                                |
| <b>MetricType</b>  | Specifies the metric type (applies to OSPF and BGP only). Specifies a type 1 or a type 2 metric. For metric type 1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type 2, the cost of the external routes is equal to the external cost alone. The default is type2. |
| <b>Subnets</b>     | Indicates that all the subnets must be advertised individually. The values are allow(1), and suppress(2). The default value is allow. This variable applies to OSPF only.                                                                                                                                                          |

## Viewing brouter port and VRF associations

### About This Task

You can view each port and associated VRFs. You can also change the VRFs associated with the port if the port has no IP address.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VRF**.
2. Click **VRF**.
3. Click the **VRF-Ports** tab.
4. To display the VRF names associated with a port, click a cell in one of the table rows and, on the toolbar, click the **ShowVRFNames** button.
5. To change the VRF, double-click the **BrouterVrflid** field for the port.

#### Tip

You can associate a port with more than one VRF.

6. Choose the required VRFs, and then click **Ok**.
7. Click **Apply**.

### **VRF-Ports** field descriptions

Use the data in the following table to use the **VRF-Ports** tab.

| Name                  | Description                                                                               |
|-----------------------|-------------------------------------------------------------------------------------------|
| <b>Index</b>          | Specifies the slot and port.                                                              |
| <b>Type</b>           | Specifies the port type.                                                                  |
| <b>Vrflids</b>        | Identifies the set of VRF IDs to which this port belongs.                                 |
| <b>VrfCount</b>       | Shows the number of VRF instances associated with this port.                              |
| <b>BrouterVrflid</b>  | Shows the VRF ID for this brouter port.                                                   |
| <b>BrouterVrfName</b> | Shows the VRF name for this brouter port.                                                 |
| <b>Show VrfNames</b>  | You can use this toolbar button to identify the set of VRF names to which a port belongs. |

Use the data in the following table to use the **Show VrfNames** button.

| Name            | Description                               |
|-----------------|-------------------------------------------|
| <b>Index</b>    | Specifies the slot and port.              |
| <b>VrfNames</b> | Shows the VRF name for this brouter port. |

## Viewing global VRF status information

### About This Task

View global VRF status information to determine the number of VRFs that are configured and active.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **VRF**.
2. Click **VRF**.
3. Click the **Global Status** tab.

### *Global Status* field descriptions

Use the data in the following table to use the **Global Status** tab.

| Name                             | Description                                                                                                         |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>ConfigNextAvailableVrflid</b> | Specifies the number of the next available Virtual Router ID (index).                                               |
| <b>ConfiguredVRFs</b>            | Specifies the number of VRFs configured on this network element.                                                    |
| <b>ActiveVRFs</b>                | Specifies the number of VRFs that are active on the network element. These are VRFs for which the OperStatus is up. |

## Viewing VRF instance statistics and status information

### About This Task

View VRF instance status information to determine the operational status of each VRF, as well as other operational parameters.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **VRF** .
2. Click **VRF**.
3. Click the **VRF Stats** tab.

### *VRF Stats* field descriptions

Use the data in the following table to use the **VRF Stats** tab.

| Name                    | Description                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------|
| <b>Id</b>               | Specifies the ID number of the VRF instance.                                                 |
| <b>StatRouteEntries</b> | Specifies the total number of routes for this VRF.                                           |
| <b>StatFIBEntries</b>   | Specifies the total number of Forwarding Information Base (FIB) entries for this VRF.        |
| <b>StatUpTime</b>       | Specifies the time in (in hundredths of a second) since this VRF entry has been operational. |

| Name                        | Description                                                                                                                                                   |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OperStatus</b>           | Shows the operational status of the Virtual Router.                                                                                                           |
| <b>RouterAddressType</b>    | Specifies the router address type of this VRF.                                                                                                                |
| <b>RouterAddress</b>        | Specifies the router address of this VRF, derived from one of the interfaces. If a loopback interface is present, you can use the loopback interface address. |
| <b>DhcpRelayNumRequests</b> | Specifies the total number of DHCP requests on this VRF.                                                                                                      |
| <b>DhcpRelayNumReplies</b>  | Specifies the total number of DHCP replies on this VRF.                                                                                                       |

## Viewing Statistics for a VRF

### About This Task

View VRF statistics to ensure the instance is performing as expected.

### Procedure

1. In the navigation pane, expand the **Configuration** > **VRF** folders.
2. Click **VRF**.
3. Click the **VRF** tab.
4. Select a VRF.
5. Click the **Stats** button.

### *Stats Field Descriptions*

Use the data in the following table to use the **Stats** tab.

| Name                    | Description                                                                     |
|-------------------------|---------------------------------------------------------------------------------|
| <b>StatRouteEntries</b> | Specifies the number of routes for this VRF.                                    |
| <b>StatFIBEntries</b>   | Specifies the number of Forwarding Information Base (FIB) entries for this VRF. |

## Select and Launch a VRF Context View

Use this procedure to open a VRF context view when you use EDM. GlobalRouter is the default view at log in. If you launch a VRF context view, EDM displays the VRF navigation in a new tab.

### About This Task

#### Important

If you log out from the GRT view, the system generates a warning: all tabs close and your session terminates. If you close a VRF view tab, you close only that view.

**Note**

The Set VRF Context view function is not available to users in a service provider deployment where only a tenant VRF view is assigned.

You can configure both Global Router (GRT) and Virtual Routing and Forwarding (VRF) instances when you launch a VRF context view. You can open five tabs for each EDM session.

**Procedure**

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Select **Set VRF Context View**.
3. Select the **VRF** tab.
4. Select a context to view.
5. Select **Launch VRF Context view**.

A new browser tab opens containing the selected VRF view

**VRF field descriptions**

Use the descriptions in the following table to use the **VRF** tab.

| Name               | Description                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------|
| <b>Id</b>          | Shows the unique VRF ID.                                                                                    |
| <b>Name</b>        | Shows the name of the virtual router.                                                                       |
| <b>ContextName</b> | Shows the SNMPv3 context name that denotes the VRF context and logically separates the MIB port management. |

## Create an IP VPN Instance on a VRF

Create an IP VPN instance to advertise IP routes from one VRF to another across a Shortest Path Bridging MAC (SPBM) network.

**Before You Begin**

- You must configure the required SPBM IS-IS infrastructure.
- The VRF must exist.

**Procedure**

1. In the navigation tree, expand **Configuration > IP**.
2. Select **IP-VPN**.
3. Select the **VPN** tab.
4. Select **Insert**.
5. Select **[...]**, and then select a VRF from the list.
6. Select **OK**.
7. Select **Insert**.

By default, the new IP VPN instance is disabled.

8. In the **Isid Number** column, double-click the **0** value, and then enter the service instance identifier (I-SID) to assign to the IP-VPN.
9. In the **Enable** column, double-click the **disable** value.
10. Select the arrow to view a list of choices, and then choose **enable**.
11. Select **Apply**.

### VPN Field Descriptions

Use the data in the following table to use the **VPN** tab.

| Name                                                                                     | Description                                                                      |
|------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| <b>Vrfid</b>                                                                             | Specifies the ID of the VRF to configure.                                        |
| <b>Enable</b>                                                                            | Enables or disables the IP VPN instance on the VRF. The default is disabled.     |
| <b>Isid Number</b>                                                                       | Specifies the I-SID to associate with the VPN. By default, no I-SID is assigned. |
| <b>Isid Name</b><br><b>Note:</b><br>This field does not apply to all hardware platforms. | Specifies the name of the I-SID associated with the VPN.                         |

## Create an IPv6 VPN Instance on a VRF

Create an IPv6 VPN instance to advertise IPv6 routes from a VRF to Shortest Path Bridging MAC (SPBM) network.

### Before You Begin

- You must configure the required SPBM IS-IS infrastructure.
- The VRF must exist.

### Procedure

1. In the navigation tree, expand **Configuration > IPv6**.
2. Select **IPv6-VPN**.
3. Select the **VPN** tab.
4. Select **Insert**.
5. Select **[...]**, and then select a VRF from the list.
6. Select **OK**.
7. Select **Insert**.
8. In the **IsidNumber** column, double-click the **0** value, and then enter the service instance identifier (I-SID) to assign to the IPv6-VPN.
9. In the **Enable** column, double-click the value and select **true** or **false** from the drop-down list.
10. Select **Apply**.

**VPN Field Descriptions**

Use the data in the following table to use the **VPN** tab.

| Name                                                                                          | Description                                                                           |
|-----------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|
| <b>VrfId</b>                                                                                  | Specifies the ID of the VRF to configure.                                             |
| <b>Enable</b>                                                                                 | Enables or disables the IPv6 VPN instance on the VRF. The default is disabled.        |
| <b>IsidNumber</b>                                                                             | Specifies the I-SID to associate with the IPv6 VPN. By default, no I-SID is assigned. |
| <b>IsidName</b><br><br><b>Note:</b><br>This field is not supported on all hardware platforms. | Specifies the name of the I-SID.                                                      |

**Configure the Maximum Number of VRFs****Note**

This procedure does not apply to XA1400 Series and VSP 8600 Series.

Perform this procedure to change the maximum number of VRFs and Layer 3 VSNs that the switch supports. By default, the switch supports 24 VRFs and Layer 3 VSNs. Increasing the number of VRFs or Layer 3 VSNs can be useful in a WAN scenario or other large network.

The maximum number of supported VRFs and Layer 3 VSNs differs depending on the hardware platform. For more information about maximum scaling numbers, see [VOSS Release Notes](#).

**About This Task****Important**

If you enable this boot config flag, and the switch operates in SPBM mode (default configuration), the switch reduces the number of configurable VLANs. In such a configuration, the switch reserves VLANs 3500 to 3998 for internal use. You cannot use these VLANs as either platform VLANs or B-VLANs. You can still use the reserved VLAN range for customer VLANs (C-VLAN) on Flex UNI and B-VLANs on FE-VID.

Enabling the boot config flag to use more than 24 VRFs requires a Premier or Premier + MACsec license.

**Before You Begin**

- If the switch operates in SPBM mode, before you enable this boot config flag, perform the following actions:
  - Check in-VLAN filters. If a filter references a VLAN in the 3500 to 3998 range, you must delete the filter or the filter configuration fails when you restart the switch.
  - Delete VLANs in the 3500 to 3998 range.
- Before you disable this boot config flag, delete additional VRFs if more than 24 exist.

**Procedure**

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **Boot Config** tab.
4. Perform one of the following actions:
  - a. To enable VRF scaling, select the **EnablevrfScaling** check box.
  - b. To disable VRF scaling, clear the **EnablevrfScaling** check box.
5. Select **Apply**.
6. Restart the switch for the change to take effect.

## VRRP Fundamentals

Because end stations often use a static default gateway IP address, a loss of the default gateway router causes a loss of connectivity to the remote networks.

The Virtual Router Redundancy Protocol (VRRP) (RFC 2338) eliminates the single point of failure that can occur when the single static default gateway router for an end station is lost. VRRP introduces a virtual IP address (transparent to users) shared between two or more routers that connect the common subnet to the enterprise network. With the virtual IP address as the default gateway on end hosts, VRRP provides dynamic default gateway redundancy in the event of failover.

The VRRP router that controls the IP addresses associated with a virtual router is the primary router and it forwards packets to these IP addresses. The election process provides a dynamic transition of forwarding responsibility if the primary router becomes unavailable.

a virtual IP address that is in the same subnet as the primary IP address of the interface (it can also be the same as the Primary IP address of the interface, in this case this is the address owner - you can add a mention to the note above here -).

#### Note

The VRRP virtual IP address can be the same as the local IP address or Primary IP address of the interface on which VRRP is enabled. In this case, the router is the VRRP address owner on that interface and the priority is set to the maximum value of 255.

In the following figure, the first three hosts install a default route to the R1 (virtual router 1) IP address and the other three hosts install a default route to the R2 (virtual router 2) IP address.

This configuration not only shares the load of the outgoing traffic, but it also provides full redundancy. If either router fails, the other router assumes responsibility for both addresses.

**Figure 270: Virtual Router Redundancy Protocol configuration**

For information about the number of supported VRRP interfaces, see the scaling information in [VOSS Release Notes](#).

The following terms are specific to VRRP:

#### VRRP router

a router running the VRRP protocol

#### Virtual router

an abstract object acting as the default router for one or more hosts, consisting of a virtual router ID and a set of addresses

#### Primary IP address of the interface

the real IP address of the interface. This IP address is used as the source of the VRRP advertisement. In the case of multinetting, this is the primary IP address of the interface.

### **Primary IP VRRP address**

a virtual IP address that is in the same subnet as the primary IP address of the interface. This address is mandatory for the creation of the VRRP instance. The primary VRRP router performs the following actions:

- adds this IP address to the VRRP advertisement
- responds to ARP requests for this IP address
- routes traffic destined to this IP address

### **Secondary IP VRRP address / Associated IP VRRP address**

an IP address that is in the same subnet as the secondary IP address of the interface. If the primary VRRP address is the same subnet as the primary IP address of the interface, the secondary IP VRRP address also needs to be the same subnet as the secondary IP address of the interface. This IP address is not mandatory for VRRP instance creation. The primary VRRP router performs the following actions:

- adds this IP address to the VRRP advertisement
- responds to ARP requests for this IP address
- routes traffic destined to this IP address

### **Virtual primary router**

the router that assumes responsibility to forward packets sent to the IP address associated with the virtual router and answer ARP requests for these IP addresses

### **Virtual router backup**

the virtual router that becomes the primary router if the current primary router fails

When a VRRP router is initialized it sends a VRRP advertisement. The VRRP router also broadcasts a gratuitous ARP request that contains the virtual router MAC address for each IP address associated with the virtual router. The VRRP router then transitions to the controlling state.

In the controlling state, the VRRP router functions as the forwarding router for the IP addresses associated with the virtual router. The VRRP router responds to ARP requests for these IP addresses, forwards packets with a destination MAC address equal to the virtual router MAC address, and accepts packets addressed to IP addresses associated with the virtual router.

In the backup state, a VRRP router monitors the availability and state of the primary router. The backup router does not respond to ARP requests and must discard packets with a MAC address equal to the virtual router MAC address. The backup router does not accept packets addressed to IP addresses associated with the virtual router. If a shutdown occurs, the backup router transitions back to the initialize state. If the primary router goes down, the backup router sends the VRRP advertisement and ARP request described in the preceding paragraph and transitions to the controlling state.

The router transitions to the backup state in the following situations:

- If the priority is greater than the local priority
- If the priority is the same as the local priority and the primary IP address of the sender is greater than the local primary IP address

Otherwise, the router discards the advertisement. If a shutdown occurs, the primary router sends a VRRP advertisement with a priority of 0 and transitions to the initialize state.

## Critical IP Address

Within a VRRP VLAN, one link can go down while the remaining links in the VLAN remain operational. Because the VRRP VLAN continues to function, a virtual router associated with that VLAN does not register a master router failure.

As a result, if the local router IP interface connecting the virtual router to the external network fails, this does not automatically trigger a master router failover.

### Note

In this context, local implies an address from the same VRF as the IP interface where VRRP is being configured.

The critical IP address resolves this issue. If the critical IP address fails, it triggers a failover of the master router.

You can specify the local router IP interface uplink from the VRRP router to the network as the critical IP address. This ensures that, if the local uplink interface fails, VRRP initiates a master router failover to one of the backup routers.

In VRRP, the local network uplink interface on router 1 is shown as the critical IP address for router 1. As well, the same network uplink is shown as the critical IP address for router 2. Router 2 also requires a critical IP address for cases in which it assumes the role of the master router.

With the support of VRRP and the critical IP interface linked to VRRP, you can build reliable small core networks that provide support for converged applications, such as voice and multimedia.

### Note

A Brouter port with a VLACP Critical IP address in a VRRP is supported.

## VRRP and SMLT

The standard implementation of VRRP supports only one active master device for each IP subnet. All other VRRP interfaces in a network are in backup mode.

A deficiency occurs when VRRP-enabled switches use Split MultiLink Trunking (SMLT). If VRRP switches are aggregated into two Split MultiLink Trunk switches, the end host

traffic is load-shared on all uplinks to the aggregation switches (based on the Multilink Trunk traffic distribution algorithm).

However, VRRP usually has only one active routing interface enabled. All other VRRP routers are in backup mode. Therefore, all traffic that reaches the backup VRRP router is forwarded over the vIST towards the master VRRP router. In this case, the vIST does not have enough bandwidth to carry all the aggregated traffic.

To resolve this issue, assign the backup router as the backup master router. The backup master router can actively load-share the routing traffic with a master router.

When the backup master router is enabled, the incoming host traffic is forwarded over the SMLT links as usual. When the backup master router is configured along with the critical IP interface and the critical IP interface goes down, the VRRP router transitions to be the backup router with the backup master state down. In this state, the VRRP router does not forward traffic.

## VRRP Fast Hello Timers

You can configure the advertisement time interval (in seconds) between sending advertisement messages. This interval permits fast network convergence with standardized VRRP failover. However, losing connections to servers for more than a second can result in missing critical failures. Customer network uptime in many cases requires faster network convergence, which means network problems must be detected within hundreds of milliseconds. Fast Advertisement Enable and Fast Advertisement Interval meet these requirements

Fast Advertisement Enable acts like a toggle device for the Advertisement Interval and the Fast Advertisement Interval. When Fast Advertisement Enable is enabled, the Fast Advertisement Interval is used instead of the Advertisement Interval.

The Fast Advertisement Interval is similar to the Advertisement Interval parameter except for the unit of measure and the range. The Fast Advertisement Interval is expressed in milliseconds and the range is from 200 to 1000 milliseconds. This unit of measure must be in multiples of 200 milliseconds, otherwise the system displays an error.

When you enable the fast advertisement interval, VRRP can communicate with other switch ports and networking products that have the same configuration.

## Handling of IPv4 Layer 2 Unicast Packets at VRRP Backup Master

For VOSS 7.1 releases and later, the handling of IPv4 Layer 2 unicast packets (for example, ARP Request/Reply) with the destination MAC as VRRP MAC has been modified on Backup-Master. These packets are now handled by VRRP Master only.

The Backup-Master forwards all IPv4 Layer 2 unicast packets to the Master and the Master VRRP sends an ARP reply only.

Processing of IP unicast packets (for example, ICMP packets to VRRP IP) or IPv4 routed packets (with destination MAC as VRRP MAC) on VRRP Backup-Master stays the same.

For example, the VRRP Backup-Master replies to ICMP requests and routes Layer 3 routed packets to the destination and does not forward these packets to the Master when they arrive at the Backup-Master.

To reflect the above changes, the VRRP MAC entry on the Backup-Master now points to the Master instead of itself, and the ARP entry for VRRP IP on the backup-master points to local.

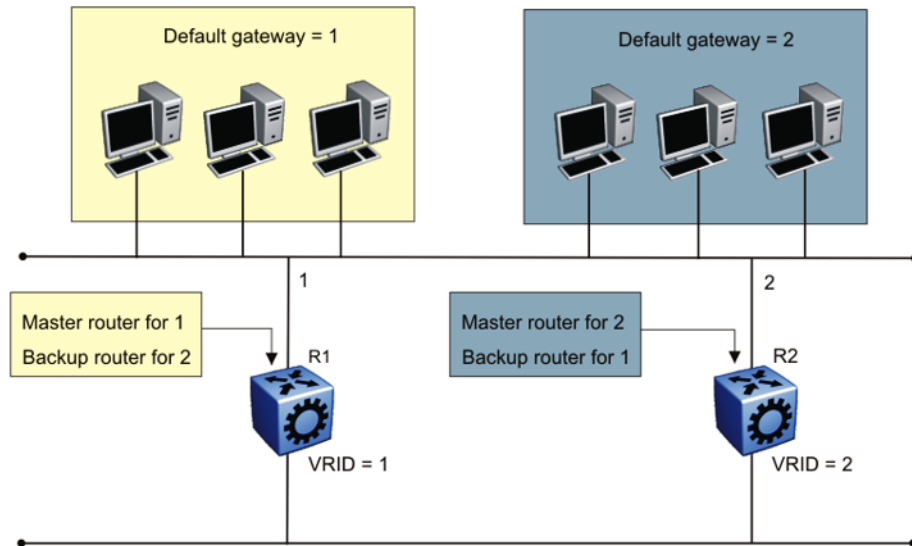

## VRRP Guidelines

VRRP provides another layer of resiliency to your network design by providing default gateway redundancy for end users. If a VRRP-enabled router that connects to the default gateway fails, failover to the VRRP backup router ensures no interruption for end users who attempt to route from their local subnet.

Only the VRRP Master router forwards traffic for a given subnet. The backup VRRP router does not route traffic destined for the default gateway.

To enable both VRRP switches to route traffic, the switch software has an extension to VRRP, the BackupMaster, that creates an active-active environment for routing. If you enable BackupMaster on the backup router, the backup router no longer switches traffic to the VRRP Master. Instead the BackupMaster routes all traffic received on the BackupMaster IP interface according to the switch routing table.

Stagger VRRP instances on a network or subnet basis. The following figure shows the VRRP Masters and BackupMasters for two subnets. For more information about how to configure VRRP using the Command Line Interface (CLI) and Enterprise Device Manager (EDM), see [Configure VRRP Using CLI](#) on page 4224 and [Configure VRRP using EDM](#) on page 4249.

**Figure 271: VRRP network configuration**

The VRRP BackupMaster uses the VRRP standardized backup switch state machine. Thus, VRRP BackupMaster is compatible with standard VRRP.

Use the following best practices to implement VRRP:

- Do not configure the virtual address as a physical interface that is used on the routing switches. Instead, use a third address, for example:
  - Interface IP address of VLAN A on Switch 1 = x.x.x.2
  - Interface IP address of VLAN A on Switch 2 = x.x.x.3
  - Virtual IP address of VLAN A = x.x.x.1

**Note**

The VRRP virtual IP address can be the same as the local IP address or Primary IP address of the interface on which VRRP is enabled. In this case, the router is the VRRP address owner on that interface and the priority is set to the maximum value of 255.

- Configure the VRRP holddown timer with enough time that the Interior Gateway Protocol (IGP) routing protocol has time to update the routing table. In some cases, configuring the VRRP holddown timer to a minimum of 1.5 times the IGP convergence time is sufficient. For OSPF, as a best practice, use a value of 90 seconds if you use the default OSPF timers.
- Implement VRRP BackupMaster for an active-active configuration (BackupMaster works across multiple switches that participate in the same VRRP domain).
- Configure VRRP priority as 200 to configure VRRP Master.
- Stagger VRRP Masters between switches in the core to balance the load between switches.

- If you implement VRRP Fast, you create additional control traffic on the network and also create a greater load on the CPU. To reduce the convergence time of VRRP, the VRRP Fast feature allows the modification of VRRP timers to achieve subsecond failover of VRRP. Without VRRP Fast, normal convergence time is approximately 3 seconds.
- Do not use VRRP BackupMaster and critical IP at the same time. Use one or the other.

### VRRP and Spanning Tree

The switch can use one of two spanning tree protocols: Rapid Spanning Tree Protocol (RSTP) and Multiple Spanning Tree Protocol (MSTP).

VRRP protects clients and servers from link or aggregation switch failures. Configure the network to limit the amount of time a link is out of service during VRRP convergence. The following figure shows two possible configurations of VRRP and spanning tree; configuration A is optimal and configuration B is not.

**Figure 272: VRRP and STG configurations**

In this figure, configuration A is optimal because VRRP convergence occurs within 2 to 3 seconds. In configuration A, three spanning tree instances exist and VRRP runs on the link between the two routers. Spanning tree instance 2 exists on the link between the two routers, which separates the link between the two routers from the spanning tree instances found on the other devices. All uplinks are active.

In configuration B, VRRP convergence takes between 30 and 45 seconds because it depends on spanning tree convergence. After initial convergence, spanning tree blocks one link (an uplink), so only one uplink is used. If an error occurs on the uplink,

spanning tree reconverges, which can take up to 45 seconds. After spanning tree reconvergence, VRRP can take a few more seconds to fail over.

## VRRP for IPv6

---

For IPv6 hosts on a LAN to learn about one or more default routers, IPv6-enabled routers send router advertisements using the IPv6 ND protocol. The routers multicast these router advertisements every few minutes.

The ND protocol uses a mechanism called neighbor unreachability detection to detect the failure of a neighbor node (router or host) or the failure of the forwarding path to a neighbor. Nodes can monitor the health of a forwarding path by sending unicast ND neighbor solicitation messages to the neighbor node. To reduce traffic, nodes only send neighbor solicitations to neighbors to which they actively send traffic and only after the node receives no positive indication that the neighbors are up for a period of time. A host takes a minimum of 5 seconds to learn that a router is unreachable before it switches to another default router, but this minimum value increases ND traffic. This delay can cause service disruption.

VRRP for IPv6 provides a faster switchover to an alternate default router than is possible using the ND protocol. With VRRP for IPv6, a backup router can take over for a failed default router in approximately three seconds (using default parameters). The switchover is accomplished without interaction with the hosts and with a minimum amount of VRRP traffic.

