<b>NssaTranslatorState</b>	Indicates if and how an NSSA border router translates Type 7 LSAs to Type 5 LSAs. The possible values are <ul style="list-style-type: none"> <li>• <b>enabled</b>—The border router always translates the LSAs.</li> <li>• <b>elected</b>—A candidate border router translates the LSAs.</li> <li>• <b>disabled</b>—A candidate border router does not translate the LSAs.</li> </ul>
<b>StubMetricType</b>	Specifies the type of metric advertised as a default route. The possible values are: <ul style="list-style-type: none"> <li>• <b>ospfv3Metric</b>—OSPF metric</li> <li>• <b>comparableCost</b>—external Type 1</li> <li>• <b>nonComparable</b>—external Type 2</li> </ul> The default is ospfv3Metric.

## Create OSPFv3 Area Ranges

Create an area address range on the OSPFv3 router to reduce the number of area border router (ABR) advertisements into other OSPF areas. An area address range is an implied contiguous range of area network addresses for which the ABR advertises a single summary route.

### Before You Begin

- You must create the OSPF area.
- Change the VRF instance as required to configure OSPFv3 on a specific VRF instance.

#### Note

Non-default VRFs do not support the configuration of the following parameters:

- OSPFv3 interfaces over IPv6 tunnels
- IPSec on OSPFv3 virtual link interfaces

### About This Task

If you create two ranges, and one range is a subset of the other, the router uses the most specific match.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Select **OSPFv3**.
3. Select the **Area Aggregate** tab.
4. Select **Insert**.
5. Select the area ID.
6. Select the type of area.

**interAreaPrefixLsa** generates an aggregated summary.

**nssaExternalLsa** generates an NSSA link summary.

7. Type the prefix for the IPv6 area address.
8. Type the number of bits from the IPv6 address that you want to advertise.
9. Select **Insert**.

### **Area Aggregate** *Field Descriptions*

Use the data in the following table to use the **Area Aggregate** tab.

Name	Description
<b>AreaID</b>	Specifies the area in which the address aggregate exists. Use dotted decimal notation to specify the area name.
<b>AreaLsdbType</b>	Specifies the area LSDB type to which the address aggregate applies. <b>interAreaPrefixLsa</b> generates an aggregated summary. <b>nssaExternalLsa</b> generates an NSSA link summary.
<b>Prefix</b>	Specifies the IPv6 prefix. The prefix and prefix length define the range.
<b>PrefixLength</b>	Specifies the length of the prefix, in bits. The prefix cannot be shorter than 3 bits. The prefix and prefix length define the range.
<b>Effect</b>	Specifies the advertisement mode for prefixes in the range. <b>advertiseMatching</b> advertises the aggregate summary LSA with the same link-state ID. <b>doNotAdvertiseMatching</b> does not advertise networks that fall within the range.
<b>AdvertiseMetric</b>	Specifies a cost value to advertise for the OSPF area range. This value applies to summary LSAs (Type 3). If the value is 0, OSPF uses the cost to the farthest point in the network that is summarized.

## Creating an OSPFv3 Virtual Link

Create a virtual link if the switch does not connect directly to the backbone. The switch can create automatic virtual links or you can perform this procedure to create virtual links manually. Manual virtual links conserve resources and provide specific control over virtual link placement in your OSPFv3 configuration.

### Before You Begin

- The router must be an ABR to create a virtual router interface.
- Change the VRF instance as required to configure OSPFv3 on a specific VRF instance.

#### Note

Non-default VRFs do not support the configuration of the following parameters:

- OSPFv3 interfaces over IPv6 tunnels
- IPsec on OSPFv3 virtual link interfaces

## About This Task

Virtual linking is similar to backup redundancy. The switch creates a virtual link for vital traffic paths in your OSPFv3 configuration if traffic is interrupted, such as when an interface cable that provides a connection to the backbone (either directly or indirectly) is disconnected from the switch. Automatic virtual linking ensures that a link is created by using another switch.

OSPF routes cannot be learned through an ABR unless it connects to the backbone directly or through a virtual link.

## Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **OSPFv3**.
3. Click the **Virtual If** tab.
4. Click **Insert**.
5. Specify the ID for the transit area.

The transit area is the common area between two ABRs.

6. Specify the router ID for the virtual neighbor.

The neighbor ID is the IP router ID of the ABR through which the other ABR must route traffic destined for the backbone.

7. Click **Insert**.
8. Click **Refresh** to verify that the virtual link is active.

If the state is point-to-point, the virtual link is active. If the state is down, the virtual link is configured incorrectly.

## *Virtual If* field descriptions

Use the data in the following table to use the **Virtual If** tab.

Name	Description
<b>AreaId</b>	Specifies the ID for the transit area that the virtual link traverses. Do not use 0.0.0.0.
<b>Neighbor</b>	Specifies the router ID of the virtual neighbor.
<b>TransitDelay</b>	Specifies the estimated number of seconds to transmit a link-state update packet over this interface. The default is 1 second.
<b>RetransInterval</b>	Specifies the number of seconds between link-state advertisement retransmissions for adjacencies that belong to this interface. This value also applies to the retransmissions of database description and link-state request packets. The default is 5 seconds.

Name	Description
<b>HelloInterval</b>	Specifies the number of seconds between hello packets that the router sends on this interface. Configure the same value on the virtual neighbor. The default is 10 seconds.
<b>RtrDeadInterval</b>	Specifies the number of seconds after which the neighbor declares the router down if it does not receive hello packets. Configure this value as a multiple of the hello interval. You must configure the same value on the virtual neighbor. The default is 60 seconds.
<b>State</b>	Shows the state of the virtual interface: either down or pointToPoint.
<b>Events</b>	Shows the number of state changes or error events on the virtual link.
<b>LinkScopeLsaCount</b>	Shows the number of link-scope LSAs in the LSDB for the virtual link.
<b>LinkLsaCksumSum</b>	Shows the sum of the checksums for the link-scope LSAs in the LSDB. Use the sum to determine if a change in the LSDB occurs, and to compare the LSDBs of the two routers.

## Create an OSPF Interface on a Brouter Port

Configure the OSPF protocol on an IPv6 interface to support dynamic routing on the interface. Perform this procedure to create an OSPF interface on a brouter port.

If you want to modify existing OSPFv3 interfaces, see [Modify an OSPFv3 Interface](#) on page 2824. To configure OSPFv3 on an IPv6 VLAN, see [Create an OSPF VLAN Interface](#) on page 2813.

### Before You Begin

- The IPv6 interface must exist.

### Procedure

- In the Device Physical view, select a port.
- In the navigation pane, expand the **Configuration > Edit > Port** folders.
- Select **IPv6**.
- Select the **IPv6 OSPF Interface** tab.
- Select **Insert**.
- Select the area ID.
- Select **enabled**.
- Select **Insert**.

**IPv6 OSPFv3 Interface** Field Descriptions

Use the data in the following table to use the **IPv6 OSPFv3 Interface** tab.

Name	Description
<b>Index</b>	Specifies the interface index for the IPv6 interface on which OSPFv3 is configured.
<b>AreaId</b>	Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.
<b>Type</b> <b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the OSPFv3 interface type as one of the following: <ul style="list-style-type: none"> <li>• broadcast</li> <li>• NBMA</li> <li>• point-to-point</li> <li>• point-to-multipoint</li> <li>• passive</li> </ul>
<b>AdminStat</b>	Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an internal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.
<b>RtrPriority</b> <b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election. A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router. The default is 1.
<b>TransitDelay</b> <b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.
<b>RetransInterval</b> <b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.

Name	Description
<b>HelloInterval</b>  <b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.
<b>RtrDeadInterval</b>  <b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.
<b>PollInterval</b>  <b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.
<b>State</b>	Shows the state of the OSPFv3 interface as one of the following: <ul style="list-style-type: none"> <li>• down</li> <li>• loopback</li> <li>• waiting</li> <li>• pointToPoint</li> <li>• designatedRouter</li> <li>• backupDesignatedRouter</li> <li>• otherDesignatedRouter</li> </ul>
<b>DesignatedRouter</b>	Shows the router ID for the designated router.
<b>BackupDesignatedRouter</b>	Shows the router ID for the backup designated router.
<b>MetricValue</b>  <b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100.  <b>Note:</b> If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface.
<b>LinkLsaSuppression</b>  <b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.	Specifies whether Link LSA suppression is enabled.

## Create an OSPF Interface on a CLIP

### Note

This procedure only applies to the VSP 8600 Series.

Configure the OSPF protocol on an IPv6 interface to support dynamic routing on the interface. Perform this procedure to create an OSPFv3 interface on a circuitless IP (CLIP).

If you want to modify existing OSPFv3 interfaces, see [Modify an OSPFv3 Interface](#) on page 2824.

### Before You Begin

- The CLIP interface must exist.

### Procedure

1. In the navigation pane, expand the **Configuration** > **IPv6** folders.
2. Select **OSPFv3**.
3. Select the **Interfaces** tab.
4. Select **Insert**.
5. Select **IPv6 Interfaces**.
6. Select the index associated to a CLIP interface, then select **Ok**.
7. Select **enabled** from AdminStat.
8. Select **Insert**.

### *Interfaces* field descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
<b>Index</b>	Specifies the interface index for the IPv6 interface on which OSPFv3 is configured.
<b>Areald</b>	Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.
<b>Type</b> <b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the OSPFv3 interface type as one of the following: <ul style="list-style-type: none"> <li>• broadcast</li> <li>• NBMA</li> <li>• point-to-point</li> <li>• point-to-multipoint</li> <li>• passive</li> </ul>
<b>AdminStat</b>	Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an internal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.

Name	Description
<p><b>RtrPriority</b></p> <p><b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.</p>	<p>Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election. A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router. The default is 1.</p>
<p><b>TransitDelay</b></p> <p><b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.</p>	<p>Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.</p>
<p><b>RetransInterval</b></p> <p><b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.</p>	<p>Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.</p>
<p><b>HelloInterval</b></p> <p><b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.</p>	<p>Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.</p>
<p><b>RtrDeadInterval</b></p> <p><b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.</p>	<p>Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.</p>
<p><b>PollInterval</b></p> <p><b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.</p>	<p>Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.</p>
<p><b>State</b></p>	<p>Shows the state of the OSPFv3 interface as one of the following:</p> <ul style="list-style-type: none"> <li>• down</li> <li>• loopback</li> <li>• waiting</li> <li>• pointToPoint</li> <li>• designatedRouter</li> <li>• backupDesginatedRouter</li> <li>• otherDesignatedRouter</li> </ul>

Name	Description
<b>DesignatedRouter</b>	Shows the router ID for the designated router.
<b>BackupDesignatedRouter</b>	Shows the router ID for the backup designated router.
<b>MetricValue</b>  <b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100.  <b>Note:</b> If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface.
<b>LinkLsaSuppression</b>  <b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.	Specifies whether Link LSA suppression is enabled.

## Create an OSPF VLAN Interface

Configure the OSPF protocol on an IPv6 VLAN to support dynamic routing on the interface.

If you want to modify existing OSPFv3 interfaces, see [Modify an OSPFv3 Interface](#) on page 2824.

### Before You Begin

- The IPv6 interface must exist.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > VLAN**.
2. Select **VLANS**.
3. Select the **Basic** tab.
4. Select a **VLAN**.
5. Select **IPv6**.
6. Select the **IPv6 OSPF Interface** tab.
7. Select **Insert**.
8. Select the area ID.
9. Select **enabled**.
10. Select **Insert**.

**IPv6 OSPF Interface** Field Descriptions

Use the data in the following table to use the **IPv6 OSPF Interface** tab.

Name	Description
<b>Index</b>	Shows the interface index for the IPv6 interface on which OSPFv3 is configured.
<b>Areaid</b>	Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.
<b>Type</b>	Specifies the OSPFv3 interface type as one of the following: <ul style="list-style-type: none"> <li>• broadcast</li> <li>• NBMA</li> <li>• point-to-point</li> <li>• point-to-multipoint</li> <li>• passive</li> </ul>
<b>AdminStat</b>	Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an internal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.
<b>RtrPriority</b>	Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election. A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router. The default is 1.
<b>TransitDelay</b>	Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.
<b>RetransInterval</b>	Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.
<b>HelloInterval</b>	Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.

Name	Description
<b>RtrDeadInterval</b>	Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.
<b>PollInterval</b>	Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.
<b>State</b>	Shows the state of the OSPFv3 interface as one of the following: <ul style="list-style-type: none"> <li>• down</li> <li>• loopback</li> <li>• waiting</li> <li>• pointToPoint</li> <li>• designatedRouter</li> <li>• backupDesignatedRouter</li> <li>• otherDesignatedRouter</li> </ul>
<b>DesignatedRouter</b>	Shows the router ID for the designated router.
<b>BackupDesignatedRouter</b>	Shows the router ID for the backup designated router.
<b>MetricValue</b>	Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100.  <b>Note:</b> If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface.
<b>LinkLsaSuppression</b>	Specifies whether Link LSA suppression is enabled.
<b>BfdEnable</b>	Enables Bidirectional Forwarding Detection (BFD) for OSPF.

## Create an OSPF Interface on a Tunnel

Configure the OSPF protocol on an IPv6 interface to support dynamic routing on the interface. Perform this procedure to create an OSPF interface on a tunnel.

If you want to modify existing OSPFv3 interfaces, see [Modify an OSPFv3 Interface](#) on page 2824. To configure OSPFv3 on an IPv6 VLAN, see [Create an OSPF VLAN Interface](#) on page 2813.

**Before You Begin**

- The IPv6 interface must exist.

**Procedure**

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Select **Tunnel**.
3. Select the **Tunnel Config** tab.
4. Select a configured tunnel.
5. Select **IPv6 OSPF**.
6. Select **Insert**.
7. Select the area ID.
8. Select **enabled**.
9. Select **Insert**.

**OSPF Interface** *Field Descriptions*

Use the data in the following table to use the **OSPF Interface** tab.

Name	Description
<b>Index</b>	Shows the interface index for the IPv6 interface on which OSPFv3 is configured.
<b>Areaid</b>	Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.
<b>Type</b>	Specifies the OSPFv3 interface type as one of the following: <ul style="list-style-type: none"> <li>• broadcast</li> <li>• NBMA</li> <li>• point-to-point</li> <li>• point-to-multipoint</li> </ul>
<b>AdminStat</b>	Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an internal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.
<b>RtrPriority</b>	Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election. A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router. The default is 1.

Name	Description
<b>TransitDelay</b>	Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.
<b>RetransInterval</b>	Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.
<b>HelloInterval</b>	Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.
<b>RtrDeadInterval</b>	Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.
<b>PollInterval</b>	Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.
<b>State</b>	Shows the state of the OSPFv3 interface as one of the following: <ul style="list-style-type: none"> <li>• down</li> <li>• loopback</li> <li>• waiting</li> <li>• pointToPoint</li> <li>• designatedRouter</li> <li>• backupDesignatedRouter</li> <li>• otherDesignatedRouter</li> </ul>
<b>DesignatedRouter</b>	Shows the router ID for the designated router.
<b>BackupDesignatedRouter</b>	Shows the router ID for the backup designated router.

Name	Description
<b>MetricValue</b>	Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100.  <b>Note:</b> If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface.
<b>LinkLsaSuppression</b>	Specifies whether Link LSA suppression is enabled.

## Viewing the AS-scope link-state database

View the AS-scope link-state database (LSDB) to see the LSAs that are flooded through the routing domain. The AS scope is used for AS external-LSAs.

### Before You Begin

- Change the VRF instance as required to view OSPFv3 on a specific VRF instance.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **OSPFv3**.
3. Click the **AS-scope LSDB** tab.

### AS-scope LSDB field descriptions

Use the data in the following table to use the **AS-scope LSDB** tab.

Name	Description
<b>Type</b>	Shows the type of the link-state advertisement. Each link state type has a separate advertisement format. AS-scope LSAs not recognized by the router may be stored in the database.
<b>RouterId</b>	Shows the 32 bit number that uniquely identifies the originating router in the autonomous system.
<b>Lsid</b>	Identifies the piece of the routing domain that is being described by the advertisement.
<b>Sequence</b>	Shows a signed 32-bit integer that detects old and duplicate link-state advertisements. The larger the sequence number, the more recent the advertisement.

Name	Description
Age	Shows the age of the link-state advertisement in seconds.
Checksum	Indicates the checksum of the complete contents of the advertisement, except the age field. The age field is not affected so that the advertisement age value increments without updating the checksum. The checksum used is the same for ISO connectionless datagrams, the Fletcher checksum.

## Viewing the area-scope LSDB

View the area-scope LSDB to see the LSAs that are flooded in a single OSPFv3 area. Area scope is used in router LSAs, network LSAs, Inter-Area-Prefix-LSAs, Inter-Area-Router LSAs, and Intra-Area-Prefix-LSAs.

### Before You Begin

- Change the VRF instance as required to view OSPFv3 on a specific VRF instance.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Click **OSPFv3**.
3. Click the **Area-scope LSDB** tab.

### *Area-scope LSDB field descriptions*

Use the data in the following table to use the **Area-scope LSDB** tab.

Name	Description
Areaid	Identifies the area ID from which the LSA is received. Area ID 0.0.0.0 is the OSPF backbone.
Type	Identifies the type of the link-state advertisement. Each link-state type has a separate advertisement format. Area-scope LSAs unrecognized by the router are also stored in this database.
RouterId	Identifies the originating router in the autonomous system.
Lsid	Identifies the piece of the routing domain that is described by the advertisement.
Sequence	Shows a signed 32-bit integer that detects old and duplicate link-state advertisements. The larger the sequence number, the more recent the advertisement.

Name	Description
<b>Age</b>	Shows the age of the link-state advertisement in seconds.
<b>Checksum</b>	Indicates the checksum of the complete contents of the advertisement, except the age field. The age field is not affected so that the advertisement age value increments without updating the checksum. The checksum used is the same for ISO connectionless datagrams, the Fletcher checksum.

## Viewing the link-scope LSDB

View the link-scope LSDB to view the LSAs that are not flooded beyond the local link.

### Before You Begin

- Change the VRF instance as required to view OSPFv3 on a specific VRF instance.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Click **OSPFv3**.
3. Click the **Link-scope LSDB** tab.

### *Link-scope LSDB field descriptions*

Use the data in the following table to use the **Link-scope LSDB** tab.

Name	Description
<b>IfIndex</b>	Shows the identifier of the link from which the LSA was received.
<b>Type</b>	Shows the type of the link-state advertisement. Each link state type has a separate advertisement format. Link-scope LSAs not recognized by the router may be stored in the database.
<b>RouterId</b>	Shows the 32 bit number that uniquely identifies the originating router in the autonomous system.
<b>Lsid</b>	Identifies the piece of the routing domain that is being described by the advertisement.
<b>Sequence</b>	Shows a signed 32-bit integer that detects old and duplicate link-state advertisements. The larger the sequence number, the more recent the advertisement.

Name	Description
<b>Age</b>	Shows the age of the link-state advertisement in seconds.
<b>Checksum</b>	Indicates the checksum of the complete contents of the advertisement, except the age field. The age field is not affected so that the advertisement age value increments without updating the checksum. The checksum used is the same for ISO connectionless datagrams, the Fletcher checksum.

## Adding an NBMA neighbor

Add an NBMA neighbor for each interface that is eligible to become the DR.

An NBMA interface with a positive nonzero router priority is eligible to become the DR for the NBMA network and is configured with the identification of all attached routers, IPv6 addresses, and router priorities.

### Before You Begin

- Identify the following information:
  - specific interfaces to include in the NBMA network
  - the IPv6 address for each interface
  - the router priority for each interface
  - the hello interval for the network
  - the router dead interval for the network
  - the poll interval for the network
- Change the VRF instance as required to configure OSPFv3 on a specific VRF instance.

### About This Task

In contrast to a broadcast network where switches multicast (send to AllSPFRouters and AllDRouters) certain OSPF protocol packets, switches replicate and send NBMA packets to each neighboring router as unicast. NBMA networks drop all OSPF packets with destination addresses AllSPFRouters and AllDRouters. Because the NBMA network does not broadcast, you must manually configure a list of neighbors and priorities for all routers in the network that can become the DR. Potential DRs use a positive nonzero router priority.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **OSPFv3**.
3. Click the **NBMA Neighbors** tab.
4. Click **Insert**.
5. Select the IPv6 port or VLAN interface.

6. Specify the IPv6 address for the neighbor.
7. Specify the priority for the neighbor.
8. Click **Insert**.

### **NBMA Neighbors** field descriptions

Use the data in the following table to use the **NBMA Neighbors** tab.

Name	Description
<b>IfIndex</b>	Specifies the link ID for the link over which the switch reaches the neighbor.
<b>Address</b>	Specifies the IPv6 address of the neighbor.
<b>Priority</b>	Specifies the priority to use for this neighbor in the designated router election process. A value of 0 indicates the neighbor cannot become the designated router. The higher the priority value, the higher chance the switch will win the election process. The default is 1.
<b>RtrId</b>	Identifies the neighboring router in the autonomous system. The value is 0.0.0.0 until the switch receives a hello message from the neighbor.
<b>State</b>	Identifies the state of the relationship with the neighbor. The state can be one of the following: <ul style="list-style-type: none"> <li>• down</li> <li>• attempt</li> <li>• init</li> <li>• twoWay</li> <li>• exchangeStart</li> <li>• exchange</li> <li>• loading</li> <li>• full</li> </ul>

## Configuring Route Redistribution to OSPFv3

Configure a redistribute entry to announce routes of a certain source protocol into the OSPFv3 domain. Optionally, use a route policy to control the redistribution of routes.

### About This Task

#### **Important**

Changing the OSPFv3 redistribute context is a process-oriented operation that can affect system performance and network reachability while you perform this procedure. As a best practice, change the default preferences for an OSPFv3 redistribute context, you must do so before you enable the protocols.

### Before You Begin

- Enable OSPFv3 globally.
- Ensure that a route policy exists if you intend to use a route policy.
- Change the VRF instance as required to configure OSPFv3 on a specific VRF instance. The VRF must have an RP trigger of OSPFv3. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **OSPFv3**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Select an option for the route source.
6. Select the **enable** option button.
7. Select a route policy.
8. Configure the metric type.
9. Click **Insert**.

### Redistribute Field Descriptions

Use the data in the following table to use the **Redistribute** tab.

Name	Description
<b>DstVrflid</b>	Specifies the destination virtual router forwarding instance. You cannot configure this variable.
<b>Protocol</b>	Specifies the dynamic routing protocol that receives the external routing information.
<b>SrcVrflid</b>	Specifies the source VRF instance. You cannot configure this variable.
<b>RouteSource</b>	Specifies the route source protocol for the redistribution entry.
<b>Enable</b>	Enables (or disables) an OSPF redistribute entry for a specified source type.
<b>RoutePolicy</b>	Configures the route policy (by name) to use for detailed redistribution of external routes from a specified source into an OSPF domain. Click the ellipsis (...) button and choose from the list in the dialog box.

Name	Description
<b>Metric</b>	Configures the OSPF route redistribution metric for basic redistribution. The value can be a range from 0–65535. A value of 0 indicates to use the original cost of the route.
<b>MetricType</b>	Configures the OSPF route redistribution metric type. The default is type 2. The cost of a type 2 route is the external cost, regardless of the interior cost. A type 1 cost is the sum of both the internal and external costs.

## Modify an OSPFv3 Interface

Configure the OSPF protocol on IPv6 interface to support dynamic routing on the interface. The IPv6 interface can be a tunnel, port, VLAN, or CLIP interface.

### Note

The OSPFv3 over CLIP interface configuration is only supported on VSP 8600 Series.

### Before You Begin

- The OSPFv3 interface must exist.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **OSPFv3**.
3. Select the **Interfaces** tab.
4. Double-click a cell to edit the value.
5. Select **Apply**.

### *Interfaces* field descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
<b>Index</b>	Specifies the interface index for the IPv6 interface on which OSPFv3 is configured.
<b>Areaid</b>	Specifies the area ID to which the IPv6 interface connects. Use 0.0.0.0 for the OSPFv3 backbone.

Name	Description
<p><b>Type</b></p> <p><b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.</p>	<p>Specifies the OSPFv3 interface type as one of the following:</p> <ul style="list-style-type: none"> <li>• broadcast</li> <li>• NBMA</li> <li>• point-to-point</li> <li>• point-to-multipoint</li> <li>• passive</li> </ul>
<p><b>AdminStat</b></p>	<p>Specifies the administrative status for the OSPFv3 interface. If you enable the status, it is advertised as an internal route to some areas. If you disable the status, the interface is external to OSPFv3. The default is enabled.</p>
<p><b>RtrPriority</b></p> <p><b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.</p>	<p>Specifies the priority of this interface. Multiaccess networks use the priority in the designated router election. A higher priority value increases the chance the router becomes the designated router. A value of zero (0) indicates the router cannot become the designated router for the network. If more than one router uses the same priority value, the router ID determines the designated router. The default is 1.</p>
<p><b>TransitDelay</b></p> <p><b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.</p>	<p>Specifies the estimated number of seconds to transmit a link-state-update packet over this interface. The default is 1.</p>
<p><b>RetransInterval</b></p> <p><b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.</p>	<p>Specifies the number of seconds between retransmission of link-state advertisements for the adjacencies that belong to this interface, and for database description and link-state request packets. The default is 5.</p>
<p><b>HelloInterval</b></p> <p><b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.</p>	<p>Specifies the number of seconds between the hello packets that the router sends on this interface. You must configure this field to the same value for all routers attached to a common network. The default is 10.</p>
<p><b>RtrDeadInterval</b></p> <p><b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.</p>	<p>Specifies the number of seconds after which to declare a router down if no hello packets are received. You must configure this field to the same value for all routers attached to a common network. The default is 40.</p>

Name	Description
<b>PollInterval</b> <b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the number of seconds between hello packets sent to an inactive NBMA neighbor. The default is 120.
<b>State</b>	Shows the state of the OSPFv3 interface as one of the following: <ul style="list-style-type: none"> <li>• down</li> <li>• loopback</li> <li>• waiting</li> <li>• pointToPoint</li> <li>• designatedRouter</li> <li>• backupDesignatedRouter</li> <li>• otherDesignatedRouter</li> </ul>
<b>DesignatedRouter</b>	Shows the router ID for the designated router.
<b>BackupDesignatedRouter</b>	Shows the router ID for the backup designated router.
<b>MetricValue</b> <b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.	Specifies the cost for the interface. The default value for a brouter port or VLAN is 1. The default value for a tunnel is 100.  <b>Note:</b> If you do not specify a cost for the interface, the switch dynamically updates the interface cost with the configured global OSPF default cost. The global OSPF default cost depends on the speed of the interface.
<b>LinkLsaSuppression</b> <b>Note:</b> Value is not configurable for OSPFv3 CLIP interfaces.	Specifies whether Link LSA suppression is enabled.

## Viewing OSPFv3 neighbors

View OSPFv3 neighbors to see routers with interfaces to a common network.

The OSPFv3 hello protocol maintains and dynamically discovers neighbor relationships.

The exception is an NBMA network; you manually configure permanent neighbors on each router eligible to become the designated router (DR).

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.

2. Click **OSPFv3**.
3. Click the **Neighbors** tab.

### **Neighbors** field descriptions

Use the data in the following table to use the **Neighbors** tab.

Name	Description
<b>IfIndex</b>	Displays the local-link ID of the link over which the neighbor can be reached.
<b>RtrId</b>	Identifies the neighboring router in the Autonomous System. The value is the router ID of the neighboring router, which in OSPF uses the same format as an IPv6 address but identifies the router independent of IPv6 address.
<b>Address</b>	Displays the IPv6 address for the neighbor associated with the local link.
<b>Options</b>	Displays the bit mask that corresponds to the options field on the neighbor.
<b>State</b>	Displays the state of the relationship with the neighbor. The value can be one of the following: <ul style="list-style-type: none"> <li>• down</li> <li>• attempt</li> <li>• init</li> <li>• twoWay</li> <li>• exchangeStart</li> <li>• exchange</li> <li>• loading</li> <li>• full</li> </ul>
<b>NbrIfId</b>	Displays the interface ID that the neighbor advertises in its hello packets on this link.
<b>DeadIntCnt</b>	Displays the Dead interval Count or TTL (time to live) field that indicates how many seconds remain before the system declares the Neighbor down. The starting value is the Router Dead Interval value and it decrements to 0 if no Hello is received for that neighbor within the interval. If no Hello is received within the interval, then the system declares the neighbor down. When a hello is received for the neighbor, the system resets the value to the Router Dead Interval value.

## Viewing virtual neighbors

View information about the neighbors on the virtual link to the OSPFv3 backbone.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Click **OSPFv3**.
3. Click the **Virtual Neighbors** tab.

### *Virtual Neighbors* field descriptions

Use the data in the following table to use the **Virtual Neighbors** tab.

Name	Description
<b>Area</b>	Shows the ID for the transit area.
<b>RtrId</b>	Shows the ID for the neighboring router in the autonomous system.
<b>LocalIfIndex</b>	Shows the local interface ID for the virtual link over which the switch can reach the neighbor.
<b>AddressType</b>	Shows the type of address as one of the following: <ul style="list-style-type: none"> <li>• ipv4</li> <li>• ipv6</li> <li>• ipv4z</li> <li>• ipv6z</li> <li>• dns</li> </ul> ipv4z and ipv6z indicate a scope zone.
<b>Address</b>	Shows the IPv6 address that this virtual neighbor advertises. This value must be a global scope address.
<b>Options</b>	Shows a bit mask that corresponds to the OSPF options field of the neighbor.
<b>State</b>	Shows the state of the virtual neighbor relationship. The value can be one of the following: <ul style="list-style-type: none"> <li>• down</li> <li>• attempt</li> <li>• init</li> <li>• twoWay</li> <li>• exchangeStart</li> <li>• exchange</li> <li>• loading</li> <li>• full</li> </ul>

## View OSPFv3 Statistics

View OSPF statistics to analyze trends. You can also graph statistics for all OSPF packets transmitted by the switch.

### Procedure

1. In the navigation pane, expand the **Configuration > IPv6** folders.
2. Select **OSPFv3**.
3. Select **Stats**.

### *Stats Field Descriptions*

Use the data in the following table to use the **Stats** tab.

Name	Description
<b>TxPackets</b>	Shows the count of sent packets.
<b>RxPackets</b>	Shows the count of received packets.
<b>TxDropPackets</b>	Shows the count of sent, dropped packets.
<b>RxDropPackets</b>	Shows the count of received, dropped packets.
<b>RxBadPackets</b>	Shows the count of received, bad packets.
<b>SpfRuns</b>	Shows the count of intra-area route table updates with calculations using this area link-state database.
<b>LastSpfRun</b>	Shows the count of the most recent SPF run.
<b>LsdbTblSize</b>	Shows the size of the link state database table.
<b>BadLsReqs</b>	Shows the count of bad link requests.
<b>SeqMismatches</b>	Shows the count of sequence mismatched packets.
<b>Routes</b>	Shows the number of OSPF routes added to the routing table.
<b>Adjacencies</b>	Shows the number of existing adjacencies.
<b>Areas</b>	Shows the number of configured areas.
<b>Nbrs</b>	Shows the number of OSPF neighbors.

## OSPFv3 Configuration Example

This section shows an example of OSPFv3 configuration. The following figure shows the network.

**Figure 216: OSPFv3 configuration**

To complete the configuration, you must perform the following actions:

- Configure an IPv6 VLAN (VLAN 2) with port member 1/1.
- Configure an IPv6 brouter port (1/2).
- Use IPv6 address 2001:100:102::/64.

Configure VLAN 2 and add port members.

```
vlan create 2 type port-mstprstp 0
vlan mlt 2 4
vlan members 2 1/1 portmember
interface vlan 2
ipv6 interface
ipv6 interface enable
ipv6 interface address 2001:100:102:202:0:0:0:1/64
exit
```

Enable OSPFv3 on VLAN 2.

```
# IPV6 OSPF VLAN CONFIGURATION
interface vlan 2
ipv6 ospf area 0.0.0.0
ipv6 ospf poll-interval 0
ipv6 ospf enable
exit
```

Create brouter port 1/2 with IPv6 and OSPFv3.

```
interface gigabitethernet 1/2
ipv6 interface vlan 3999
ipv6 interface enable
ipv6 interface address 2001:100:102:201:0:0:0:1/64
ipv6 ospf area 0.0.0.0
ipv6 ospf enable
exit
```

## Verification

The following example shows the Global Router example for OSPFv3 Area configuration:

```
Switch:1#show ipv6 ospf area

=====
                        OSPF Area - GlobalRouter
=====

# Port Performance Management

---

[Digital Diagnostic Monitoring](#) on page 2832

[Port Performance Management Using CLI](#) on page 2832

[Port Performance Management using EDM](#) on page 2838

The topics in this section provide information to configure and view Digital Diagnostic Monitoring (DDM).

## Digital Diagnostic Monitoring

---

Use Digital Diagnostic Monitoring (DDM) to monitor laser operating characteristics such as temperature, voltage, current, and power. This feature works at any time during active laser operation without affecting data traffic.

The following optical transceivers support DDM:

- 1 Gbps Small Form Factor Pluggable (SFP)
- 10 Gbps Small Form Factor Pluggable plus (SFP+)
- 25 Gbps Small Form Factor Pluggable 28 (SFP28)
- 40 Gbps Quad Small Form Factor Pluggable plus (QSFP+)
- 100 Gbps Quad Small Form Factor Pluggable 28 (QSFP28)

Digital Diagnostic Interface (DDI) is an interface that supports DDM. These devices provide real-time monitoring of individual DDI transceivers. The DDM software provides warnings or alarms after the temperature, voltage, laser bias current, transmitter power or receiver power fall outside of vendor-specified thresholds during initialization.

For information about optical transceivers, see [Extreme Optics](#) website

## Port Performance Management Using CLI

---

This section contains procedures to monitor individual DDI transceivers using the CLI.

## Configure DDM

Configure Digital Diagnostic Monitoring to get information concerning the status of the transmitted and received signals to allow better fault isolation and error detection.

### About This Task

When you enable DDM, you see the internal performance condition (temperature, voltage, bias, Tx power and Rx power) of the pluggable transceiver. The default is disabled.

For information about how to reset a transceiver for troubleshooting purposes, see [Reset a QSFP+ or QSFP28 Transceiver](#) on page 3975.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. (Optional) Configure an alarm to occur if the port goes down:  

```
pluggable-optical-module ddm-alarm-portdown
```
3. (Optional) Configure the DDM interval:  

```
pluggable-optical-module ddm-monitor-interval <5-60>
```
4. (Optional) Enable the sending of trap messages when an alarm occurs:  

```
pluggable-optical-module ddm-traps-send
```
5. Enable DDM:  

```
pluggable-optical-module ddm-monitor
```

### Example

Configure the interval to 10 seconds and enable DDM.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#pluggable-optical-module ddm-monitor-interval 10
Switch:1(config)#pluggable-optical-module ddm-monitor
```

### Variable Definitions

Use the data in the following table to use the **pluggable-optical-module** command

Variable	Value
<i>ddm-alarm-portdown</i>	When enabled, the port goes down when any alarm occurs. The default is disabled.
<i>ddm-monitor</i>	Enables DDM. When enabled, you see the internal performance condition (temperature, voltage, bias, Tx power and Rx power) of the pluggable transceiver. The default is disabled.

Variable	Value
<code>dmd-monitor-interval &lt;5-60&gt;</code>	Configures the DDM monitor interval. If an alarm occurs, the log message is received within the specific interval. The default value is 5 seconds.
<code>dmd-traps-send</code>	Enables or disables the sending of trap messages. When enabled, the trap message is sent to the device manager any time the alarm occurs. The default is enabled.

## View DDI Port Information

Perform this procedure to view basic manufacturing information and characteristics, and the current configuration.

### About This Task

This command displays information for DDI transceivers.

#### Note

Transceiver support differs across hardware platforms. For information about supported parts, see [Extreme Optics](#) website.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View basic manufacturing information and characteristics:

```
show pluggable-optical-modules basic [{slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]]
```

3. View configuration information:

```
show pluggable-optical-modules config
```

4. View detailed manufacturing information and characteristics:

```
show pluggable-optical-modules detail [{slot/port[/sub-port] [-slot/
port[/sub-port]] [,...]]
```

### Examples

```
Switch:1#show pluggable-optical-modules config
```

```
=====
Pluggable Optical Module Global Configuration
=====
```

```

          ddm-monitor : disabled
dmd-monitor-interval : 5
          ddm-traps-send : enabled
          ddm-alarm-portdown : disabled
```

The following example includes Extreme extended diagnostic information. Not all parts support this information. A value of 254 indicates the part has not been initialized.

```
Switch:1#show pluggable-optical-modules detail 1/29

### Variable Definitions

Use the data in the following table to use the **show pluggable-optical-modules basic** and **show pluggable-optical-modules detail** commands.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## View DDI Temperature Information

### About This Task

This command displays information for DDI transceivers.

#### Note

Transceiver support differs across hardware platforms. For information about supported parts, see [Extreme Optics](#) website.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View temperatures:  
show pluggable-optical-modules temperature [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]

### Example

```
Switch:1#show pluggable-optical-modules temperature
```

```

```

Variable Definitions

Use the data in the following table to use the **show pluggable-optical-modules temperature** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

View DDI Voltage Information

About This Task

This command displays information for DDI transceivers.

Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View voltages:

```
show pluggable-optical-modules voltage [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

Example

```
Switch:1#show pluggable-optical-modules voltage
```

```
=====
```

```
Pluggable Optical Module Voltage (V)
```

```
=====
```

PORT NUM	LOW_ALARM THRESHOLD	LOW_WARN THRESHOLD	ACTUAL VALUE	HIGH_WARN THRESHOLD	HIGH_ALARM THRESHOLD	THRESHOLD STATUS
1/2	0.1281	0.0	1.2596	0.5376	1.6396	Normal
1/3	0.0001	0.0	1.2596	0.3072	1.6396	Normal
1/9	0.0006	0.0	1.2596	2.6368	0.0	Normal
1/15	0.0006	0.0	1.2596	2.6368	0.0	Normal
2/1	0.0006	0.0	1.2596	2.6368	0.0	Normal
2/17	0.0006	0.0	1.2596	2.6368	0.0	Normal
2/40	0.0006	0.0	1.2596	2.6368	0.0	Normal

### Variable Definitions

Use the data in the following table to use the **show pluggable-optical-modules voltage** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Port Performance Management using EDM

This section contains procedures to monitor individual DDI transceivers using EDM.

### View DDI Information

#### About This Task

You can view Digital Diagnostic Interface (DDI) information, for example, port information, temperature, and voltages for DDI transceivers.

#### Note

Transceiver support differs across hardware platforms. For information about supported parts, see the [Extreme Optics](#) website.

#### Procedure

1. On the Physical Device view, select one or more ports.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **DDI/SFP** tab.

### DDI/SFP Field Descriptions

Use the data in the following table to understand the information displayed in the **DDI/SFP** tab.

Name	Description
<b>ConnectorType</b>	Indicates the type of connector.
<b>SupportsDDM</b>	Indicates if the transceiver supports DDM.
<b>DdmStatusMask</b>	Indicates the DDM status. A value other than ddm-ok represents a specific error.
<b>CLEI</b>	Indicates the Telcordia register assignment CLEI code.
<b>VendorName</b>	Indicates the name of the manufacturer.