The IPv6 VRRP implementation is similar to the existing IPv4 VRRP operation, including support for holddown timer, critical IP, fast advertisements, and backup master. With backup master enabled, the backup switch routes all traffic according to its routing table. The backup master switch does not perform Layer 2 switching for the traffic to the VRRP master.

You must specify a link-local address to associate with the virtual router. Optionally, you can also assign global unicast IPv6 addresses to associate with the virtual router. Network prefixes for the virtual router are derived from the global IPv6 addresses assigned to the virtual router.

One active master switch exists for each IPv6 network prefix. All other VRRP interfaces in a network are in backup mode.

## VRRP for IPv6 operation

VRRP uses a virtual IP address shared between two or more routers connecting the common network prefix to the enterprise network. With the virtual IP address as the default gateway on end hosts, VRRP provides dynamic default gateway redundancy in the event of failover.

The VRRP router with higher priority is called the master router. In case of equal priority the router with higher link-local address becomes the master router. The master router forwards packets sent to the virtual router IP addresses.

The following figure shows the minimum VRRP topology.

**Figure 273: VRRP network topology**

Traffic flows between users A and users B.

Router A uses VRRP global addresses as next hops for users B, and Router B for users A.

The VRRP master forwards the traffic and sends VRRP advertisements in the VLAN to announce to the backups that it is the master. If the master is no longer available, the backup takes over and becomes master. The only change occurs to the state of VRRP.

The VRRP router then transitions to the controlling state.

**Note**

The VRRP virtual IP address can be the same as the local IP address or Primary IP address of the interface on which VRRP is enabled. In this case, the router is the VRRP address owner on that interface and the priority is set to the maximum value of 255.

In the controlling state, the VRRP router functions as the forwarding router for the IP addresses associated with the virtual router. The router responds to ND neighbor solicitation and ND router solicitation messages for these IP addresses, forwards packets with a destination MAC address equal to the virtual router MAC address, and accepts packets addressed to IP addresses associated with the virtual router.

If you initialize the VRRP router and the priority is not 255, the router transitions to the backup state to ensure that all Layer 2 switches in the downstream path relearn the new origin of the VRRP MAC addresses.

In the backup state, a VRRP router monitors the availability and state of the master router. The backup does not respond to ND neighbor solicitation and ND router solicitation messages for virtual router IP addresses and discards packets with a MAC address equal to the virtual router MAC address. The backup does not accept packets addressed to IP addresses associated with the virtual router. If a shutdown occurs, it transitions back to the initialize state. If the master router goes down, the backup router sends the VRRP advertisement and unsolicited ND neighbor advertisements and ND

router advertisements described in the preceding paragraphs and transitions to the controlling state.

## VRRP Advertisements and Master Router Failover

When you initialize a VRRP router, the master router continues to send advertisement messages at the advertisement interval period.

The other VRRP routers transition to the backup state in the following situations:

- if the priority in the received advertisement is greater than the local priority
- if the priority in the received advertisement is the same as the local priority and the primary IP address of the sender is greater than the local primary IP address

The backup routers use the advertisements from the master router as a keepalive to monitor the health of the master router. If the backup router does not receive an advertisement during the master downtime interval, calculated as  $3 * \text{advertisement interval}$ , then the master router is declared down.

If a shutdown occurs, the master router sends a VRRP advertisement with a priority of 0 and transitions to the initialize state.

The priority value 0 indicates that the master router has stopped participating in VRRP. This value triggers the backup router to transition to the master state without waiting for the current master to time out.

Edge devices learn the VRRP MAC address towards the master. After the backup becomes master and sends the advertisements, this causes the VRRP MAC address to move on the edge devices and point towards the new master.

## Critical IPv6 Address and holddown Timer

The critical IPv6 address is an interface that has primary impact on VRRP. If you enable critical IPv6 and the status of the critical IP changes, the master and backup relationship also changes.

If you configure and enable critical IPv6 address, the master transitions to backup if the critical IPv6 is down, and the backup becomes the master. After the critical IPv6 address of the original master resumes, if the hold-down timer is configured to 0, it becomes the master immediately. Otherwise, the original master transitions to the master state after the hold-down timer time out.

You can specify the local router IP interface uplink from the VRRP router to the network as the critical IP address. This ensures that, if the local uplink interface fails, VRRP initiates a master router failover to one of the backup routers.

The critical address can be one of the global unicast IPv6 addresses assigned to any local IPv6 interfaces.

The holddown timer is a proprietary enhancement to VRRP.

After a master transitions to backup by critical IP changing, one of the backup routers will be elected as the master router. After the critical IPv6 of the original master is restored, the original master remains in the backup state for a period of time that you configure by using the **holddown-timer** parameter. The router becomes the master immediately if you use the command **ipv6 vrrp <1-255> action preempt**.

The holddown timer allows the master router enough time to detect and update the dynamic routes. The timer delays the preemption of the master over the backup, when the master becomes available. If the hold-timer is configured to 0, it becomes the master router immediately. Otherwise, it transitions to the master state only after the holddown timer times out.

The holddown timer does not apply during failovers caused by VRRP router priority change. The holddown timer applies only to failovers caused by a critical IP failure.

Configure all of your routers to use identical values for the holddown timer.

#### **Important**

Do not use VRRP backup master and critical IP at the same time. Use one or the other. The critical IP address must be a local address.

## VRRP Backup Master with Triangular SMLT

The standard implementation of VRRP supports one active master switch for each IPv6 subnet. All other VRRP interfaces in a network are in backup mode.

A deficiency occurs when VRRP-enabled switches use SMLT. If VRRP switches are aggregated into two SMLT switches, the end host traffic is load-shared on all uplinks to the aggregation switches (based on the Multilink Trunk [MLT] traffic distribution algorithm).

However, VRRP usually has only one active routing interface enabled. All other VRRP routers are in backup mode. Therefore, all traffic that reaches the backup VRRP router is forwarded over Virtual Inter-Switch Trunk (vIST) toward the master VRRP router. In this case, vIST potentially does not have enough bandwidth to carry all the aggregated traffic.

To resolve this issue, assign the backup router as the backup master router. The backup master router can actively load-share the routing traffic with a master router.

Because the two VRRP peer nodes exchange MAC address tables, the VRRP backup master can forward traffic directly, on behalf of the master router. The switch in the backup master state routes all traffic received on the backup master IP interface according to its routing table. The backup master switch does not perform Layer 2 switching for the traffic to the VRRP master.

If you enable SMLT on the backup master router, the incoming host traffic is forwarded over the SMLT links as usual.

**Important**

Do not use VRRP backup master and critical IP at the same time. Use one or the other.

## Fast Advertisement

You can configure the advertisement time interval (in seconds) between sending advertisement messages. This interval permits fast network convergence with standardized VRRP failover. However, losing connections to servers for more than a second can result in missing critical failures. Customer network uptime in many cases requires faster network convergence, which means network problems must be detected within hundreds of milliseconds.

To meet these requirements, the fast advertisement interval are provided.

The fast advertisement interval is similar to the advertisement interval parameter except for the unit of measure and the range. The fast advertisement interval is expressed in milliseconds and the range is from 200 to 1,000 milliseconds. This unit of measure must be in multiples of 200 milliseconds.

To configure fast advertisement, you must specify a fast advertisement interval and explicitly enable the fast advertisement option. After you enable fast advertisement, the fast advertisement interval is used instead of the advertisement interval.

If you enable fast advertisement, VRRP can only communicate with other products that have the same configuration.

## Accept-mode

When you configure VRRP for IPv6 on an interface you can configure the `accept-mode` parameter, which controls whether the VRRP master or backup master accepts packets destined for the IPv6 address associated with the virtual router.

By default, `accept-mode` is disabled. The `accept-mode` parameter does not affect the Neighbor Discovery packets. The master router forwards packets with a destination link-layer MAC address that matches the virtual MAC address, and accepts packets forwarded over the virtual interswitch trunk (VIST) toward the master router, if `accept-mode` is enabled. If you disable `accept-mode`, you cannot ping the virtual IPv6 address. If you enable `accept-mode`, the master router accepts packets addressed to the IPv6 address that is associated with the virtual router.

When you configure VRRP for IPv6 on an interface, you can configure the `accept-mode` parameter. By default, `accept-mode` is disabled. If you disable `accept-mode`, the master router does not drop neighbor solicitations or neighbor advertisements. The master router forwards packets with a destination link-layer MAC address that matches the virtual MAC address. If you disable `accept-mode`, you cannot ping the virtual IPv6 address.

## VRRPv3

---

VRRPv3 is a combined protocol for both IPv4 and IPv6. It specifies an election protocol that dynamically assigns responsibility for a virtual router to one of the VRRP routers on a LAN. The VRRP router that controls the IPv4 or IPv6 addresses associated with a virtual router is called the Master, and it forwards packets sent to these IPv4 or IPv6 addresses. VRRP Backups wait for a Master and take ownership when the Master is no longer detected.

The election protocol provides dynamic failover in the forwarding responsibility when the Master is unavailable. VRRP for IPv4 gains a higher-availability default path without configuring dynamic routing or router discovery protocols on every end-host. VRRP for IPv6 gains a quick switch-over to Backup routers compared to the standard IPv6 Neighbor Discovery mechanisms.

### Note

The VRRP IPv6 link-local address must be the same for all VRRP routers sharing the same link and the same virtual router ID, that is, the same VRRP instance. It is the address the VRRP advertisements are sent from. Also, the Router Advertisement packets from the VRRP interface are transmitted using this address, so, when IPv6 Stateless Address Autoconfiguration is used, this address is added to host Default Router List and is used as a gateway.

The software supports VRRPv3 for IPv4 and VRRPv3 for IPv6. VRRPv3 for IPv6 is compliant to RFC 5798. The software also supports VRRPv2 for IPv4.

## VRRPv3 guidelines

The switch also supports VRRPv2 for IPv4. If you configure VRRP IPv6 on an interface, it runs independently of the IPv4 version. Configure the version of the VRRP IPv4 on the interface before you configure any other IPv4 VRRP attributes. By default, the version is not configured to a particular value. However, when sourcing older configuration files that do not have the version saved, the router configures the version to VRRPv2 by default. If you change the version, all IPv4 configuration under that interface is automatically removed, and you are prompted for a confirmation before this operation.

Perform the CLI configuration through **ip vrrp** or **ipv6 vrrp** nodes; CLI commands for IPv4 are common for version 2 and version 3.

The following list identifies the features that make both IPv4 and IPv6 VRRPv3 features compliant to RFC 5798:

- Advertisement vs Fast-advertisement — Prior to RFC 5798, the minimum advertisement interval was 1 second, with Fast-advertisement a sub-second interval could be configured. When this feature is enabled, the VRRP ADVERTISEMENT packets are sent with type 7 instead of 1. With RFC 5798 the sub-second interval is standardised, and the switch sends all packets for VRRPv3 with type 1. The use

of Fast-advertisement remains the same. VRRPv2 packets send with type 7, if Fast-advertisement is enabled.

- Add Master-advertisement-interval — Prior to RFC 5798 compliance, all virtual routers on the same VLAN had the same Advertisement-Interval configured. RFC 5798 states that you can use different Advertisement Intervals on the Master and Backup. On the Master, the Master-advertisement-interval and the Advertisement-Interval have the same value. On the Backup, the Master-advertisement-interval is used to calculate the timers, and the locally configured Advertisement-Interval is ignored until the Backup transitions to Master. The Master-advertisement-interval value is put in the advertisement packet type sent by the Master
- Transition to master as specified in RFC 5798 — Prior to RFC 5798, if a Backup receives an advertisement with a lower priority (or same priority but lower IP), it immediately sends its own advertisement and transitions to Master. However, RFC 5798 states that such packets must be discarded, which means it will transition to Master after the Master\_Down\_Timer expires
- Add skew-time — RFC 5798 states that skew-time is calculated depending on the priority, and Master-advertisement-interval assures that the Backup with highest priority sends the first advertisement when the Master goes down

Skew time is calculated using the formula:  $((256 - \text{priority}) * \text{Master\_Adver\_Interval}) / 256$ .

- Add preempt-mode — Preempt-mode is different from the `ipv6 vrrp <vrid> action preempt` command, which is an operational command issued when you want to stop the hold-down timer. RFC 5798 states that preempt-mode should be set to false when you do not want a higher priority Backup to transition to Master. By default, it is set to true

#### Note

Accept-mode is not fully implemented for IPv4 VRRPv3. You can only ping the virtual IP address, the same way as it is for IPv4 VRRPv2.

## Configure VRRP Using CLI

---

Virtual Router Redundancy Protocol (VRRP) eliminates the single point of failure that can occur after the single static default gateway router for an end station is lost. VRRP introduces the concept of a virtual IP address shared between two or more routers connecting the common subnet to the enterprise network.

One active master switch exists for each IP subnet. All other VRRP interfaces in a network are in backup mode.

The first virtual IP configured on a VRRP interface is the primary virtual IP. This primary address is the equivalent of IPv6 VRRP link-local address and must be in the same subnet as the primary IP of the interface. The address owner of a VRRP interface is determined by the primary virtual IP. If the primary virtual IP matches the primary IP address, then this VRRP interface is set as address owner and VRRP priority for it is set to 255. All other VRRP interfaces in a network are in backup mode. If you have VRRP and IP routing protocols configured on the same IP physical interface, you cannot

select the interface address as the VRRP virtual IP address (logical IP address). You must use a separate dedicated IP address for VRRP.

After you create a VRRP interface, you can add Secondary IP Interfaces, which are the equivalent of IPv6 VRRP global addresses.

**Note**

Secondary virtual IP addresses must be in the same subnet as a Secondary IP Interface on the VLAN.

You can replace a primary virtual IP only if no secondary virtual IPs exist on the VRRP interface.

To modify the behavior of the VRRP failover mechanism, use the hold-down timer to enable the router enough time to detect and update routes. The timer delays the preemption of the primary over the backup, when the primary becomes available. Configure all routers to the identical number of seconds for the hold-down timer. You can manually force the preemption of the primary over the backup before the delay timer expires.

**Important**

The switch, when it acts as a VRRP master, does not reply to Simple Network Management Protocol (SNMP) Get requests to the VRRP virtual interface address. However, if the switch acts as a VRRP master, and receives SNMP Get requests to its physical IP address, then it does respond.

The Simple Network Management Protocol (SNMP) provides facilities to manage and monitor network resources. An SNMP manager and agent communicate through the SNMP protocol. The manager sends queries and the agent responds. An SNMP Get request is a message that requests the values of one or more objects.

**Note**

The VRRP IP address responds only to ICMP-based traceroute requests. It does not respond to UDP-based traceroute requests.

When you use the fast advertisement interval option to configure a master and backup device, you must enable the fast advertisement interval option on both systems for VRRP to work correctly. If you configure one device with the regular advertisement interval, and the other device with the fast advertisement interval, it causes an unstable state and drops advertisements.

**Before You Begin**

- Assign an IP address to the interface.
- Enable VRRP globally.

## Configure the VRRP Version on an Interface

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the VRRP version:

```
ip vrrp version <2-3>
```

### Example

Configure VRRP version 3 for the specified interface:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/2
Switch:1(config-if)# ip vrrp version 3
```

### Variable definitions

Use the data in the following table to use the **ip vrrp version** command.

| Variable                         | Value                                                           |
|----------------------------------|-----------------------------------------------------------------|
| <code>version &lt;2-3&gt;</code> | Configures the VRRP version (2 or 3) on the specified interface |

## Configure VRRP on a Port or a VLAN

Configure VRRP on a port or a VLAN to forward packets to the virtual IP addresses associated with the virtual router and customize the VRRP configuration.

### Before You Begin

- Create primary and, optionally, Secondary IP Interfaces on the VLAN.
- Configure the VRRP version on the interface.

### About This Task

You can create secondary virtual IP addresses for VRRP instances on VLAN interfaces using the same **ip vrrp address** command included in this procedure. The first address you configure is the primary virtual IP address. Secondary virtual IP addresses must be in the same subnet as a Secondary IP Interface on the VLAN.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure a primary virtual address and create the VRRP instance:

```
ip vrrp address <1-255> <A.B.C.D>
```

3. (Optional) Create a secondary virtual IP address:

### Note

This step does not apply to brouter ports.

```
ip vrrp address <1-255> <A.B.C.D>
```

4. Enable the VRRP instance:

```
ip vrrp <1-255> enable
```

5. Show the global VRRP configuration:

```
show ip vrrp
```

## Example

```
Switch:1>enable  
Switch:1#configure terminal  
Enter configuration commands, one per line. End with CNTL/Z.  
Switch:1(config)#interface gigabitethernet 1/2
```

Configure a primary VRRP address:

```
Switch:1(config-if)#ip vrrp address 28 192.0.2.1
```

Enable VRRP:

```
Switch:1(config-if)#ip vrrp 28 enable
```

## Variable Definitions

Use the data in the following table to use the **ip vrrp** command.

| Variable                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>1-255</code>                                 | Specifies the number of the VRRP to create or modify.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>action {none preempt}</code>                 | <p>Causes the virtual router to disregard the timer and transition to Master state immediately, provided the hold-down timer is running.</p> <p><b>Note:</b><br/>You can use this parameter only if the hold-down timer is active.</p> <p>To set this option to the default value, use the <b>default</b> operator with this command.</p>                                                                                                                                                                                |
| <code>action {none preempt}</code>                 | <p>Enables the choice option to manually override the hold-down timer and force preemption. You can configure <code>none preempt</code> to preempt the timer or configure it as <code>none</code> to allow the timer to keep working.</p> <p>To configure this option to the default value, use the default operator with this command.</p>                                                                                                                                                                              |
| <code>address &lt;1-255&gt; &lt;A.B.C.D&gt;</code> | <p>Configures the IP address of the VRRP physical interface that forwards packets to the virtual IP addresses associated with the virtual router. <i>A.B.C.D</i> is the IP address of the master VRRP.</p> <p>Use the <b>no</b> operator to remove the IP address of the VRRP physical interface: <code>no ip vrrp address &lt;1-255&gt; &lt;A.B.C.D&gt;</code>. To configure this option to the default value, use the <b>default</b> operator with this command.</p>                                                   |
| <code>adver-int &lt;1-255&gt;</code>               | <p>Configures the the time interval between sending VRRP advertisement messages. The range is between 1 and 255 seconds. This value must be the same on all participating routers. The default is 1.</p> <p>To configure this option to the default value, use the <b>default</b> operator with this command.</p>                                                                                                                                                                                                        |
| <code>backup-master enable</code>                  | <p>Enables the VRRP backup master. Use the <b>no</b> operator to disable the VRRP backup master: <code>no ip vrrp &lt;1-255&gt; backup-master enable</code>. To configure this option to the default value, use the <b>default</b> operator with this command.</p> <p>When backup master functionality is enabled, the VRRP router will IP-forward packets destined to the VRRP MAC even when the router is not the VRRP Master.</p> <p><b>Important:</b><br/>Do not enable backup master if you enable critical IP.</p> |

| Variable                                                      | Value                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>critical-ip-addr</code><br><code>&lt;A.B.C.D&gt;</code> | Configures the critical IP address for VRRP.<br><i>A.B.C.D</i> is the IP address on the local router, which is configured so that a change in its state causes a role switch in the virtual router (for example, from master to backup) in case the interface stops responding.<br><br><b>Note:</b><br>In this context, <i>local</i> implies an address from the same VRF as the IP interface where VRRP is being configured. |
| <code>critical-ip enable</code>                               | Enables the critical IP address option.<br>Use the <b>no</b> operator to disable the critical IP address option: <code>no ip vrrp &lt;1-255&gt; critical-ip enable</code> . To configure this option to the default value, use the <b>default</b> operator with this command.<br><br><b>Important:</b><br>Do not enable Critical IP if backup master is enabled.                                                              |
| <code>enable</code>                                           | Enables VRRP on the port.<br>Use the <b>no</b> operator to disable VRRP on the port: <code>no ip vrrp &lt;1-255&gt; enable</code> . To configure this option to the default value, use the <b>default</b> operator with this command.                                                                                                                                                                                         |
| <code>fast-adv enable</code>                                  | Enables the Fast Advertisement Interval. The default is disabled.<br>Use the <b>no</b> operator to disable VRRP on the port: <code>no ip vrrp &lt;1-255&gt; fast-adv enable</code> . To configure this option to the default value, use the <b>default</b> operator with this command.                                                                                                                                        |
| <code>fast-adv-int &lt;200-1000&gt;</code>                    | Configures the Fast Advertisement Interval, the time interval between sending VRRP advertisement messages.<br><i>200-1000</i> is the range in milliseconds, and must be the same on all participating routers. The default is 200. You must enter values in multiples of 200 milliseconds.<br>To configure this option to the default value, use the <b>default</b> operator with this command.                               |

| Variable                                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>holddown-timer &lt;0-21600&gt;</code> | <p>Specifies the time interval (in seconds) for which the transition of virtual router to Master state is delayed in case of the following conditions:</p> <ul style="list-style-type: none"> <li>• The VRRP hold-down timer runs only when the VRRP virtual router transitions from initialization to backup to master. This occurs only on a system startup.</li> <li>• The VRRP hold-down timer does not run if the amount of time passed since VRRP virtual router initialization is greater than preset hold-down time. In such a case, VRRP virtual router transitions to Master happens irrespective of the hold-down timer.</li> <li>• The VRRP hold-down timer also applies to the VRRP BackupMaster feature.</li> </ul> <p><i>0-21600</i> is the time interval range (in seconds). To configure this option to the default value, use the <b>default</b> operator with this command. The default value for hold-down timer is 0, that is, the timer is disabled by default.</p> |
| <code>priority &lt;1-255&gt;</code>         | <p>Configures the port VRRP priority.<br/> <i>1-255</i> is the value used by the VRRP router. The default is 100. Assign the value 255 to the router that owns the IP address associated with the virtual router. To configure this option to the default value, use the <b>default</b> operator with this command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Show Information for all Configured VRRP Addresses

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about all addresses or filter the output based on a specified address, VRF name or ID, or VRRP ID:  

```
show ip vrrp address [addr <A.B.C.D>] [vrf WORD<1-16>] [vrfids WORD<0-512>] [vrid <1-255>]
```
3. Display information for a specific VRRP version:  

```
show ip vrrp address version <2-3>
```
4. Display version-based VRRP configuration for the specified VRF name:  

```
show ip vrrp address vrf WORD<1-16> version <2-3>
```
5. Display version-based VRRP configuration for the specified VRF ID:  

```
show ip vrrp address vrfids WORD<0-512> version <2-3>
```

### Example

```
Switch:1>show ip vrrp address
=====
                        VRRP Info - GlobalRouter

### Variable Definitions

The following table defines parameters for the **show ip vrrp address** command.

| Variable                  | Value                                                                                                                                                     |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>addr</i> <A.B.C.D>     | Specifies the physical local address of the master VRRP.                                                                                                  |
| <i>vrf</i> WORD<1-16>     | Specifies the name of the VRF.                                                                                                                            |
| <i>vrid</i> <1-255>       | Specifies a unique integer value that represents the virtual router ID. The virtual router acts as the default router for one or more assigned addresses. |
| <i>vrfids</i> WORD<0-512> | Specifies the ID of the VRF.                                                                                                                              |
| <i>version</i> <2-3>      | Specifies the VRRP version to include in the command output.                                                                                              |

## Showing Extended VLAN VRRP

Perform this procedure to display the extended VRRP configuration for all VLANs or a specified VLAN on the device.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the extended VRRP configuration for all VLANs on the device or for the specified VLAN:

```
show ip vrrp interface vlan [<1-4059>] [portList] verbose [vrf
WORD<1-16>] [vrfids WORD<0-512>]
```

## Example

```
Switch:1>show ip vrrp interface vlan
=====
                        Vlan Vrrp
=====
VLAN VRF          VRRP IP          VIRTUAL          VERSION  ORIGIN
ID  NAME          ID  ADDRESS          MAC ADDRESS
-----
 2   GlobalRouter   10   203.0.113.2     00:00:5e:00:01:0a   2   config
222  GlobalRouter    1    192.0.2.1       00:00:5e:00:01:01   2   config
223  GlobalRouter    1    198.51.100.1    00:00:5e:00:01:01   3   config
```

## Variable Definitions

The following table defines parameters for the **show ip vrrp interface vlan** command.

| Variable                  | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                  | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <i>portList</i>           | Specifies the slot or port number of a range of ports.                                                                                                                                                                                                                                                                                                                                                                     |
| <i>vrf</i> WORD<1-16>     | Specifies the name of the VRF.                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>vrfids</i> WORD<0-512> | Specifies the ID of the VRF and is an integer in the range of 0-512.                                                                                                                                                                                                                                                                                                                                                       |

Use the data in the following table to use the **show ip vrrp interface vlan** command output with the optional *verbose* parameter.