Name	Description
<b>VendorPartNumber</b>	Indicates the part number for the transceiver. Select the part number to access the technical specifications for the part.
<b>VendorRevNumber</b>	Indicates the manufacturer revision level for the transceiver.
<b>VendorSN</b>	Indicates the manufacturer serial number for the transceiver.
<b>VendorDateCode</b>	Indicates the manufacturer date code for the transceiver.
<b>Wavelength</b>	Indicates the wavelength in nm. This field is valid for optical transceivers only.
<b>Calibration</b>	Indicates if the calibration is internal or external.
<b>PowerMeasure</b>	Indicates Rx power measurement as average or OMA.
<b>Aux1Monitoring</b>	Indicates if auxiliary monitoring is implemented for the transceiver.
<b>Aux2Monitoring</b>	Indicates if auxiliary monitoring is implemented for the transceiver.
<b>TemperatureLowAlarmThreshold</b>	Indicates the low alarm threshold in degrees Celsius.
<b>TemperatureLowWarningThreshold</b>	Indicates the low warning threshold in degrees Celsius.
<b>Temperature</b>	Indicates the current temperature in degrees Celsius of the transceiver.
<b>TemperatureHighWarningThreshold</b>	Indicates the high warning threshold in degrees Celsius.
<b>TemperatureHighAlarmThreshold</b>	Indicates the high alarm threshold in degrees Celsius.
<b>TemperatureStatus</b>	Indicates if any temperature thresholds were exceeded.
<b>VoltageLowAlarmThreshold</b>	Indicates the low alarm threshold in volts.
<b>VoltageLowWarningThreshold</b>	Indicates the low warning threshold in volts.
<b>Voltage</b>	Indicates the current voltage in volts.
<b>VoltageHighWarningThreshold</b>	Indicates the high warning threshold in volts.
<b>VoltageHighAlarmThreshold</b>	Indicates the high alarm threshold in volts.
<b>VoltageStatus</b>	Indicates if any voltage thresholds were exceeded.
<b>BiasLowAlarmThreshold</b>	Indicates the bias current low alarm threshold in mA.
<b>BiasLowWarningThreshold</b>	Indicates the bias current low warning threshold in mA.

Name	Description
<b>Bias</b>	Indicates the laser bias current in mA.
<b>BiasHighWarningThreshold</b>	Indicates the bias current high warning threshold in mA.
<b>BiasHighAlarmThreshold</b>	Indicates the bias current high alarm threshold in mA.
<b>BiasStatus</b>	Indicates if any bias thresholds were exceeded.
<b>TxPowerLowAlarmThreshold</b>	Indicates the low alarm threshold in dBm for the Tx power.
<b>TxPowerLowWarningThreshold</b>	Indicates the low warning threshold in dBm for the Tx power.
<b>TxPower</b>	Indicates the current Tx power in dBm.
<b>TxPowerHighWarningThreshold</b>	Indicates the high warning threshold in dBm for the Tx power.
<b>TxPowerHighAlarmThreshold</b>	Indicates the high alarm threshold in dBm for the Tx power.
<b>TxPowerStatus</b>	Indicates if any Tx power thresholds were exceeded.
<b>RxPowerLowAlarmThreshold</b>	Indicates the low alarm threshold in dBm for the Rx power.
<b>RxPowerLowWarningThreshold</b>	Indicates the low warning threshold in dBm for the Rx power.
<b>RxPower</b>	Indicates the current Rx power in dBm.
<b>RxPowerHighWarningThreshold</b>	Indicates the high warning threshold in dBm for the Rx power.
<b>RxPowerHighAlarmThreshold</b>	Indicates the high alarm threshold in dBm for the Rx power.
<b>RxPowerStatus</b>	Indicates if any Rx power thresholds were exceeded.
<b>Aux1LowAlarmThreshold</b>	Indicates the low alarm threshold auxiliary 1 reading.
<b>Aux1LowWarningThreshold</b>	Indicates the low warning threshold auxiliary 1 reading.
<b>Aux1</b>	Indicates the current auxiliary 1 reading.
<b>Aux1HighWarningThreshold</b>	Indicates the high warning threshold auxiliary 1 reading.
<b>Aux1HighAlarmThreshold</b>	Indicates the high alarm threshold auxiliary 1 reading.
<b>Aux1Status</b>	Indicates if any auxiliary 1 thresholds were exceeded.
<b>Aux2LowAlarmThreshold</b>	Indicates the low alarm threshold auxiliary 2 reading.

Name	Description
<b>Aux2LowWarningThreshold</b>	Indicates the low warning threshold auxiliary 2 reading.
<b>Aux2</b>	Indicates the current auxiliary 2 reading.
<b>Aux2HighWarningThreshold</b>	Indicates the high warning threshold auxiliary 2 reading.
<b>Aux2HighAlarmThreshold</b>	Indicates the high alarm threshold auxiliary 2 reading.
<b>Aux2Status</b>	Indicates if any auxiliary 2 thresholds were exceeded.
<b>PowerOnCounter</b>	Tracks the power-on-life of the part. This value increments by 1 every 48 hours of consecutive power. This value is never decremented or cleared. If you remove or reinsert the part, reset or reboot the chassis, reset the slot, or channelize or dechannelize the port, then the 48-hour time period restarts.
<b>TxDdmInitial</b>	Indicates the Tx dB from low alarm, which is the difference between the TxPower dBm and the TxPower low alarm. The host provides the value after the first 48 consecutive hours of operation.
<b>TxDdmLastGasp</b>	Indicates the last gasp of Tx dB from low alarm. The host updates this value every 48 hours.
<b>RxDdmInitial</b>	Indicates the Rx dB from low alarm, which is the difference between the RxPower dBm and the RxPower low alarm. The host provides the value after the first 48 consecutive hours of operation after a power cycle.
<b>RxDdmLastGasp</b>	Indicates the last gasp of Rx dB from low alarm. The host updates this value every 48 hours.
<b>ExtremeExtraFeatures</b>	Indicates if the device supports the extra Extreme features.

#### Note

1. Threshold and actual values for TxBias, TxPower, and RxPower are provided for all four channels in QSFP+ and QSFP28 optical transceivers.
2. Auxiliary monitoring does not apply to QSFP+s or QSFP28s.

Power over Ethernet (PoE) is the implementation of IEEE 802.3af, IEEE 802.3at, and IEEE 802.3bt (Type 3 and Type 4), which allows for both data and power to pass over a copper Ethernet LAN cable. Typical power devices include wireless Access Points and VoIP telephones.

Depending on the technology and application requirements, PoE is classified into classes. Depending on the power requirements, the PoE devices are categorized by type. Classes range from Class 0 to 8 whereas types range from Type 1 to 4. Each type associates with an IEEE 802.3 PoE standard. These standards provide signaling

between the power sourcing equipment (PSE) and the powered device (PD). PSE devices, such as switches, provide power on the network cable. The devices that PSE provides power to are called PDs, such as VoIP phones, wireless access points, and IP surveillance cameras.

To know which ports support PoE, see the following documents:

- [Installing the Virtual Services Platform 4450GSX-PWR+](#) or [Installing the Virtual Services Platform 4450GTX-HT-PWR+](#)
- [VSP 4900 Series Switches: Hardware Installation Guide](#)

The switch uses the Dynamic Power Allocation scheme when supplying power to devices. Only the power being consumed by the device is allocated, improving efficiency and enabling support for more number of devices.

You can configure PoE from CLI and Enterprise Device Manager (EDM).

## PoE Overview

---

You can plug any IEEE 802.3af-compliant, 802.3at-compliant, or 802.3bt-compliant (Type 3 and Type 4) for PWR+ powered device into a front-panel port and receive power in that port. Data also can pass simultaneously on that port. This capability is called PoE.

For more information about PoE and power supplies, see your hardware documentation.

The IEEE 802.3af draft standard regulates a maximum of 15.4 W of power for each port; that is, a power device cannot request more than 15.4 W of power. As different network devices require different levels of power, the overall available power budget of the switch depends on your power configuration and the particular connected network devices. If you connect an IP device that requires more than 16 W of power, you see an error on that port notifying you of an overload.

The switch automatically detects each IEEE 802.3af-compliant powered device attached to each front-panel port and immediately sends power to that appliance. The switch also automatically detects how much power each device requires and supply the required DC voltage at a set current based on the load conditions and current availability. The switch supports both PoE and standard LAN devices.

Similarly, the switch automatically detects any IEEE 802.3at-compliant (maximum 25.5 W) or IEEE 802.3bt-compliant (maximum 60W for Type 3, maximum 90W for Type 4) powered device attached to any PoE front panel port and immediately sends power to that appliance.

The power detection function of the switch operates independently of the data link status. A device that is already operating the link for data or a device that is not yet operational can request power. That is, the switch provides power to a requesting device even if the data link for that port is disabled. The switch monitors the connection and automatically disconnects power from a port when you remove or change the device, as well as when a short occurs.

The switch automatically detects devices that require no power connections from them, such as laptop computers or other switching devices, and sends no power to those devices. You control the supply of power to specific ports by setting the maximum allowed power to each port in 1 W increments, from 3 W to 98W.

#### Important

Wait for 30 seconds between unplugging and replugging an IP device to the switch to enable the IP device to discharge. If you attempt to connect earlier, the switch cannot detect the IP device.

The switch provides the capability to set a PoE power threshold, which lets you set a percentage of the total PoE power usage at which the switch sends a warning message. If the power consumption is below the threshold, the switch logs an information message.

#### Important

- After you enable Fast PoE or Perpetual PoE or both, you must save the running configuration file.
- If Fast PoE or Perpetual PoE are enabled and you change any other global or port-specific PoE settings (for example, power limits, or port power priority), you must resave the running configuration file.

## PoE Detection Types

The following table identifies product support for the different PoE types.

**Table 191: PoE type support**

Product	Highest PoE Standard
VSP 4450GSX-PWR+	802.3at Type 2 PoE (30W)
VSP 4450GTX-HT-PWR+	802.3at Type 2 PoE (30W)
VSP4900-12MXU-12XE	802.3bt Type 3 PoE (60W)
VSP4900-48P	802.3at Type 2 PoE (30W)

The global configured detection type specifies the following versions of the IEEE standard to support. Standards are arranged from oldest (top) to newest (bottom).

Detection Type	Power Mode
802.3af	Normal
802.3af and legacy	Normal
802.3at	High
802.3at and legacy	High
802.3bt type 3	Normal

Detection Type	Power Mode
802.3bt type 4	Normal
802.3bt and legacy	Normal

The default detection type is automatically configured for the highest PoE standard supported on the switch.

#### Note

802.3at is backwards compatible with 802.3af. Therefore, both normal power and high power devices are supported in this mode.

Changing from a newer IEEE standard to an older IEEE standard is permitted, however power delivery is interrupted during this operation, and all PoE devices are reset. There is no service interruption when changing from an older IEEE standard to a newer IEEE standard.

## Power Usage Threshold

The power usage threshold is a chassis configurable percent of the total power available on the switch. When the POE power consumption exceeds this threshold, a log message is generated to warn such an event. When power consumption transitions below the threshold, an informational log message is logged. The default threshold is 80%.

## Port Power Limit

Each PoE port has a configurable power limit. This configuration attribute limits the amount of power supplied on a particular port and varies across different hardware platforms. If a PD requires more than the configured limit, the device will not connect properly or is forced to run at a lower limit.

The following table lists the power limit for different hardware platforms:

**Table 192: Power Limits**

Platform	Power Limit
VSP 4450 Series	32 watts
VSP4900-48P	32 watts
VSP4900-12MXU-12XE	64 watts

## Port Power Priority

You can configure the power priority of each port by choosing low, high, or critical power priority settings.

The switch automatically drops low-priority ports when the power requirements exceed the available power budget. When the power requirements become lower than the switch power budget, the power returns to the dropped port. When several ports

have the same priority and the power budget is exceeded, the ports with the highest interface number are dropped until the consumption is within the power budget.

The priority methods are:

1. Port configured PoE priority

- Low: (default) standard priority for standard devices
- High: higher priority than low for important devices
- Critical: highest priority for critical devices like wireless APs

2. Port number priority where the lower port numbers have a higher priority.

### PD Classification

The PDs are classified during initial connection establishment as defined in IEEE 802.3 standards. The classification defines the amount of power a device is expected to consume.

**Table 193: Classification Chart for Various Standards**

Name	Standard	Class	Type	PSE Min Output Power (in W)	PD Min Input Power (in W)	Example of Supported PDs
PoE	IEEE 802.3af	0	1	15.4	12.95	Static surveillance camera, VoIP phones, wireless access points
		1	1	4	3.84	IP phones
		2	1	7	6.49	IP camera
		3	1	15.4	12.95	Wireless access points
PoE+	IEEE 802.3at	4	2	30	25.5	High power PD
PoE++	IEEE 802.3bt	5	3	45	40	Video conferencing equipment, multi-radio wireless access points
		6	3	60	51	

**Table 193: Classification Chart for Various Standards (continued)**

Name	Standard	Class	Type	PSE Min Output Power (in W)	PD Min Input Power (in W)	Example of Supported PDs
PoE++	IEEE 802.3bt	7	4	75	62	Laptops, flat screens
		8	4	90	73	

## PoE/PoE+ Allocation Using LLDP

Power over Ethernet/Power over Ethernet Plus allocation using Link Layer Discovery Protocol (LLDP) supports Ethernet switches, which do not support hardware-level power negotiation. With this feature, these switches support IEEE-based PoE and play the role of power sourcing equipment (PSE).

The devices that are powered using PoE, such as IP Phone and Video Surveillance Cameras, are classified as Powered Devices (PD). The maximum allowed continuous output power per cable for each standard is:

- IEEE 802.3af: 15.4 W
- IEEE 802.3at: 25.5 W
- IEEE 802.3bt Type 3: 60 W
- IEEE 802.3bt Type 4: 90 W

The negotiation of actual power supply and demand between a PSE and a PD can be executed at either the physical layer or at the data link layer. After the link is established at the physical layer, the PSE can use the IEEE 802.1AB LLDP protocol to repeatedly query the PD to discover its power needs. Communication using LLDP allows for a finer control of power allocation, making it possible for the PSE to dynamically supply the exact power levels needed by individual PDs, and globally for all PDs that are attached. Using LLDP is optional for the PSE, however, it is mandatory for a Type 2 PD that requires more than 12.95 watts of power.

### Important

LLDP supports PoE discovery and power allocation because some switches do not support hardware-level power negotiation. This allows Type 2 PDs such as PTZ (pan-tilt-zoom) Video Surveillance Cameras to be fully functional when connected to one of these switches. This functionality is enabled by default and is not configurable.

### Note

Some switches feature a hardware design that supports hardware-level detection. Therefore, they do not require LLDP.

## Fast PoE and Perpetual PoE

Fast PoE minimizes the PoE controller recovery time in case of a power failure. With Fast PoE, the PoE controller initializes the moment the switch powers on, which results in a faster recovery period.

Perpetual PoE provides uninterrupted power to all connected devices during a switch reboot.

### Important

- After you enable Fast PoE or Perpetual PoE or both, you must save the running configuration file.
- If Fast PoE or Perpetual PoE are enabled and you change global or port-specific PoE configuration, you must save the running configuration file.

## PoE Ports in EDM

The front panel view of Enterprise Device Manager (EDM) provides additional information for Power over Ethernet (PoE) ports for switches that support PoE.

This additional information is in the form of a colored **P** that displays inside the graphical representation of the port. This colored P represents the current power aspect of the PoE port.

**Table 194: Power Aspect color codes**

Color	Description
Green	The port is currently delivering power.
Red	The power and detection mechanism for the port is disabled.
Orange	The power and detection mechanism for the port is enabled. The port is not currently delivering power.
White/Gray	The power and detection mechanism for the port is unknown.

### Important

The data and power aspect coloring schemes are independent of each other. You can view the initial status for both data and power aspect for the port. To refresh the power status, right-click the unit, and then select **Refresh Port Tooltips** from the shortcut menu.

## Power over Ethernet Configuration using CLI

This section provides details to configure PoE settings using CLI.

### Important

- After you enable Fast PoE or Perpetual PoE or both, you must save the running configuration file.
- If Fast PoE or Perpetual PoE are enabled and you change any other global or port-specific PoE settings, you must resave the running configuration file.

## Disabling PoE on a port

### About This Task

Perform the following procedure to disable PoE on a port. The Ethernet connected device does not receive any power over Ethernet if you shutdown PoE on the port.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Disable PoE on the port:

```
poe poe-shutdown [port <portlist>]
```

<portlist> is the port on which you want to disable PoE. The default is enable.

### What to Do Next

To return power to the port, enter `no poe-shutdown [port <portlist>]`.

## Configure PoE Detection Type

Perform the following procedure to configure the PoE powered device (PD) detection type. You can enable either 802.3af and Legacy compliant PD detection methods, or 802.3at and Legacy compliant PD detection methods. The default is automatically configured for the highest PoE standard supported on the switch. For more information, see [PoE Detection Types](#) on page 2848.

- 802.3af : normal power mode
- 802.3af and legacy

- 802.3at : high power mode
- 802.3at and legacy
- 802.3bt Type 3 : normal power mode
- 802.3bt Type 4 : normal power mode

802.3at is backwards compatible with 802.3af. Therefore, normal power and high power devices are supported in 802.3at.

### Important

Changing from a newer IEEE standard to an older IEEE standard is permitted, however power delivery is interrupted during this operation, and all PoE devices are reset. There is no service interruption when changing from an older IEEE standard to a newer IEEE standard.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure PoE detection type:

```
po e poe-pd-detect-type {802dot3af | 802dot3af_and_legacy | 802dot3at | 802dot3at_and_legacy | 802dot3bt_type3 | 802dot3bt_type4}
```

### Variable Definitions

The following table defines parameters for the **poe-pd-detect-type** command.

Variable	Value
<code>{802dot3af   802dot3af_and_legacy   802dot3at   802dot3at_and_legacy   802dot3bt_type3   802dot3bt_type4}</code>	<p>Configures the detection type to one of the following values:</p> <ul style="list-style-type: none"> <li>• 802dot3af: Set PD detection mode in 802.3af</li> <li>• 802dot3af_and_legacy: Set PD detection mode in 802.3af and legacy</li> <li>• 802dot3at: Set PD detection mode in 802.3at</li> <li>• 802dot3at_and_legacy: Set PD detection mode in 802.3at and legacy</li> <li>• 802dot3bt_type3: Set PD detection mode in 802dot3bt Type3</li> <li>• 802dot3bt_type4: Set PD detection mode in 802dot3bt Type4</li> </ul> <p><b>Note:</b> The default detection type is automatically configured for the highest PoE standard supported on the switch.</p>

## Configuring PoE Power Usage Threshold

### About This Task

Perform the following procedure to configure the PoE power usage threshold limit globally as a percentage on the switch. The switch logs a warning message when a PoE PD power usage exceeds the configured threshold. The switch logs an informational message when a PoE PD power usage is below the configured threshold.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the power usage threshold:
 

```
poe poe-power-usage-threshold <1-99>.
```

### Variable Definitions

The following table defines parameters for the **poe-power-usage-threshold** command.

Variable	Value
<1-99>	Specifies the PoE usage threshold in the range of 1—99 percent.

## Configure Power Limits for Channels

### About This Task

Perform the following procedure to configure the PoE power limit for specific ports or channels. You can limit the PoE wattage available from an individual port or list of ports.

### Procedure

1. Enter Interface Configuration mode:
 

```
enable

configure terminal

interface GigabitEthernet {slot/port[/sub-port]} [-slot/port[/sub-port]]
[,...] or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure PoE channel limits:
 

```
poe poe-limit [port <portlist>] <power_limit>
```

*Variable definitions*

The following table defines parameters for the **poe-limit** command.

Variable	Value
<code>&lt;portlist&gt;</code>	Identifies the ports on which the limit is set.
<code>&lt;power_limit&gt;</code>	Specifies the configurable power limit, in watts on a particular port. To see the available range for the switch, use the CLI Help.

## Configuring Port Power Priority

### About This Task

Perform the following procedure to configure the PoE power priority for a port or list of ports. You can configure the PoE power priority of ports to manage availability of the connected PDs. If the switch needs to shut down PDs because PoE exceeds the power limit threshold, low priority devices are shut down before high priority, and high priority are shut down before critical.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure port power priority:

```
po e poe-priority [port <portlist>] {critical| high| low}
```

*Variable Definitions*

The following table defines parameters for the **po e-priority** command.

Variable	Value
<code>&lt;portlist&gt;</code>	Identifies the ports to set priority for.
<code>{low   high   critical}</code>	Identifies the PoE priority.

## Enable Fast PoE Globally

### About This Task

Perform this procedure to enable Fast PoE on the switch. After you enable Fast PoE, you must save the running configuration file.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable Fast PoE:

```
poe fast-poe-enable
```

3. Save the configuration file:

```
save config
```

## Enable Perpetual PoE Globally

### About This Task

Perform this procedure to enable Perpetual PoE on the switch. After you enable Perpetual PoE, you must save the running configuration file.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable Perpetual PoE:

```
poe perpetual-poe-enable
```

3. Save the configuration file:

```
save config
```

## Enable Fast PoE on a Port

### About This Task

Perform this procedure to enable Fast PoE on a specific copper port of the switch. After you enable Fast PoE, you must save the running configuration file.

**Procedure**

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

2. Enable Fast PoE on the copper port:

```
poE fast-poe-enable [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]]
```

3. Save the configuration file:

```
save config
```

*Variable Definitions*

The following table defines parameters for the **fast-poe-enable** command.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the port or ports to be configured.

**Enable Perpetual PoE on a Port****About This Task**

Perform this procedure to enable Perpetual PoE on a specific copper port of the switch. After you enable Perpetual PoE, you must save the running configuration file.

**Procedure**

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

2. Enable Fast PoE on the copper port:

```
poE perpetual-poe-enable [port {slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]]
```

3. Save the configuration file:

```
save config
```

*Variable Definitions*

The following table defines parameters for the **fast-poe-enable** command.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the port or ports to be configured.

## Display Global PoE Configuration

### About This Task

Perform the following procedure to display the global PoE configuration. You can view the global PoE status, power consumption, power limit threshold, and more.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the global configuration:  
show poe-main-status

### Example

```
Switch:1#show poe-main-status
=====
                          PoE Main Status - Stand-alone
=====
Available DTE Power       : 1855 Watts
DTE Power Status         : NORMAL
DTE Power Consumption     : 92 Watts
DTE Power Usage Threshold : 80
PD Detect Type           : 802.3at and Legacy
Power Source Present     : AC Only
Primary Power Status     : Present and operational
Redundant Power Status   : Present and Operational
Fast POE Status          : Enabled
Perpetual POE Status     : Enabled
POE Firmware Version:    : 3.0.0.6
```

## Displaying PoE Port Status

### About This Task

Perform the following procedure to display the PoE status for each port. You can use this information to view the status, classification, watts, and priority for each PoE port.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the port status:  
show poe-port-status

### Example

```
Switch:1#show poe-port-status
=====
```

```

=====
POE Port Status
=====
PORT      ADMIN  CURRENT          LIMIT          FAST PERPETUAL

-----
Port mgmt does not support DTE power
-----
1/1  Enable  DeliveringPower Class0          98      Low      Disable  Disable
1/2  Enable  DeliveringPower Class0          98      Low      Disable  Disable
1/3  Enable  DeliveringPower Class0          98      High     Disable  Disable
1/4  Enable  Searching        Class0          98      Low      Disable  Disable
1/5  Enable  Searching        Class0          98      Low      Disable  Disable
1/6  Enable  Searching        Class0          98      Low      Disable  Disable
1/7  Enable  Searching        Class0          98      Low      Disable  Disable
1/8  Enable  Searching        Class0          98      Low      Disable  Disable
1/9  Enable  Searching        Class0          98      Low      Disable  Disable
1/10 Enable  Searching        Class0          98      Low      Disable  Disable
    
```

**Note**

The PoE status of all ports is displayed. The preceding output is a sample of the full output.

## Displaying Port Power Measurement

### About This Task

Perform the following procedure to display the PoE power measurement. You can view the voltage, amperage, and wattage for every PoE port. PoE ports without a PD in use are measured as zeros.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View measurement information:  
show poe-power-measurement

### Example

```

Switch:1#show poe-power-measurement
=====
POE Port Measurement
=====
PORT  Volt (V)  CURRENT (mA)  POWER(Watt)
-----
1/1   34.0      117           6.200
1/2   34.0      94            5.000
1/3   34.0      535           28.500
1/4   0.0       0             0.000
1/5   0.0       0             0.000
1/6   34.0      525           27.900
    
```

1/7	34.0	152	8.100
1/8	34.0	49	2.600

**Note**

The PoE port measurement for all ports is displayed. The preceding output is a sample of the full output.

## Power over Ethernet configuration using EDM

This section provides details to configure PoE settings using EDM.

### Configure PoE Globally

#### About This Task

Configure PoE usage threshold and device type settings, and enable Fast PoE and Perpetual PoE globally on a switch.

**Important**

- After you enable Fast PoE or Perpetual PoE or both, you must save the running configuration file.
- If Fast PoE or Perpetual PoE are enabled and you change any other global or port-specific PoE settings, you must resave the running configuration file.

#### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **PoE** tab.
4. For **Usage Threshold%**, type the value in percentage for comparing the measured power.
5. For **PoweredDeviceDetectType**, select the PoE detection type depending on the capabilities of the switch.
6. Select **FastPoeEnable**.

**Note**

This step only applies to VSP 4900 Series.

7. Select **PerpetualPoeEnable**.

**Note**

This step only applies to VSP 4900 Series.

8. Select **Apply**.

**PoE** Field Descriptions

Use the data in the following table to use the **PoE** tab.

Name	Description
<b>Power(watts)</b>	Specifies the nominal power of the Power Sourcing Entity expressed in Watts.
<b>OperStatus</b>	Specifies the operational status of the main Power Sourcing Entity.
<b>ConsumptionPower(watts)</b>	Specifies the measured usage power expressed in Watts.
<b>UsageThreshold%</b>	Configures the usage threshold in percent for comparing the measured power and initiating an alarm if the threshold is exceeded.
<b>PoweredDeviceDetectType</b>	<p>Configures the mechanism used to detect powered ethernet devices attached to a powered ethernet port. The options are:</p> <ul style="list-style-type: none"> <li>• 802.3af</li> <li>• 802.3afAndLegacySupport</li> <li>• 802.3at</li> <li>• 802.3atAndLegacySupport</li> <li>• 802.3bt Type 3</li> <li>• 802.3bt Type 4</li> </ul> <p><b>Note:</b> The default detection type is automatically configured for the highest PoE standard supported on the switch.</p>
<b>PowerPresent</b>	<p>Specifies the current power source present on the switch. Available power sources are AC and DC.</p> <p>A value of <b>acOnly</b> indicates that the only power supply is AC.</p> <p>A value of <b>dcOnly</b> indicates that the only power supply is DC.</p> <p>A value of <b>acDc</b> indicates that the two power supplies, AC and DC are supplying power.</p>
<b>FastPoeEnable</b>  <b>Note:</b> Exception: only supported on VSP 4900 Series.	<p>Enables Fast PoE on the switch. The default is disabled.</p>
<b>PerpetualPoeEnable</b>  <b>Note:</b> Exception: only supported on VSP 4900 Series.	<p>Enables Perpetual PoE on the switch. The default is disabled.</p>

## Configure PoE on Ports

### About This Task

Enable or disable PoE on a port, and configure PoE priority and power limit settings.

#### Important

If Fast PoE or Perpetual PoE are enabled and you change any other global or port-specific PoE settings, you must resave the running configuration file.

### Procedure

1. In the Device Physical View, select one or more ports that support PoE. For information about which ports support PoE, see your hardware documentation.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **PoE** tab.
5. Configure the fields as required.
6. Click **Apply**.

### PoE Field Descriptions

Use the data in the following table to use the **PoE** tab.

Name	Description
<b>AdminEnable</b>	Enabled or disables PoE on this port.
<b>FastPoeEnable</b>  <b>Note:</b> Exception: only supported on VSP 4900 Series.	Enables or disables Fast PoE on this port. The default is disabled.
<b>PerpetualPoeEnable</b>  <b>Note:</b> Exception: only supported on VSP 4900 Series.	Enables or disables Perpetual PoE on this port. The default is disabled.
<b>DetectionStatus</b>	Specifies the operational status of the power device detecting mode on this port: <ul style="list-style-type: none"> <li>• Disabled—detecting function disabled</li> <li>• Searching—detecting function is enabled and the system is searching for a valid powered device on this port</li> <li>• DeliveringPower—detection found a valid powered device and the port is delivering power</li> <li>• Fault (OtherFault)—a power-specific fault has been detected on the port</li> <li>• Test—detecting device is in test mode</li> </ul>

Name	Description
<b>PowerClassifications</b>	Specifies the power classification of the device connected to this port. Power classification tags different terminals on the Power over LAN network according to their power consumption. Devices such as IP telephones, WLAN access points, and others can be classified according to their power requirements.
<b>PowerPriority</b>	Configures the power priority for this port: <ul style="list-style-type: none"><li>• critical</li><li>• high</li><li>• low</li></ul>
<b>PowerLimit(Watts)</b>	Configures the maximum power that the switch can supply to a port.
<b>Voltage(volts)</b>	Specifies the power measured in volts.
<b>Current(amps)</b>	Specifies the power measured in amps.
<b>Power(Watts)</b>	Specifies the power measured in watts.

# Power Savings

---

[Energy Saver](#) on page 2866

[Energy Efficient Ethernet](#) on page 2869

[Power Savings Configuration Using CLI](#) on page 2870

[Power Savings Configuration Using EDM](#) on page 2878

Power savings allow you to reduce network infrastructure power consumption during periods of low data activity without impacting network connectivity.

Depending on the power saving option you choose, you can implement power savings on a switch-wide, or on a per-port basis. The following power saving options are supported:

- Energy Saver (switch-wide or per-port)
- Energy Efficient Ethernet (EEE) (per-port only)

You must choose either Energy Saver, or Energy Efficient Ethernet (EEE)—you cannot use both options together.

The following sections describe the Energy Saver and Energy Efficient Ethernet (EEE) features, and how to configure them.

## Energy Saver

**Table 195: Energy Saver product support**

Feature	Product	Release introduced
Energy Saver	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4 Switch models: 5420F-24T-4XE, 5420F-24P-4XE, 5420F-48T-4XE, 5420F-48P-4XE, 5420F-48P-4XL, 5420F-8W-16P-4XE, 5420F-16W-32P-4XE, 5420F-16MW-32P-4XE, 5420M-24W-4YE, 5420M-48W-4YE, 5420M-24T-4YE, 5420M-48T-4YE, 5420M-16MW-32P-4YE
	5520 Series	VOSS 8.2.5 All fixed ports on 5520-24T, 5520-24W, 5520-48T, 5520-48W, and 5520-12MW-36W
	5720 Series	Fabric Engine 8.7
	7520 Series	7520-48XT-6C model only
	7720 Series	Not Supported
	VSP 4450 Series	VOSS 7.0
	VSP 4900 Series	VOSS 8.1 VSP4900-48P and ports 1/1 to 1/12 onVSP4900-12MXU-12XE only
	VSP 7200 Series	VOSS 7.0 VSP 7254XTQ only
	VSP 7400 Series	Not Supported
	VSP 8200 Series	Not Supported
	VSP 8400 Series	VOSS 7.0
	VSP 8600 Series	Not Supported
XA1400 Series	Not Supported	

To reduce direct power consumption by up to 40%, Energy Saver uses intelligent-switching capacity reduction in off-peak mode by controlling port link speeds and optionally powering off low priority Power over Ethernet (PoE) devices during off-peak periods. You can schedule Energy Saver to activate during multiple specific time

periods. These time periods can be as short as one minute, or can last a week, a weekend, or individual days.

**Note**

- Energy Saver is supported only on copper ports that have auto-negotiation enabled on them.
- If auto-negotiation is disabled on a port and a custom port speed is configured, Energy Saver will not change the speed of that port.

**Important**

- Configuring the port link speed to a low value impacts the overall network performance. The best practice is to use the Energy Saver feature during the hours when the network is not overburdened.
- If a switch is reset while Energy Saver is activated, the PoE power-saving calculation might not accurately reflect the power saving, and in some cases might display zero savings. This problem occurs because the switch did not have sufficient time to record PoE usage between the reset of the switch and the reactivation of Energy Saver. When Energy Saver is next activated, the PoE power saving calculation is correctly updated.
- When Energy Saver is active and you replace a unit, that unit will not be in Energy Saver mode. You must configure Energy Saver directly after replacing a unit.

## Interaction with PoE

Energy Saver can use Power over Ethernet (PoE) port-power priority levels to shut down low-priority PoE ports and provide power savings. The power consumption savings of each switch is determined by the number of ports with Energy Saver enabled, and by the power consumption of PoE ports that are powered off. If Energy Saver is disabled on a port, the port is not powered off, irrespective of the PoE configuration. Energy Saver turns off the power to a port only when PoE is enabled globally, the port Energy Saver is enabled, and the PoE priority for the port is configured to Low.

## Configuration Fundamentals

To fully configure and use Energy Saver, you must first enable Energy Saver on ports, create a schedule, and then enable Energy Saver globally.

Alternatively, you can configure Energy Saver using the Efficiency Mode quick configuration method, which enables Energy Saver on all ports, creates a default schedule, and enables Energy Saver globally.

You can manually deactivate and reactivate Energy Saver at any time, without affecting the port configurations.

**Note**

- Energy Saver is supported only on copper ports that have auto-negotiation enabled.
- Network Time Protocol (NTP) must be enabled and configured to use Energy Saver.

## Energy Efficient Ethernet

**Table 196: Energy Efficient Ethernet product support**

Feature	Product	Release introduced
Energy Efficient Ethernet (EEE)	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4 All fixed ports on 5420F-24T-4XE, 5420F-24P-4XE, 5420F-48T-4XE, 5420F-48P-4XE, 5420F-48P-4XL, 5420F-8W-16P-4XE, 5420F-16MW-32P-4XE, 5420M-24W-4YE, 5420M-48W-4YE, 5420M-24T-4YE, 5420M-48T-4YE, 5420M-16MW-32P-4YE
	5520 Series	VOSS 8.2.5 All fixed ports on 5520-24T, 5520-24W, 5520-48T, 5520-48W, and 5520-12MW-36W
	5720 Series	Fabric Engine 8.7
	7520 Series	Fabric Engine 8.10 7520-48XT-6C model only
	7720 Series	Not Supported
	VSP 4450 Series	Not Supported
	VSP 4900 Series	VOSS 8.1 All fixed ports on VSP4900-48P and ports 1/1-1/12 on VSP4900-12MXU-12XE
	VSP 7200 Series	Not Supported
	VSP 7400 Series	Not Supported
	VSP 8200 Series	Not Supported
	VSP 8400 Series	VOSS 8.1 8424GT ESM only
	VSP 8600 Series	Not Supported
XA1400 Series	Not Supported	

Energy Efficient Ethernet (EEE) supports the IEEE 802.3az standard for power savings in Ethernet networks for a select group of physical layer devices. A physical device that can support low power idle (LPI) mode is considered EEE-capable. Legacy devices that do not support EEE can be made EEE-compliant with an EEE-compliant PHY and an SDK version that allows the MAC device to interact with the PHY EEE functionality.

In a typical configuration, the EEE protocol communicates with the switch and the physical device to determine when to enter LPI mode during a period of inactivity, and to exit LPI mode when data transmission resumes.

**Note**

EEE is supported only on copper ports that have auto-negotiation enabled on them.

## Power Savings Configuration Using CLI

---

Configure Energy Saver or Energy Efficient Ethernet using the command line interface (CLI).

### Enable Energy Saver on Ports

#### About This Task

Perform this procedure to enable Energy Saver on a specific port or range of ports.

#### Before You Begin

- If you have previously enabled Energy Saver globally, you must disable it globally before enabling Energy Saver on individual ports.
- If you have previously enabled Efficiency Mode, you must disable it before enabling Energy Saver on individual ports.

#### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Energy Saver on the specified port:

Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port).

```
energy-saver port {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} enable
```

## Example

Enable energy savings on slot 1 port 2:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface GigabitEthernet 1/2
Switch:1(config-if)#energy-saver port 1/2 enable
```

## What to Do Next

Configure an Energy Saver schedule.

### Variable Definitions

The following table defines parameters for the **energy-saver** command.

Variable	Value
<i>enable</i>	Enables energy savings on ports. The default is disabled.
<i>{slot/port[/sub-port][-slot/port[/sub-port]][,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Create an Energy Saver Schedule

### About This Task

Perform this procedure to configure scheduled time intervals during which the switch will operate in low power state. This time interval can be for a week, weekend, or individual days.

#### Note

You can configure a maximum of 84 entries in the Energy Saver schedule.

### Before You Begin

- If you have previously enabled Energy Saver globally, you must disable it globally before creating a schedule.
- If you have previously enabled Efficiency Mode, you must disable it before creating a schedule. You cannot change the default Efficiency Mode schedule entries when Efficiency Mode is enabled.
- You must enable Energy Saver on every port affected by the schedule.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the Energy Saver schedule:  

```
energy-saver schedule {friday | monday | saturday | sunday | thursday | tuesday | wednesday | weekday | weekend} <hhmm> {activate | deactivate}
```

### Example

Configure an Energy Saver schedule:

```
Switch:1>enable
Switch:1# configure terminal
Switch:1(config)#energy-saver schedule weekend 0735 activate
Switch:1(config)#energy-saver schedule monday 0600 deactivate
```

### What to Do Next

Enable Energy Saver globally.

#### Variable Definitions

The following table defines parameters for the **energy-saver schedule** command.

Variable	Value
<i>{activate   deactivate}</i>	Activates or deactivates the scheduled event.
<i>&lt;hhmm&gt;</i>	Specifies the hour and minutes to enable Energy Saver feature on the switch.
<i>{friday   monday   saturday   sunday   thursday   tuesday   wednesday   weekday   weekend}</i>	Specifies the day(s) to enable Energy Saver feature on the switch.

## Enable Energy Saver Globally

### About This Task

Perform this procedure to enable Energy Saver globally on the switch. You can optionally configure PoE power savings, to power off low priority PoE devices during off-peak times.

### Before You Begin

- You must enable Energy Saver on individual ports.
- You must create an Energy Saver schedule.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. (Optional) Configure PoE power savings:  

```
energy-saver poe-power-saving
```

**Note**

You must configure PoE power savings before you enable Energy Saver globally.

3. Enable Energy Saver:  

```
energy-saver enable
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#energy-saver poe-power-saving
Switch:1(config)#energy-saver enable
```

*Variable Definitions*

The following table defines parameters for the **energy-saver** command.

Variable	Value
<i>enable</i>	Enables Energy Saver feature. The default is disabled.
<i>poe-power-saving</i>	Enables PoE power saving. The default is disabled.

## Enable and Configure Energy Saver using Quick Configuration

**About This Task**

Perform this procedure to enable and configure Energy Saver globally using the quick configuration Efficiency Mode. Efficiency Mode automatically configures the following:

- enables Energy Saver on all ports.
- creates a default schedule with a weekday schedule of Energy Saver activated from 6:00 p.m. to 7:30 a.m., and during weekends. You cannot change this default schedule while Efficiency Mode is enabled.
- enables Energy Saver globally.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```

## 2. Enable efficiency mode:

```
energy-saver efficiency-mode
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#energy-saver efficiency-mode
```

*Variable Definitions*

The following table defines parameters for the **energy-saver** command.

Variable	Value
<i>efficiency-mode</i>	Enables efficiency mode. The default is disabled.

## Activate or Deactivate Energy Saver Manually

**About This Task**

Perform this procedure to activate or deactivate Energy Saver on the switch at any time. Energy Saver is deactivated by default.

Activating Energy Saver reduces the port speed to the minimum value supported by the switch and enables PoE power saving, even if PoE is globally disabled. Deactivating Energy Saver restores the previous configuration.

**Before You Begin**

Before you can change any previously saved Energy Saver settings, you must disable Energy Saver globally.

**Procedure**

## 1. Enter Privileged EXEC mode:

```
enable
```

## 2. Activate or deactivate Energy Saver:

```
energy-saver {activate | deactivate}
```

**Example**

```
Switch:1> enable
```

## Activate Energy Saver:

```
Switch:1# energy-saver activate
```

## Deactivate Energy Saver:

```
Switch:1# energy-saver deactivate
```

### Variable Definitions

The following table defines parameters for the **energy-saver** command.

Variable	Value
<code>activate</code>	Activates Energy Saver manually.
<code>deactivate</code>	Deactivates Energy Saver manually.

## Energy Saver Show Commands

Use the procedures in this section to display specific information about Energy Saver configuration on the switch.