| Variable | Value                                             |
|----------|---------------------------------------------------|
| VLAN ID  | Indicates the VLAN ID.                            |
| VRRP ID  | Indicates the virtual router ID.                  |
| VRF NAME | Indicates the associated VRF name, if applicable. |

| Variable           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STATE              | Indicates the current state of the virtual router. <ul style="list-style-type: none"> <li>initialize—waiting for a startup event</li> <li>backup—monitoring the state or availability of the master router</li> <li>master—forwarding IP addresses associated with this virtual router</li> </ul>                                                                                                                                                                           |
| CONTROL            | Indicates the virtual router function. Configure the value to enabled to transition the state of the router from initialize to backup. Configure the value to disabled to transition the router from master or backup to initialize.                                                                                                                                                                                                                                        |
| PRIORITY           | Indicates the priority for the virtual router (for example, master election) with respect to other virtual routers that are backing up one or more associated IP addresses. Higher values indicate higher priority.<br>A priority of 0, which you cannot configure, indicates that this router ceased to participate in VRRP and a backup virtual router transitions to become a new master.<br>Use a priority of 255 for the router that owns the associated IP addresses. |
| MASTER IPADDR      | Indicates the master router real (primary) IP address. The master IP address is listed as the source in the VRRP advertisement last received by this virtual router.                                                                                                                                                                                                                                                                                                        |
| ADVERTISE INTERVAL | Indicates the time interval, in seconds, between sending advertisement messages. Only the master router sends VRRP advertisements.                                                                                                                                                                                                                                                                                                                                          |
| CRITICAL IPADDR    | Indicates the IP address of the interface that causes a shutdown event.                                                                                                                                                                                                                                                                                                                                                                                                     |
| VERSION            | Indicates the VRRP version.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| HOSTNAME           | Displays the SPBM host name of the VRRP primary router for a Distributed Virtual Routing (DvR) interface.<br><b>Note:</b><br>Exception: not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.                                                                                                                                                                                                                                                                |
| ORIGIN             | Displays how the VRRP interface was configured, either manually or via DvR.<br><b>Note:</b><br>Exception: not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.                                                                                                                                                                                                                                                                                              |
| HOLDDOWN_TIME      | Indicates the configured time (in seconds) that the system waits before it preempts the current VRRP master.                                                                                                                                                                                                                                                                                                                                                                |
| ACTION             | Indicates the trigger for an action on this VRRP interface. Options include none and preemptHoldDownTimer.                                                                                                                                                                                                                                                                                                                                                                  |

| Variable                 | Value                                                                                                                                                                                                                                 |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CRITICAL IP ENABLE       | Indicates that a user-defined critical IP address is enabled. No indicates the use of the default IP address (0.0.0.0).                                                                                                               |
| BACKUP MASTER            | Indicates the state of designating a backup master router.                                                                                                                                                                            |
| BACKUP MASTER STATE      | Indicates the state of the backup master router.                                                                                                                                                                                      |
| FAST ADV INTERVAL        | Indicates the time interval, in milliseconds, between sending Fast Advertisement messages. When the Fast Advertisement Interval is enabled, the Fast Advertisement Interval is used instead of the regular advertisement interval.    |
| FAST ADV ENABLE          | Indicates the Fast Advertisement Interval status.                                                                                                                                                                                     |
| MASTER ADV INTERVAL (ms) | On the VRRPv3 master, the master advertisement interval is same as the advertisement interval. On the VRRPv3 Backup, the master advertisement interval is set to the Advertisement configured on the Master (received in the packet). |
| PREEMPT MODE             | Indicates if the router operates in preempt mode. If a new router is added to the network with its priority higher than the existing routers, then the new router becomes the master.                                                 |
| PSEUDO-HEADER CHECKSUM   | Specifies the type of checksum computation, with Pseudo Header or without Pseudo Header.                                                                                                                                              |

## Show VRRP Interface Information

### About This Task

If you enter a virtual router ID or an IP address when showing VRRP interface information, the system displays the information only for that virtual router ID or for that interface.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display VRRPv2 information about the specified interface:  
show ip vrrp interface version <2-3>
3. Display additional VRRPv2 information about the specified interface:  
show ip vrrp interface verbose version <2-3>
4. Display VRRPv2 information for the specified VRF:  
show ip vrrp interface vrf WORD<1-16> version <2-3>
5. Display VRRPv2 information for the specified virtual router:  
show ip vrrp interface vrfids WORD<0-512> [version <2-3>]

### Examples

```
Switch:1#show ip vrrp interface
=====
```

## Vlan Vrrp

```

*Variable definitions*

Use the data in the following table to use the **show ip vrrp interface** command.

| Variable                                                                | Value                                                                                                                                                                        |
|-------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>gigabitethernet</i> { <i>slot/port</i> [- <i>slot/port</i> ][, ...]} | Specifies to show the VRRP information of which interface.                                                                                                                   |
| <i>verbose</i>                                                          | Specifies to show all available information about the VRRP interfaces.                                                                                                       |
| <i>vlan</i>                                                             | Specifies the VLAN that contains the VRRP.                                                                                                                                   |
| <i>vrf</i> <i>WORD</i> <1-16>                                           | Specifies the name of the VRF.                                                                                                                                               |
| <i>vrid</i> <1-255>                                                     | Specifies a unique integer value that represents the virtual router ID in the range 1–255. The virtual router acts as the default router for one or more assigned addresses. |
| <i>vrfids</i> <i>WORD</i> <0-512>                                       | Specifies the ID of the VRF and is an integer in the range of 0–512.                                                                                                         |
| <i>version</i> <2-3>                                                    | Specifies the VRRP version (2 or 3) configured.                                                                                                                              |

## Viewing IP VRRPv3 Statistics

Use the following procedure to view IP VRRPv3 statistics to monitor network performance.

**Procedure**

1. Enter Privileged EXEC mode:  
`enable`
2. Enter the following command to view VRRP statistics:  
`show ip vrrp statistics version <2-3>`
3. Enter the following command to view VRRP statistics for the specified VRF:  
`show ip vrrp statistics vrf WORD<1-16> version <2-3>`
4. Enter the following command to view VRRP statistics for the specified virtual router:  
`show ip vrrp statistics vrfids WORD<0-512> version <2-3>`

**Example**

View IP VRRPv3 statistics:

```
Switch:1#show ip vrrp statistics
```

```
=====

```

### Variable Definitions

Use the data in the following table to use the **ip vrrp version** command.

| Variable                        | Value                                                                               |
|---------------------------------|-------------------------------------------------------------------------------------|
| <i>version</i>                  | Configures the VRRP version on the specified interface.                             |
| <2-3>                           | Specifies the version of VRRP (2 or 3) to be configured on the specified interface. |
| <i>vrf WORD&lt;1-16&gt;</i>     | Specifies the name of the VRF.                                                      |
| <i>vrfids WORD&lt;0-512&gt;</i> | Specifies the ID of the VRF, and is an integer in the range of 0-512.               |

## Enable Ping to a Virtual IP Address

Use the following procedure to enable ping to a virtual IP address. The default is enabled.

### Procedure

1. Enter VRRP Router Configuration mode:
 

```
enable
configure terminal
router vrrp
```
2. Enable ping to a virtual IP address:
 

```
ping-virtual-address enable [vrf WORD<1-16>]
default ping-virtual-address enable [vrf WORD<1-16>]
```

### 3. Display the configuration:

```
show ip vrrp [vrf WORD<1-16>]
```

#### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrrp
Switch:1(config-vrrp)#ping-virtual-address enable vrf mgmtrouter
Switch:1(config)#show ip vrrp vrf mgmtrouter

=====
VRRP Global Settings - VRF mgmtrouter
=====
ping-virtual-address : enabled
send-trap : enabled
```

#### Variable definitions

Use the data in the following table to use the `ping-virtual-address enable` and `show ip vrrp` commands.

| Variable                          | Value                                 |
|-----------------------------------|---------------------------------------|
| <code>enable</code>               | Enables ping to a virtual IP address. |
| <code>vrf WORD&lt;1-16&gt;</code> | Specifies the VRF.                    |

## Configure VRRP Notification Control

Use the following procedure to enable VRRP notification control. The generation of SNMP traps for VRRP events is enabled, by default.

### About This Task

You can configure traps by creating SNMPv3 trap notifications, creating a target address to send the notifications, and specify target parameters. For more information about how to configure trap notifications, see [Logs and Traps](#) on page 2463.

### Procedure

1. Enter VRRP Router Configuration mode:
 

```
enable

configure terminal

router vrrp
```
2. Enable a trap for VRRP events:
 

```
send-trap enable [vrf WORD<1-16>]
```
3. Disable a trap for VRRP events:
 

```
no send-trap enable [vrf WORD<1-16>]
```
4. Configure a trap for VRRP events to the default:
 

```
default send-trap enable [vrf WORD<1-16>]
```

## 5. Display the configuration:

```
show ip vrrp [vrf WORD<1-16>]
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router vrrp
Switch:1(config-vrrp)#send-trap enable vrf mgmtrouter
Switch:1(config)#show ip vrrp vrf mgmtrouter

=====
VRRP Global Settings - VRF mgmtrouter
=====
ping-virtual-address : enabled
send-trap : enabled
```

*Variable definitions*

Use the data in the following table to use the **send-trap** and **show ip vrrp** commands.

| Variable                    | Value                                          |
|-----------------------------|------------------------------------------------|
| <i>enable</i>               | Enables generation of SNMP traps.              |
| <i>vrf WORD&lt;1-16&gt;</i> | Configures the send-trap for a particular VRF. |

**Enabling IPv4 VRRP preempt-mode**

You can configure VRRP to preempt the existing router. If a new VRRP router is added to the network with a higher priority than the existing routers, then the new router becomes the master. If preempt-mode is disabled, then the new router does not become a master, it transitions to master only when the current master is down, that is when it does not receive any advertisement packets from the current master. By default, preempt-mode is enabled.

**Procedure**

## 1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} Or interface vlan <1-4059>
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## 2. Enter the following command:

```
ip vrrp <vrid> preempt-mode enable
```

## 3. Use the following command to set the preempt-mode to its default value:

```
default ip vrrp <vrid> preempt-mode
```

4. Use the following command to disable the preempt-mode:

```
no ip vrrp <vrid> preempt-mode enable
```

### Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/2
```

Enabling preempt-mode on interface 1/2:

```
Switch:1(config-if)# ip vrrp 1 preempt-mode enable
```

### Variable definitions

Use the data in the following table to use the **ip vrrp <vrid>** command.

| Variable                                           | Value                                                    |
|----------------------------------------------------|----------------------------------------------------------|
| <i>preempt-mode enable</i>                         | Enables preempt-mode for VRRPv3 for IPv4.                |
| <i>default ip vrrp &lt;vrid&gt; preempt-mode</i>   | Sets the default preempt-mode value for VRRPv3 for IPv4. |
| <i>no ip vrrp &lt;vrid&gt; preempt-mode enable</i> | Disables preempt-mode for VRRPv3 for IPv4.               |

## IPv6 VRRP Configuration using CLI

This section provides procedures to configure IPv6 VRRP using the command line interface (CLI).

### Configuring the VRRP interface

Configure VRRP to provide fast failover of a default router for IPv6 LAN hosts, in order to create a VRRP instance.

#### Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Do not configure RSMLT on the VLAN.
- You must specify a link-local address to associate with the virtual router.

#### About This Task

VRRP supports a virtual IPv6 address shared between two or more routers that connect the common subnet to the enterprise network.

VRRP for IPv6 provides a faster switchover to an alternate default router than is possible using the ND protocol.

Perform this procedure to also configure the additional addresses for which the virtual router acts as a backup.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Associate an address with the virtual router for either link-local or global:

- `ipv6 vrrp address <1-255> link-local WORD <0-127>`

- `ipv6 vrrp address <1-255> global WORD <0-255>`

### Note

You must configure the link-local address before you configure the global address.

3. Enable VRRP for the interface:

```
ipv6 vrrp <1-255> enable
```

## Example

Associate a link-local address with the virtual router ID 12:

```
Switch:1(config-if)#ipv6 vrrp address 12 link-local fe80::1234
```

Associate a global address with the virtual router ID 12

```
Switch:1(config-if)#ipv6 vrrp address 12 global 3333::1234/64
```

Enable VRRP for the interface:

```
Switch:1(config-if)#ipv6 vrrp 12 enable
```

### Variable Definitions

Use the data in the following table to use the **ipv6 vrrp address** command.

| Variable      | Value                                                                                                                |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| <1-255>       | Specifies the virtual router ID. The virtual router acts as the default router for one or more associated addresses. |
| <i>enable</i> | Enables IPv6 VRRP. The default is disabled.                                                                          |

| Variable                       | Value                                                                          |
|--------------------------------|--------------------------------------------------------------------------------|
| global WORD <0-255>            | Specifies a global IPv6 address and mask to associate with the virtual router. |
| <i>link-local</i> WORD <0-127> | Specifies a link-local IPv6 address to associate with the virtual router.      |

Use the data in the following table to use the **interface** command.

| Variable                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-4059>                                              | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                              |

## View VRRP Information

Display VRRP port or VLAN information to verify your configuration. Show VRRP information by IPv6 address or virtual router ID. If you enter a virtual router ID or an IPv6 address when you view VRRP information, the information applies only to that virtual router ID or for that interface.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the configuration information for all interfaces:  
show ipv6 vrrp interface [verbose] [vrf WORD<1-16> | vrfids WORD<0-512>]
3. View the configuration information for one or more ports:  
show ipv6 vrrp interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} [verbose] [vrf WORD<1-16> | vrfids WORD<0-512>]
4. View the configuration information for one or more VLANs:  
show ipv6 vrrp interface vlan [<1-4059>] [verbose] [vrf WORD<1-16> | vrfids WORD<0-512>]
5. View the configuration information for one or more virtual router IDs:  
show ipv6 vrrp interface vrid <1-255> [verbose] [vrf WORD<1-16> | vrfids WORD<0-512>]
6. View VRRP address information:  
show ipv6 vrrp address [vrf WORD<1-16> | vrfids WORD<0-512>]

## 7. View VRRP address information for a link-local address:

```
show ipv6 vrrp address link-local WORD<0-127> [verbose] [vrf WORD<1-16> | vrfids WORD<0-512>]
```

## 8. View VRRP address information for a virtual router ID:

```
show ipv6 vrrp address vrid <1-255> [vrf WORD<1-16> | vrfids WORD<0-512>]
```

**Example**

```
Switch:1>show ipv6 vrrp address
```

```

### Variable Definitions

Use the data in the following table to use the **show ipv6 vrrp** commands.

| Variable                                                     | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <i>link-local WORD&lt;0-127&gt;</i>                          | Displays information by link-local IPv6 address.                                                                                                                                                                                                                                                                                                              |
| <i>verbose</i>                                               | Displays extended information.                                                                                                                                                                                                                                                                                                                                |

| Variable                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>vlan [&lt;1-4059&gt;]</code>    | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |
| <code>vrid &lt;1-255&gt;</code>       | Displays information by virtual router ID.                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>vrf WORD&lt;1-16&gt;</code>     | Specifies the VRF name.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>vrfids WORD&lt;0-512&gt;</code> | Specifies the VRF ID.                                                                                                                                                                                                                                                                                                                                                                                                      |

## Configuring VRRP notification control

Perform this procedure to configure VRRP notification control.

### Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.

### About This Task

By default, generation of SNMP traps for VRRP events is enabled.

### Procedure

1. Enter VRRP Router Configuration mode:
 

```
enable

configure terminal

router vrrp
```
2. Enable the VRRP-router to generate SNMP traps for events:
 

```
ipv6 send-trap enable
```

### Example

Disable generation of SNMP traps for VRRP events:

```
Switch:1(config-vrrp)#no ipv6 send-trap enable
```

## Configuring additional VRRP parameters for an interface

Configure VRRP to provide fast failover of a default router for IPv6 LAN hosts. VRRP supports a virtual IPv6 address shared between two or more routers that connect the common subnet to the enterprise network. VRRP for IPv6 provides a faster switchover to an alternate default router than is possible using the ND protocol.

Configure the parameters in this procedure if the default values do not meet your requirements.

### Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Do not configure RSMLT on the VLAN.

### About This Task

A switch that acts as a VRRP master does not reply to SNMP get requests to the VRRP virtual interface address. The switch will, however, respond to SNMP get requests to the physical IP address.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the accept mode of the master router:

```
ipv6 vrrp <1-255> accept-mode enable
```

3. Determine if the router overrides the holddown timer:

```
ipv6 vrrp <1-255> action <none|preempt>
```

4. Configure the interval between advertisement messages:

```
ipv6 vrrp <1-255> adver-int <1-40>
```

5. Enable the backup VRRP switch for traffic forwarding:

```
ipv6 vrrp <1-255> backup-master enable
```

6. Configure the IP interface on the local router:

```
ipv6 vrrp <1-255> critical-ipv6-addr WORD<0-46> [critical-ipv6 enable]
```

7. Configure the fast advertisement interval:

```
ipv6 vrrp <1-255> fast-adv enable [fast-adv-int <200-1000>]
```

8. Configure the holddown timer:

```
ipv6 vrrp <1-255> holddown-timer <0-21600>
```

9. Configure the priority for the VRRP router:

```
ipv6 vrrp <1-255> priority <1-255>
```

### Example

Configure the fast advertisement interval:

```
Switch:1(config-if)#ipv6 vrrp 12 fast-adv enable fast-adv-int 400
```

Configure the holddown timer:

```
Switch:1(config-if)#ipv6 vrrp 12 holddown-timer 30
```

### Variable Definitions

Use the data in the following table to use the **ipv6 vrrp** command.

| Variable                                   | Value                                                                                                                                                                                                                                                                               |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <1-255>                                    | Specifies a number that uniquely identifies a virtual router on a VRRP router. The virtual router acts as the default router for one or more assigned addresses.                                                                                                                    |
| <i>accept-mode enable</i>                  | Controls whether the VRRP master or backup master accepts packets (other than neighbor discovery packets) destined to the IPv6 address associated with the virtual router. The default value is disable.                                                                            |
| <i>action &lt;none preempt&gt;</i>         | Lists options to override the holddown timer manually and force preemption: <ul style="list-style-type: none"> <li>• <i>none</i> does not override the timer.</li> <li>• <i>preempt</i> preempts the timer.</li> </ul> This parameter applies only if the holddown timer is active. |
| <i>adver-int &lt;1-40&gt;</i>              | Specifies the time interval, in seconds, between sending advertisement messages. The default is 1 second. Only the master router sends advertisements.                                                                                                                              |
| <i>backup-master enable</i>                | Uses the backup VRRP switch for traffic forwarding. This option reduces the traffic on the v1ST. The default is disabled.                                                                                                                                                           |
| <i>critical-ipv6 enable</i>                | Enables or disables the use of critical IP. When disabled, the VRRP ignores the availability of the address configured as critical IP. This address must be a local address. The default is disabled.                                                                               |
| <i>critical-ipv6-addr WORD&lt;0-46&gt;</i> | Specifies an IP interface on the local router configured so that a change in its state causes a role switch in the virtual router (for example, from master to backup) in case the interface stops responding.                                                                      |
| <i>fast-adv enable</i>                     | Enables or disables the fast advertisement interval. When disabled, the regular advertisement interval is used. The default is disable.                                                                                                                                             |
| <i>fast-adv-int &lt;200-1000&gt;</i>       | Configures the interval between VRRP advertisement messages. You must configure the same value on all participating routers. This unit of measure must be in multiples of 200 milliseconds. The default is 200.                                                                     |
| <i>holddown-timer &lt;0-21600&gt;</i>      | Configures the amount of time, in seconds, to wait before preempting the current VRRP master. The default is 0.                                                                                                                                                                     |
| <i>priority &lt;1-255&gt;</i>              | Specifies the priority value used by this VRRP router. The value 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.                                                                                                  |

## Viewing IPv6 VRRP Statistics

View IPv6 VRRP statistics to monitor network performance

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View statistics for the device and for all interfaces:

```
show ipv6 vrrp statistics [link-local WORD<0-127>]] [vrid <1-255>]
```

### Example

View IPv6 VRRP statistics for VRID 1.

```
Switch:1(config)#show ipv6 vrrp statistics vrid 1

### Variable Definitions

Use the data in the following table to use the **show ipv6 vrrp statistics** command.

| Variable                      | Value                                               |
|-------------------------------|-----------------------------------------------------|
| <i>link-local</i> WORD<0-127> | Shows statistics for a specific link-local address. |
| <i>vrid</i> <1-255>           | Shows statistics for a specific VRID.               |

## Enabling IPv6 VRRP preempt-mode

You can configure IPv6 VRRP to preempt the existing router. If a new VRRP router is added to the network with a higher priority than the existing routers, then the new router becomes the master. If preempt-mode is disabled, then the new router does not become a master, it transitions to master only when the current master is down. By default, preempt-mode is enabled.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enter the following command:

```
ipv6 vrrp <vrid> preempt-mode enable
```

3. Use the following command to set the IPv6 VRRP preempt-mode to its default value:

```
default ipv6 vrrp <vrid> preempt-mode
```

4. Use the following command to disable the IPv6 VRRP preempt-mode:

```
no ipv6 <vrid> preempt-mode enable
```

## Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface gigabitethernet 1/2
```

### Enabling IPv6 VRRP preempt-mode for interface 1/2

```
Switch:1(config-if)# ipv6 vrrp 1 preempt-mode enable
```

### Variable definitions

Use the data in the following table to use the **ipv6 vrrp <vrid>** command.

| Variable     | Value                                     |
|--------------|-------------------------------------------|
| enable       | Enables preempt-mode for VRRPv3 for IPv6. |
| vrid <1-255> | Specifies the virtual router ID.          |

## Configure VRRP using EDM

Virtual Router Redundancy Protocol (VRRP) eliminates the single point of failure that can occur after the single static default gateway router for an end station is lost. VRRP introduces the concept of a virtual IP address shared between two or more routers connecting the common subnet to the enterprise network.

One active master switch exists for each IP subnet. All other VRRP interfaces in a network are in backup mode.

The first virtual IP configured on a VRRP interface is the primary virtual IP. This primary address is the equivalent of IPv6 VRRP link-local address and must be in the same

subnet as the primary IP of the interface. The address owner of a VRRP interface is determined by the primary virtual IP. If the primary virtual IP matches the primary IP address, then this VRRP interface is set as address owner and VRRP priority for it is set to 255. All other VRRP interfaces in a network are in backup mode. If you have VRRP and IP routing protocols configured on the same IP physical interface, you cannot select the interface address as the VRRP virtual IP address (logical IP address). You must use a separate dedicated IP address for VRRP.

After you create a VRRP interface, you can add Secondary IP Interfaces, which are the equivalent of IPv6 VRRP global addresses.

**Note**

Secondary virtual IP addresses must be in the same subnet as a Secondary IP Interface on the VLAN.

You can replace a primary virtual IP only if no secondary virtual IPs exist on the VRRP interface.

To modify the behavior of the VRRP failover mechanism, use the hold-down timer to enable the router enough time to detect and update routes. The timer delays the preemption of the primary over the backup, when the primary becomes available. Configure all routers to the identical number of seconds for the hold-down timer. You can manually force the preemption of the primary over the backup before the delay timer expires.

**Important**

The switch, when it acts as a primary VRRP, does not reply to Simple Network Management Protocol (SNMP) Get requests to the VRRP virtual interface address. However, if the switch acts as a primary VRRP, and receives SNMP Get requests to its physical IP address, then it does respond.

The Simple Network Management Protocol (SNMP) provides facilities to manage and monitor network resources. An SNMP manager and agent communicate through the SNMP protocol. The manager sends queries and the agent responds. An SNMP Get request is a message that requests the values of one or more objects.

**Note**

The VRRP IP address responds only to ICMP-based traceroute requests. It does not respond to UDP-based traceroute requests.

When you use the fast advertisement interval option to configure a master and backup device, you must enable the fast advertisement interval option on both systems for VRRP to work correctly. If you configure one device with the regular advertisement interval, and the other device with the fast advertisement interval, it causes an unstable state and drops advertisements.

**Before You Begin**

- Assign an IP address to the interface.
- Enable VRRP globally.

## Enable VRRP Global Variables

Enable VRRP global variables to enable the VRRP function.

### Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **VRRP**.
3. Select the **Globals** tab.
4. Configure the required features.
5. Select **Apply**.

### *Globals* field descriptions

Use the data in the following table to use the **Globals** tab.

| Name                         | Description                                                                                                                                                                                                                        |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NotificationCntl</b>      | Indicates whether the VRRP-enabled router generates SNMP traps for events. <ul style="list-style-type: none"> <li>• enabled—SNMP traps are generated</li> <li>• disabled—no SNMP traps are sent</li> </ul> The default is enabled. |
| <b>PingVirtualAddrEnable</b> | Configures whether this device responds to pings directed to a virtual router IP address. The default is enabled.                                                                                                                  |

## Modifying VRRP parameters for an interface

### Before You Begin

- You must enable VRRP on a brouter port or VLAN.

### About This Task

You can manage and configure VRRP parameters for the routing interface.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **VRRP**.
3. Click the **Interface** tab.

4. Double-click the **HoldDownTimer** field, and enter the number of seconds for the timer.

The **HoldDownState** field displays active when the hold-down timer is counting down and preemption occurs. The field displays dormant when preemption is not pending. When the hold-down timer is active, the **HoldDownTimeRemaining** field displays the seconds remaining before preemption.

5. In the **Action** check box, select an option.
6. Click **Apply**.

### *Interface Field Descriptions*

Use the data in the following table to use the **Interface** tab.

| Name                         | Description                                                                                                                                                                                                                                                                                                                                    |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>               | Specifies the index value that uniquely identifies the interface to which this entry applies.                                                                                                                                                                                                                                                  |
| <b>VrId</b>                  | Specifies a number that uniquely identifies a virtual router on a Virtual Router Redundancy Protocol (VRRP) router. The virtual router acts as the default router for one or more assigned addresses.                                                                                                                                          |
| <b>IpAddr</b>                | Specifies the assigned IP addresses for which a virtual router is responsible to provide backup.                                                                                                                                                                                                                                               |
| <b>VirtualMacAddr</b>        | Specifies the MAC address of the virtual router interface.                                                                                                                                                                                                                                                                                     |
| <b>State</b>                 | Specifies the state of the virtual router interface: <ul style="list-style-type: none"> <li>• Initialize—waiting for a startup event</li> <li>• Backup—monitoring availability and state of the master router</li> <li>• Master—functioning as the forwarding router, the primary VRRP router, for the virtual router IP addresses.</li> </ul> |
| <b>Control</b>               | Specifies whether VRRP is enabled or disabled for the port (or VLAN). The default is enabled.                                                                                                                                                                                                                                                  |
| <b>Priority</b>              | Specifies the priority value used by this VRRP router. The value 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.                                                                                                                                                             |
| <b>AdvertisementInterval</b> | Specifies the time interval, in seconds, between sending advertisement messages. The default is 1 second. Only the primary VRRP router sends advertisements. The default is 1.                                                                                                                                                                 |

| Name                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MasterIpAddr</b>          | Specifies the IP address of the physical interface of the primary virtual router that forwards packets sent to the virtual IP addresses associated with the virtual router.                                                                                                                                                                                                                                                  |
| <b>VirtualRouterUpTime</b>   | Specifies the time interval, in hundredths of a second, since the virtual router was initialized.                                                                                                                                                                                                                                                                                                                            |
| <b>Action</b>                | Lists options to override the delay timer manually and force preemption: <ul style="list-style-type: none"> <li>• <b>none</b> does not override the timer</li> <li>• <b>preemptHoldDownTimer</b> preempts the timer</li> </ul>                                                                                                                                                                                               |
| <b>HoldDownTimer</b>         | Configures the amount of time, in seconds, to wait before preempting the current VRRP primary router.                                                                                                                                                                                                                                                                                                                        |
| <b>HoldDownState</b>         | Indicates the hold-down state of this VRRP interface. If the hold-down timer is operational, this variable is set to active; otherwise, this variable is set to dormant.                                                                                                                                                                                                                                                     |
| <b>HoldDownTimeRemaining</b> | Indicates the amount of time, in seconds, left before the HoldDownTimer expires.                                                                                                                                                                                                                                                                                                                                             |
| <b>CriticalIpAddr</b>        | Configures the critical IP address for VRRP. This command specifies an IP interface on the local router, which is configured so that a change in its state causes a role switch in the virtual router (for example, from primary to backup) in case the interface stops responding. <p><b>Note:</b><br/>In this context, <i>local</i> implies an address from the same VRF as the IP interface where VRRP is configured.</p> |
| <b>CriticalIpAddrEnable</b>  | Configures the IP interface on the local router to enable or disable the backup. The default is disabled.                                                                                                                                                                                                                                                                                                                    |
| <b>BackUpMaster</b>          | Enables the backup VRRP system traffic forwarding. The default is disabled.                                                                                                                                                                                                                                                                                                                                                  |
| <b>BackUpMasterState</b>     | Indicates whether the backup VRRP system traffic forwarding is enabled or disabled. The default is disabled.                                                                                                                                                                                                                                                                                                                 |
| <b>FasterAdvInterval</b>     | Configures the Fast Advertisement Interval between sending VRRP advertisement messages. You must configure the same value on all participating routers. Enter the value in multiples of 200 milliseconds. The default is 200.                                                                                                                                                                                                |

| Name                                                                                                                     | Description                                                                                                                             |
|--------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>FasterAdvIntervalEnable</b>                                                                                           | Enables or disables the Fast Advertisement Interval. When disabled, the regular advertisement interval is used. The default is disable. |
| <b>MasterHostname</b><br><b>Note:</b><br>Exception: not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series. | Displays the SPBM host name of the VRRP primary router for a Distributed Virtual Routing (DvR) interface.                               |
| <b>Origin</b><br><b>Note:</b><br>Exception: not supported on VSP 4450 Series, VSP 8600 Series, or XA1400 Series.         | Displays how the VRRP interface was configured, either manually or via DvR.                                                             |

### **NEW!** Add a Secondary Virtual IP for VRRPv2

The first virtual IP configured on a VRRP interface is the primary virtual IP. After you create a VRRP interface, you can create secondary virtual IPs.

#### Before You Begin

- Create primary and secondary IP addresses on the VLAN.
- Create a VRRP instance on the VLAN.
- Configure a primary virtual IP.

#### About This Task

Secondary virtual IP addresses must be in the same subnet as a Secondary IP Interface on the VLAN.

#### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **VRRP**.
3. Select the **Interface** tab.
4. Select an interface, and then select **AssociatedIPAddr**.
5. On the **Address List** tab, select **Insert**.
6. Type the IP address.
7. Select **Insert**.

### **NEW!** Address List Field Descriptions

Use the data in the following table to use the **Address List** tab.

| Name          | Description                               |
|---------------|-------------------------------------------|
| <b>IpAddr</b> | Specifies a secondary virtual IP address. |

## Configuring VRRP on a V3 interface

Perform this procedure to configure VRRP on a V3 interface on either a brouter port or a VLAN.

### Before You Begin

- Assign an IPv4 address to the interface
- Enable routing globally
- Do not configure RSMLT on the VLAN

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **VRRP**.
3. Click the **V3 Interface** tab.
4. Click **Insert**.
5. Beside the **IfIndex** field, click **Port** or **VLAN**.
6. Select a port or VLAN.
7. Click **OK**.
8. Type the virtual router ID.
9. Type the primary IP address.
10. Type the advertisement interval.
11. Click **Insert**.

### Interface field descriptions

Use the data in the following table to use the **Interface** tab.

| Name                  | Description                                                                                                                                                                                                                                                                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>        | Shows the index value that uniquely identifies the interface to which this entry applies.                                                                                                                                                                                                                                               |
| <b>InetAddrType</b>   | Specifies the source network INET Address Type.                                                                                                                                                                                                                                                                                         |
| <b>VrId</b>           | Specifies a number that uniquely identifies a virtual router on a VRRP router.                                                                                                                                                                                                                                                          |
| <b>PrimaryIpAddr</b>  | Specifies the virtual address assigned to the VRRP.                                                                                                                                                                                                                                                                                     |
| <b>VirtualMacAddr</b> | Specifies the MAC address of the virtual router interface.                                                                                                                                                                                                                                                                              |
| <b>State</b>          | Shows the state of the virtual router interface. The possible states are <ul style="list-style-type: none"> <li>• initialize—waiting for a startup event</li> <li>• backup—monitoring availability and state of the master router</li> <li>• master—functioning as the forwarding router for the virtual router IP addresses</li> </ul> |

| Name                            | Description                                                                                                                                                                                           |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Control</b>                  | Displays whether VRRP is enabled or disabled for the port or VLAN.                                                                                                                                    |
| <b>Priority</b>                 | Specifies the priority value used by this VRRP router. The value 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.                    |
| <b>AdvInterval</b>              | Specifies the time interval, in seconds, between sending advertisement messages. The default is 1 second.                                                                                             |
| <b>MasterIpAddr</b>             | Specifies the IP address of the physical interface of the Master's virtual router.                                                                                                                    |
| <b>UpTime</b>                   | Indicates the time interval since this virtual router exited the INIT state.                                                                                                                          |
| <b>CriticalIpAddr</b>           | Indicates the IP address of the interface that is critical to VRRP. If that IP interface is down, the VRRP state will transition to Backup, even if it has higher priority.                           |
| <b>CriticalIpAddrEnabled</b>    | Enables or disables the use of critical IP. When disabled, the VRRP ignores the availability of the address configured as critical IP. This address must be a local address. The default is disabled. |
| <b>BackUpMaster</b>             | Uses the backup VRRP switch for traffic forwarding. This option reduces the traffic on the v1ST. The default is disabled.                                                                             |
| <b>BackUpMasterState</b>        | Indicates if the Backup-Master is operational up. If the switch is in Master state but the Backup-Master is enabled, then the BACKUP MASTER STATE will be down.                                       |
| <b>FasterAdvIntervalEnabled</b> | Enables or disables the fast advertisement interval. When disabled, the regular advertisement interval is used. The default is disable.                                                               |
| <b>FasterAdvInterval</b>        | Configures the interval between VRRP advertisement messages. The default is 200.<br>Enter the values in multiples of 200 milliseconds.                                                                |
| <b>PreemptMode</b>              | Issued to preempt the existing router. If a new router is added to the network with its priority higher than the existing routers, then the new router becomes the master. The default is enabled.    |

| Name                         | Description                                                                                                                                                                                                                                                                                       |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Action</b>                | Lists options to override the hold-down timer manually and force preemption: <ul style="list-style-type: none"> <li>• <b>none</b> does not override the timer.</li> <li>• <b>preemptHoldDownTimer</b> preempts the timer.</li> </ul> This parameter applies only if the holddown timer is active. |
| <b>HoldDownTimer</b>         | Configures the amount of time, in seconds, to wait before preempting the current VRRP master. The default is 0.                                                                                                                                                                                   |
| <b>HoldDownTimeRemaining</b> | Indicates the amount of time, in seconds, left before the HoldDownTimer expires.                                                                                                                                                                                                                  |
| <b>MasterAdvInterval</b>     | On the VRRPv3 master, the master advertisement interval is same as the advertisement interval. On the VRRPv3 Backup, the master advertisement interval is set to the Advertisement configured on the Master (received in the packet).                                                             |

## **NEW!** Add a Secondary Virtual IP for VRRPv3

The first virtual IP configured on a VRRP interface is the primary virtual IP. After you create a VRRP interface, you can create secondary virtual IPs.

### Before You Begin

- Create primary and secondary IP addresses on the VLAN.
- Create a VRRP instance on the VLAN.
- Configure a primary virtual IP.

### About This Task

Secondary virtual IP addresses must be in the same subnet as a Secondary IP Interface on the VLAN.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **VRRP**.
3. Select the **V3 Interface** tab.
4. Select an interface, and then select **AssociatedIPAddr**.
5. On the **Address List** tab, select **Insert**.
6. Type the IP address.
7. Type the prefix length.
8. Select **Insert**.

**NEW!** *Address List Field Descriptions*

Use the data in the following table to use the **Address List** tab.

| Name                      | Description                                                       |
|---------------------------|-------------------------------------------------------------------|
| <b>IpAddr</b>             | Specifies a secondary virtual IP addresses.                       |
| <b>IpAddrPrefixLength</b> | Specifies the prefix length for the secondary virtual IP address. |

## Configuring VRRPv3 Checksum

Perform this procedure to configure VRRPv3 checksum on either a brouter port or a VLAN.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **VRRP**.
3. Click the **V3 Checksum** tab.
4. Click **Insert**.
5. In the **Interface** field, click **Port** or **Vlan**.
6. Select a type of checksum computation.
7. Select a VRRP version.
8. Click **Insert**.

### **V3 Checksum** field descriptions

Use the data in the following table to use the **V3 Checksum** tab.

| Name                     | Description                                                                               |
|--------------------------|-------------------------------------------------------------------------------------------|
| <b>Interface</b>         | Shows VRRPv3 information about a specified interface.                                     |
| <b>rcIpConflIndex</b>    | Shows the index value that uniquely identifies the interface to which this entry applies. |
| <b>ChkSumComputation</b> | Specifies the type of checksum computation, with Pseudo Header or without Pseudo Header.  |
| <b>VrrpVersion</b>       | Specifies the VRRP version as unspecified, v2, or v3.                                     |

## Configuring Fast Advertisement Interval on a port or a VRF instance

### About This Task

Configure the Fast Advertisement Interval to send VRRP advertisement messages. The interval can be between 200 and 1000 milliseconds, and it must be the same

on all participating routers. The default is 200. Enter the values in multiples of 200 milliseconds.

#### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **VRRP** tab.
5. Click **Insert**.
6. In the **Insert VRRP** dialog box, enable **FasterAdvIntervalEnable**.
7. In the **FasterAdvInterval** field, enter a value. You must set this value using multiples of 200 milliseconds.
8. Click **Insert**.

## Configuring Fast Advertisement Interval on a VLAN or a VRF instance

#### About This Task

Configure the Fast Advertisement Interval to send VRRP advertisement messages. The interval can be between 200 and 1000 milliseconds, and it must be the same on all participating routers. The default is 200. Enter the values in multiples of 200 milliseconds.

#### Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Click **VLANS > Basic**.
3. Select a VLAN.
4. Click **IP**.
5. Click the **VRRP** tab.
6. Click **Insert**.
7. In the IP, VLAN, Insert VRRP dialog box, click the **FasterAdvIntervalEnable** enable option.
8. In the **FasterAdvInterval**, box, enter a value. You must set the value using multiples of 200 milliseconds.
9. Click **Insert**.

## Viewing VRRP Statistics

#### About This Task

View VRRP statistics to monitor network performance.

#### Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **VRRP**.

3. Select the **Stats** tab.

### **Stats** Field Descriptions

The following table describes parameters on the VRRP statistics tab.

| Name                  | Description                                                                                  |
|-----------------------|----------------------------------------------------------------------------------------------|
| <b>ChecksumErrors</b> | Specifies the number of VRRP packets received with an invalid VRRP checksum value.           |
| <b>VersionErrors</b>  | Specifies the number of VRRP packets received with an unknown or unsupported version number. |
| <b>VrIDErrors</b>     | Specifies the number of VRRP packets received with an invalid VrID for this virtual router.  |

## Viewing VRRP Interface Statistics

### About This Task

View VRRP statistics to manage network performance.

### Procedure

1. In the navigation pane, expand the **Configuration > IP** folders.
2. Click **VRRP**.
3. Select the **Interface** tab.
4. Select an interface.
5. Click **Graph**.

### Interface Field Descriptions

The following table describes parameters on the **Interface** tab.

| Name                           | Description                                                                                                                            |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvertiseRcvd</b>           | Specifies the number of VRRP advertisements received by this virtual router.                                                           |
| <b>AdvertiseIntervalErrors</b> | Specifies the number of received VRRP advertisement packets with a different interval is than configured for the local virtual router. |
| <b>IPtTlErrors</b>             | Specifies the number of VRRP packets received by the virtual router with IP TTL (Time-To-Live) not equal to 255.                       |
| <b>PriorityZeroPktsRcvd</b>    | Specifies the number of VRRP packets received by the virtual router with a priority of 0.                                              |
| <b>PriorityZeroPktsSent</b>    | Specifies the number of VRRP packets sent by the virtual router with a priority of 0.                                                  |

| Name                       | Description                                                                                                                     |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>InvalidTypePktsRcvd</b> | Specifies the number of VRRP packets received by the virtual router with an invalid value in the 'type' field.                  |
| <b>AddressListErrors</b>   | Specifies the packets received address list the address list does not match the locally configured list for the virtual router. |
| <b>AuthTypeMismatch</b>    | Specifies the count of authentication type mismatch messages.                                                                   |
| <b>PacketLengthErrors</b>  | Specifies the count of packet length errors.                                                                                    |
| <b>AuthFailures</b>        | Specifies the count of authentication failure messages.                                                                         |

## Viewing IP VRRPv3 Statistics

### About This Task

Use the following procedure to view IPv6 VRRPv3 statistics for monitoring the network performance.

### Procedure

1. In the navigation pane, expand the **Configuration** --> **IP** folders.
2. Click **VRRP**.
3. Click the **V3 Stats** tab.

### **V3 Stats** Field Descriptions

Use the data in the following table to interpret the **V3 Stats** tab.

| Name                  | Description                                                                                        |
|-----------------------|----------------------------------------------------------------------------------------------------|
| <b>InetAddrType</b>   | Shows that the address type of the statistical entry is IPv4.                                      |
| <b>ChecksumErrors</b> | Specifies the total number of VRRP packets received with an invalid VRRP checksum value.           |
| <b>VersionErrors</b>  | Specifies the total number of VRRP packets received with an unknown or unsupported version number. |
| <b>VrIdErrors</b>     | Specifies the total number of VRRP packets received with an invalid VRID for the virtual router.   |

## Graphing IP VRRPv3 Statistics

### About This Task

Use the following procedure to view and graph IP VRRPv3 statistics for monitoring the network performance.

### Procedure

1. In the navigation pane, expand the **Configuration** --> **IP** folders.
2. Click **VRRP**.
3. Click the **V3 Interface** tab.
4. Select an interface, and click **Graph**.
5. Select one or more values.
6. Select a graph type, click one of the icons in the upper-left corner of the menu bar. Your choices are:
  - Line Chart
  - Area Chart
  - Bar Chart
  - Pie Chart

### **V3 Interface** Field Descriptions

Use the data in the following table to use the **V3 Interface** tab.

| Name                  | Description                                                                                                                                                                                                                                                                                                          |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>        | Shows the index value that uniquely identifies the interface to which this entry applies.                                                                                                                                                                                                                            |
| <b>VrId</b>           | Specifies a number that uniquely identifies a virtual router on a VRRP router.                                                                                                                                                                                                                                       |
| <b>PrimaryIpAddr</b>  | Specifies the virtual address assigned to the VRRP.                                                                                                                                                                                                                                                                  |
| <b>VirtualMacAddr</b> | Specifies the MAC address of the virtual router interface.                                                                                                                                                                                                                                                           |
| <b>State</b>          | Specifies the state of the virtual router interface: <ul style="list-style-type: none"> <li>• Initialize—waiting for a startup event</li> <li>• Backup—monitoring availability and state of the master router</li> <li>• Master—functioning as the forwarding router for the virtual router IP addresses.</li> </ul> |
| <b>Control</b>        | Specifies whether VRRP is enabled or disabled for the port (or VLAN). The default is enabled.                                                                                                                                                                                                                        |

| Name                            | Description                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Priority</b>                 | Specifies the priority value used by this VRRP router. Set a value from 1 to 255, where 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.                                                                                                                                                                            |
| <b>AdvInterval</b>              | Specifies the time interval (in seconds) between sending advertisement messages. The range is 1 to 255 seconds with a default of 1 second. Only the master router sends advertisements. The default is 1.                                                                                                                                                                            |
| <b>UpTime</b>                   | Specifies the time interval (in hundredths of a second) since the virtual router was initialized.                                                                                                                                                                                                                                                                                    |
| <b>CriticalIpAddr</b>           | <p>This command specifies an IP interface on the local router, which is configured so that a change in its state causes a role switch in the virtual router (for example, from master to backup) in case the interface stops responding.</p> <p><b>Note:</b><br/>In this context, local implies an address from the same VRF as the IP interface where VRRP is being configured.</p> |
| <b>CriticalIpAddrEnabled</b>    | Configures the IP interface on the local router to enable or disable the backup. The default is disabled.                                                                                                                                                                                                                                                                            |
| <b>BackUpMaster</b>             | Enables the backup VRRP system traffic forwarding. The default is disabled.                                                                                                                                                                                                                                                                                                          |
| <b>BackUpMasterState</b>        | Indicates whether the backup VRRP system traffic forwarding is enabled or disabled. The default is disabled.                                                                                                                                                                                                                                                                         |
| <b>FasterAdvIntervalEnabled</b> | Enables or disables the Fast Advertisement Interval. When disabled, the regular advertisement interval is used. The default is disable.                                                                                                                                                                                                                                              |
| <b>FasterAdvInterval</b>        | Configures the Fast Advertisement Interval between sending VRRP advertisement messages. The interval is between 200 and 1000 milliseconds, and you must enter the same value on all participating routers. The default is 200. You must enter the values in multiples of 200 milliseconds.                                                                                           |
| <b>PreemptMode</b>              | Issued to preempt the existing router. If a new router is added to the network with its priority higher than the existing routers, then the new router becomes the master.                                                                                                                                                                                                           |

| Name                         | Description                                                                                                                                                                                                                           |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Action</b>                | Lists options to override the delay timer manually and force preemption: <ul style="list-style-type: none"> <li>• <b>none</b> does not override the timer</li> <li>• <b>preemptHoldDownTimer</b> preempts the timer</li> </ul>        |
| <b>HoldDownTimer</b>         | Indicates the hold-down state of this VRRP interface. If the hold-down timer is operational, this variable is set to active; otherwise, this variable is set to dormant.                                                              |
| <b>HoldDownTimeRemaining</b> | Indicates the amount of time (in seconds) left before the HoldDownTimer expires.                                                                                                                                                      |
| <b>MasterAdvInterval</b>     | On the VRRPv3 master, the master advertisement interval is same as the advertisement interval. On the VRRPv3 Backup, the master advertisement interval is set to the Advertisement configured on the Master (received in the packet). |

## IPv6 VRRP Configuration using EDM

This section provides procedures to configure IPv6 VRRP using Enterprise Device Manager (EDM).

### Configure VRRP for an Interface

Configure VRRP to provide fast failover of a default router for IPv6 LAN hosts. VRRP supports a virtual IPv6 address shared between two or more routers that connect the common subnet to the enterprise network. VRRP for IPv6 provides a faster switchover to an alternate default router than is possible using the ND protocol.

Perform this procedure to configure VRRP on either a brouter port or a VLAN.

#### Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Do not configure RSMLT on the VLAN.
- Change the VRF instance as required to configure a VRRP for an interface on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

#### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IPv6**.
2. Select **VRRP**.
3. Select the following tab:
  - For VSP 8600 Series, select **Interface**.
  - For all other platforms, select **V3 Interface**.

4. Select **Insert**.
5. Beside the **IfIndex** field, click **Port** or **VLAN**.
6. In the dialog box that opens, select a port or VLAN.
7. Select **OK**.
8. Type the virtual router ID.
9. To control the packets sent to the IPv6 address associated to the virtual router, select the **AcceptMode** check box.
10. Type the primary IP address.
11. Select **Insert**.

### **V3 Interface** or **Interface** Field Descriptions

Use the data in the following table to use the **V3 Interface** or **Interface** tab.

| Name                  | Description                                                                                                                                                                                                                                                                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IfIndex</b>        | Shows the index value that uniquely identifies the interface to which this entry applies.                                                                                                                                                                                                                                               |
| <b>InetAddrType</b>   | Specifies the address type for the VRRP interface.                                                                                                                                                                                                                                                                                      |
| <b>VrId</b>           | Specifies a number that uniquely identifies a virtual router on a VRRP router.                                                                                                                                                                                                                                                          |
| <b>PrimaryIpAddr</b>  | Specifies the link-local address assigned to the VRRP.                                                                                                                                                                                                                                                                                  |
| <b>VirtualMacAddr</b> | Specifies the MAC address of the virtual router interface.                                                                                                                                                                                                                                                                              |
| <b>State</b>          | Shows the state of the virtual router interface. The possible states are <ul style="list-style-type: none"> <li>• initialize—waiting for a startup event</li> <li>• backup—monitoring availability and state of the master router</li> <li>• master—functioning as the forwarding router for the virtual router IP addresses</li> </ul> |
| <b>Control</b>        | Displays whether VRRP is enabled or disabled for the port or VLAN.                                                                                                                                                                                                                                                                      |
| <b>Priority</b>       | Specifies the priority value used by this VRRP router. The value 255 is reserved for the router that owns the IP addresses associated with the virtual router. The default is 100.                                                                                                                                                      |
| <b>AdvInterval</b>    | Specifies the time interval, in seconds, between sending advertisement messages. The default is 1 second.                                                                                                                                                                                                                               |
| <b>MasterIpAddr</b>   | Specifies the IP address of the physical interface of the Master's virtual router.                                                                                                                                                                                                                                                      |

| Name                            | Description                                                                                                                                                                                                                                                                                       |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>UpTime</b>                   | Indicates the time interval since this virtual router exited the INIT state.                                                                                                                                                                                                                      |
| <b>CriticalIpAddr</b>           | Indicates the IP address of the interface that is critical to VRRP. If that IP interface is down, the VRRP state will transition to Backup, even if it has higher priority.                                                                                                                       |
| <b>CriticalIpAddrEnabled</b>    | Enables or disables the use of critical IP. When disabled, the VRRP ignores the availability of the address configured as critical IP. This address must be a local address. The default is disabled.                                                                                             |
| <b>BackUpMaster</b>             | Uses the backup VRRP switch for traffic forwarding. This option reduces the traffic on the v1ST. The default is disabled.                                                                                                                                                                         |
| <b>BackUpMasterState</b>        | Indicates if the Backup-Master is up. If the switch is in Master state, but Backup-Master is enabled, then the BACKUP MASTER STATE will be down.                                                                                                                                                  |
| <b>FasterAdvIntervalEnabled</b> | Enables or disables the fast advertisement interval. When disabled, the regular advertisement interval is used. The default is disable.                                                                                                                                                           |
| <b>FasterAdvInterval</b>        | Configures the interval between VRRP advertisement messages. The default is 200.<br>Enter the values in multiples of 200 milliseconds.                                                                                                                                                            |
| <b>AcceptMode</b>               | Controls whether the VRRP master or backup master accepts packets (other than neighbor discovery packets) destined to the IPv6 address associated with the virtual router. The default value is disable.                                                                                          |
| <b>PreemptMode</b>              | Issued to preempt the existing router. If a new router is added to the network with its priority higher than the existing routers, then the new router becomes the master. The default is enabled.                                                                                                |
| <b>Action</b>                   | Lists options to override the hold-down timer manually and force preemption: <ul style="list-style-type: none"> <li>• <b>none</b> does not override the timer.</li> <li>• <b>preemptHoldDownTimer</b> preempts the timer.</li> </ul> This parameter applies only if the holddown timer is active. |
| <b>HoldDownTimer</b>            | Configures the amount of time, in seconds, to wait before preempting the current VRRP master. The default is 0.                                                                                                                                                                                   |

| Name                         | Description                                                                                                                                                                                                                         |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>HoldDownTimeRemaining</b> | Indicates the amount of time, in seconds, left before the HoldDownTimer expires.                                                                                                                                                    |
| <b>MasterAdvInterval</b>     | On the VRRP master, the master advertisement interval is same as the advertisement interval. On the VRRPv3 Backup, the master advertisement interval is set to the Advertisement configured on the Master (received in the packet). |

## Configuring VRRP notification control

Perform this procedure to configure VRRP notification control.

### Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Change the VRF instance as required to configure VRRP notification control on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Click **VRRP**.
3. Click the **Globals** tab.
4. Select **enabled**.
5. Click **Apply**.

### *Globals* field descriptions

Use the data in the following table to use the **Globals** tab.

| Name                     | Description                                                                                                                                                                                                                                         |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NotificationCntrl</b> | Indicates whether the VRRP-enabled router generates SNMP traps for events. <ul style="list-style-type: none"> <li>• <b>enabled</b>: Generate SNMP traps.</li> <li>• <b>disabled</b>: Do not generate SNMP traps.</li> </ul> The default is enabled. |

## View IPv6 VRRP Statistics

View IPv6 VRRP statistics to monitor network performance.

### Procedure

1. In the navigation pane, expand **Configuration** > **IPv6**.
2. Select **VRRP**.

3. Select the **Stats** tab.

### **Stats** Field Descriptions

Use the data in the following table to use the **Stats** tab.

| Name                  | Description                                                                              |
|-----------------------|------------------------------------------------------------------------------------------|
| <b>InetAddrType</b>   | Shows the type of IP address (IPv4 or IPv6).                                             |
| <b>ChecksumErrors</b> | Shows the number of VRRP packets received with an invalid VRRP checksum value.           |
| <b>VersionErrors</b>  | Shows the number of VRRP packets received with an unknown or unsupported version number. |
| <b>VrIdErrors</b>     | Shows the number of VRRP packets received with an invalid VrID for this virtual router.  |

## Viewing IPv6 VRRP Statistics for an Interface

View IPv6 VRRP statistics for a VLAN or port.

### Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Click **VRRP**.
3. Click the **Interface** tab.
4. Select an interface.
5. Click **Statistics**.

### **Statistics** Field Descriptions

Use the data in the following table to use the **Statistics** tab.

| Name                     | Description                                                                                                                                                                                                                                                                              |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MasterTransitions</b> | Shows the total number of times that the state of this virtual router has transitioned to master. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of <code>DiscontinuityTime</code> . |
| <b>RcdAdvertisements</b> | Shows the total number of VRRP advertisements received by this virtual router. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of <code>DiscontinuityTime</code> .                    |

| Name                       | Description                                                                                                                                                                                                                                                                                                                                    |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdvIntervalErrors</b>   | Shows the total number of VRRP advertisement packets received for which the advertisement interval is different than the one configured for the local virtual router. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime. |
| <b>IpTtlErrors</b>         | Shows the total number of VRRP packets received by the virtual router with IPv4 TTL (for VRRP over IPv4) or IPv6 Hop Limit (for VRRP over IPv6) not equal to 255. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.     |
| <b>RcvdPriZeroPackets</b>  | Shows the total number of VRRP packets received by the virtual router with a priority of 0. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.                                                                           |
| <b>SentPriZeroPackets</b>  | Shows the total number of VRRP packets sent by the virtual router with a priority of 0. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.                                                                               |
| <b>RcvdInvalidTypePkts</b> | Shows the number of VRRP packets received by the virtual router with an invalid value in the 'type' field. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime.                                                            |
| <b>AddressListErrors</b>   | Shows the total number of packets received for which the address list does not match the locally configured list for the virtual router. Discontinuities in the value of this counter can occur at reinitialization of the management system, and at other times as indicated by the value of DiscontinuityTime.                               |

| Name                              | Description                                                                                                                                                                                                                                                                       |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PacketLengthErrors</b>         | Shows the total number of packets received with a packet length less than the length of the VRRP header. Discontinuities in the value of this counter can occur at re-initialization of the management system, and at other times as indicated by the value of DiscontinuityTime. |
| <b>RcvdInvalidAuthentications</b> | Shows the total number of packets received with an unknown authentication type.                                                                                                                                                                                                   |

## Configure IPv6 VRRP Statistics

View IPv6 VRRP statistics for a VLAN or port.

### Before You Begin

Change the VRF instance as required to view IPv6 VRRP statistics on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Port**.
2. Select **IPv6**.
3. Select the **VRRP** tab.
4. Select an interface.
5. Select **Statistics**.

## Graphing IPv6 VRRP Statistics

### About This Task

Use the following procedure to graph IPv6 VRRPv3 statistics for monitoring the network performance.

### Procedure

1. In the navigation pane, expand the **Configuration --> IPv6** folders.
2. Click **VRRP**.
3. Click the **Stats** tab.
4. Select an interface, and click **Graph**.
5. Select one or more values.

6. Select a graph type, click one of the icons in the upper-left corner of the menu bar. Your choices are:
- Line Chart
  - Area Chart
  - Bar Chart
  - Pie Chart

### **Stats** Field Descriptions

Use the data in the following table to use the **Stats** tab.

| Name                  | Description                                                                              |
|-----------------------|------------------------------------------------------------------------------------------|
| <b>InetAddrType</b>   | Shows the type of IP address (IPv4 or IPv6).                                             |
| <b>ChecksumErrors</b> | Shows the number of VRRP packets received with an invalid VRRP checksum value.           |
| <b>VersionErrors</b>  | Shows the number of VRRP packets received with an unknown or unsupported version number. |
| <b>VrIdErrors</b>     | Shows the number of VRRP packets received with an invalid VrID for this virtual router.  |

## Configuring additional addresses on the VRRP brouter port

Perform this procedure to configure the additional addresses for which the virtual router acts as a back up.

### Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
2. Click **IPv6**.
3. Click the **VRRP** tab.
4. Click **AssociatedIPAddr**.
5. Click **Insert**.
6. Type the address.
7. Type the prefix length.
8. Click **Insert**.

## Configuring additional addresses on the VRRP interface

Perform this procedure to configure the additional addresses for which the virtual router acts as a back up.

### Before You Begin

- Assign an IPv6 address to the interface.
- Enable routing globally.
- Do not configure RSMLT on the VLAN.
- Change the VRF instance as required to configure additional addresses on the VRRP interface on a specific VRF instance. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Click **VRRP**.
3. Click the **Interface** tab.
4. Select an interface.
5. Click **AssociatedIPAddr**.
6. Click **Insert**.
7. Type the address.
8. Type the prefix length.
9. Click **Insert**.

### **Address List** *field descriptions*

Use the data in the following table to use the **Address List** tab.

| Name                      | Description                                                                                                                                                                     |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IpAddr</b>             | Specifies an IP address that is associated with a virtual router. The number of rows on this tab equals the number of IP addresses associated (backed up) by the virtual router |
| <b>IpAddrPrefixLength</b> | Specifies the length of the prefix in bits.                                                                                                                                     |

# VXLAN Gateway

[Configuration Examples](#) on page 4311

VXLAN Gateway terminates virtual extensible LAN (VXLAN) tunnels that stretch emulated Layer 2 segments over an IP network.

The following topics provide necessary concepts and procedures to configure VXLAN Gateway and Open vSwitch Database Management Protocol (OVSDB) support for VXLAN Gateway.

## VXLAN Gateway Fundamentals

**Table 315: VXLAN Gateway product support**

| Feature                                  | Product         | Release introduced |
|------------------------------------------|-----------------|--------------------|
| VXLAN Gateway                            | 5320 Series     | Not Supported      |
|                                          | 5420 Series     | Not Supported      |
|                                          | 5520 Series     | Not Supported      |
|                                          | 5720 Series     | Not Supported      |
|                                          | 7520 Series     | Fabric Engine 8.10 |
|                                          | 7720 Series     | Fabric Engine 8.10 |
|                                          | VSP 4450 Series | Not Supported      |
|                                          | VSP 4900 Series | Not Supported      |
|                                          | VSP 7200 Series | VOSS 6.0           |
|                                          | VSP 7400 Series | VOSS 8.0           |
|                                          | VSP 8200 Series | VOSS 6.0           |
|                                          | VSP 8400 Series | VOSS 6.0           |
|                                          | VSP 8600 Series | Not Supported      |
|                                          | XA1400 Series   | Not Supported      |
| OVSDB protocol support for VXLAN Gateway | 5320 Series     | Not Supported      |
|                                          | 5420 Series     | Not Supported      |
|                                          | 5520 Series     | Not Supported      |
|                                          | 5720 Series     | Not Supported      |
|                                          | 7520 Series     | Fabric Engine 8.10 |
|                                          | 7720 Series     | Fabric Engine 8.10 |
|                                          | VSP 4450 Series | Not Supported      |
|                                          | VSP 4900 Series | Not Supported      |
|                                          | VSP 7200 Series | VOSS 7.1           |
|                                          | VSP 7400 Series | VOSS 8.0           |
|                                          | VSP 8200 Series | VOSS 7.1           |
|                                          | VSP 8400 Series | VOSS 7.1           |
|                                          | VSP 8600 Series | Not Supported      |
|                                          | XA1400 Series   | Not Supported      |

**Table 315: VXLAN Gateway product support (continued)**

| Feature                        | Product         | Release introduced |
|--------------------------------|-----------------|--------------------|
| ECMP support for VXLAN Gateway | 5320 Series     | Not Supported      |
|                                | 5420 Series     | Not Supported      |
|                                | 5520 Series     | Not Supported      |
|                                | 5720 Series     | Not Supported      |
|                                | 7520 Series     | Fabric Engine 8.10 |
|                                | 7720 Series     | Fabric Engine 8.10 |
|                                | VSP 4450 Series | Not Supported      |
|                                | VSP 4900 Series | Not Supported      |
|                                | VSP 7200 Series | VOSS 6.0           |
|                                | VSP 7400 Series | VOSS 8.0           |
|                                | VSP 8200 Series | VOSS 6.0           |
|                                | VSP 8400 Series | VOSS 6.0           |
|                                | VSP 8600 Series | Not Supported      |
|                                | XA1400 Series   | Not Supported      |

VXLAN Gateway terminates virtual extensible LAN (VXLAN) tunnels that stretch emulated Layer 2 segments over an IP network.

VXLAN is an encapsulation protocol for running an overlay network over an existing Layer 3 infrastructure. This tunneling scheme uses a VLAN-like encapsulation mechanism to encapsulate MAC-based traffic. The VXLAN overlays separate workloads from physical networks, which facilitates the movement of VMs in a multi-tenant environment.

For more information about VXLAN, see the Internet Engineering Task Force (IETF) standard RFC 7348.

## VXLAN Gateway as a VTEP

The VXLAN Gateway feature terminates VXLAN tunnels and operates as a VXLAN tunnel endpoint (VTEP). The VXLAN Gateway is a hardware-based VTEP that allows a VXLAN to communicate with VLANs, other VXLANs, as well as Fabric Connect I-SIDs.

The following figure shows a VXLAN Gateway (labeled as VTEP Source) connecting VXLAN segments to an SPB network. This type of deployment provides a solution for VXLAN in data centers to interoperate with Fabric Connect networks (labeled as SPB).

## VXLAN Segments

VXLAN tunnels are also called VXLAN segments. VXLAN segments provide the ability to separate, abstract, and decouple the physical topology from a logical or virtual topology by using encapsulated tunneling. VXLAN segments allows only VMs within the same VXLAN tunnel to communicate with each other.

## VNID

Each VXLAN segment has a 24-bit segment ID called a VXLAN Network Identifier (VNID). VNID allows up to 16 million VXLAN segments to coexist within the same administrative domain, which enables VMs to migrate between servers in the same data center or between distributed data centers. Each VTEP can support multiple VNIDs. For information about maximum scaling numbers, see [VOSS Release Notes](#).

The VNID uses the inner MAC frame originated by the individual VM. Overlapping MAC addresses can cross VXLAN segments, but never have traffic crossover because the traffic is isolated using the VNID qualifier. Due to this encapsulation, only the VTEP knows the VNID and its associated VXLAN tunnel. VMs are unaware of the VXLAN.

## VM Traffic

Only VMs within the same VXLAN segment can communicate with each other. The following steps show how a VM communicates with a VM on a different host within the same VXLAN segment:

1. The VM sends a MAC frame destined to the target.
2. The VTEP looks up the VNID that the VM is associated with to verify that the destination MAC is on the same segment. If the destination MAC is on the same segment, the process continues.
3. The VTEP inserts an outer header comprising an outer MAC, outer IP address, and VXLAN header in front of the original MAC frame.
4. The VTEP transmits the final packet out to the destination IP address of the remote VTEP, connecting the destination VM addressed by the inner MAC destination address.
5. The remote VTEP verifies that the VNID is valid for the destination VM.
6. If the VNID is valid, the remote VTEP strips the packet outer header and passes the packet to the destination VM. The destination VM never knows about the VNID, or that the frame transmitted with VXLAN encapsulation.

## VXLAN Gateway Management Methods

Two methods are available to manage VXLAN Gateway:

- Static management using CLI and local configuration files.
- Dynamic management using OVSDB protocol support for VXLAN Gateway.

For static management, you use CLI or local configuration files to configure and manage the VXLAN Gateway hardware-based VTEP functions. You must manually configure the Source-VTEP, VNID, VNID to I-SID bindings, Remote-VTEP, and VNI to Remote-VTEP associations, and MAC learning on the VNID only occurs at the data-plane level.

For dynamic management, you use OVSDB protocol support for VXLAN Gateway to configure and manage the VXLAN Gateway hardware-based VTEP functions with Open vSwitch Database Management Protocol (OVSDB). You must configure at least one physical Network Virtualization Controller (NVC) running VMware NSX with OVSDB features. You can add a Hardware VTEP, add a logical switch, configure VNID to VTEP bindings, and configure a replication cluster in NSX. The VXLAN Gateway must have OVSDB enabled and the Network Virtualization Controller (NVC) must communicate on the OVSDB managed interface. You must manually configure the Source-VTEP and NVC IP addresses, and the VNID to I-SID binding in NSX. The NVC can manage the VNID, Remote-VTEP, and VNI to Remote-VTEP associations. The NVC distributes the hosts MAC and IP addresses learned by the VTEP over the VXLAN.

The following table shows the functional differences between the two VXLAN Gateway management methods.

**Table 316: VXLAN Gateway Management Methods**

| Function                                             | Static management                       | Dynamic management                           |
|------------------------------------------------------|-----------------------------------------|----------------------------------------------|
| VNID provisioning                                    | Manually from CLI or EDM                | Automatically from NVC                       |
| VNID to I-SID binding                                | Manually from CLI or EDM                | Automatically from NVC                       |

## VXLAN Gateway Licensing

VXLAN Gateway requires a Premier or Premier with MACsec license. If a Premier License is not present, you cannot configure VXLAN Gateway.

## VXLAN Modes

The VXLAN Gateway implementation is available in two modes: Base Interworking Mode and Full Interworking Mode. By default, the Base Interworking Mode is enabled and Full Interworking Mode is disabled. You change modes through the **vxlan-gw-full-interworking-mode** boot flag.

### Important

Changing the mode requires a reboot for the change to take effect, which can cause a loss of traffic.

### *Base Interworking Mode*

Base Interworking Mode is the default mode. In this mode, VXLAN Gateway supports Layer 2 gateway communication at line rate between VXLAN and traditional VLAN environments.

Base Interworking Mode has the following limitations:

- No support for VXLAN-to-VXLAN communication.
- No support for VXLAN-to-SPB communication.
- No support for SMLT, vIST, or Simplified vIST.
- No support for OVSDB protocol support for VXLAN Gateway.

Each VNID represents a service instance for the VXLAN Gateway. To enable a VNID to extend into the SPB network, you must use Full Interworking Mode.

**Note**

If your configuration does not have a VXLAN Gateway but has SMLT or vIST, you can enable VXLAN Gateway in the Full Interworking Mode only. SMLT and vIST are incompatible and mutually exclusive with the Base Interworking Mode.

*Full Interworking Mode*

Full Interworking Mode is not the default mode. To configure Full Interworking Mode, you must enable the **vxlan-gw-full-interworking-mode** boot flag, save the configuration, and then reboot the switch.

Full Interworking Mode supports the Base Interworking Mode communication between VXLAN and traditional VLAN environments as well as VXLAN-to-VXLAN communication and all SPB functionality including vIST and SMLT. Layer 2 and Layer 3 services extend across VXLAN, VLAN, and SPB domains using an internal loopback. In Full Interworking Mode, VXLAN traffic flows at less than full line rate and the total amount of available internal loopback bandwidth depends on the platform used.

Full Interworking Mode has the following limitations:

- No support for Simplified vIST.
- A VNID cannot have the same value as an I-SID. A consistency check ensures that this does not happen if you change the boot configuration flag to turn off Full Interworking Mode and go into Base Interworking Mode.

## Types of VXLAN Gateway Deployments

VXLAN Gateway provides the following deployment solutions:

- [VXLAN-to-VLAN Layer 2 gateway deployment](#)
- [VXLAN-to-VXLAN Layer 3 gateway deployment](#)
- [VXLAN-to-SPB gateway deployment](#)

These gateways provide VXLAN tunnel termination functions for switches that could be Top of Rack (ToR) switches, access switches, or switches higher up in the data center network topology such as a core switch or even WAN edge devices. The last case (WAN edge) could involve a Provider Edge (PE) router that terminates VXLAN tunnels in a hybrid cloud environment.

*VXLAN-to-VLAN Layer 2 Gateway Deployment*

The VXLAN-to-VLAN deployment is where the VXLAN Gateway communicates between VXLAN segments and VLAN segments. Use this scenario when nodes on a VXLAN overlay network need to communicate with nodes on legacy networks that are VLAN based as shown in the following figure.

**Figure 274: VXLAN-to-VLAN deployment**

In this type of deployment, the VXLAN Gateway maps the VXLAN VNID to a VLAN in the following way:

- When packets traverse a VXLAN segment into the VLAN segment, the VXLAN VTEP removes the VXLAN header and forwards regular VLAN packets to a physical port based on the destination MAC address of the inner Ethernet frame.

The VTEP discards decapsulated frames with the inner VLAN ID unless you explicitly configure them to be passed on to the non-VXLAN interface. The VXLAN VNID to VLAN mapping is statically configured.

- In the reverse direction when packets traverse a VLAN segment into a VXLAN segment, the VXLAN VTEP maps the incoming frames from the non-VXLAN interfaces to a specific VXLAN overlay network based on the VLAN ID in the frame. This complies with the standard VXLAN RFC.

The VTEP also accepts both untagged and tagged inner frames and adds or replaces the tag of the inner frame with the local VLAN mapped to the VNID before sending out the frame.

The VTEP removes the VLAN ID of the original frame before it encapsulates the frame for VXLAN.

#### *VXLAN-to-VXLAN Layer 3 Gateway Deployment*

The VXLAN-to-VXLAN deployment is where the VXLAN Gateway communicates between VXLAN segments. Use this scenario when one VXLAN segment needs to communicate with another VXLAN segment.

When a packet traverses a VXLAN segment and enters the VXLAN Gateway, the VXLAN VTEP maps one VXLAN segment to another in the following way:

- Decapsulates the VXLAN header.
- Performs a route lookup of the customer packet.
- Identifies that the next hop VLAN is in another VXLAN segment.

- Encapsulates the packet with a new VXLAN header with a new VNID.
- Forwards the packet out.

The following figure shows two virtualized servers attached to a Layer 3 infrastructure. The servers could be on the same rack, on different racks, or across data centers within the same administrative domain.

There are four VXLAN overlay networks identified by the VNIDs: 22, 34, 74, and 98. Notice how the VMs are associated with a VNID. For example, VM1-1 in Server 1 and VM2-4 on Server 2 are on the same VXLAN overlay network identified by VNID 22.

The VMs do not know about the overlay networks and transport method because the encapsulation and decapsulation happen transparently at the VTEPs on Servers 1 and 2. The other overlay networks and the corresponding VMs are: VM1-2 on Server 1 and VM2-1 on Server 2 both on VNID 34, VM1-3 on Server 1 and VM2-2 on Server 2 on VNID 74, and finally VM1-4 on Server 1 and VM2-3 on Server 2 on VNID 98.

**Figure 275: VXLAN-to-VXLAN deployment**

#### *VXLAN-to-SPB Gateway Deployment*

The VXLAN-to-SPB deployment is where the VXLAN Gateway communicates between a VXLAN segment and an SPB domain. This type of deployment provides a solution for customers using VXLAN in their data-centers to interoperate with Fabric Connect as shown in the following figure.

**Figure 276: VXLAN-to-SPB deployment**

The VXLAN Gateway maps the VXLAN VNID to I-SID in the following way:

- When packets traverse a VXLAN segment into an SPB domain, the VXLAN VTEP decapsulates the VXLAN packet, encapsulates it with MAC-in-MAC encapsulation, and then forwards it into the SPB domain.
- In the reverse direction, the VXLAN VTEP decapsulates the MAC-in-MAC packet from an SPB domain, encapsulates it with a VXLAN header, and then forwards it into a VXLAN segment.

## VXLAN Gateway Considerations and Limitations

Review the following considerations, limitations, and behavioral characteristics associated with VXLAN Gateway.

### *Unsupported Features*

VXLAN Gateway does not support the following features:

- IP Multicast over Layer 3 VSN Fabric Connect traffic cannot be carried over into a VXLAN domain through a VXLAN Gateway. Layer 3 VSN Fabric Connect requires MAC-in-MAC encapsulation over VXLAN encapsulation, and the VXLAN Gateway data plane does not support double-encapsulation. However, IP Multicast over IP Shortcuts Fabric Connect can be carried over into a VXLAN domain through a VXLAN Gateway.
- SPB-PIM Gateway and VXLAN Gateway interoperability is not supported.
- VXLAN Gateway does not support Simplified vIST in any mode.

### *QoS and VXLAN Gateway*

- If present in the packet, VXLAN Gateway honors user-configured ingress dot1p and DSCP mappings to derive the internal CoS.
- Customer packets are not remarked.
- Control packets are handled by high priority CoS queues.
- DSCP bits in the outer IP header of VXLAN-encapsulated packets are always derived from the internal QoS, irrespective of the ingress port DiffServ configuration.

Customer packet IP DSCP bits are not modified as part of VXLAN encapsulation. For more information about QoS, see [Quality of Service](#) on page 2884.

- DSCP bits in the inner IP header of VXLAN-encapsulated packets change when traffic comes in on a Layer 2 Trusted or a Layer 3 Untrusted port with DiffServ enabled.

#### *ECMP Support for VXLAN Gateway and Fabric Extend*

VXLAN Gateway requires ECMP support to communicate with remote VTEPs. The software extended this ECMP support to Fabric Extend Layer 3 core tunnels. Therefore, if your switch supports VXLAN Gateway, it also supports ECMP for both VXLAN Gateway and Fabric Extend.

#### *Base Interworking Mode Considerations and Limitations*

- After associating a VNID with an I-SID (**vnid <vnid value> i-sid <isid value>**), you cannot create an I-SID with the same value as the **<vnid value>** and vice versa.
- There is no support for SMLT, vIST, or Simplified vIST in Base Interworking Mode.
- Neither Base Interworking Mode nor Full Interworking Mode support Fabric Attach endpoints.
- Base Interworking Mode does not allow SMLT and vIST configurations. If you change from Full Interworking Mode to Base Interworking Mode, make sure there are none of these configurations.
- In Base Interworking Mode, the **untagged-traffic <port >> mlt>** support is limited to untagged traffic forwarding only. No control packet forwarding is supported on this port or MLT.