### Display Energy Saver Global Information

#### About This Task

Perform this procedure to display information about Energy Saver global configuration.

#### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Display global configuration:  
`show energy-saver global`

#### Example

```
Switch:1#show energy-saver global
Energy Saver: Disabled
Energy Saver PoE Power Saving Mode: Disabled
Energy Saver Efficiency-Mode Mode: Disabled
Day/Time: Wednesday 02:31:12
Current Energy Saver state: Energy Saver is Inactive
```

### Display Energy Saver Interface Information

#### About This Task

Perform this procedure to display information about Energy Saver configuration on the ports.

#### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Display information about all ports or specify a particular port:  
`show energy-saver interface [slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]`

#### Example

```
Switch:1>enable
Switch:1#show energy-saver interface
Port ES State PoE Savings PoE Priority
```

```

-----
1/1      Enabled  Enabled  Low
1/2      Enabled  Enabled  Low
1/3      Enabled  Enabled  Low
1/4      Enabled  Enabled  Low
1/5      Enabled  Enabled  Low
1/6      Enabled  Enabled  Low
1/7      Enabled  Enabled  Low
1/8      Enabled  Enabled  Low
1/9      Enabled  Enabled  Low
1/10     Enabled  Enabled  Low
1/11     Enabled  Enabled  Low
1/12     Enabled  Enabled  Low
1/13     Disabled N/A      N/A
1/14     Disabled N/A      N/A
1/15     Disabled N/A      N/A

```

### Display Energy Saver Power Savings Information

#### About This Task

Perform this procedure to display information about Energy Saver power savings on the switch.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display information about energy savings:  
show energy-saver savings

#### Example

```

Switch:1#show energy-saver savings
-----
Unit Model          Switch Capacity      Saving PoE Saving
-----
8404C                0.0 watts            N/A
=====

```

### Display Energy Saver Schedule Information

#### About This Task

Perform this procedure to display information about Energy Saver schedules configured on the switch.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display information about Energy Saver schedules:  
show energy-saver schedule

#### Example

```

Switch:1#show energy-saver schedule
-----
Day      Time  Action
-----

```

```
Monday 18:00 Activate
Monday 07:00 Deactivate
```

## Enable Energy Efficient Ethernet (EEE)

### About This Task

Perform this procedure to enable Energy Efficient Ethernet (EEE) on a port. The default is disabled.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable Energy Efficient Ethernet:

```
energy-saver eee enable
```

## Display Energy Efficient Ethernet (EEE) Statistics

### About This Task

Perform this procedure to display information about Energy Efficient Ethernet (EEE) statistics for all ports on a switch, or for a specific port.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display information about all ports or specify a particular port:

```
show energy-saver eee statistics [{slot/port[/sub-port] [-slot/port[/
sub-port]] [,...]]
```

### Example

```
Switch:1>show energy-saver eee statistics
```

```
=====
EEE Port Status
=====
```

PortId	EEE Status	Tx LPI Events	Tx Idle Duration (micro seconds)	Rx LPI Events	Rx Idle Duration (micro seconds)
1/1	enabled	847	963657920	115	965100020

*Variable Definitions*

Use the data in following table to use the `show energy-saver eee statistics` command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Clear Energy Efficient Ethernet (EEE) Statistics