LACP MLT is not supported as part of **untagged-traffic <mlt>**.

#### *Full Interworking Mode Considerations and Limitations*

- Whenever you change from Base Interworking Mode to Full Interworking Mode, you have to reboot the switch. The software automatically changes the configuration to be in line with Full Interworking Mode.
- Full Interworking Mode does not have VXLAN endpoints. Configure ELAN endpoints under the ELAN I-SID only.
- Neither Base Interworking Mode nor Full Interworking Mode support Fabric Attach endpoints.

#### *General Configuration Guidelines*

- In VXLAN environments that have an underlying IP network with SMLT deployment, you must enable RSMLT in the underlying network on vIST VTEP devices.
- If you use more than one VXLAN Gateway node for the same I-SID, you must ensure that loops are prevented.
- The VTEP remote destination IP table in the datapath hardware is shared with the Fabric Extend IP core remote tunnel destination IP table.
  - The maximum number of FE tunnel destination IP addresses is 256.
  - The maximum number of VTEP IP addresses is 500.

For every FE tunnel destination IP you configure, you must reduce the number of VTEP IPs by one. For example, if you configure the maximum number of FE tunnel destination IPs then the maximum of VTEP remote destination that you can configure is  $500-256=244$ .

- The total number of MACs that the VTEP learns in the switch is constant and includes the MACs learned on VNID, I-SID, and on VLANs (normal and CVLANs).
  - MAC addresses that the VTEP learns from the VNID table are also learned when an I-SID is associated with the VNID. Therefore, the maximum number of MAC addresses that the VTEP can support is reduced accordingly.
  - If a VLAN is associated with an I-SID, and that I-SID is associated with a VNID, then the VTEP learns each customer MAC address from three different tables (VLAN, I-SID, and VNID). This consumes three MAC entry records. In a vIST scenario where all I-SIDs have associated VNIDs, then the max number of C-MACs that the VTEP learns is reduced by  $224K$  divided by  $3 = 74K$  MAC addresses.
  - If a Switched-UNI endpoint is associated with an I-SID, then the VTEP learns the C-MAC only once in the I-SID table. If this I-SID is associated with a VNID, then the VTEP learns the C-MAC twice: once in the I-SID table and once in the VXLAN VNID table.
- IP filter rules that you create do not work for VXLAN tunnel terminated packets. This restriction also applies to the Fabric Extend Layer 3 core.
- All ports in an MLT configured as a Switched-UNI endpoint or a VXLAN endpoint have the same properties as configured under the MLT interface.
- A VXLAN tunnel VTEP source IP cannot be a broadcast or multicast IP address. Configure it as a loopback IP address and not a router IP address.
- The VXLAN source address (**vtep-source-ip**) should be different from the SPBM IP Shortcut (**ip-source-address**) and Fabric Extend (**ip-tunnel-source-address**) source addresses.
- If you configure the loopback IP address under a VRF, the **vtep-source-ip** address must be set up under the same VRF.
- The remote VTEP IP address (**vtep <id> ip <ip address>**) cannot be local to the system.
- You can configure a maximum of 500 remote VTEPs per VNID.
- You can change the VTEP source IP and remote VTEP IP dynamically.
- VTEPs have to be reachable for the tunnel to be up.
- The tunnel ID for a VTEP has to be the same on both vIST peers.
- If the VTEP source IP is configured under a VRF, then the VRF cannot have an I-SID associated with it or vice versa.
- Two VNIDs cannot be mapped to the same I-SID.
- An I-SID associated with a VNID cannot be a T-UNI or E-Tree I-SID.
- To prevent routing loops, the platform VLANs used for VXLAN interworking should NOT be in the same VRF or GRT as the IP interfaces in the underlay network.
- You cannot delete a VTEP source IP address (**vtep-source-ip**) when VTEPs are configured.

- If an ELAN I-SID attached to a VNID has a platform VLAN associated with it, then you cannot delete the platform VLAN or change the I-SID associated with that VLAN.
- You cannot delete the loopback IP associated with a VTEP source IP.
- If the VTEP source IP is configured under a VRF, then you cannot delete the VRF.
- You cannot delete or modify the VLAN with I-SID that is associated with a VNID.
- If an ELAN I-SID attached to a VNID also has a platform VLAN associated with it, then you cannot delete the platform VLAN or change the I-SID associated with that VLAN.

## OVSDB protocol support for VXLAN Gateway Considerations and Limitations

Review the following considerations, limitations, and behavioral characteristics associated with OVSDB protocol support for VXLAN Gateway.

### *Network Virtualization Controllers Dependencies and Restrictions*

OVSDB protocol support for VXLAN Gateway requires at least one Network Virtualization Controller (NVC) that runs OVSDB:

- OVS is an open source implementation of a virtual switch and OVSDB is a standard defined in RFC 7047.
- You require at least one NVC. The NVC is an ESXi host server that runs the VMware NSX Network Virtualization and Security Platform (minimum version 6.2.4).

#### **Note**

VMware NSX 6.2.4 has known issues that can cause VXLAN discovery delays and NVC connectivity issues in certain scenarios, for more information see [VOSS Release Notes](#).

- You must configure VMware NSX. You can add a Hardware VTEP, add a logical switch, configure VNID to VTEP bindings, and configure a replication cluster in NSX.
- The NSX logical switch on the NVC is assigned a VNID. The VXLAN Gateway is assigned an OVSDB managed interface I-SID. You must configure the VNID to I-SID binding in NSX.
- SSL is the default protocol for NVC to VXLAN Gateway communications.
- You can configure more than one NVC in a controller cluster for high availability and load-balancing.
- The NVC performs MAC learning on the VXLAN tunnel.
- ARP suppression is not supported.
- One NVC manages all encapsulated Broadcast, Unknown Unicast, and Multicast (BUM) traffic. This NVC replicates the BUM traffic to all other VTEPs in the network. If connectivity to the NVC managing BUM traffic fails, a loss of BUM traffic can occur. NVC cluster NSX service node replication is not applicable for BUM traffic.

The following diagram shows an example of NVCs managing a distributed virtual network.

*OVSDB protocol support for VXLAN Gateway Dependencies and Restrictions*

- The VXLAN Gateway must operate in Full Interworking mode.
- You must configure at least one NVC connection to the VXLAN Gateway.
- You can configure up to three NVCs connections to one VXLAN Gateway in this release.
- The VXLAN Gateway must use the Segmented Management Instance IP address to connect with the NVCs. For more information about how to configure Segmented Management Instance, see [Segmented Management](#) on page 86.
- You cannot change or delete the VTEP source IP address when OVSDB is enabled.
- The OVSDB managed interface I-SIDs are communicated to the NVC as physical ports of the switch.
- EDM support for OVSDB is limited in this release. You can use CLI where EDM configuration is unavailable.
- The VXLAN Gateway general considerations and limitations also apply to OVSDB protocol support for VXLAN Gateway.

**Note**

NVC connectivity issues for SSL communication failures are not logged on the switch. You can use the logs on the NVC to troubleshoot SSL communications with the VXLAN Gateway.

### *OVS Modules on VXLAN Gateway*

OVSDB protocol support for VXLAN Gateway uses OVS modules on the VXLAN Gateway. The switch runs the following OVS modules:

- OVSDB server — Manages the database.
- Database — Manages the OVS schema and HW VTEP schema and JSON content.

### *OVSDB Replication Considerations and Limitations*

#### **Note**

OVSDB replication is different than NSX service node replication. Service node replication is configured and supported in NSX. OVSDB replication uses vIST and is configured and supported on the VXLAN Gateway.

- You require at least two NVCs to enable OVSDB replication.
- OVSDB replication operates in an ACTIVE-STANDBY server configuration.
- You must disable OVSDB on the standby vIST device before disabling OVSDB on the active vIST device.
- One active NVC and one standby NVC are supported by the VXLAN Gateway.
- VNID to I-SID binding, Remote VTEPs, VNI to Remote VTEPs for BUM, Remote MACs, and Local MACs are replicated across NVCs.

## VXLAN Gateway configuration using the CLI

---

This section provides procedures to configure VXLAN Gateway using the CLI.

### Enable VXLAN Gateway in Full Interworking Mode

#### **Note**

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Enables VXLAN Gateway in Full Interworking Mode, which supports SPB, SMLT, and vIST.

#### **Important**

After you change this boot flag, you must save the change to the configuration file and reboot the switch.

#### **About This Task**

By default, the Base Interworking Mode is enabled and Full Interworking Mode is disabled. You change modes by enabling this boot configuration flag.

The **no** operator results in the default Base Interworking Mode. In this mode, VXLAN Gateway supports Layer 2 gateway communication between VXLAN and traditional VLAN environments.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Enable Full Interworking Mode:  
`boot config flags vxlan-gw-full-interworking-mode`
3. Save the changed configuration.  
`save config`
4. Restart the switch.  
`reset`
5. Verify that VXLAN Gateway is in Full Interworking Mode:  
`show boot config flags`

The **true** parameter in the output indicates that Full Interworking Mode is enabled.

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags vxlan-gw-full-interworking-mode
```

## Configure VXLAN Gateway

Use the following procedure to configure VXLAN Gateway parameters to enable SPBM to operate on the switch.

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

### Before You Begin

Use the **show boot config flags** to verify that you are in the mode you want. The **vxlan-gw-full-interworking-mode** should be set to `false` for the Base Interworking Mode (default) and `true` for the Full Interworking Mode.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Configure the VTEP source IP address:  
`vtep source-ip <A.B.C.D> [vrf WORD<1-16>]`
3. Configure the remote VTEP IP address:  
`vtep <1-500> ip <A.B.C.D> [name WORD<1-64>]`

## 4. Create a VNID instance:

```
vnid <1-16777215> i-sid <1-16777215>
```

**Note**

The command prompt changes to **#vxlan** to indicate that you are now in VXLAN Configuration mode for the VNID specified in `vnid <1-16777215>`.

## 5. Associate VLANs in a port or MLT list to this VNID instance:

```
c-vid <1-4094> port <{slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}>
```

or

```
c-vid <1-4094> mlt <1-4094>
```

## 6. Specify the ports or MLT in this VNID instance that will support untagged traffic:

```
untagged-traffic port <{slot/port[/sub-port]}>
```

or

```
untagged-traffic mlt <1-4094>
```

## 7. Associate VTEPs to this VNID instance:

```
vtep <1-255>
```

**Example**

For an example of this procedure, see [VXLAN Gateway configuration example in Base Interworking mode](#) or [VXLAN Gateway configuration example in Full Interworking mode](#).

*Variable definitions*

Use the data in the following table to use the **vtep** command.

| Variable                                                                                              | Value                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>source-ip</code><br><code>&lt;A.B.C.D&gt; [vrf</code><br><code>WORD&lt;1-16&gt;]</code>         | Specifies the VXLAN tunnel end point (VTEP) source IP address, which can be on the GRT or a VRF.<br><br><b>Note:</b><br>The VTEP source IP address must be on a loopback interface.                                                                                                                                                                                 |
| <code>&lt;1-500&gt; ip</code><br><code>&lt;A.B.C.D&gt; [name</code><br><code>WORD&lt;1-64&gt;]</code> | Specifies an index value and an IP address that uniquely identifies this remote VTEP.<br>Optionally, you can assign a specific name to this tunnel. By default, the switch assigns a name in this format: <code>VTEP-&lt;#ID&gt;-&lt;IP address&gt;</code><br><br><b>Note:</b><br>The remote VTEP IP address cannot be a local, broadcast, or multicast IP address. |

Use the data in the following table to use the **vnid** command.

| Variable                                                 | Value                                                                                                                                                                                         |
|----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;1-16777215&gt; i-sid &lt;1-16777215&gt;</code> | <p>Uses this VNID and I-SID information to create a VNID instance and enter VXLAN Configuration Mode in the CLI.</p> <p><b>Note:</b><br/>A VNID must not have the same value as an I-SID.</p> |

Use the data in the following table to configure commands in the VXLAN Configuration Mode (`#vxlan`). These commands apply to the VNID instance that you specified in the `vnid <1-16777215> i-sid <1-16777215>` command.

| Variable                                                                                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <code>vtep &lt;1-255&gt;</code>                                                                      | Lists the remote VTEP destinations to associate with the specified VNID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Flush the MAC Forwarding Table

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use this procedure to flush all the learned MAC addresses from the forwarding database of the selected VNID.

### Procedure

1. Enter Global Configuration mode:  

```
enable

configure terminal
```
2. Flush the MAC FDB:  

```
vnid mac-address-entry <1-16777215> flush
```

### Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# vnid mac-address-entry 100 flush
```

## VXLAN Gateway show commands

Use the procedures in this section to display specific information about VXLAN Gateway on the switch.

### Display VTEP Source Information

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to display information about the VTEP source.

### Procedure

1. Enter Privileged EXEC mode:  

```
enable
```
2. Display the VTEP's source IP address and the name of the VRF:  

```
show vtep local
```

### Example

```
Switch:1# show vtep local
=====
                        VTEP General Info
=====
vtep source-ip-address: 198.51.100.1
                        vtep vrf : GlobalRouter
```

*Display Remote VTEP Information***Note**

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to display information about the remote VTEP.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Display information about all of the remote VTEPs or use the option to specify a particular VTEP:  
show vtep remote [<1-500>]

**Example**

```
Switch:1# show vtep remote
=====
Remote VTEP Info
=====
ID      NAME      VTEP      L3_VTEP_NEXT_HOP_INFO
  DEST-IP  PORT/MLT  VLAN      VRF
-----
1       vtep-1    198.51.100.6  Mlt78     3851     GlobalRouter
56      vtep-56   198.51.100.22 Mlt130    3855     underlay-vxlan
-----
2 out of 2 Total Num of remote vteps
=====
```

*Display the Name of the Remote VTEP***Note**

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to display the name of the remote VTEP.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Display the names of all remote VTEPs or use the option to specify a particular VTEP:  
show vtep remote name [<vtepId>]

**Example**

```
Switch:1# show vtep remote name
=====
Remote VTEP Name
=====
ID      NAME
-----
1       vxlan_tunnel_1
2       --
-----
```

```

3      --
-----
3 out of 3 Total Num of remote vteps
-----

```

### Display VNID Information

#### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to display information about the VNID.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display information about all the VNIDs or use the option to specify a particular VNID:  
show vnid i-sid [<1-500>]

#### Example

```

Switch:1# show vnid i-sid
=====
                        vnid Info
=====
VNID      ISID      PORT      MLT      VTEP
ID        ID        INTERFACES INTERFACES IDS
-----
110       120       c3:1/10   -        2,56
11000060  1060     c60:1/10  -        56
11000065  1065     c65:1/10  -        56
11000066  1066     c66:1/48  -        2
.
.
.

```

### Display the MAC Addresses in the VNID FDB

#### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to display the MAC addresses in the VNID forwarding database.

#### Procedure

1. Enter Privileged EXEC mode:  
enable

2. Display all the VNIDs in the FDB table or use one of the options to specify a particular VNID:

```
show vnid mac-address-entry [<1-16777215> | port <{slot/
port[/sub-port] [-slot/port[/sub-port]] [,...]}> | mac
<0x00:0x00:0x00:0x00:0x00:0x00> | remote]
```

### Example

```
Switch:1# show vnid mac-address-entry
=====
                        VNID Fdb Table
=====
VNID          STATUS      MAC-ADDRESS      INTERFACE      TYPE
-----
11000065     learned    00:00:5e:00:01:01  vtep_56       REMOTE
14000100     learned    a4:25:1b:51:a5:04  vtep_67       REMOTE
14000100     learned    a4:25:1b:52:a5:04  vtep_67       REMOTE
14000100     learned    a4:25:1b:52:bd:03  vtep_2        REMOTE

c: customer vid   u: untagged-traffic

All 4 out of 4 Total Num of vnid FDB Entries displayed
=====
```

### Display the VXLAN Running Configuration

#### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to display the currently running VXLAN configuration.

### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Display the running configuration:
 

```
show running-config module vxlan
```

### Example

This example shows the VXLAN information only; it does not show the hardware-specific information that the system also displays in the output for this command. The example shows the VXLAN Gateway in Base Interworking Mode. It also shows an external loopback (see **c-vid** commands), which enables communication between the VNID and an I-SID in an SPB network.

```
Switch:1# show running-config module vxlan

#
# VTEP CONFIGURATION
#
vtep source-ip 1.1.1.1 vrf underlay-vxlan

#
# REMOTE VTEP CONFIGURATIONS
#
```

```
vtep 2 ip 1.1.1.1 name "vtep-2"  
vtep 67 ip 1.1.1.67 name "vtep-67"  
  
#  
# VNID CONFIGURATION  
#  
vnid 12002105 i-sid 102105  
c-vid 105 port 1/11  
c-vid 2105 port 1/10  
vtep 67  
exit
```

## OVSDB protocol support for VXLAN Gateway configuration using CLI

This section provides procedures to configure OVSDB protocol support for VXLAN Gateway using the Command Line Interface (CLI).

### Configure OVSDB Managed Interfaces

#### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to configure OVSDB managed interfaces on the switch.

#### Before You Begin

- You must enable VXLAN Gateway Full Interworking Mode. For more information, see [Enable VXLAN Gateway in Full Interworking Mode](#) on page 4287.
- You must create the required Flex UNI or CVLAN I-SIDs before you configure the OVSDB managed interface.

#### Procedure

1. Enter OVSDB Configuration mode:  

```
enable  
  
configure terminal  
  
ovsdb
```
2. Configure the OVSDB managed interface:  

```
managed-interface i-sids WORD<1-1024>
```

#### Example

The following is an example configuring two I-SIDs as OVSDB management interfaces.

```
SWITCH:1>enable  
SWITCH:1#configure terminal  
Enter configuration commands, one per line. End with CNTL/Z.  
SWITCH:1(config)#ovsdb  
SWITCH:1(config-ovsdb)#managed-interface i-sids 300  
SWITCH:1(config-ovsdb)#managed-interface i-sids 500
```

## What to Do Next

Configure the OVSDB protocol support for VXLAN Gateway, see [Configure OVSDB protocol support for VXLAN Gateway](#) on page 4296.

### Variable definitions

Use the data in the following table to use the **managed-interface** command.

| Variable                               | Value                                                                                                                                                                                                                                             |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>i-sids WORD&lt;1-1024&gt;</code> | <p>Specifies the I-SID information to create an interface to manage OVSDB protocol support for VXLAN Gateway.</p> <p><b>Note:</b><br/>You must create the required Flex UNI or CVLAN I-SIDs before you configure the managed interface I-SID.</p> |

## Configure OVSDB protocol support for VXLAN Gateway

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to configure OVSDB protocol support for VXLAN Gateway on the switch.

### Before You Begin

- You must enable VXLAN Gateway Full Interworking Mode. You can use **show boot config flags** to verify the current VXLAN Gateway mode. For more information, see [Enable VXLAN Gateway in Full Interworking Mode](#) on page 4287.
- You must configure and use the Segmented Management Instance IP address on the VXLAN Gateway to establish connectivity with the NVC. For more information about Segmented Management Instance, see [Segmented Management Instance Configuration using the CLI](#) on page 107.
- You must configure an OVSDB management interface. For more information, see [Configure OVSDB Managed Interfaces](#) on page 4295.
- You must transfer an OVSDB certificate file and private-key file to the flash storage of the switch. You can use an `ovs-pki` utility with SSL libraries to generate the private keys and certificates. You can use **boot config flags FTDP** and then an SCP utility to transfer the private key and certificate file to the flash storage of the switch.
- If the switch is an aggregation switch, the IST peer must support OVSDB, have the same source VTEP-IP and OVSDB managed-interface, and must communicate with the NVC management IP.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the source VTEP IP address:  

```
vtepl source-ip <A.B.C.D> [vrf WORD<1-16>]
```
3. Enter OVSDb Configuration mode:  

```
ovsdb
```
4. Install the OVSDb certificate file:  

```
install-cert-file WORD<1-128>
```
5. Install the OVSDb private key:  

```
private-key WORD<1-128>
```
6. Enable OVSDb protocol support for VXLAN Gateway:  

```
enable
```
7. Configure the NVC:  

```
controller <1-100> ip address <A.B.C.D> protocol <ssl|tcp> [port <1-65535>]
```

## Example

The following is an example of configuring a VTEP source IP, installing an OVSDb certificate file, installing an OVSDb private key, enabling OVSDb protocol support for VXLAN Gateway, and configuring the IP address, protocol, and port for one NVC.

```
SWITCH:1>enable
SWITCH:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
SWITCH:1(config)#vtepl source-ip 192.0.2.1 vrf vxlan-underlay
SWITCH:1(config)#ovsdb
SWITCH:1(config-ovsdb)#install-cert-file /intflash/tom/sc-cert.pem
SWITCH:1(config-ovsdb)#private-key /intflash/tom/sc-privkey.pem
SWITCH:1(config-ovsdb)#enable
SWITCH:1(config-ovsdb)#controller 1 ip address 192.0.2.2 protocol ssl port 6640
```

### Note

You can configure multiple controllers for high availability. One VXLAN Gateway can support a maximum of three controllers.

### Important

If you add or delete a controller, or modify the OVSDb managed interface when a controller is configured, the existing controller connections reset. Log messages generate to indicate the status changes as the controllers disconnect and reconnect.

If you change a previously configured VTEP source-ip and re-enable OVSDb, the controller sees a new VXLAN tunnel instead of updating the existing VXLAN. You must configure the VNID to I-SID binding on the controller for the new VXLAN tunnel associated with the new VTEP IP address.

### Variable definitions

Use the data in the following table to use the **vtep source-ip** command.

| Variable                                            | Value                                                                                                                                                                                              |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;A.B.C.D&gt; [vrf WORD&lt;1-16&gt;]</code> | Specifies the VXLAN tunnel end point (VTEP) source IP address in IPv4 format. Optionally you can specify a VRF.<br><br><b>Note:</b><br>The VTEP source IP address must be on a loopback interface. |

Use the data in the following table to use the **install-cert-file** command.

| Variable                       | Value                                                           |
|--------------------------------|-----------------------------------------------------------------|
| <code>WORD&lt;1-128&gt;</code> | Specifies the path and file name of the OVSDB certificate file. |

Use the data in the following table to use the **private-key** command.

| Variable                       | Value                                                      |
|--------------------------------|------------------------------------------------------------|
| <code>WORD&lt;1-128&gt;</code> | Specifies the path and file name of the OVSDB private key. |

Use the data in the following table to use the **controller** command.

| Variable                                | Value                                                                          |
|-----------------------------------------|--------------------------------------------------------------------------------|
| <code>&lt;1-100&gt;</code>              | Specifies the ID of the controller.                                            |
| <code>ip address &lt;A.B.C.D&gt;</code> | Specifies the IP address of the controller in IPv4 format.                     |
| <code>protocol &lt;ssl tcp&gt;</code>   | Specifies the networking protocol as SSL or TCP for controller communications. |
| <code>port &lt;1-65535&gt;</code>       | Specifies the networking port of the controller.                               |

## Configure OVSDB Replication

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to configure OVSDB replication to support vIST.

### Before You Begin

- You must enable VXLAN Gateway Full Interworking Mode on the switch.
- You must configure an OVSDB managed interface on the switch.

- You must configure and enable OVSDB protocol support for VXLAN Gateway on the switch.
- You must have at least two NVCs configured to communicate on the managed interface network.

### Procedure

1. Enter OVSDB Configuration mode:
 

```
enable

configure terminal

ovsdb
```
2. Configure the OVSDB replication:
 

```
replication peer-ip <A.B.C.D> local-ip <A.B.C.D>
```

### Example

The following is an example configuring OVSDB replication to support VIST.

```
SWITCH:1>enable
SWITCH:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
SWITCH:1(config)#ovsdb
SWITCH:1(config-ovsdb)#replication peer-ip 192.0.2.3 local-ip 192.0.2.2
```

#### Variable definitions

Use the data in the following table to use the **replication** command.

| Variable                  | Value                                                                               |
|---------------------------|-------------------------------------------------------------------------------------|
| <i>peer-ip</i> <A.B.C.D>  | Specifies the IP address of the secondary controller for OVSDB replication support. |
| <i>local-ip</i> <A.B.C.D> | Specifies the IP address of the primary controller for OVSDB replication support.   |

## Display the OVSDB Configuration

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to display the OVSDB protocol support for VXLAN Gateway configuration.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the OVSDB configuration:
 

```
show ovsdb config
```

### Example

The following is an example of displaying the OVSDB configuration.

```
SWITCH:1>show ovbdb config
=====
                        Ovbdb Config Info
=====
                        Status - Enabled
                        Certificate - Installed
                        Private Key - Installed
                        Replication Peer NLS-IP - 192.0.2.3
                        Replication Local NLS-IP - 192.0.2.2
=====
                        Ovbdb Controller Config Info
=====
ID          Protocol      IP          Port
-----
1           ssl             192.0.2.10 6640
```

## Display the OVSDB Controller Status

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to display the OVSDB controller status.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the OVSDB controller status:

```
show ovbdb controller status
```

### Example

The following is an example of displaying the OVSDB controller status.

```
SWITCH:1>show ovbdb controller status
=====
                        OVSDB Controller Status
=====
Protocol      IP          Port      status      source
-----
ssl           192.0.2.2  6640      Up          Learnt
ssl           192.0.2.3  6640      Down       Learnt

2 out of 2 Total Num of Controllers displayed
```

## Display the OVSDB Replication State

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to display the OVSDB replication state.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the OVSDB controller status:

```
show ovssdb replication state
```

**Example**

The following is an example of displaying the OVSDB replication state.

```
SWITCH:1>show ovssdb replication state
=====
                        Ovssdb Replication Status
=====
Local NLS IP           Peer NLS IP           State
-----
192.0.2.2              192.0.2.3            ENABLED
```

## Display the OVSDB Managed Interfaces

**Note**

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to display the OVSDB managed interfaces.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the OVSDB managed interfaces:

```
show ovssdb managed-interface
```

**Example**

The following is an example of displaying the OVSDB managed interfaces.

```
SWITCH:1>show ovssdb managed-interface
=====
                        OVSDB Managed Interfaces - ISID
=====
50001
1 out of 1 Total Num of Managed Interfaces displayed
```

## VXLAN Gateway configuration using EDM

This section provides procedures to configure VXLAN Gateway using the Enterprise Device Manager (EDM).