### About This Task

Perform this procedure to clear information about Energy Efficient Ethernet (EEE) statistics for all ports on a switch, or for a specific port.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Clear Energy Efficient Ethernet statistics on all ports or specify a particular port:

```
clear energy-saver eee stats [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

*Variable Definitions*

Use the data in following table to use the `clear energy-saver eee stats` command.

Variable	Value
<code>port</code>	Specifies one or more ports.
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Power Savings Configuration Using EDM

Use the following procedures to configure either Energy Saver or Energy Efficient Ethernet EEE using Enterprise Device Manager (EDM).

## Enable Energy Saver Globally

### About This Task

Perform this procedure to enable Energy Saver globally.

### Procedure

1. In the navigation pane, expand **Configuration > Power Management**.
2. Click **Energy Saver**.
3. Click the **Energy Saver Globals** tab.
4. Configure the fields as required.
5. Click **Apply**.

### *Energy Saver Globals* Field Descriptions

Name	Description
<b>EnergySaverEnabled</b>	Enables Energy Saver globally on the switch. The default is disabled.
<b>PoePowerSavingEnabled</b>	Enables Energy Saver PoE power saving. The default is disabled.
<b>EfficiencyModeEnabled</b>	Enables Energy Saver efficiency mode. The default is disabled. Efficiency mode enables Energy Saver globally and on all ports, it also enables PoE power saving. It also creates a weekday schedule that starts at 6:00 p.m. and ends at 7:30 a.m., and during the weekend Energy Saver is always activated.
<b>EnergySaverActive</b>	Activates Energy Saver on the switch. Energy Saver is deactivated by default.

## Configure Energy Saver Schedule

### About This Task

Perform this procedure to configure a scheduled time interval during which the switch will operate in low power state. This time interval can be for a week, weekend, or individual days.

#### Note

- You can configure maximum 84 entries in the Energy Saver schedule.
- If efficiency mode is enabled, you cannot configure any other entries in the Energy Saver schedule.

### Before You Begin

- You must disable Energy Saver globally.
- You must enable Energy Saver on every port affected by the schedule.
- You must deactivate Energy Saver efficiency-mode.

### Procedure

1. In the navigation pane, expand **Configuration > Power Management**.
2. Click **Energy Saver**.
3. Click the **Energy Saver Schedules** tab.
4. Click **Insert**.
5. Configure the fields as required.
6. Click **Insert**.
7. Click **Apply**.

### *Energy Saver Schedules Field Descriptions*

Name	Description
<b>ScheduleDay</b>	Specifies the day on which Energy Saver is activated or deactivated. The options are: <ul style="list-style-type: none"> <li>• <b>monday</b></li> <li>• <b>tuesday</b></li> <li>• <b>wednesday</b></li> <li>• <b>thursday</b></li> <li>• <b>friday</b></li> <li>• <b>saturday</b></li> <li>• <b>sunday</b></li> <li>• <b>weekdays</b></li> <li>• <b>weekend</b></li> </ul>
<b>ScheduleHour</b>	Specifies the hour at which Energy Saver is activated or deactivated. The range is 0 to 23.  <b>Note:</b> 0 is equivalent to 12 a.m., and 12 is equivalent to 12 p.m.
<b>ScheduleMinute</b>	Specifies the minute at which Energy Saver is activated or deactivated. The range is 0 to 59.
<b>ScheduleAction</b>	Specifies if Energy Saver is activated or deactivated. The options are: <ul style="list-style-type: none"> <li>• <b>activate</b></li> <li>• <b>deactivate</b></li> </ul>

## Enable Energy Saver or EEE on Ports

You can enable Energy Saver or EEE using the Energy Saver tab accessed by the Edit navigation path, or the Power Management navigation path. Use one of the following procedures to enable either Energy Saver or EEE on ports.

### *Enable Energy Saver or EEE on Ports*

#### About This Task

Perform this procedure to enable Energy Saver or EEE on one or more ports.

#### Procedure

1. On the Device Physical View tab, select one or more ports.
2. In the navigation pane, expand **Edit > Port**.
3. Select **General**.
4. Select the **Energy Saver** tab.
5. Enable either Energy Saver or EEE:
  - To enable Energy Saver, select **EnergySaverEnabled**.
  - To enable EEE, select **EnergySaverEEEEEnable**.
6. Select **Apply**.

#### Energy Saver Field Descriptions

Use the data in the following table to use the **Energy Saver** tab.

Name	Description
<b>Port</b>	Specifies the port number.
<b>EnergySaverEnabled</b>	Configures whether Energy Saver is enabled on the specific port.
<b>EnergySavedPoeStatus</b>	Specifies the Energy Saver PoE status for the specific port.
<b>EnergySaverEEEEEnable</b>	Configures whether EEE is enabled on the specific port.

### *Enable Energy Saver or EEE on Ports*

#### About This Task

Perform this procedure to enable Energy Saver or EEE on one or more ports.

#### Procedure

1. In the navigation pane, expand **Configuration > Power Management**.
2. Select **Energy Saver**.
3. Select the **Ports** tab.
4. Enable either Energy Saver or EEE:
  - To enable Energy Saver, in the **EnergySaverEnabled** column, double-click the field associated with the specific ports, and then select **true**.
  - To enable EEE, in the **EnergySaverEEEEEnable** column, double-click the field associated with the specific ports, and then select **true**.

5. Select **Apply**.

### Energy Saver Field Descriptions

Use the data in the following table to use the **Energy Saver** tab.

Name	Description
<b>Port</b>	Specifies the port number.
<b>EnergySaverEnabled</b>	Configures whether Energy Saver is enabled on the specific port.
<b>EnergySaverPoEStatus</b>	Specifies Energy Saver PoE status for the specific port.
<b>EnergySaverEEEEEnable</b>	Configures whether EEE is enabled on the specific port.

## View Energy Savings

### About This Task

Perform this procedure to view the amount of switch capacity and PoE power being saved on the units.

### Procedure

1. In the navigation pane, expand **Configuration > Power Management**.
2. Click **Energy Saver**.
3. Click the **Energy Savings** tab.

### *Energy Savings field descriptions*

Name	Description
<b>UnitIndex</b>	Specifies the unit number.
<b>UnitSavings(1/10 watts)</b>	Specifies the amount of switch capacity power being saved on the specific unit.
<b>PoeSavings(1/10 watts)</b>	Specifies the amount of PoE power being saved on the specific unit.

## Display Energy Efficient Ethernet Statistics

Perform this procedure to display information about Energy Efficient Ethernet (EEE) statistics for all ports on a switch, or for a specific port.

### Procedure

1. In the navigation pane, expand **Configuration > Power Management**.
2. Select **Energy Saver**.
3. Select the **EEE Statistics** tab.
4. (Optional) Select **Clear Stats** to clear information about EEE statistics.

**EEE Statistics** *Field Descriptions*

The following table describes parameters on the **EEE Statistics** tab.

Name	Description
<b>Port</b>	Shows the port number.
<b>State</b>	Shows the state of Energy Efficient Ethernet (EEE) on the port.
<b>TxEvents</b>	Shows the EEE Tx event count for the port.
<b>TxDuration</b>	Shows the EEE Tx durations for the port.
<b>RxEvents</b>	Shows the EEE Rx event count for the port.
<b>RxDuration</b>	Shows the EEE Rx durations for the port.

# Quality of Service

---

[QoS fundamentals](#) on page 2884

[Basic DiffServ configuration using CLI](#) on page 2921

[Basic DiffServ configuration using EDM](#) on page 2926

[QoS configuration using CLI](#) on page 2928

[QoS configuration using EDM](#) on page 2952

This section provides conceptual and procedural information about Quality of Service (QoS).

## QoS fundamentals

---

Use the information in this section to help you understand Quality of Service (QoS).

This section describes a range of features that you can use on the switch to manage traffic flowing through your network. You can configure your network to prioritize specific types of traffic to ensure that the traffic receives the appropriate QoS level. For those cases where traffic levels are so high that congestion occurs despite management, the switch provides additional congestions handling features that are described in this section.

QoS refers to the ability to control network flows either by prioritizing traffic or by guaranteeing performance levels. QoS does not refer to a specifically achieved service quality. To provide QoS, you can use some combination of the switch's traffic management tools to help deliver provisioned network QoS. It is up to the network administrator to accurately analyze a given situation and select the proper tool(s) for the task.

## Introduction to QoS

The switch comes with a set of traffic management tools that you can use to provide QoS for Layer 2 (bridged) or Layer 3 (routed) traffic flows. Many of these flows are multiplexed across a set of network switches and compete for network resources at convergence points. Without traffic management, the congested data flows compete for resources and the result is unpredictable. The resulting QoS can only be described as best-effort. The opposite is also true, without congestion there are sufficient network resources for all traffic to pass without competition. Without congestion, traffic management is not required. In this sense, you cannot separate discussions about QoS and traffic management from those on congestion. The switch provides a set of tools

that you can use to provide network services that are far superior to best-effort thereby enabling the delivery of provisioned QoS.

To deliver QoS, the switch uses two types of traffic management tools:

- Congestion management
- Congestion handling

**Congestion management** acts to prevent congestion by prioritizing traffic flows through priority queuing and priority-aware servicing methods. Other functions, such as policing, are also considered congestion management. Policing indirectly prioritizes some traffic by limiting the rates of other traffic.

**Congestion handling** alleviates existing congestion by dropping lower priority traffic before higher priority traffic. The switch handles the congestion by queue-specific tail dropping. The basic QoS architecture of the switch identifies three primary functional areas:

- Ingress QoS identification and classification
- the switch's internals and queuing architecture
- QoS marking/remarking for downstream use

#### Important

Remarking packets with an ACL filter does not change the internal QoS level of the packets. You must add the **permit internal-qos [value]** statement to the ACL filter.

The QoS architecture is coherent end-to-end across a network. The QoS at any particular network element can be marked in the relevant Layer 2 or Layer 3 protocol fields and provided to the next hop. The receiving next hop can then use this information to classify its own ingress traffic, apply its specific internal traffic management features, and remark the results for subsequent hops.

Depending on the product, the QoS implementation on the switch can support the following options:

1. Ingress priority mappings including: DSCP to internal QoS, 802.1p-bits to internal QoS, and port-level QoS configuration.
2. Egress priority mappings including: internal QoS to DSCP and internal QoS to 802.1p-bits.
3. Automatic QoS
4. Port-based rate limiting or ingress policers

#### Note

The VSP 7400 Series does not support port-based rate limiting or ingress policers.

5. Port-based broadcast and multicast rate limiting
6. Port-based egress shaping
7. Egress queue rate limiting

For information about feature support, see [Fabric Engine and VOSS Feature Support Matrix](#).

### *Traffic management*

Prioritized traffic handling requires QoS classification first. The switch typically classifies traffic by using the endpoint switch configuration in conjunction with the protocol elements of the incoming frame such as *priority*. You can add additional classification by using access control lists (ACLs) and other filtering functionality.

The switch's internal traffic management functions use the results of classification to determine the prioritization of traffic. Examples of internal functions that prioritize traffic would be both strict and weighted round robin (WRR) queue scheduling. These mechanisms prioritize data by favorable scheduling or weighting.

The disposition of a particular data frame is not necessarily fully determined as a result of classification. You can apply additional traffic management functions such as Ingress Port Rate Limiting or Policing depending on your switch features. Ingress Port Rate Limiting is a congestion management mechanism to limit the traffic rate accepted by the specified ingress port. Policing is a congestion management method that limits incoming traffic at the ingress that could cause congestion at the egress. While queuing strategies affect prioritization by favoring some traffic; policing is essentially the opposite. Policing works not by favoring some traffic, but by penalizing the bursty traffic. Queue scheduling and policing are only two of the available tools for congestion management. Additional details are presented in subsequent sections of this document.

In addition to the traffic management tools which aid in the prevention of congestion, tools are also provided to handle congestion as it occurs. Congestion handling tools monitor congestion levels at convergence points in the switch and selectively discard frames if congestion begins to increase. Per queue tail dropping is the primary congestion handling function of the switch. You can also use ACLs and filtering as congestion handling tools.

*Differentiated Services (DiffServ)***Table 197: Differentiated Services product support**

Feature	Product	Release introduced
Differentiated Services (DiffServ) including Per-Hop Behavior	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	VSP 4450 Series	VSP 4000 4.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VSP 8200 4.0
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	VOSS 8.0.50

Differentiated Services (DiffServ) is a traffic management tool that classifies network traffic into eight traffic classes, and then gives each class differentiated treatment. DiffServ networks map the traffic's class into a set of packet forwarding behavior, referred to as a *Per-Hop Behavior (PHB)*. A PHB could specify which egress queue to use. For example, a switch may classify a packet by determining its protocol to be IPv4, subsequently extract the DSCP value, and apply a PHB by directing the packet to a specific queue. DiffServ does not prescribe a set of traffic classes and does not predetermine which types of traffic should be handled by a given class. DiffServ simply provides a generic means of classifying packets so they may be treated differently.

DiffServ applies to IP packets only.

**DiffServ Access and DiffServ Core**

A fundamental characteristic of DiffServ networks is the distinction made between switches at the network edges and those residing in the network interior. The switch refers to this distinction as DiffServ Access (edge) and DiffServ Core (interior), respectively.

It is important to note that the switch operates simultaneously as both a DiffServ Access switch and a DiffServ Core switch. The architectural premise is that the edge or access nodes perform the bulk of the work (classification, policing, etc.) and mark the packet for downstream processing. In theory this would permit the interior or core switches to bypass much of the edge processing as they would "trust" the classification

and marking performed by the access switch. The notion of trust is key to the access/core switch distinction.

- If you configure a port as an access port, the system does not trust packet markings.
- If you configure a port as a core port, the system trusts packet markings.

On the access side, malicious users can send packets into a network with intent to cause serious harm (e.g., denial of service attacks). However, on core switches, the only traffic sources are one's own upstream switches. As such, a core switch has the opportunity to trust the classification, markings (and implied PHB) determined by the previous hop.

The following figure shows DiffServ network operations. The devices are on the network edge where they perform classification, marking, policing, and shaping functions.

**Figure 217: DiffServ network core and edge devices**

Use a DiffServ Access port at the edge of a DiffServ network. The access port classifies traffic according to port QoS. Outgoing packet DSCP and 802.1p values are derived from port QoS and QoS maps. The system strips Dot1Q headers at ingress, and adds them back at egress only if you configure the egress port as a tagged or trunk port.

A DiffServ Core port does not change packet classification or markings; the port trusts the incoming traffic markings. A core port preserves the DSCP marking of all incoming packets, and uses these markings to assign the packet to an internal QoS level. For tagged packets, the port honors the 802.1p bits within a Dot1Q header, and uses these bits to classify ingress traffic. You can control the honoring (or not) of 802.1p bits by configuring the 802.1p override.

#### Per-Hop Behavior (PHB)

Traffic entering the DiffServ network enter a queue according to their marking, which determines the PHB of the packets. For example, if the system marks a video stream to receive the highest priority, it enters a high-priority queue. As these packets traverse the DiffServ network, the system forwards the video stream before other packets.

As a standard, DiffServ is described in the context of Layer 3. Classification is accomplished by mapping a packet priority field from the packet and then applying a per-hop behavior. DiffServ standards define the IPv4 header's Differentiated Services Code Point (DSCP) field to determine classification and subsequent per-hop behavior.

The RFC2598 standard provides only the following four fundamental per-hop behaviors:

- Default (DF) — This PHB provides best-effort forwarding behavior.
- Expedited Forwarding (EF) — This PHB provides performance-critical forwarding.
- Assured Forwarding (AF) — This PHB classifies traffic based upon **class** (priority) only.

#### **Important**

The switch never classifies nor takes action based upon drop precedence. In response to congestion, the only drops available for a given traffic class are tail drops.

- Class Selector (CS) — This PHB provides a simple mapping of a DSCP to one of eight traffic classes. While the switch provides all four PHBs, the CS PHB is most analogous to the switch's internal processing – classification occurs to derive priority, which subsequently determine the per-hop behavior (e.g., queuing).

#### **DiffServ and filters**

QoS (DiffServ) and filters operate independently; you do not have to use filters to provide QoS. However, filters can override QoS operations. For more information, see [Traffic filtering fundamentals](#) on page 3695.

#### **DiffServ and VXLAN Gateway**

DSCP bits in the outer IP header of VXLAN-encapsulated packets are always derived from the internal QoS, irrespective of the ingress port DiffServ configuration. Customer packet IP DSCP bits are not modified as part of VXLAN encapsulation. For more information about VXLAN, see [VXLAN Gateway](#) on page 4273.

#### *Traffic traversing the switch*

The switch's traffic management capabilities are best understood by examining the functionality that is invoked as packets flow from ingress ports, through the switch, to egress ports. The following list includes the set of features and processing that the switch performs as flows traverse the switch:

- Classification and ingress mapping
- Filtering
- Rate Limiting or Policing
- Queuing
- Remarking
- Shaping

The switch classifies packets to determine their priority. While DiffServ is traditionally defined as Layer 3 functionality, the switch extends the logical concept to Layer 2. The switch can, based upon user configuration, determine a packet's priority from either its Layer 2 (p-bits) or Layer 3 (DSCP) information.

- If the packet arrives on an untrusted port (DiffServ Access), then the packet's priority comes from user-configured parameters such as port priority.
- If the packet arrives on a trusted port, priority comes from information contained in the packet's header (p-bits or DSCP).

After the switch determines the packet's configured or marked priority, it maps that value to be used internally. The QoS level used by the switch is referred to as the **Internal QoS Level (IQL)**. The IQL is the internal numerical value that the switch uses to determine the packets per-hop behaviors such as queue selection and bandwidth guarantee.

The following list identifies the order of DiffServ operations for a packet:

- Packet classification: IEEE 802.1p and DSCP markings classify (map) the packet to its appropriate PHB and QoS level.
- Remarking: The switch can remark packets according to QoS actions you configure on the switch (internal QoS mappings).
- Shaping: The switch provides port-based shaping. Port-based shaping shapes all outgoing traffic to a specific rate.

## Classification and mapping

Traffic classification includes functions that examine a packet to determine further actions according to defined rules. Classification involves identifying flows so that the router can modify the packet contents or Per-Hop Behavior (PHB), apply conditioning treatments to the packet, and determine how to forward the packet to the egress interface. Packet classification depends on the service type of the packet and the point in the traffic management process where the classification occurs.

The device classifies traffic as it enters the DiffServ network, and assigns appropriate PHB based on the classification. To differentiate between classes of service, the device marks the DiffServ (DS) parameter in the IP packet header, as defined in RFC2474 and RFC2475. The DSCP marking defines the forwarding treatment of the packet at each network hop. This marking (or classification) occurs at the edge of the DiffServ domain, and is based on the policy (or filter) associated with the particular microflow or aggregate flow.

You can configure the mapping of DSCP-to-forwarding behaviors and DSCP re-markings. Re-marking the DSCP resets the treatment of packets based on new network specifications or desired levels of service.

Layer 3 marking uses the DSCP parameter. Layer 2 (Ethernet) marking involves the 802.1p-bits parameter.

For Layer 2 packets, priority bits (or 802.1p bits) define the traffic priority of the Ethernet packet. You can configure an interface to map DSCP or 802.1p bits to internal QoS levels on ingress. You can configure an interface to map internal QoS levels to DSCP or 802.1p bits at egress. 802.1p bit mapping provides the Ethernet VLAN QoS requirements.

Within the network, a packet PHB associated with the DSCP determines how a device forwards the packet to the next hop—if at all. Consequently, nodes can allocate buffer and bandwidth resources to each competing traffic stream. The initial DSCP value is based on network policies for the type of service required. The objective of DSCP-to-Service Class mapping is to translate the QoS characteristics defined by the packet DSCP marker to a Service Class. The DSCP-to-Service Class mapping occurs at ingress. For each received packet, the mapping function assigns a Service Class.

The switch maintains four mapping tables. These tables translate the ingress 802.1p-bits or DSCP markings to an internal QoS level, and then retranslate the internal QoS level to an egress DSCP or 802.1p-bits marking as follows:

- ingress 802.1p-bits to QoS level
- ingress DSCP to QoS level
- QoS level to egress 802.1p-bits
- QoS level to egress DSCP

### *Service classes*

Service classes define a standard architecture to provide end-to-end QoS on a broad range of Ethernet switching and voice products. They function as default QoS policies built into the product. They incorporate the various QoS technologies to provide a complete end-to-end QoS behavioral treatment. The switch includes a built-in QoS implementation for service classes.

The switch includes eight preconfigured queues (corresponding to the eight service classes) on each port of an interface module.

A service class domain classifies traffic as one of the following:

- Network control traffic (Critical/Network)
- Subscriber traffic (Premium, Metal, or Standard)

#### **Queue 7 — Critical/Network Service Class (PHB of CS6/CS7)**

The switch uses the Critical/Network Service Class for traffic within a single administrative network domain. If such traffic does not get through, the network cannot function.

#### **Queue 6 — Premium Service Class (PHB of CS5/EF)**

The switch uses the Premium Service Class for IP telephony services, and provides the low latency and low jitter required to support such services. IP telephony services include Voice over IP (VoIP), voice signaling, Fax over IP (FoIP), and voice-band data services over IP (for example, analog modem). The switch can also use the Premium Service Class for Circuit Emulation Services over IP (CESoIP).

#### **Metal Service Classes**

The Platinum, Gold, Silver, and Bronze Service Classes are collectively referred to as the metal classes. The metal Service Classes provide a minimum bandwidth guarantee and are for variable bit rate or bursty types of traffic. Applications that use the metal Service Class support mechanisms that dynamically adjust their transmit rate and burst size based on congestion (packet loss) detected in the network. The following list describes the individual metal classes:

- Queue 5 — Platinum Service Class (PHB of CS4/AF41)

The switch uses the Platinum Service Class for applications that require low latency, for example, real-time services such as video conferencing and interactive gaming. Platinum Service Class traffic provides the low latency required for interhuman (interactive) communications. The Platinum Service Class provides a minimum

bandwidth assurance for Assured Forwarding (AF) 41 and Class Selector (CS) 4-marked flows.

- Queue 4 — Gold Service Class (PHB of CS3/AF31)

The switch uses the Gold Service Class for applications that require near-real-time service and are not as delay-sensitive as applications that use the Platinum service. Such applications include streaming audio and video, video on demand, and surveillance video.

The Gold Service Class assumes that traffic buffers at the source and destination and, therefore, the traffic is less sensitive to delay and jitter. By default, the Gold Service Class provides a minimum bandwidth assurance for AF31, AF32, AF33 and CS3-marked flows.

- Queue 3— Silver Service Class (PHB of CS2/AF21)

The switch uses the Silver Service Class for responsive (typically client- and server-based) applications. Such applications include Systems Network Architecture (SNA) terminals (for example, a PC or Automatic Teller Machine) to mainframe (host) transactions that use Data Link Switching (SNA over IP), Telnet sessions, web-based ordering and credit card processing, financial wire transfers, and Enterprise Resource Planning applications.

Silver Service Class applications require a fast response and have asymmetrical bandwidth needs. The client sends a short message to the server and the server responds with a much larger data flow back to the client. For example, after a user clicks a hyperlink (that sends a few dozen bytes) on a webpage, a new webpage opens (that downloads kilobytes of data). The Silver Service Class provides a minimum bandwidth assurance for AF21 and CS2-marked flows.

The Silver Service Class favors short-lived, low-bandwidth TCP-based flows.

- Queue 2 — Bronze Service Class (PHB of CS1/AF11)

The switch uses the Bronze Service Class for longer-lived TCP-based flows, such as file transfers, e-mail, or noncritical Operation, Administration, and Maintenance (OAM) traffic. The Bronze Service Class provides a minimum bandwidth assurance for AF11 and CS1-marked flows. As a best practice, use the Bronze Service Class for noncritical OAM traffic with the CS1 DSCP marking.

#### **Queue 1 and 0 — Standard (PHB of CS0/DF) and Custom Service Classes**

The switch uses the Standard and Custom Service Classes for best-effort services. Delays, loss, or jitter guarantees for these service classes are not specified. However, the Standard Service Class has more forwarding resources than the custom service classes.

#### *Internal QoS level*

The internal QoS level or effective QoS level is a key element in the switch QoS architecture. The internal QoS level specifies the kind of treatment a packet receives. The switch classifies every packet that enters and assigns it an internal QoS level.

Internal QoS levels map to the queues on a port. For example, for an access port the internal QoS level is derived from the port QoS level. For Layer 3 trusted (core) ports,

the system honors incoming DSCP or type of service (TOS) bits. The system assigns the internal QoS level using the ingress DSCP to QoS level map.

### Important

Remarking packets with an ACL filter does not change the internal QoS level of the packets. You must add the **permit internal-qos [value]** statement to the ACL filter. For more information, see [Internal QoS Level and Remarking](#) on page 3713.

### Ingress mappings

The system uses ingress maps to translate incoming packet QoS markings to the internal QoS level. The system uses the internal QoS level to classify packets.

Ingress mappings include

- 802.1p to (internal) QoS level
- DSCP to (internal) QoS level

The following logical table shows how the system performs ingress mappings for data packets and for control packets not destined for the Control Processor (CP).

**Table 198: Data packet ingress mapping**

DSCP	Layer 2 trusted	Layer 3 trusted (DiffServ enabled and Access-diffserv disabled)	IP packet	Routed packet	Ingress tagged	Internal QoS
x	No	x	No	x	x	Use port QoS
x	Yes	x	No	x	No	Use port QoS
x	Yes	x	No	x	Yes	Use ingress p-bits mapping
0x1B	x	x	Yes	x	x	4
0x23	x	x	Yes	x	x	5
0x29	x	x	Yes	x	x	5
0x2F	x	x	Yes	x	x	6
x	No	No	x	x	x	Use port QoS
x	No	Yes	Yes	x	x	Use ingress DSCP mapping

**Table 198: Data packet ingress mapping (continued)**

DSCP	Layer 2 trusted	Layer 3 trusted (DiffServ enabled and Access-diffserv disabled)	IP packet	Routed packet	Ingress tagged	Internal QoS
x	Yes	No	Yes	x	No	Use port QoS
x	Yes	No	Yes	x	Yes	Use ingress p-bits mapping
x	Yes	Yes	Yes	No	No	Use ingress DSCP mapping
x	Yes	Yes	Yes	No	Yes	Use ingress p-bits mapping
x	Yes	Yes	Yes	Yes	Yes	Use ingress DSCP mapping

**Important**

On a tagged port that is Layer-2 trusted, Layer-3 trusted and DiffServ enabled, all multicast packets honor the ingress DSCP value.

The QoS level for control packets destined for the CPU is assigned internally to ensure timely packet processing and scaling numbers. You cannot configure the QoS level for these control packets. The system assigns the highest QoS-level to time-critical protocols.

The following table shows ingress IEEE 802.1p to QoS level mappings.

**Table 199: Default ingress 802.1p to QoS mappings**

Ingress IEEE 802.1p	PHB	QoS Level	Network Service Class (NSC)
0	CS0/DF	1	Standard
1	Custom	0	Custom
2	CS1/AF11	2	Bronze
3	CS2/AF21	3	Silver
4	CS3/AF31	4	Gold

**Table 199: Default ingress 802.1p to QoS mappings (continued)**

Ingress IEEE 802.1p	PHB	QoS Level	Network Service Class (NSC)
5	CS4/AF41	5	Platinum
6	CS5/EF	6	Premium/EF
7	CS6/CS7	7	Network/Critical

The following table shows DSCP to internal QoS level mappings.

**Table 200: Default ingress DSCP to QoS mapping**

Ingress				Internal QoS level	PHB level
DSCP (decimal)	DSCP (binary)	DSCP (hexadecimal)	TOS (hexadecimal)		
00	000000	00	00	1	CS0/DF

*Egress mappings*

Egress mappings include:

- QoS level to IEEE 802.1p mappings
- QoS level to DSCP mappings

When a packet is forwarded by the switch, the software does the following:

- Always performs 802.1p remarking before the packet egresses.
- If the ingress port has **enable-diffserv** and **access-diffserv** enabled, then the IP packet is DSCP remarked before the packet egresses.

If the ingress port is not configured this way, the packets are not DSCP remarked.

The following table shows egress QoS level to IEEE 802.1p mappings.

**Table 201: Default egress QoS level to IEEE 802.1p mappings**

QoS level	PHB	Default 1p remarking on egress	Network Service Class (NSC)
0	Custom	1	Custom
1	CS0/DF	0	Standard
2	CS1/AF11	2	Bronze
3	CS2/AF21	3	Silver
4	CS3/AF31	4	Gold
5	CS4/AF41	5	Platinum

**Table 201: Default egress QoS level to IEEE 802.1p mappings (continued)**

QoS level	PHB	Default 1p remarking on egress	Network Service Class (NSC)
6	CS5/EF	6	Premium/EF
7	CS6/CS7	7	Network/Critical

The following table shows QoS level to DSCP mappings.

**Table 202: Default egress QoS level to DSCP mappings**

Egress			
QoS level	DSCP (binary)	DSCP (hexadecimal)	DSCP
0	000000	00	0
1	000000	00	0

The switch QoS implementation supports the following two features for bandwidth management and traffic control:

- ingress port-based rate limiting—a mechanism to limit the traffic rate accepted by the specified ingress port
- egress port-based shaping—the process by which the system delays and transmits packets to produce an even and predictable flow rate

Each port has eight unicast and multicast queues, Class of Service (CoS) 0 to CoS 7. Traffic shaping exists on the egress CoS 6 and CoS 7, but you cannot change the configuration. CoS 6 and CoS 7 are strict priority queues, with traffic shaping for CoS 6 at 50 percent and CoS 7 to five percent of line rate.

Some VOSS hardware platforms allow you to configure an egress shaping rate for each port manually. For XA1400 Series, the egress shaping rate for each front panel port dynamically adjusts to the auto-negotiated link speed, up to the maximum link speed of the port.

The VSP 4450 Series switch QoS implementation supports the following two features for bandwidth management and traffic control:

- ingress port-based traffic policing—a mechanism to limit the number of packets in a stream that matches a particular classification
- egress port-based traffic shaping—the process by which the system delays (or drops) and transmits packets to produce an even and predictable flow rate

Each feature is important to deliver DiffServ within a QoS network domain.

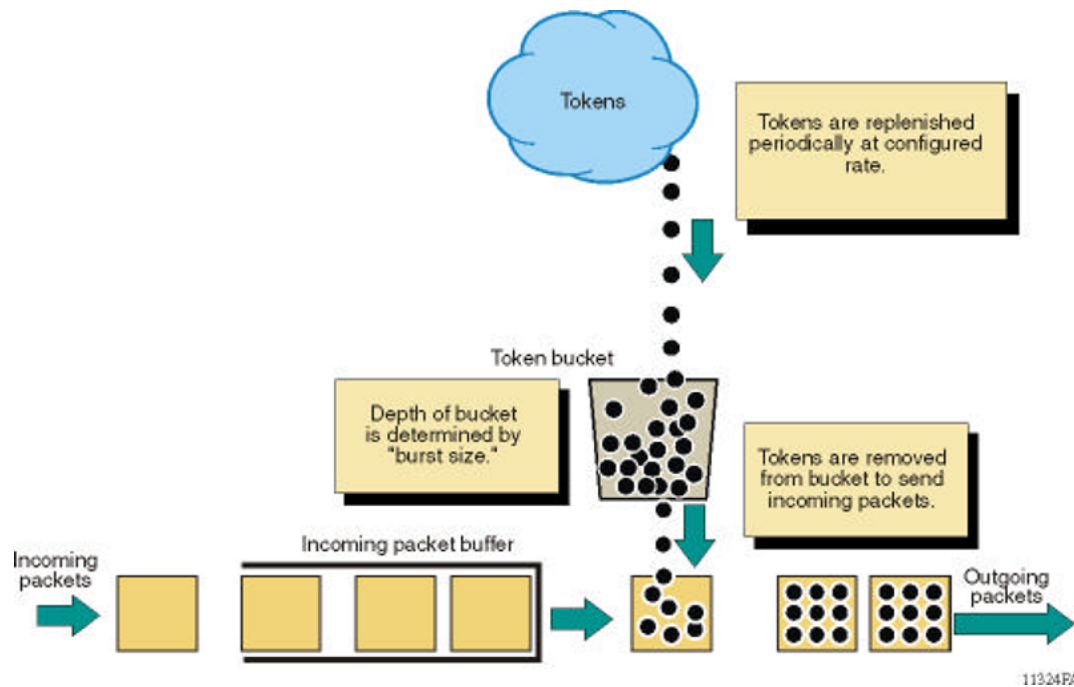

Some hardware platforms support an ingress flow-based policer for ACLs. For information about Ingress Flow-based Policers, see [Ingress Bandwidth Rate Limiter](#) on page 3720.

#### *Token Buckets*

Tokens are a key concept in traffic control. A port-based rate limiter, policer, shaper, or an ingress flow-based policer calculates the number of packets that passed, and at what data rate. Each packet corresponds to a token, and the port-based rate limiter, policer, shaper, or an ingress flow-based policer transmits or passes the packet if the token is available. For more information, see [Figure 218](#).

The token container is like a bucket. In this view, the bucket represents both the number of tokens that a port-rate limiter, policer, or shaper can use instantaneously (the depth of the bucket) and the rate at which the tokens replenish (how fast the bucket refills).

Each policer has two token buckets: one for the peak rate and the other for the service rate. The following figure shows the flow of tokens.

**Figure 218: Token flow**

*Ingress port-rate limiter*

Ingress port-rate limiter limits the traffic rate accepted by the specified ingress port. The port drops or re-marks violating traffic. The line rate of the port is the maximum rate that can be set.

For more information on ingress port-rate limiter, see:

- [View the Ingress Port-Rate Limit Information](#) on page 2934
- [Configuring the ingress port-rate limiter](#) on page 2933

**Note**

If Ingress Flow policer and Ingress port rate limiter features are configured together it might result in more traffic drop than expected. Since both are partially incompatible, best practice is to not configure both together that could affect same traffic. Below are the best practices:

- If ACL type is inPort, do not configure Qos Port Limiter on any of the ports that are part of ACL
- If ACL type is inVlan, do not configure Qos Port Limiter on ports that are part of any VLAN in the ACL
- If ACL type is inVsn, do not configure Qos Port Limiter on ports that are part of any VSN in the ACL

## Queuing

Queuing is a congestion-avoidance function that prioritizes packet delivery. Queuing ensures discriminate packet discard during network congestion, and can delay a packet in memory until the scheduled transmission.

You can use queuing to manage congestion. Congestion management involves the creation of queues, assignment of packets to the queues based on the classification of the packet, and scheduling of the packets in a queue for transmission.

The system schedules packets for transmission according to their assigned priority and the queuing mechanism configured for the interface. The scheduler determines the order of packet transmission by controlling how the system services queues with respect to each other. The switch uses 16 CPU queues (used by traffic destined to the CPU), and eight unicast and eight multicast queues for each port. The deepest queue does not go beyond 60,000 packets.

A scheduler services the eight queues for each port, using a combination of strict priority and round-robin. Queue zero through five use round robin, and queues six and seven drain completely, or up to certain rate limits.

There are eight priorities on each egress port. Each Weighted Round Robin (WRR) queue has a minimum guaranteed weight to ensure fair bandwidth allocation for each queue in case all QoS queues are utilized and there is congestion. With the default profile, Class of Service (CoS) 0 to CoS 5 are WRR, and the default weights are 10, 20, 30, 40, 50, and 50 respectively. CoS 6 and CoS 7 are strict priority queues. The switch subjects CoS 6 and CoS 7 to traffic shaping at 50 per cent and five per cent of line rate respectively.

### Note

VSP 4450 Series switches use Weighted Deficit Round Robin (WDRR). The priorities and default weights are the same as WRR.

For the VSP 8600 Series, 8 CPU queues are implemented. The highest priority packets, such as VLACP, are routed to the highest priority CPU queue (COS 7). The least time critical packets are routed to the lowest CPU queue (COS 0). Statistics for the CPU port are displayed using the CLI command **show qos cosq-stats cpu-port**.

All packets destined for the CPU are sent as unicast packets.

Front panel ports also have 8 queues. When a front panel port is oversubscribed with both unicast and multicast packets, the bandwidth is divided so that the unicast packets receive 80% of the bandwidth and multicast packets 20% of the bandwidth.

If there are no multicast packets using the reserved 20%, the bandwidth is evenly distributed between COS levels 0 to 6. This results in approximately 3.3% more bandwidth for each level. If a specific COS level is not oversubscribed, the unused

bandwidth is evenly distributed between the other COS levels. The CLI provides commands to map ingress packets to specific COS levels.

**Note**

Unicast packets will be tail dropped on the ingress card. Multicast packets will be dropped at egress card.

Among the WRR queues, the approximate bandwidth percentage is relative to the remaining bandwidth after subtracting the Strict Priority queues. The following tables provide the approximate bandwidth percentage based on queue congestion.

**Table 204: Bandwidth for Queue 0 to 5 congestion**

Queue	Approximate bandwidth percentage*
0	5%
1	10%
2	15%
3	20%
4	25%
5	25%
* The approximate value assumes that all queues 0 to 5 are congested and similar packet sizes. Any queue that does not require bandwidth results in adding more bandwidth to the WRR queues. Percentage is relative to the total bandwidth minus the bandwidth consumed by Cos 6 and 7 (strict queues).	

**Table 205: Bandwidth for Queue 0 to 7 congestion**

Queue	Approximate bandwidth percentage*
0	2.25%
1	4.5%
2	6.75%
3	9%
4	11.25%
5	11.25%
6	50%
7	5%
* The approximate value assumes that all queues 0 to 7 are congested and similar packet sizes.	

### CPU Queues

This section provides information about CPU traffic and queues.

#### Note

To view the CPU traffic and queue information for the VSP 8600 Series use the command `show qos cosq-stats cpu-port`.

The following table outlines the CPU traffic, and which queue it uses, for the VSP 4450 Series.

Queue description	Queue ID	Queue pps, burst size	Traffic type
Other	0	125 pps, 1500 kbps	Data Exception
BC_Other	1	4000 pps, 1400 kbps	Broadcast
HI_CPU looper	2	4000 pps, 1000 kbps	RIP
HI_CPU	3	4000 pps, 1000 kbps	PIM Unicast, IGMP
HI_CPU	4	4000 pps, 1000 kbps	OSPF Unicast, BGP
HI_CPU	5	4000 pps, 1000 kbps	Multicast Data
HI_CPU	6	4000 pps, 12000 kbps	ISIS
HI_CPU	7	4000 pps, 6000 kbps	OSPF Multicast, PIM Multicast
mgmt	8	4000 pps, 2000 kbps	Telnet, SSH, DNS, HTTP, TFTP, FTP, SNMP
Low rate looper	9	4000 pps, 5000 kbps	ICMP Broadcast, DHCP, ARP, ND Multicast and Unicast
Low rate 1	10	4000 pps, 1000 kbps	ISIS Hello, RADIUS, EAP, NTP, LLDP, ICMP Unicast, IST Control
Low latency	11	250 pps, 20 kbps	CFM, VRRP
Low latency	12	250 pps, 20 kbps	LACP
Low latency	13	250 pps, 20 kbps	BPDU, SLPP
Low latency	14	300 pps, 1000 kbps	ISIS Hello
Low latency	15	250 pps, 20 kbps	VLACP

The following table outlines the CPU traffic, and which queue it uses, for the VSP 4900 Series, VSP 7200 Series, VSP 7400 Series, VSP 8200 Series, and VSP 8400 Series.

Queue description	Queue ID	Queue pps, burst size	Traffic type
Other	0	1400 pps, 100 kbps	Others
BC_Other	1	1400 pps, 100 kbps	Broadcast
HI_CPU looper	2	4000 pps, 100 kbps	IP_COS01
HI_CPU	3	4000 pps, 100 kbps	IP_COS23, Multicast Data
HI_CPU	4	4000 pps, 100 kbps	IP_COS4
HI_CPU	5	4000 pps, 100 kbps	IP_COS5, IGMP, PIM Unicast
HI_CPU	6	4000 pps, 100 kbps	ARP, RARP, ND Multicast and Unicast, MLD
HI_CPU	7	4000 pps, 100 kbps	IP_COS6, Telnet, SSH
mgmt	8	4000 pps, 200 kbps	IP_COS7, OSPF
Low rate looper	9	4000 pps, 6000 kbps	OSPF Multicast, PIM Multicast, RIP_v1, RIP_v2
Low rate 1	10	4000 pps, 12000 kbps	ISIS
Low latency	11	4000 pps, 1000 kbps	ISIS Hello, LLDP, EAP, IST Control
Low latency	12	500 pps, 32 kbps	VRRP, CFM
Low latency	13	256 pps, 32 kbps	SLPP
Low latency	14	100 pps, 32 kbps	BPDU
Low latency	15	250 pps, 32 kbps	LACP, VLACP, TUNI-extract

The XA1400 Series uses filters to rate limit packets to the CPU.

Packet Type	Rate (PPS)	Packet Size (Bytes)
CFM, VLACP, RIPv2, SONMP, RIPv1, VRRP, ARP.	100	64
DHCP	50	1400
ISIS, OSPF	100	1400
Other Packets	Not rate limited	

## Queue profiles

**Table 206: Queue Profiles product support**

Feature	Product	Release introduced
QoS per queue rate limiting	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	VSP 4450 Series	VOSS 5.1
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 5.1.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 5.1.1
	VSP 8400 Series	VOSS 5.1.1
	VSP 8600 Series	Not Supported
	XA1400 Series	Not Supported

This section identifies optional ways to customize the egress queues and scheduling depending on your need to override the default configuration. You can also enable egress queue rate limiting, if desired.

Use a queue profile to apply configured egress queue parameters and modify each queue individually. You can use the queue profile to configure a minimum weight for the queue and to enable rate limiting for the queue. The queue profile applies to all ports in the switch.

**Note**

If you enable rate limiting for all queues, the scheduler treats all queues as strict priority queues. If all queues are strict priority, the scheduler services the highest priority queue first until the maximum bandwidth is met, and then it services the next highest priority queue. Queue 0 is the lowest priority queue, which means that when over-subscribed, the lower priority queues are serviced last, or not at all.

The switch supports six queue profiles. The default queue profile, with the name default and ID 1, is automatically created during system startup and cannot be deleted.

**Note**

The egress queues with rate limiting enabled must be contiguous. For example, you can configure queues 3–6, but you cannot configure 3 and 6.

After you make a configuration change to a queue profile, you must apply the profile before the changes take effect.

## Configuration considerations

If you modify the QoS configuration for a port that is a member of MultiLink Trunking (MLT), all ports in the MLT inherit the same configuration. If you remove the port from the MLT, it keeps the QoS configuration it inherited from the MLT.

## QoS Support for 10 GbE Interface in 1GbE mode

If you use QoS with a 10 gigabit Ethernet (GbE) interface and re-purpose the interface as a 1 GbE interface, you must make the necessary configuration changes to accommodate the new link speed.

Check your rate limiting and shaping configuration, if you choose to change the port link speed from 10 GbE to 1 GbE.

Review the following commands to ensure proper configuration for the port speed you use.

Command	Description
<code>qos if-rate-limiting [port {slot/port}] rate &lt;1000-40000000&gt;</code>	Configures ingress port rate limiting in kbps.  <b>Note:</b> The range can vary depending on your hardware platform.
<code>rate-limit broadcast {&lt;1-65535&gt;   &lt;50-65000000&gt;}</code>	Configures ingress port broadcast/unknown unicast rate limiting in packets/second.  <b>Note:</b> The <50-65000000> range only applies to VSP 8600 Series.
<code>rate-limit multicast {&lt;1-65535&gt;   &lt;50-65000000&gt;}</code>	Configures ingress port multicast rate limiting in packets/second.  <b>Note:</b> The <50-65000000> range only applies to VSP 8600 Series.
<code>qos if-shaper [port {slot/port[/sub-port]} [-slot/port[/sub-port]][, ...] ] shape-rate &lt;shape-rate&gt;</code>	Specifies the shaping rate in Kb/s. Different hardware platforms support different egress rate limits, depending on the port with the highest speed available on the platform. If you try to configure a limit that is too high for the port speed, the switch displays the following message: Error: port slot/port, The QOS Egress shaper rate can not exceed the port capability.

## 802.1p and 802.1Q Best Practices

In a network, to map the 802.1p user priority bits, use 802.1Q-tagged encapsulation on customer-premises equipment (CPE). You require encapsulation because the switch does not provide classification when it operates in bridging mode.

To ensure consistent Layer 2 QoS boundaries within the service provider network, you must use 802.1Q encapsulation to connect a CPE directly to the switch access node. If you do not require packet classification, use Ethernet Routing Switch 5600 to connect to the access node. In this case, configure the traffic classification functions in the Ethernet Routing Switch 5600.

At the egress access node, packets are examined to determine if their IEEE 802.1p or DSCP values must be re-marked before leaving the network. Upon examination, if the packet is a tagged packet, the IEEE 802.1p tag is configured based on the QoS level-to-IEEE 802.1p-bit mapping. For bridged packets, the DSCP is re-marked based on the QoS level.

## Network congestion and QoS design

When you provide QoS in a network, one of the major elements you must consider is congestion, and the traffic management behavior during congestion. Congestion in a network is caused by many different conditions and events, including node failures, link outages, broadcast storms, and user traffic bursts.

At a high level, three main types or stages of congestion exist:

1. No congestion
2. Bursty congestion
3. Severe congestion

In a noncongested network, QoS actions ensure that delay-sensitive applications, such as real-time voice and video traffic, are sent before lower-priority traffic. The prioritization of delay-sensitive traffic is essential to minimize delay and reduce or eliminate jitter, which has a detrimental impact on these applications.

A network can experience momentary bursts of congestion for various reasons, such as network failures, rerouting, and broadcast storms. The switch has sufficient capacity to handle bursts of congestion in a seamless and transparent manner. If the burst is not sustained, the traffic management and buffering process on the switch allows all the traffic to pass without loss.

Severe congestion is defined as a condition where the network or certain elements of the network experience a prolonged period of sustained congestion. Under such congestion conditions, congestion thresholds are reached, buffers overflow, and a substantial amount of traffic is lost.

When you perform traffic engineering and link capacity analysis for a network, the standard design rule is to design the network links and trunks for a maximum average-peak utilization of no more than 80%. This value means that the network peaks to up to 100% capacity, but the average-peak utilization does not exceed 80%. The network is expected to handle momentary peaks above 100% capacity.

## Layer 2 and Layer 3 trusted and untrusted ports

You can configure interface module ports as trusted or untrusted at both Layer 2 (802.1p) or Layer 3 (DSCP) for ingress packet classification.

The switch provides eight internal QoS levels. These eight levels, numbered zero to seven, map to the queues through

- the ingress 802.1p to (internal) QoS mapping table
- the ingress DSCP to (internal) QoS mapping table

To configure a port as trusted or untrusted, use the commands and the parameter values as shown in the following tables:

Layer 2 Trusted	Layer 2 Untrusted
<b>802.1p-override</b>	<b>802.1p-override</b>
disable	enable

Layer 3 Trusted		Layer 3 Untrusted	
<b>enable-diffserv</b>	<b>access-diffserv *</b>	<b>enable-diffserv</b>	<b>access-diffserv *</b>
enable	disable	disable	disable
		disable	enable
		enable	enable **

\* Configure **access-diffserv** as either a core or access port. If enabled, this command specifies an access port and overrides incoming DSCP bits. If disabled, it specifies a core port that honors and services incoming DSCP bits.

\*\* If the ingress port has **enable-diffserv** and **access-diffserv** enabled, then the packet is DSCP remarked at egress.

### *Layer 2 untrusted and Layer 3 untrusted*

To configure a port as Layer 2 untrusted and Layer 3 untrusted, refer to the tables above and assign the parameter values accordingly.

For more information, see [Table 198](#) on page 2893.

### *Layer 2 untrusted and Layer 3 trusted*

To configure a port as Layer 2 untrusted and Layer 3 trusted, refer to the tables above and assign the parameter values accordingly.

Use these configuration options to classify packet QoS through the DSCP parameter for all IP packets, whether tagged or untagged. Use this configuration when another QoS or DiffServ enabled and configured switch marks the IP packets at the edge. These already-marked packets arrive Layer 3 trusted, and the switch continues with the trust (DiffServ core port operation). For tagged packets, the system does not examine the

802.1p bits. For non-IP packets, this configuration causes classification by port QoS settings.

**Note**

For IP switched and tagged packets, use the 802.1p bits to derive the internal QoS. For untagged or routed packets, use the DSCP to derive the internal QoS.

For more information, see [Table 198](#) on page 2893.

*Layer 2 trusted and Layer 3 trusted*

To configure a port as Layer 2 trusted and Layer 3 trusted, refer to the tables above and assign the parameter values accordingly.

Use these configuration options to classify packet QoS through DSCP for all IP packets, and through 802.1p for all tagged non IP packets. If it is an IP packet, DSCP is used. If it is a tagged non IP packet, 802.1p bits are used. If it is an untagged non IP packet, the port QoS is used.

For more information, see [Table 198](#) on page 2893.

*Layer 2 trusted and Layer 3 untrusted*

To configure a port as Layer 2 trusted and Layer 3 untrusted, refer to the tables above and assign the parameter values accordingly.

Use these configuration options to classify packet QoS through 802.1p for all tagged packets, and port QoS levels for all untagged (IP or non-IP) packets. If the packet is an IP packet, the system does not modify or examine the DSCP parameter bits.

For more information, see [Table 198](#) on page 2893.

*DiffServ disabled*

If you disable the DiffServ parameter, the system ignores the Layer 3 DSCP parameter. For more information, see [Table 198](#) on page 2893.

## Broadcast, Unknown Unicast, and Multicast Traffic Bandwidth Limiters per Ingress Port

The switch supports bandwidth limiters for ingress broadcast/unknown unicast and multicast traffic. The system drops traffic that violates the bandwidth limit. Enable this feature by configuring the rate limit, in packets per second (pps), on an individual port basis.

**Note**

VSP 8600 Series does not support this feature for unknown unicast traffic. XA1400 Series does not support this feature.

## QoS and VoIP

**Table 207: QoS and VoIP product support**

Feature	Product	Release introduced
Automatic QoS	5320 Series	Not Supported Use Auto-sense with IP Phone support instead.
	5420 Series	Not Supported Use Auto-sense with IP Phone support instead.
	5520 Series	Not Supported Use Auto-sense with IP Phone support instead.
	5720 Series	Not Supported Use Auto-sense with IP Phone support instead.
	7520 Series	Not Supported Use Auto-sense with IP Phone support instead.
	7720 Series	Not Supported Use Auto-sense with IP Phone support instead.
	VSP 4450 Series	VSP 4000 4.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VSP 8200 4.0
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	VOSS 8.0.50

VoIP traffic requires low latency and jitter.

If you use edge routers, configure ingress ports as core ports to treat VoIP traffic appropriately. In this case, the system trusts QoS markings that apply to VoIP traffic, and the system does not re-mark QoS settings. However, if this configuration is not sufficient, you can also apply filters, route policies, or re-mark traffic.

#### *Automatic QoS*

Automatic QoS specifically supports converged voice deployments. Automatic QoS automatically recognizes the DSCP value voice applications can use, and associates these DSCP values with the proper queue.

When you use Automatic QoS, the system recognizes application traffic and prioritizes the traffic through the system. Automatic QoS offers a simplified and resource-

efficient mechanism to prioritize application traffic within the network. Automatic QoS supersedes DiffServ mode configuration.

The following table shows the traffic types, the standard DSCP value, the specific Automatic QoS DSCP values, and the queue mappings for the Automatic QoS DSCP values.

**Table 208: Automatic QoS DSCP values**

Traffic type	Automatic QoS DSCP value	Queue
VoIP data (Premium)	0x2F (47)	6
VoIP signaling (Platinum)	0x29 (41)	5
Video (Platinum)	0x23 (35)	5
Streaming (Gold)	0x1B (27)	4

The traffic that the system identifies, based on these DSCP values, receives preferential queuing treatment within the system and is re-marked for preferential downstream processing

The system associates additional filtering (ACL filters) to ensure that Auto-QoS DSCP values are honored no matter what the QoS configuration of the ingress is.

These additional filtering components target ingress traffic with the designated private DSCP values. After a match occurs, the system re-marks the traffic based on the application mode. Ingress traffic that is not marked with a recognized private DSCP value receives the same treatment as it receives without the Automatic QoS feature.

The switch activates Automatic QoS automatically; you cannot deactivate this feature but you can remap these DSCP values to use a different queue. The system displays a warning that these values should not be modified.