### Configure the VXLAN Gateway Boot Flag

**Note**

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

There are two configuration modes: Base Interworking Mode and Full Interworking Mode. The Base Interworking Mode is the default mode. To switch to the Full Interworking Mode, use this procedure.

### Important

After you change this boot flag, you must save the change to the configuration file and reboot the switch.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Chassis**.
2. Select the **Boot Config** tab.
3. Select **EnableVxlanGwFullInterworkingMode** to enable Full Interworking Mode.
4. Select **Apply**.

## Configure a VTEP Source IP Address

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to configure the VXLAN Gateway source IP address.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **VTEP**.
3. Select the **Globals** tab.
4. In the **Sourcelp** field, type the VTEP source IP address.
5. In the **Vrf** field, select `GlobalRouter` or a VRF ID.
6. Select **Apply**.

### *Globals field descriptions*

Use the data in the following table to use the **Globals** tab.

| Name            | Description                                                                                                                                                                                                                     |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Sourcelp</b> | Specifies the VXLAN tunnel end point (VTEP) source IP address in an A.B.C.D format.                                                                                                                                             |
| <b>Vrf</b>      | Specifies the VRF name used for the source IP address, which you select from the drop down menu. This IP address can be on the GRT or a VRF.<br><br><b>Note:</b><br>The VTEP source IP address must be on a loopback interface. |

## Configure a Remote VTEP

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to configure the remote VTEP destination. The total number of VTEP remote destination IPs that you can configure is 500.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **VTEP**.
3. Select the **Vtep** tab.
4. In the **Id** field, assign a unique index value to this remote VTEP.
5. In the **IpAddr** field, enter the IP address of this remote VTEP.
6. In the **Name** field, assign a name to this remote VTEP.
7. Select **Apply**.

### *Vtep field descriptions*

Use the data in the following table to use the **Vtep** tab.

| Name                   | Description                                                                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Id</b>              | Specifies an index value in the range from 1 to 500 that uniquely identifies this remote VTEP.                                                                              |
| <b>IpAddr</b>          | Specifies an IP address that uniquely identifies this remote VTEP.<br><br><b>Note:</b><br>The remote VTEP IP address cannot be a local, broadcast, or multicast IP address. |
| <b>Name</b>            | Assigns a name to this remote VTEP tunnel.                                                                                                                                  |
| <b>NextHopVrfName</b>  | Displays the VRF name of the next hop to reach the remote VTEP.                                                                                                             |
| <b>OvsdbConfigured</b> | Specifies if the VTEP is configured with OVSDB protocol support for VXLAN Gateway.                                                                                          |

## Configure a VNID

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to configure a VNID, which identifies one of the potential 16 million VXLAN segments that can coexist within the same administrative domain.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **VTEP**.
3. Select the **Vnid** tab.
4. In the **Identifier** field, assign a unique value to this VNID.
5. In the **Isid** field, specify the I-SID associated with this VNID.
6. In the **Action** field, select one of the available actions: none or flush.
7. Select **Apply**.

### Vnid field descriptions

Use the data in the following table to use the **Vnid** tab.

| Name                   | Description                                                                                                                                                                                                                                                                                      |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Identifier</b>      | Specifies a value that uniquely identifies the VNID of this VXLAN tunnel end point.                                                                                                                                                                                                              |
| <b>Isid</b>            | Specifies a value that uniquely identifies the I-SID associated with this VXLAN tunnel end point.<br><br><b>Note:</b><br>A VNID must not have the same value as an I-SID.                                                                                                                        |
| <b>Action</b>          | Choose one of the following actions to take with the MAC FDB: <ul style="list-style-type: none"> <li>• <b>none:</b> Don't take any action. This is the default.</li> <li>• <b>flushMacFdb:</b> Flush all the learned MAC addresses from the forwarding database of the selected VNID.</li> </ul> |
| <b>OvsdbConfigured</b> | Specifies if the VNID is configured with OVSDB protocol support for VXLAN Gateway.                                                                                                                                                                                                               |

## Configure VNID Endpoints

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to configure a VNID and the VXLAN tunnel end point.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.

2. Select **VTEP**.
3. Select the **Vnid End Points** tab.
4. In the **Vnid** field, type the VNID ID.
5. In the **Vtepid** field, type the ID of the remote VTEP.
6. Select **Apply**.

#### *Vnid End Points field descriptions*

Use the data in the following table to use the **Vnid End Points** tab.

| Name          | Description                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------|
| <b>Vnid</b>   | Specifies a value that uniquely identifies the VNID of this VXLAN tunnel end point.              |
| <b>Vtepid</b> | Specifies an index value in the range from 1 to 500 that uniquely identifies this remote VTEP.   |
| <b>Isid</b>   | Displays a value that uniquely identifies the I-SID associated with this VXLAN tunnel end point. |

## Configure ELAN Endpoints

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to configure information associated with ELAN end points.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **VTEP**.
3. Select the **Elan End Points** tab.
4. In the **Vnid** field, specify the VNID associated with this ELAN.
5. In the **Cvid** field, specify the customer VLAN ID.
6. In the **IfIndex** field, specify the interface index for this ELAN endpoint.
7. Select **Apply**.

#### *Elan End Points field descriptions*

Use the data in the following table to use the **Elan End Points** tab.

| Name           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Vnid</b>    | Specifies a value that uniquely identifies the VNID of this ELAN tunnel end point.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Cvid</b>    | Specifies a value that uniquely identifies the customer VLAN ID of this ELAN endpoint.<br>The switch reserves the following VLAN IDs: <ul style="list-style-type: none"> <li>• VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.</li> <li>• VLAN IDs 4060 to 4094 are reserved for internal use.</li> <li>• VLAN IDs 3500 to 3999 are reserved if you enable VRF scaling and SPBM mode.</li> <li>• VLAN ID 4095 is not used.</li> <li>• VLAN ID 4096 is reserved for untagged traffic.</li> </ul> |
| <b>IfIndex</b> | Specifies the interface index for the MLT or port for this ELAN endpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Isid</b>    | Specifies the I-SID associated with this VNID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Display the VTEP Next Hop

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to display information about the remote VTEP.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **VTEP**.
3. Select the **Next Hop** tab.

### Next Hop field descriptions

Use the data in the following table to use the **Next Hop** tab.

| Name          | Description                                                                                    |
|---------------|------------------------------------------------------------------------------------------------|
| <b>Vtepld</b> | Specifies an index value in the range from 1 to 500 that uniquely identifies this remote VTEP. |
| <b>Ip</b>     | Specifies an IP address that uniquely identifies this remote VTEP tunnel.                      |

| Name           | Description                                                             |
|----------------|-------------------------------------------------------------------------|
| <b>IfIndex</b> | Specifies the interface index of the next hop to reach the remote VTEP. |
| <b>Vid</b>     | Specifies the VLAN ID of the next hop to reach remote VTEP.             |

## Display the VNID Forwarding Database

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to display information about the VNID forwarding database (FDB).

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **VTEP**.
3. Select the **Vnid FDB** tab.

### *Vnid FDB field descriptions*

Use the data in the following table to use the **Vnid FDB** tab.

| Name                  | Description                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------|
| <b>Vnid</b>           | Displays the VNID IDs of the VXLAN tunnel endpoints.                                    |
| <b>Address</b>        | Displays all the learned MAC addresses in the forwarding database of the selected VNID. |
| <b>Status</b>         | Displays whether or not the MAC address was learned.                                    |
| <b>InterfaceIndex</b> | Displays the interface index name for the VNID.                                         |
| <b>Type</b>           | Displays whether the VNID is local or remote.                                           |

## OVSDB protocol support for VXLAN Gateway configuration using EDM

This section provides procedures to configure OVSDB protocol support for VXLAN Gateway using the Enterprise Device Manager (EDM).

## Configure OVSDB Globally

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to configure the OVSDB certificates, private key, and replication global settings.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **OVSDB**.
3. Select the **Globals** tab.
4. Select **Enable**.
5. In the **CertificateFilename** field, type the `filepath/filename`.
6. In the **CertFileInstallAction** field, select **install**.
7. Select **Apply**.
8. In the **PrivateKeyFilename** field, type the `filepath/filename`.
9. In the **PrivateKeyInstallAction** field, select **install**.
10. Select **Apply**.
11. Select **ReplicationEnable**.
12. In the **ReplicationPeerIpAddr** field, type the IP address.
13. In the **ReplicationLocalIpAddr** field, type the IP address.
14. Select **Apply**.
15. Verify the **ReplicationState**.

### *Globals field descriptions*

Use the data in the following table to use the **Globals** tab.

| Name                           | Description                                                                                        |
|--------------------------------|----------------------------------------------------------------------------------------------------|
| <b>Enable</b>                  | Enables or disables the feature. Default is disabled (cleared).                                    |
| <b>CertificateFilename</b>     | Specifies the filename of the certificate.                                                         |
| <b>CertFileInstallAction</b>   | Specifies to install or uninstall the certificate. You must have a certificate file on the switch. |
| <b>PrivateKeyFilename</b>      | Specifies the filename of the private key.                                                         |
| <b>PrivateKeyInstallAction</b> | Specifies to install or uninstall the private key. You must have a private key file on the switch. |
| <b>ReplicationEnable</b>       | Enables or disables replication support. Default is disabled (cleared).                            |
| <b>ReplicationPeerIpAddr</b>   | Specifies the replication server peer IP address in A . B . C . D format.                          |

| Name                          | Description                                                   |
|-------------------------------|---------------------------------------------------------------|
| <b>ReplicationLocalIpAddr</b> | Specifies the replication local IP address in A.B.C.D format. |
| <b>ReplicationState</b>       | Displays the current replication status.                      |

## Configure an OVSDB Controller

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to configure an OVSDB controller ID, IP address, protocol, and port.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **OVSDB**.
3. Select the **Controller** tab.
4. Select **Insert**.
5. In the **Id** field, assign a unique index value to this controller.
6. In the **IpAddr** field, enter the IP address of this controller.
7. In the **Protocol** field, select **tcp** or **ssl**.
8. In the **Port** field, enter a port number.
9. Select **Insert**.

### Controller field descriptions

Use the data in the following table to use the **Controller** tab.

| Name            | Description                                                                                 |
|-----------------|---------------------------------------------------------------------------------------------|
| <b>Id</b>       | Specifies an ID number for a controller. Value range of 1 to 100.                           |
| <b>IpAddr</b>   | Specifies the IP address of a controller. Type an IP address in A.B.C.D format.             |
| <b>Protocol</b> | Specifies the communications protocol for the controller. Select <b>tcp</b> or <b>ssl</b> . |
| <b>Port</b>     | Specifies the communications port for the controller. Value range of 1 to 65535.            |

## Display the OVSDB Controller Status

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to display status information about the OVSDB controller.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **OSVDB**.
3. Select the **Status** tab.

### Status field descriptions

Use the data in the following table to use the **Status** tab.

| Name              | Description                                                                     |
|-------------------|---------------------------------------------------------------------------------|
| <b>IpAddress</b>  | Displays the IP address of a controller.                                        |
| <b>Protocol</b>   | Displays the communications protocol of a controller as TCP or SSL.             |
| <b>Port</b>       | Displays the communications port for the controller. Value range of 1 to 65535. |
| <b>Source</b>     | Displays the source of the controller as learned or configured.                 |
| <b>OperStatus</b> | Displays the operational status of the controller.                              |

## Configure OVSDB Managed Interface

### Note

Exception: only supported on VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Use the following procedure to configure a I-SID interface for the OVSDB.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **OSVDB**.
3. Select the **Interface** tab.
4. Select **Insert**.
5. In the **Isid** field, type the I-SID identifier.
6. Select **Insert**.

### Interface field descriptions

Use the data in the following table to use the **Interface** tab.

| Name        | Description                                         |
|-------------|-----------------------------------------------------|
| <b>Isid</b> | Specifies an I-SID to use as the managed interface. |

## Configuration Examples

This section provides network configuration examples for VXLAN Gateway and OVSDB protocol support for VXLAN Gateway.

### VXLAN Gateway Configuration Example

This example shows how to configure the VXLAN Gateway. Remember that there are two modes:

- Base Interworking Mode is the default mode so there is no need to set the mode boot flag. However, you should use the **show boot config flags** command to verify that the **vxlan-gw-full-interworking-mode** is set to *false*.
- Full Interworking Mode supports all SPB functionality including vIST and SMLT using an internal loopback. Full Interworking Mode is not the default mode. To configure Full Interworking mode, you must enable the **vxlan-gw-full-interworking-mode** boot flag.

#### Important

Changing the mode requires a reboot for the change to take effect, which can cause a loss of traffic.

**Figure 277: VXLAN Gateway configuration example**

## OVSDB protocol support for VXLAN Gateway Configuration Example

This example shows how to configure OVSDB protocol support for VXLAN Gateway.

### Important

OVSDB protocol support for VXLAN Gateway also requires an ESXi host running VMware NSX configured with a HW-VTEP, and a Logical Switch configured with VNID to HW-VTEP bindings to function. See VMware NSX documentation for more information.

### Important

OVSDB requires full interworking mode on the VXLAN Gateway. Changing the mode requires a reboot for the change to take effect, which can cause a loss of traffic.

# Port Numbering and MAC Address Assignment Reference

---

[Port Numbering](#) on page 4317

[Interface Indexes](#) on page 4327

[MAC Address Assignment](#) on page 4329

This section provides information about the port numbering and Media Access Control (MAC) address assignment used on the switch.

## Port Numbering

---

A port number includes the slot location of the port in the chassis, as well as the port position. For example, the first port in the first slot is structured as 1/1. The number of slots and ports varies depending on the hardware platform. For more information about hardware, see the hardware documentation for your platform.

### VSP 4450 Series

The following diagrams illustrate the components on the front panels of the VSP 4450 Series switches. Ethernet ports 1-50 on the switch are considered to be in slot 1.

#### Note

VSP 4450 Series supports 100BASE-FX transceivers (AA14019074-E6) on the VSP 4450GSX model in SFP ports only. This model does not support 100BASE-FX in SFP+ ports.

*VSP 4450GSX-PWR+***Figure 278: VSP 4450GSX-PWR+**

1. USB port.
2. Switch LEDs for system power (PWR), switch status (Status), and redundant power supply (RPS).
3. 12 10/100/1000 Mbps RJ-45 ports with PoE+. LEDs indicating port activity are above the ports.
4. 36 100/1000 Mbps SFP ports.
5. Two 1/10G SFP+ ports.
6. Console Port.

*VSP 4450GTX-HT-PWR+***Figure 279: VSP 4450GTX-HT-PWR+**

1. USB port but without a USB or a USB device cover.

**Note**

The VSP 4450GTX-HT-PWR+ model does not require a USB device in the USB port for normal operation. The USB port can be used for additional storage using a USB memory stick.

2. Switch LEDs for system power (PWR), switch status (Status), and redundant power supply (RPS).
3. 48 10/100/1000 Mbps RJ-45 ports with 802.3at PoE+. LEDs indicating port activity are above the ports.
4. Two combo port SFP slots. Supports 1G SFPs and 100Base low speed SFPs.
5. Two SFP+ slots. Supports 1G SFPs and 10G SFP+s.
6. Console Port.

7. Field-replaceable 1000W AC power supply unit (PSU).
8. Second field-replaceable AC power supply unit for redundancy or additional PoE.

*VSP 4450GSX-DC*

**Figure 280: VSP 4450GSX-DC**

1. USB port.
2. Switch LEDs for system power (PWR), switch status (Status), and redundant power supply (RPS).
3. 12 10/100/1000 Mbps RJ-45 ports. LEDs indicating port activity are above the ports.
4. 36 100/1000 Mbps SPF ports.
5. Two SFP+ slots. Supports 1G SFPs and 10G SFP+s.
6. Console Port.

*Notes on Combination Ports*

When the VSP 4450 Series is reset, the peer connections for all ports, including combination ports 47 and 48 on VSP 4450GTX-HT-PWR+, will transition down. During the reset, the fiber ports remain down, but only the copper ports 47 and 48 come up periodically throughout the reset. The copper ports 47 and 48 come up approximately 15 seconds into the reset, remain up for approximately 60 seconds, and then transition down until the boot sequence is complete and all ports come back up.

The following is an example of the status of the combination ports during reset.

```
CP1 [03/18/70 09:55:35.890] 0x0000c5e7 00300001.238 DYNAMIC SET
GlobalRouter HW INFO Link Down(1/47)

CP1 [03/18/70 09:55:35.903] 0x0000c5e7 00300001.239 DYNAMIC SET
GlobalRouter HW INFO Link Down(1/48)

CP1 [03/18/70 09:55:49.994] 0x0000c5ec 00300001.239 DYNAMIC CLEAR
GlobalRouter HW INFO Link Up(1/48)

CP1 [03/18/70 09:55:50.322] 0x0000c5ec 00300001.238 DYNAMIC CLEAR
GlobalRouter HW INFO Link Up(1/47)

CP1 [03/18/70 09:56:43.131] 0x0000c5e7 00300001.238 DYNAMIC SET
GlobalRouter HW INFO Link Down(1/47)
```

```
CP1 [03/18/70 09:56:43.248] 0x0000c5e7 00300001.239 DYNAMIC SET
GlobalRouter HW INFO Link Down(1/48)
```

#### *Cabled Connections for Both Copper and Fiber Ports*

The following limitations apply when the combination ports have cabled connections for both the copper and fiber ports.

Do not use the fiber port and do not insert an SFP into the optical module slot in the following situations:

- a copper speed setting of either 10M or 100M is required
- a copper duplex setting of half-duplex is required

#### **Note**

These limitations apply only when Auto-Negotiation is disabled. To avoid this limitation, use Auto-Negotiation to determine the speed to 10/100/1000 and to determine the duplex.

The 100M-FX SFP requires Auto-Negotiation to be disabled. Therefore, Auto-Negotiation will also be disabled for the copper port. Configure the peer switch to disable Auto-Negotiation.

## VSP 4900 Series

The following diagrams illustrate the components on the front panels of the VSP 4900 switches.

#### *VSP4900-48P*

The following diagram illustrates the components of the front panel of the VSP4900-48P switch. Slot 1 is used for the 48 fixed ports and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

1. Mode button for port LED control. Port LED mode indicators (SYS, SPD). Switch LEDs for system power (P1, P2) and fans (F1, F2, F3). System Locator LED (LOC).

#### **Note**

Note: STK and BT port LED mode indicators are not supported.

2. One USB micro B console port. An alternative RJ-45 console port is provided on the back panel (not shown).

3. Two USB ports, for removable storage.
4. 48 10/100/1000 Mbps RJ-45 Ethernet ports that provide 802.3at PoE+. LEDs that indicate the port activity and statuses are below the ports.
5. VIM slot (shown with VIM installed). Port numbering depends on the type of VIM installed in the slot. For more information about VIM modules, see [VSP 4900 Series Switches: Hardware Installation Guide](#).

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, and hot-swappable power supply and fan units.

#### VSP4900-24XE

The following diagram illustrates the components on the front panel of the VSP4900-24XE switch. Slot 1 is used for the 24 fixed ports and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

1. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2) and fans (F1, F2, F3). System Locator LED (LOC).
2. One USB micro B console port. An alternative RJ-45 console port is provided on the back panel (not shown).
3. Two USB ports, for removable storage.
4. 24 1/10 Gbps ports. LEDs that indicate the port activity and statuses are below the ports.
5. VIM slot. Port numbering depends on the type of VIM installed in the slot. For more information about VIM modules, see [VSP 4900 Series Switches: Hardware Installation Guide](#).

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, Solid State Drive (SSD) slot, and hot-swappable power supply and fan units.

#### VSP4900-12MXU-12XE

The following diagram illustrates the components on the front panel of the VSP4900-12MXU-12XE switch. Slot 1 is used for the 24 fixed ports and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

1. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2) and fans (F1, F2, F3). System Locator LED (LOC).
2. One USB micro B console port. An alternative RJ-45 console port is provided on the back panel (not shown).
3. Two USB ports, for removable storage.
4. Ports 1 to 12 are 100 Mbps and 1/2.5/5/10 Gbps RJ-45 ports that provide PoE (60W) and ports 13-24 are 1/10 Gbps ports. LEDs that indicate the port activity and statuses are below the ports.
5. VIM slot. Port numbering depends on the type of VIM installed in the slot. For more information about VIM modules, see [VSP 4900 Series Switches: Hardware Installation Guide](#).

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, SSD slot, and hot-swappable power supply and fan units.

#### VSP4900-24S

The following diagram illustrates the components on the front panel of the VSP4900-24S switch. Slot 1 is used for the 24 fixed ports and slot 2 is used for Versatile Interface Module (VIM) ports, if a VIM is installed in the VIM slot.

1. Mode button for port LED control. Port LED mode indicators (SYS, SPD, STK and BT). Switch LEDs for system power (P1, P2) and fans (F1, F2, F3). System Locator LED (LOC).
2. One USB micro B console port. An alternative RJ-45 console port is provided on the back panel (not shown).
3. Two USB ports, for removable storage.
4. 24 1 Gbps ports. LEDs that indicate the port activity and statuses are below the ports.
5. VIM slot. Port numbering depends on the type of VIM installed in the slot. For more information about VIM modules, see [VSP 4900 Series Switches: Hardware Installation Guide](#).

The back panel (not shown) includes an RJ-45 out of band (OOB) management port, an RJ-45 console port, and hot-swappable power supply and fan units.

## VSP 7200 Series

The following figure illustrates the front view of the VSP 7200 Series switch.

When looking at the front of the switch:

- Slot 1 is the grouping of the 48 10 Gbps ports on the left.
- Slot 2 is the grouping of the 6 40 Gbps ports on the right.

1. LEDs indicating port activity are above the RJ-45 and SFP+ port. The up arrow on the left indicates the top port; the down arrow on the right indicates the bottom port.
2. 48 ports — The VSP 7254XSQ has 48 SFP/SFP+ fiber ports. The VSP 7254XTQ has 48 RJ-45 copper ports.
3. Six QSFP+ ports — The LEDs are below each port. There are four LEDs per port to support channelization. The up arrows refer to the port above.
4. USB port.
5. LEDs for system power (PWR), switch status (Status), redundant power supply (RPS), and fan modules (Fan).

## VSP 7400 Series

The following diagrams illustrate the components on the front panels of the switches. For more information on hardware, see [VSP 7400 Series Switches: Hardware Installation Guide](#).

### VSP 7432CQ

The following figure illustrates the components on the front panel of the VSP 7432CQ. Slot 1 is used for all of the ports.

**Figure 281: VSP 7432CQ**

1. 32 100-Gigabit QSFP28/QSFP+ ports each with 4 LEDs — the top row of LEDs is for the top port and the lower row of LEDs is for the lower port.
2. RJ-45 console port.
3. USB port.
4. OOB Management port — LinkSpeed LED on the left and Activity LED on the right.
5. LEDs for system power, power supply units (PSU1 and PSU2), fan modules, and system.

The VSP 7432CQ supports two internal Extreme Integrated Application Hosting (IAH) ports labeled as Insight ports, 1/s1 and 1/s2, used by IAH virtual machines. For conceptual information see [Extreme Integrated Application Hosting](#) on page 928. For configuration instructions to use internal IAH ports, see [Virtual Services Configuration using CLI](#) on page 936 and [Virtual Services Configuration using EDM](#) on page 950.

#### VSP 7400-48Y

The following figure illustrates the components on the front panel of the VSP 7400-48Y. Slot 1 is used for all of the ports.

**Figure 282: VSP 7400-48Y**

1. 48 25-Gigabit SFP28 ports.
2. 8 100-Gigabit QSFP28/QSFP+ ports each with 4 LEDs.
3. USB port.
4. RJ-45 console port.
5. OOB Management RJ-45 port — A single LinkSpeed and Activity LED on the left.  
LEDs for system power, power supply units (PSU1 and PSU2), fan modules, and system are to the right of the management port.
6. Management Set sliding button.

The VSP 7400-48Y supports one internal IAH port, 1/s1, used by IAH virtual machines. For conceptual information see [Extreme Integrated Application Hosting](#) on page 928. For configuration instructions to use internal IAH ports, see [Virtual Services Configuration using CLI](#) on page 936 and [Virtual Services Configuration using EDM](#) on page 950.

## VSP 8200 Series and VSP 8400 Series

The following diagrams illustrate the components on the front panels of the switches. For more information on hardware, see [Installing the Virtual Services Platform 8000 Series](#).

### VSP 8200 Series

The following figure illustrates the front view of the VSP 8284XSQ switch. There are 42 ports in Slot 1 on top, and 42 ports in Slot 2 on the bottom.

**Figure 283: VSP 8284XSQ front view**

1. SFP+ port LEDs are in between the ports on each slot. The up arrows refer to the port above and the down arrows refer to the port below.
2. 80 SFP+ ports that support 1G SFPs and 10G SFP+s.
  - 40 ports in Slot 1 on top
  - 40 ports in Slot 2 on the bottom
3. QSFP+ port LEDs are in between the ports on each slot. The up arrows refer to the port above and the down arrows refer to the port below.
4. Four QSFP+ ports: two in Slot 1 and two in Slot 2.
5. USB port
6. Console port (10101)
7. Management port — The LEDs are on the bottom of the port.
8. LEDs for system power (PWR), switch status (Status), redundant power supply (RPS), and fan modules(Fan).

### VSP 8400 Series Series

The following figure illustrates the front view of the VSP 8400 Series switch.

**Figure 284: VSP 8404 front view**

Looking at the front of the switch, slot numbering begins at the top row and increases from left to right. Slot 1 is the top-left slot; slot 2 is the top-right slot. Slot 3 is the bottom-left slot; slot 4 is the bottom-right slot.

Port numbering depends on the type of Ethernet Switch Module (ESM) installed in the slot. For more information about ESMs, see [Installing the Virtual Services Platform 8000 Series](#).

1. Displays the four slots to install ESMs.
2. LEDs for system power (PWR), switch status (Status), redundant power supply (RPS), and fan modules (Fan).
3. USB port
4. Console port
5. OOB management port

## XA1400 Series

### XA1440 and XA1480 Switches

The following figure illustrates the components on the rear panel of the XA1440 and XA1480. Slot 1 is used for all of the ports.

**Figure 285: XA1400 Series switches rear panel**

1. DC power adapter input
2. Power button
3. Micro USB console port used to connect a terminal and perform local management.
4. RJ45 Console port used to connect a terminal and perform local management.

5. USB Type A ports for access to external storage.
6. RJ45 10/100/1000BASE-T Ethernet ports
7. 10G SFP+ Ethernet ports

## Interface Indexes

---

The Simple Network Management Protocol (SNMP) uses interface indexes to identify ports, Virtual Local Area Networks (VLAN), and Multilink Trunking (MLT).

### Port Interface Index

To determine the interface index (IfIndex), you can calculate it, or use the CLI command provided in this section.

As a result of channelization support, the ifIndex of each channelization-capable port increases by 4. The number is reserved for the 3 sub-ports when channelization is enabled.

#### *VSP 4450 Series and XA1400 Series*

For switches that do not include channelization-capable ports, use the following equation to determine the IfIndex of a port:

$$(192 \times \text{slot number}) + (\text{port number} - 1)$$

For example, the interface index of port 1/50 is 241.

The VSP 4450 Series and XA1400 Series use one slot.

#### *VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series*

For switches that include channelization-capable ports, use the following equations to determine the IfIndex of a port:

- If the port does not support channelization, use  $(64 \times \text{slot number}) + 128 + (\text{port number} - 1)$ .
- If the port supports channelization, use the following equations:
  - for the port in question:  $(64 \times \text{slot number}) + 128$
  - for subsequent ports:  $(64 \times \text{slot number}) + 128 + ((\text{port number} - 1) * 4)$

This equation reserves space for the creation of the 3 sub-ports on the previous port, if or when you enable channelization.

The slot numbers are 1-2 for the VSP 4900 Series.

The slot numbers are 1-2 for the VSP 7200 Series.

The slot number is 1 for the VSP 7400 Series.

The slot numbers are 1-2 for the VSP 8200 Series.

The slot numbers are 1-4 for VSP 8400 Series.

### CLI command

To determine the port interface index through the CLI, use the following command:

```
show interfaces gigabitEthernet
```

The following example shows an output for this command:

```
Switch:1(config)#show interfaces gigabitEthernet
```

| Port Interface |       |                    |              |              |      |                     |        |         |  |
|----------------|-------|--------------------|--------------|--------------|------|---------------------|--------|---------|--|
| PORT<br>NUM    | INDEX | DESCRIPTION        | LINK<br>TRAP | PORT<br>LOCK | MTU  | PHYSICAL<br>ADDRESS | STATUS |         |  |
|                |       |                    |              |              |      |                     | ADMIN  | OPERATE |  |
| 1/1/1          | 192   | 40GbCR4BoC-Channel | true         | false        | 1950 | 00:c0:ff:8b:50:00   | up     | up      |  |
| 1/1/2          | 193   | 40GbCR4BoC-Channel | true         | false        | 1950 | 00:c0:ff:8b:50:01   | down   | down    |  |
| 1/1/3          | 194   | 40GbCR4BoC-Channel | true         | false        | 1950 | 00:c0:ff:8b:50:02   | down   | down    |  |
| 1/1/4          | 195   | 40GbCR4BoC-Channel | true         | false        | 1950 | 00:c0:ff:8b:50:03   | down   | down    |  |
| 1/2            | 196   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:04   | down   | down    |  |
| 1/3            | 200   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:08   | down   | down    |  |
| 1/4            | 204   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:0c   | down   | down    |  |
| 1/5            | 208   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:10   | down   | down    |  |
| 1/6            | 212   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:14   | down   | down    |  |
| 1/7            | 216   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:18   | down   | down    |  |
| 1/8            | 220   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:1c   | down   | down    |  |
| 1/9            | 224   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:20   | down   | down    |  |
| 1/10           | 228   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:24   | down   | down    |  |
| 1/11           | 232   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:28   | down   | down    |  |
| 1/12/1         | 236   | 100GbNone-Channel  | true         | false        | 1950 | 00:c0:ff:8b:50:2c   | down   | down    |  |
| 1/12/2         | 237   | 100GbNone-Channel  | true         | false        | 1950 | 00:c0:ff:8b:50:2d   | down   | down    |  |
| 1/12/3         | 238   | 100GbNone-Channel  | true         | false        | 1950 | 00:c0:ff:8b:50:2e   | down   | down    |  |
| 1/12/4         | 239   | 100GbNone-Channel  | true         | false        | 1950 | 00:c0:ff:8b:50:2f   | down   | down    |  |
| 1/13           | 240   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:30   | down   | down    |  |
| 1/14           | 244   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:34   | down   | down    |  |
| 1/15           | 248   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:38   | down   | down    |  |
| 1/16           | 252   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:3c   | down   | down    |  |
| 1/17           | 256   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:40   | down   | down    |  |
| 1/18           | 260   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:44   | down   | down    |  |
| 1/19           | 264   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:48   | down   | down    |  |
| 1/20           | 268   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:4c   | down   | down    |  |
| 1/21           | 272   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:50   | down   | down    |  |
| 1/22           | 276   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:54   | down   | down    |  |
| 1/23           | 280   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:58   | down   | down    |  |
| 1/24           | 284   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:5c   | down   | down    |  |
| 1/25           | 288   | 100GbCR4           | true         | false        | 1950 | 00:c0:ff:8b:50:60   | down   | down    |  |
| 1/26           | 292   | 100GbCR4           | true         | false        | 1950 | 00:c0:ff:8b:50:64   | down   | down    |  |
| 1/27           | 296   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:68   | down   | down    |  |
| 1/28           | 300   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:6c   | down   | down    |  |
| 1/29           | 301   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:6d   | down   | down    |  |
| 1/30           | 305   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:71   | down   | down    |  |
| 1/31           | 309   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:75   | down   | down    |  |
| 1/32           | 313   | 100GbNone          | true         | false        | 1950 | 00:c0:ff:8b:50:79   | down   | down    |  |
| 1/s1           | 320   | 10GbInsight        | true         | false        | 1950 | 00:c0:ff:8b:50:7d   | down   | down    |  |
| 1/s2           | 321   | 10GbInsight        | true         | false        | 1950 | 00:c0:ff:8b:50:7e   | down   | down    |  |

### Note

1/s1 and 1/s2 are ports used by Extreme Integrated Application Hosting (IAH) virtual machines only.

## VLAN interface index

The interface index of a VLAN is computed using the following formula:

Because the default VLAN always uses an MGID value of 1, its interface index is always 2049.

$$\text{ifIndex} = 2048 + \text{VLAN multicast group ID (MGID)}$$

## MLT interface index

The interface index of a multilink trunk (MLT) is computed using the following formula:

$$\text{ifIndex} = 6143 + \text{MLT ID number}$$

## MAC Address Assignment

You must understand MAC addresses assignment if you perform one of the following actions:

- Define static Address Resolution Protocol (ARP) entries for IP addresses in the switch
- Use a network analyzer to decode network traffic

Each chassis is assigned a base number of MAC addresses with a number reserved for ports and other internal purposes, and the remainder assigned to routable VLANs. The following table identifies the numbers provided by product.

| Product                                                                                 | Base assignment | Reserved  | Assigned to routable VLANs |
|-----------------------------------------------------------------------------------------|-----------------|-----------|----------------------------|
| VSP 4450 Series                                                                         | 256             | First 128 | remaining 128              |
| VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series | 1,024           | First 256 | remaining 768              |
| XA1400 Series                                                                           | 1,024           | First 8   | remaining 1,016            |

## Virtual MAC Addresses

Virtual MAC addresses are the addresses assigned to VLANs. The system assigns a virtual MAC address to a VLAN when it creates the VLAN. The MAC address for a VLAN IP address is the virtual MAC address assigned to the VLAN.

This section provides information about supported IEEE standards, RFCs, and MIBs.

## Supported IEEE Standards

---

**Table 317: Supported IEEE Standards**

| IEEE standard                       | Description                                                                                                 |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------|
| 802.1AB                             | LLDP                                                                                                        |
| 802.1ag                             | Connectivity Fault Management                                                                               |
| 802.1ah                             | Provider Backbone Bridging                                                                                  |
| 802.1aq                             | Shortest Path Bridging (SPB)                                                                                |
| 802.1AX                             | Link Aggregation                                                                                            |
| 802.1D                              | MAC Bridges                                                                                                 |
| P802.1p                             | Traffic Class Expediting and Dynamic Multicast Filtering                                                    |
| 802.1Q                              | Virtual LANs                                                                                                |
| 802.1s                              | Multiple Spanning Trees                                                                                     |
| 802.1t                              | 802.1D Technical & Editorial Corrections                                                                    |
| 802.1w                              | Rapid Spanning Tree Protocol (RSTP)                                                                         |
| 802.1X-2010                         | Port-based Network Access Control (NAC)                                                                     |
| 802.3 CSMA/CD Ethernet ISO/IEC 8802 | International Organization for Standardization (ISO) /International Eletrotechnical Commission (IEC) 8802-3 |
| 802.3ab                             | 1000 Mbps Operation, implemented as 1000BASE-T Copper                                                       |

**Table 317: Supported IEEE Standards (continued)**

| IEEE standard                                     | Description                                                                                                                                                |
|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 802.3ac                                           | Carrier sense multiple access with collision detection (CSMA/CD) frame extensions for Virtual Bridged Local Area Networks (VLAN) tagging on 802.3 networks |
| 802.1AE                                           | MAC Security                                                                                                                                               |
| 802.3ae                                           | 10 Gbps Operation, implemented as 10GBASE-X SFP+                                                                                                           |
| 802.3af<br>802.3at<br>802.3bt (Type 3 and Type 4) | Power over Ethernet (PoE)                                                                                                                                  |
| 802.3az                                           | Energy Efficient Ethernet (EEE)                                                                                                                            |
| 802.3ba                                           | 40 Gbps and 100 Gbps Operation, implemented as 40GBASE-QSFP+ and 100GBASE-QSFP28                                                                           |
| 802.3x                                            | Full Duplex & Flow Control                                                                                                                                 |
| 802.3z                                            | 1000 Mbps Operation, implemented as 1000BASE-X SFP                                                                                                         |
| ANSI/TIA-1057                                     | LLDP-MED                                                                                                                                                   |

## Supported RFCs

The following table and sections list the RFCs that the switch supports.

**Table 318: Supported request for comments**

| Request for comment       | Description                                                            |
|---------------------------|------------------------------------------------------------------------|
| draft-grant-tacacs-02.txt | TACACS+ Protocol                                                       |
| RFC 768                   | UDP Protocol                                                           |
| RFC 783                   | Trivial File Transfer Protocol (TFTP)                                  |
| RFC 791                   | Internet Protocol (IP)                                                 |
| RFC 792                   | Internet Control Message Protocol (ICMP)                               |
| RFC 793                   | Transmission Control Protocol (TCP)                                    |
| RFC 815                   | IP Datagram Reassembly Algorithm                                       |
| RFC 826                   | Address Resolution Protocol (ARP)                                      |
| RFC 854                   | Telnet protocol                                                        |
| RFC 894                   | A standard for the Transmission of IP Datagrams over Ethernet Networks |
| RFC 896                   | Congestion control in IP/TCP internetworks                             |
| RFC 906                   | Bootstrap loading using TFTP                                           |

**Table 318: Supported request for comments (continued)**

| Request for comment             | Description                                                                                                                                        |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| RFC 950                         | Internet Standard Subnetting Procedure                                                                                                             |
| RFC 951                         | BootP                                                                                                                                              |
| RFC 959, RFC 1350, and RFC 2428 | FTP and TFTP client and server                                                                                                                     |
| RFC 1027                        | Using ARP to implement transparent subnet gateways/Nortel Subnet based VLAN                                                                        |
| RFC 1058                        | RIPv1 Protocol                                                                                                                                     |
| RFC 1112                        | Host Extensions for IP Multicasting (IGMPv1)                                                                                                       |
| RFC 1122                        | Requirements for Internet Hosts                                                                                                                    |
| RFC 1195                        | Use of OSI IS-IS for Routing in TCP/IP and Dual Environments                                                                                       |
| RFC 1042                        | Encapsulating the Internet Protocol (IP) datagrams and Address Resolution Protocol (ARP)<br><br><b>Note:</b><br>Applicable for 802.3 networks only |
| RFC 1253                        | OSPF MIB                                                                                                                                           |
| RFC 1256                        | ICMP Router Discovery                                                                                                                              |
| RFC 1323                        | TCP Timestamp (The switch is only compliant if the TCP timestamp is enabled.)                                                                      |
| RFC 1340                        | Assigned Numbers                                                                                                                                   |
| RFC 1519                        | Classless Inter-Domain Routing (CIDR): an Address Assignment and Aggregation Strategy                                                              |
| RFC 1541                        | Dynamic Host Configuration Protocol                                                                                                                |
| RFC 1542                        | Clarifications and Extensions for the Bootstrap Protocol                                                                                           |
| RFC 1587                        | The OSPF NSSA Option                                                                                                                               |
| RFC 1591                        | DNS Client                                                                                                                                         |
| RFC 1723                        | RIP v2 — Carrying Additional Information                                                                                                           |

| RFC 4302            | IP Authentication Header (AH)                                                                                                                   |
| RFC 4303            | IP Encapsulated Security Payload (ESP)                                                                                                          |
| RFC 4305            | Cryptographic algorithm implementation requirements for ESP and AH                                                                              |
| RFC 4308            | Cryptographic suites for Internet Protocol Security (IPsec)                                                                                     |
| RFC 4443            | ICMP for IPv6                                                                                                                                   |
| RFC 4541            | Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) Snooping                                                       |
| RFC 4552            | OSPFv3 Authentication and confidentiality for OSPFv3                                                                                            |
| RFC 4601            | Protocol Independent Multicast - Sparse Mode (PIM-SM)                                                                                           |
| RFC 4604            | Internet Group Management Protocol Version 3 (IGMPv3) and Multicast Listener Discovery Protocol Version 2 (MLDv2) for Source-Specific Multicast |
| RFC 4607            | Source-Specific Multicast (SSM)                                                                                                                 |
| RFC 4649            | Dynamic Host Configuration Protocol for IPv6 (DHCPv6) Relay Agent Remote-ID Option                                                              |
| RFC 4675            | Egress VLAN                                                                                                                                     |
| RFC 4750            | OSPFv2 MIB                                                                                                                                      |
| RFC 4760            | Multiprotocol Extensions for BGP-4                                                                                                              |

**Table 318: Supported request for comments (continued)**

| Request for comment | Description                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------|
| RFC 4835            | Cryptographic algorithm implementation for ESP and AH                                            |
| RFC 4861            | IPv6 Neighbor discovery                                                                          |
| RFC 4862            | IPv6 stateless address autoconfiguration                                                         |
| RFC 4893            | BGP Support for Four-octet AS Number Space                                                       |
| RFC 5095            | Deprecation of Type 0 Routing headers in IPv6                                                    |
| RFC 5176            | Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)          |
| RFC 5187            | OSPFv3 Graceful Restart (helper-mode only)                                                       |
| RFC 5242            | The Syslog Protocol                                                                              |
| RFC 5321            | Simple Mail Transfer Protocol                                                                    |
| RFC 5340            | OSPF for IPv6                                                                                    |
| RFC 5746            | Secure SSL Renegotiation                                                                         |
| RFC 5798            | Virtual Router Redundancy Protocol (VRRP) Version 3 for IPv4 and IPv6                            |
| RFC 5905            | Network Time Protocol Version 4: Protocol and Algorithms Specification                           |
| RFC 5997            | Use of Status-Server Packets in the Remote Authentication Dial In User Service (RADIUS) Protocol |
| RFC 6105            | IPv6 Router Advertisement Guard                                                                  |
| RFC 6329            | IS-IS Extensions supporting Shortest Path Bridging                                               |
| RFC 7047            | The Open vSwitch Database Management Protocol                                                    |
| RFC 7348            | Virtual Extensible LAN (VXLAN)                                                                   |
| RFC 7610            | DHCPv6 Shield                                                                                    |
| RFC 7627            | Transport Layer Security (TLS) Session Hash and Extended Master Secret Extension                 |

## Quality of service

**Table 319: Supported request for comments**

| Request for comment | Description                  |
|---------------------|------------------------------|
| RFC2474 and RFC2475 | DiffServ Support             |
| RFC2597             | Assured Forwarding PHB Group |
| RFC2598             | An Expedited Forwarding PHB  |

## Network management

**Table 320: Supported request for comments**

| Request for comment | Description                                                                                  |
|---------------------|----------------------------------------------------------------------------------------------|
| RFC1155             | SMI                                                                                          |
| RFC1157             | SNMP                                                                                         |
| RFC1215             | Convention for defining traps for use with the SNMP                                          |
| RFC1305             | Network Time Protocol v3 Specification, Implementation and Analysis <sup>3</sup>             |
| RFC1350             | The TFTP Protocol (Revision 2)                                                               |
| RFC1907             | Management Information Base for Version 2 of the Simple Network Management Protocol (SNMPv2) |
| RFC1930             | Guidelines for creation, selection, and registration of an Autonomous System (AS)            |
| RFC2428             | FTP Extensions for IPv6                                                                      |
| RFC2541             | DNS Security Operational Considerations                                                      |
| RFC2572             | Message Processing and Dispatching for the Simple Network Management Protocol (SNMP)         |
| RFC2573             | SNMP Applications                                                                            |

| RFC1450             | Management Information Base for v2 of the Simple Network Management Protocol (SNMPv2)                |
| RFC1573             | Interface MIB                                                                                        |
| RFC1650             | Definitions of Managed Objects for the Ethernet-like Interface Types                                 |
| RFC1657             | BGP-4 MIB using SMIPv2                                                                               |
| RFC2021             | RMON MIB using SMIPv2                                                                                |
| RFC2452             | IPv6 MIB: TCP MIB                                                                                    |
| RFC2454             | IPv6 MIB: UDP MIB                                                                                    |
| RFC2466             | IPv6 MIB: ICMPv6 Group                                                                               |
| RFC2578             | Structure of Management Information v2 (SMIPv2)                                                      |
| RFC2787             | Definitions of Managed Objects for the Virtual Router Redundancy Protocol                            |
| RFC2863             | Interface Group MIB                                                                                  |
| RFC2925             | Remote Ping, Traceroute & Lookup Operations MIB                                                      |
| RFC3416             | v2 of the Protocol Operations for the Simple Network Management Protocol (SNMP)                      |
| RFC4022             | Management Information Base for the Transmission Control Protocol (TCP)                              |

**Table 321: Supported request for comments (continued)**

| Request for comment | Description                                                      |
|---------------------|------------------------------------------------------------------|
| RFC4113             | Management Information Base for the User Datagram Protocol (UDP) |
| RFC4292             | IP Forwarding Table MIB                                          |
| RFC4363             | Bridges with Traffic MIB                                         |
| RFC4673             | RADIUS Dynamic Authorization Server MIB                          |

## Standard MIBs

The following table details the standard MIBs that the switch supports.

**Table 322: Supported MIBs**

| Standard MIB name                                                                                              | Institute of Electrical and Electronics Engineers/<br>Request for Comments<br>(IEEE/RFC) | File name        |
|----------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|------------------|
| STDMIB2— Link Aggregation Control Protocol (LACP) (802.3ad)                                                    | 802.3ad                                                                                  | ieee802-lag.mib  |
| STDMIB3—Exensible Authentication Protocol Over Local Area Networks (EAPoL) (802.1x)                            | 802.1x                                                                                   | ieee8021x.mib    |

## ICMPv6 Type and Code

The Internet Control Message Protocol (ICMPv6) uses many messages identified by a type and code field (see RFC 4443). Error messages use message types 0 to 127. Informational messages use message types 128 to 255. The following table provides the type and code reference.

**Table 324: ICMPv6 type and code details**

| Type | Name                      | Code                                                                                                                                                         | Reference |
|------|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| 1    | Destination Unreachable   | 0—no route to destination<br>1—communication with destination administratively prohibited<br>2—(not assigned)<br>3—address unreachable<br>4—port unreachable | RFC 4443  |
| 2    | Packet Too Big            |                                                                                                                                                              | RFC 4443  |
| 3    | Time Exceeded             | 0—hop limit exceeded in transit<br>1—fragment reassembly time exceeded                                                                                       | RFC 4443  |
| 4    | Parameter Problem         | 0—erroneous header field encountered<br>1—unrecognized Next Header type encountered<br>2—unrecognized IPv6 option encountered                                | RFC 4443  |
| 128  | Echo Request              |                                                                                                                                                              | RFC 4443  |
| 129  | Echo Reply                |                                                                                                                                                              | RFC 4443  |
| 130  | Multicast Listener Query  |                                                                                                                                                              |           |
| 131  | Multicast Listener Report |                                                                                                                                                              |           |
| 132  | Multicast Listener Done   |                                                                                                                                                              |           |

**Table 324: ICMPv6 type and code details (continued)**

| Type | Name                                             | Code                                                                                     | Reference |
|------|--------------------------------------------------|------------------------------------------------------------------------------------------|-----------|
| 133  | Router Solicitation                              |                                                                                          | RFC 4861  |
| 134  | Router Advertisement                             |                                                                                          | RFC 4861  |
| 135  | Neighbor Solicitation                            |                                                                                          | RFC 4861  |
| 136  | Neighbor Advertisement                           |                                                                                          | RFC 4861  |
| 137  | Redirect Message                                 |                                                                                          | RFC 4861  |
| 138  | Router Renumbering                               | 0—router renumbering command<br>1—router renumbering result<br>255—sequence number reset |           |
| 139  | ICMP Node Information Query                      |                                                                                          |           |
| 140  | ICMP Node Information Response                   |                                                                                          |           |
| 141  | Inverse neighbor discovery Solicitation Message  |                                                                                          | RFC 3122  |
| 142  | Inverse neighbor discovery Advertisement Message |                                                                                          | RFC 3122  |
| 143  | Version 2 Multicast Listener Report              |                                                                                          | RFC 3810  |
| 144  | Home Agent Address Discovery Request Message     |                                                                                          | RFC 3775  |
| 145  | Home Agent Address Discovery Reply Message       |                                                                                          | RFC 3775  |
| 146  | Mobile Prefix Solicitation                       |                                                                                          | RFC 3775  |
| 147  | Mobile Prefix Advertisement                      |                                                                                          | RFC 3775  |