```
Switch:1(config)#qos ingressmap ds 47 2
DSCP values should not be modified.
Do you want to continue ? (y/n) ? y
```

You do not need to configure individual QoS components across a variety of platforms. Automatic QoS applies end-to-end.

#### Important

For VSP 8600 Series switches, automatic QoS derives internal QoS based on DSCP and is honored for routed traffic *only*. For switched traffic, Automatic QoS does not work and falls back to deriving internal QoS based on VLAN .1p bits or uses the port's default QoS level.

## QoS re-marking on a Transparent Port UNI

A Transparent Port UNI port is normally configured as a Layer 2 trusted port. The T-UNI port honors incoming customer 802.1p bits and derives an internal QoS level. The 802.1p bit marking of the Backbone VLAN (B-VLAN) is derived from the internal QoS level.

If the T-UNI port is set as a Layer 2 untrusted port, a best-effort queue is assigned. Customer packet headers are not modified.

The T-UNI port QoS configurations are:

- DiffServ = disable
- Layer3Trusted = access (for EDM configuration)
- access-diffserv enable (for CLI configuration)

*QoS considerations when a port is associated with a T-UNI I-SID*

- You cannot configure `access-diffserv` and `enable diffserv` on a T-UNI port.
- When a port is associated with a T-UNI I-SID, the T-UNI QoS configuration automatically takes effect.
- When the port is removed from the T-UNI I-SID, the default port QoS configuration takes effect.

*QoS considerations when an MLT is associated with a T-UNI I-SID*

- When an MLT, static or LACP, is added to a T-UNI I-SID, the T-UNI QoS configuration take effect on all the ports of the MLT.
- When an MLT, static or LACP, is removed from a T-UNI I-SID, the port default QoS configuration is configured on all the member ports of the MLT.
- If a port is added dynamically to a T-UNI MLT, static or LACP, the port inherits the QoS properties of the T-UNI MLT ports.
- If a port is dynamically removed from a T-UNI MLT, static or LACP, the port retains the QoS configuration inherited from the MLT.

## QoS and Channelization

Use channelization to configure a single port to operate as four subports. By default, the ports are not channelized.

You can enable or disable channelization on a channelization-capable port. Enabling or disabling channelization on a port resets the port QoS configuration to default values. For more information on channelization, see [Enable Channelization](#) on page 604.

The switch automatically channelizes a port if the port operates in Auto-sense mode and you insert one of the following:

- QSFP+ to SFP+ adapter
- QSFP28 to SFP28 adapter
- QSFP+ to 2xSFP+ passive or active breakout cable
- QSFP28 to 4xSFP28 passive or active breakout cable

## QoS examples and Best Practices

The sections that follow present QoS network scenarios for bridged and routed traffic over the core network.

### Bridged traffic

If you bridge traffic over the core network, you keep customer VLANs separate (similar to a Virtual Private Network). Normally, a service provider implements VLAN bridging (Layer 2) and no routing. In this case, the 802.1p-bit marking determines the QoS level assigned to each packet. If DiffServ is active on core ports, the level of service received is based on the highest of the DiffServ or 802.1p settings.

The following cases provide sample QoS design guidelines you can use to provide and maintain high service quality in a network.

If you configure a core port, you assume that, for all incoming traffic, the QoS value is properly marked. All core switch ports simply read and forward packets; they are not re-marked or reclassified. All initial QoS markings are performed at the customer device or on the edge devices.

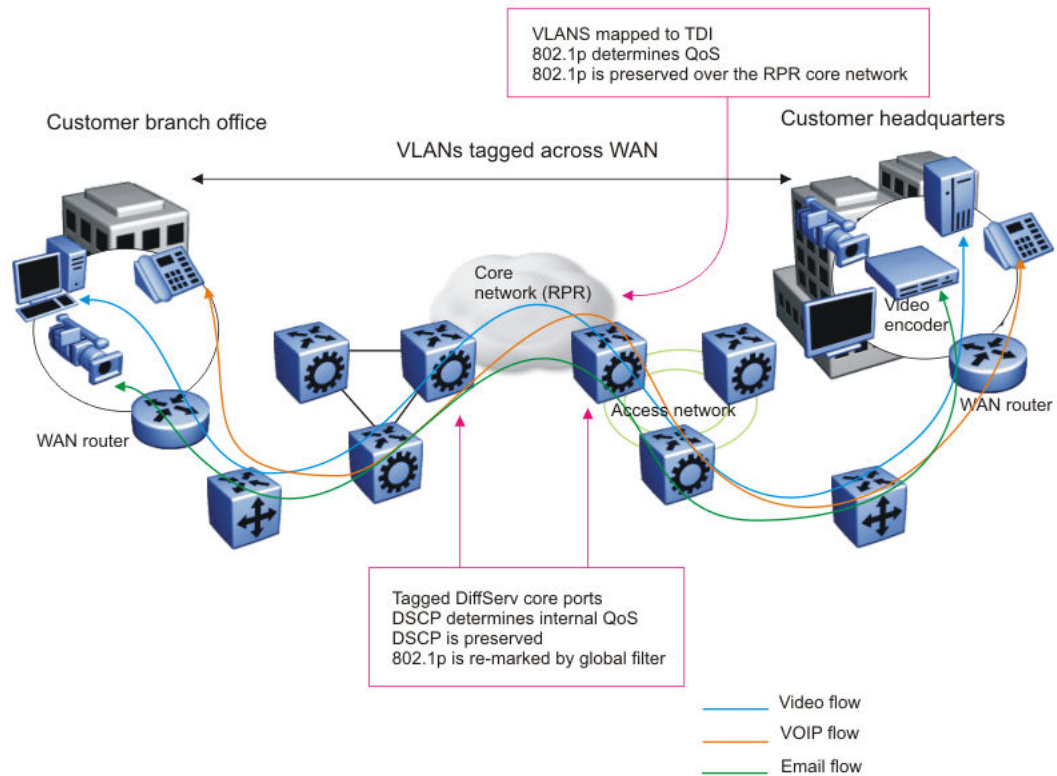

The following figure illustrates the actions performed on three different bridged traffic flows (that is VoIP, video conference, and email) at access and core ports throughout the network.

**Figure 219: Trusted bridged traffic**

For bridged, untrusted traffic, if you configure the port to access, mark and prioritize traffic on the access node using global filters. Reclassify the traffic to ensure it complies with the class of service specified in the SLA.

For Resilient Packet Ring (RPR) interworking, you can assume that, for all incoming traffic, the QoS configuration is properly marked by the access nodes. The core switch ports, configured as core or trunk ports, perform the RPR interworking. These ports preserve the DSCP marking and re-mark the 802.1p bit to match the 802.1p bit of the RPR. The following figure shows the actions performed on three different traffic flows (VoIP, video conference, and email) over an RPR core network.

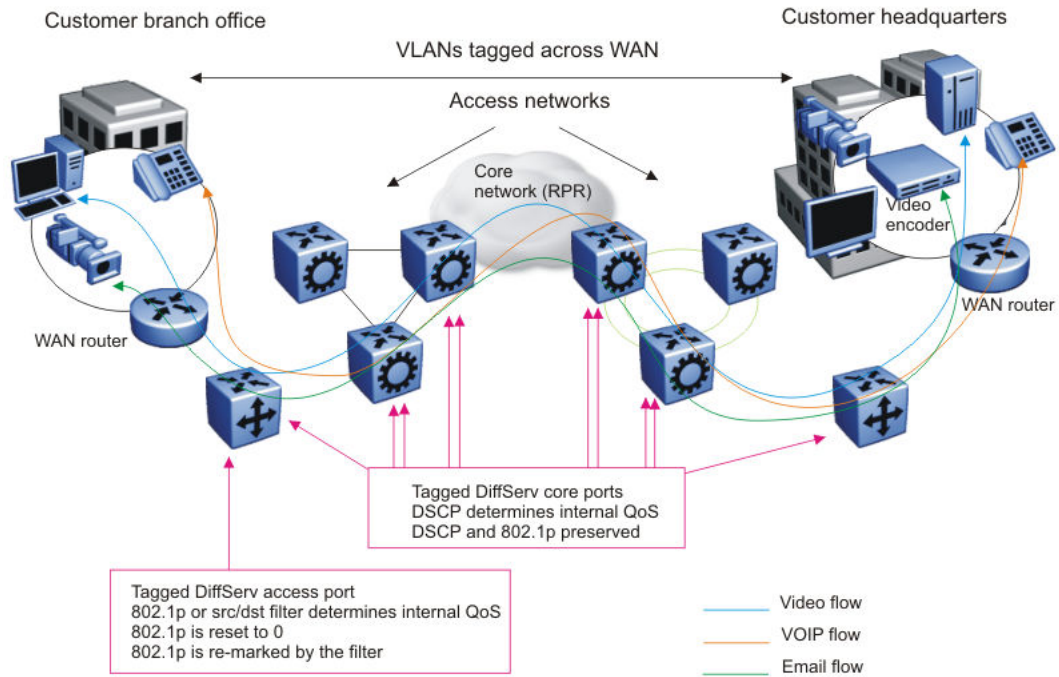

**Figure 220: RPR QoS internetworking**

#### *Routed traffic*

If you route traffic over the core network, VLANs are not kept separate.

If you configure the port to core, you assume that, for all incoming traffic, the QoS configuration is properly marked. All core switch ports simply read and forward packets. The switch does not re-mark or classify the packets. The customer device or the edge devices perform all initial QoS markings.

The following figure shows the actions performed on three different routed traffic flows (that is VoIP, video conference, and email) at access and core ports throughout the network.

**Figure 221: Trusted routed traffic**

For routed, untrusted traffic, in an access node, packets that enter through a tagged or untagged access port exit through a tagged or untagged core port.

## Egress Tunnel Shaping

Egress Tunnel Shaping shapes traffic on a Fabric Extend (FE) tunnel. Egress Tunnel Shaping limits transmission rate by shaping the output load. Egress Tunnel Shaping

differs from Port Egress Shaping. Port Egress Shaping limits transmission rate by port and by queue. Egress Tunnel Shaping operates on VXLAN virtual ports.

On XA1400 Series the default egress tunnel shaper is 1 Gbps on all FE tunnels and has only one QoS queue.

When you enable Egress Tunnel Shaping, it shapes unicast, multicast, and unknown unicast egress traffic according to the feature configuration. Shapers you configure shape all traffic on the tunnel. Shapers you configure can have between 1 Mbps and 1 Gbps of bandwidth allocated to them.

Eight traffic queues are created for the tunnel traffic when a new shaper is configured. Packets are mapped to any of these queues based on the internal Class of Service (CoS) of the packets. When multiple tunnels use the common shaper value, an internally unique shaper is associated for each tunnel. The following table shows the default minimum weight for each queue.

Queue	Default Minimum Weight
0	5
1	20
2	30
3	40
4	50
5	50
6	Rate limited to 50% of configured shaper rate
7	Rate limited to 5% of configured shaper rate

Queues 6 and 7 are rate limited and have a higher priority. The maximum traffic allowed out of queue 6 and queue 7 would be shape rate/2 (50% bandwidth) and shape rate/20 (5% bandwidth).

The XA1400 Series uses a Hierarchical Token Bucket (HTB) scheduling algorithm. HTB controls the use of the outbound bandwidth on a link, allowing the use of one physical link or virtual link to simulate several slower links and to send different kinds of traffic on different simulated links. HTB shapes traffic based on the Token Bucket Filter algorithm which does not depend on interface characteristics, or the underlying bandwidth of the outgoing interface.

The configured bandwidth sum of all shaped FE tunnels is higher than the total amount of available head-end bandwidth. Egress Tunnel Shaping is oversubscribed so that all the available and unused bandwidth is allotted to a branch node if other branch nodes are not using it.

Buffer allocation and burst rate are fixed and cannot be configured.

#### Note

Tunnel shaping granularity may not be accurate, and differ from the user configured values, when packets are fragmented if the packet size is greater than the FE tunnel MTU. This is because when packet fragmentation happens there is a higher packet header overhead.

Configuration of Egress Tunnel Shaping requires supporting SPBM and Fabric Extend configurations. For more information on these configurations, see the following sections:

- [Fabric Basics and Layer 2 Services](#) on page 1001
- [Fabric Layer 3 Services](#) on page 1462
- [IP Multicast over Fabric Connect](#) on page 1825

## QoS Behavior Differences

The implementation of QoS is similar in all switches but there are some differences as summarized in the following table.

QoS	VSP 4450 Series	VSP 4900 Series/VSP 7200 Series/VSP 8200 Series/VSP 8400 Series	VSP 7400 Series	VSP 8600 Series	XA1400 Series
Ingress traffic	Policing	Port-rate limiting	Not available	Port-rate limiting	Not available
Egress traffic	Shaping	Shaping	Shaping	Shaping	Follows default queue profile weights
Egress queuing CoS 0–5	WDRR	WRR	WRR	WRR	Heirarchy Token Bucket (HTB)
Classification	Routed packet classification	No routed packet classification	No routed packet classification	No routed packet classification	No routed packet classification

QoS	VSP 4450 Series	VSP 4900 Series/VSP 7200 Series/VSP 8200 Series/VSP 8400 Series	VSP 7400 Series	VSP 8600 Series	XA1400 Series
Internal QoS derivation for ingress Layer 3 trusted port	<ul style="list-style-type: none"> <li>Routed IP packet-derived from DSCP</li> <li>Switched IP packet-derived from 802.1p</li> </ul>	Always derived from DSCP	Always derived from DSCP	Always derived from DSCP	Always derived from DSCP
Automatic QoS	Always derived from DSCP	Always derived from DSCP	Always derived from DSCP	Derived from DSCP for routed traffic only. Automatic QoS is not available for switched traffic.	Always derived from DSCP

For QoS scaling and filter scaling information, see [VOSS Release Notes](#).

## Basic DiffServ configuration using CLI

Use Differentiated Services (DiffServ) to provide appropriate Quality of Service (QoS) to specific traffic types.

### Enabling DiffServ on a port

Enable DiffServ so that the system provides DiffServ-based QoS on the port. By default, DiffServ is enabled.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable DiffServ:

```
enable-diffserv [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] [enable]
```

3. Disable Diffserv:

```
no enable-diffserv [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] [enable]
```

### Variable definitions

Use the data in the following table to use the **enable-diffserv** command.

Variable	Value
<i>enable</i>	Enables DiffServ for the specified port. The default is enabled.
<i>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Configuring Layer 3 trusted or untrusted ports

Configure a port as trusted or untrusted to determine the Layer 3 QoS actions the switch performs. A trusted (core) port honors incoming Differentiated Services Code Point (DSCP) markings. An untrusted (access) port overrides DSCP markings. The default configuration is trusted.

### Before You Begin

Enable DiffServ.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the port as an access port, use one of the following options:

```
no enable-diffserv [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] [enable]
```

OR configure both parameters:

```
enable-diffserv [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] [enable]
```

```
access-diffserv [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] [enable]
```

3. Configure the port as a core port:

```
no access-diffserv [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] [enable]
```

## Variable definitions

Use the data in the following table to use the **access-diffserv** commands.

Variable	Value
<i>enable</i>	If enabled, specifies an access port and overrides incoming DSCP bits. If disabled, specifies a core port that honors and services incoming DSCP bits.
<i>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Configuring Layer 2 trusted or untrusted ports

Configure a port as trusted or untrusted to determine the Layer 2 QoS actions the switch performs. A trusted port (override disabled) honors incoming 802.1p bit markings. An untrusted port (override enabled) overrides 802.1p bit markings.

## Before You Begin

Enable DiffServ.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the port as Layer 2 untrusted:

```
qos 802.1p-override [enable]
```

3. Configure the port as Layer 2 trusted:

```
no qos 802.1p-override [enable]
```

## Variable Definitions

Use the data in the following table to use the `qos 802.1p-override` command.

Variable	Value
<code>enable</code>	If you use this variable, the port overrides incoming 802.1p bits; if you do not use this variable, the port honors and services incoming 802.1p bits. The default is disable (Layer 2 trusted).

## Viewing the port 802.1p override status

Use this procedure to view the port 802.1p override status. The system displays the port and 801.1p override status.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. View the port 802.1p override status:

```
show qos 802.1p-override
```

## Example

```
Switch:1# show qos 802.1p-override
```

```
=====
Port 802.1p-Override Status
```

```

=====
-----
PORT      802.1P  OVERRIDE
-----
1/1      DISABLED
1/2      DISABLED
1/3      DISABLED
1/4      DISABLED
1/5      DISABLED
1/6      DISABLED
1/7      DISABLED
1/8      DISABLED
1/9      DISABLED
1/10     DISABLED
1/11     DISABLED
1/12     DISABLED
1/13     DISABLED
1/14     DISABLED
1/15     DISABLED
1/16     DISABLED

```

## Configuring the port QoS level

Configure the port QoS level to assign a default QoS level for all traffic if the packet does not match an access control list (ACL) that re-marks the packet. If you configure port QoS levels, Layer 2 and Layer 3 traffic from the same port use the same QoS level. The default value is 1.

### About This Task

For VoIP traffic, as a best practice, use QoS level 6.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the port QoS level:

```
qos level [port {slot/port[sub-port]}] <0-6>
```

*Variable definitions*

Use the data in the following table to use the `qos level` command.

Variable	Value
<0-6>	Specifies the default QoS level for the port traffic. The system reserves QoS level 7 for network control traffic. The default is 1.
<code>port {slot/port[/sub-port]}</code>	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Basic DiffServ configuration using EDM

Use DiffServ to implement classification and mapping functions at the network boundary or access points to regulate packet behavior. You can configure a port as a trusted (core) or an untrusted (access) port at both Layer 2 and Layer 3.

You can also perform many of the procedures in this section on the Interface tab for the selected port. The procedures in this section show only one configuration method.

### Enabling DiffServ for a port

Enable DiffServ so that the switch provides DiffServ-based Quality of Service (QoS) on the port.

#### About This Task

#### Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **QOS**.
2. Click **Port QoS Config**.
3. In the row for the port, double-click the cell in the **DiffServ** column.
4. Select **true**.
5. Click **Apply**.

**QoS Port Config** field descriptions

Use the data in the following table to use the **Port QoS Config** tab.

Name	Description
<b>Index</b>	Specifies an index value that uniquely identifies a port.
<b>DiffServ</b>	Specifies whether DiffServ is enabled (true) or disabled (false) on the port. The default is true. This variable works in conjunction with Layer3Trust. The DiffServ variable is a global parameter that affects QoS DSCP operations. If the DiffServ parameter is false (DiffServ disabled), the system does not use the DSCP parameter for classification or modify it. If this variable is true, it activates the Layer3Trust parameter.
<b>Layer3Trust</b>	Configures the Layer 3 trusted port as an access or core port. The default is core. Core configures the port to a trusted state and access configures the port to an untrusted state. The DiffServ parameter determines the operation of this variable. If DiffServ is false, Layer3Trust has no effect; no modification of the DSCP or TOS bits occurs. If DiffServ is true, the core and access configuration take effect.
<b>Layer2Override8021p</b>	Specifies whether Layer 2 802.1p override is enabled (true) or disabled (false) on the port. The default is false. This variable primarily affects tagged packet treatment. If Layer2Override8021p is false, the port trusts the 802.1p-bits portion of a Q-tagged packet. The port trusts the 802.1p-bits marking regardless of the port setting (tagged or untagged); however, if the discard tagged packets parameter (DiscardTaggedFrames) on an untagged port is true, the system discards the packet. If Layer2Override8021p is true, the port does not trust the 802.1p bit marking. In this case, the QoS operation depends on other parameters, such as the port QoS level.
<b>QoSLevel</b>	Specifies the QoS level to use when the system processes packets carried on this port. Values range from level 0–6 (the system reserves 7 for network control traffic). The default is 1.

## Configuring Layer 3 trusted or untrusted ports

Configure a port as trusted or untrusted to determine the Layer 3 QoS actions the switch performs. A trusted port honors incoming DSCP markings. An untrusted port overrides DSCP markings. The default is trusted.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **QOS**.
2. Click **Port QoS Config**.
3. In the row for the port, double-click the cell in the **Layer3Trust** column.
4. Select **core** (trusted) or **access** (untrusted) as the port setting.

5. Click **Apply**.

## Configuring Layer 2 trusted or untrusted ports

Configure a port as trusted or untrusted to determine the Layer 2 QoS actions the switch performs. A trusted port (override false) honors incoming 802.1p bit markings. An untrusted port (override true) overrides 802.1p bit markings.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > QoS**.
2. Click **Port QoS Config**.
3. In the row for the port, double-click the cell in the **Layer2 Override 8021p** column.
4. To configure the port as a Layer 2 untrusted port, select **true**. To configure it as a Layer 2 trusted port, select **false**.  
By default, all ports are Layer 2 trusted (Layer2 Override 8021p is false).
5. Click **Apply**.

## Configuring the port QoS level

Use the default port QoS level to assign a default QoS level for all traffic, if the packet does not match an access control list (ACL) to remark the packet.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > QoS**.
2. Click **Port QoS Config**.
3. In the row for the port, double-click the cell in the **QoSLevel** column.
4. Select the new level.
5. Click **Apply**.

## QoS configuration using CLI

---

Use the procedures in this section to configure Quality of Service (QoS) on the switch.

## Configure Broadcast, Unknown Unicast, and Multicast Bandwidth Limiting

### Note

This procedure does not apply to XA1400 Series.

Configure broadcast/unknown unicast and multicast bandwidth limiting to limit the amount of ingress traffic on a port. The switch drops traffic that violates the bandwidth limit.

### About This Task

### Note

VSP 8600 Series does not support this feature for unknown unicast traffic.

## Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure broadcast and unknown unicast bandwidth limiting:

```
rate-limit [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
broadcast {<1-65535> | <50-65000000>}
```

3. Configure multicast bandwidth limiting:

```
rate-limit [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
multicast {<1-65535> | <50-65000000>}
```

4. Verify the configuration:

```
show interfaces gigabitethernet rate-limit [<1-4059> | {slot/port[/
sub-port] [-slot/port[/sub-port]] [,...]]
```

## Variable Definitions

The following table defines parameters for the **rate-limit** command.

Variable	Value
{<1-65535>   <50-65000000>}	Specifies the bandwidth limit for broadcast/unknown unicast and multicast traffic, in packets per second (pps).  <b>Note:</b> The <50-65000000> range only applies to VSP 8600 Series.
port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Viewing the port-based shaper information

### About This Task

Use this procedure to view the port-based shaper information. The system displays the port, egress rate limit in Kbps, and the rate limit status.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. View the ingress port-rate limit information:  
show qos shaper interface gigabitEthernet [{slot/port[/sub-port]}[-slot/port[/sub-port]}[,...]]

**Example**

```
Switch:1#show qos shaper interface gigabitEthernet 1/1
=====
Port Egress Rate-Limiting(Shape)
=====
-----
PORT      EGRESS RATE-LIMIT(kbps)  ENABLED/DISABLED
-----
1/1      0                          DISABLED
```

## Configuring the port-based shaper

Use port-based shaping to rate-limit all outgoing traffic to a specific rate.

**Procedure**

1. Enter GigabitEthernet Interface Configuration mode:  
enable  
  
configure terminal  
  
interface GigabitEthernet {slot/port[/sub-port]}[-slot/port[/sub-port]}[,...]]

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure port-based shaping:  
qos if-shaper [port {slot/port[/sub-port]} [-slot/port[/sub-port]}[,...]] shape-rate <shape-rate>

### Variable definitions

Use the data in the following table to use the **qos if-shaper** command.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the slot and port number to which to apply shaping. This variable is optional. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>shape-rate &lt;shape-rate&gt;</code>	Specifies the shaping rate in Kb/s. Different hardware platforms support different egress rate limits, depending on the port with the highest speed available on the platform. If you try to configure a limit that is too high for the port speed, the switch displays the following message: <code>Error: port slot/port, The QOS Egress shaper rate can not exceed the port capability.</code> The default is 0, which means shaping is disabled on the port.

## Configuring a port-based policer

Use a port policer to bandwidth-limit incoming traffic. The port drops or re-marks violating traffic.

### Note

This procedure only applies to VSP 4450 Series and VSP 8600 Series.

### About This Task

The interface policer has two configurable rates: peak rate (PIR) and service or committed rate (CIR). Traffic above PIR is marked as red. Traffic above CIR is qualified as yellow. Normally, CIR is lower than PIR. However, in CLI you can configure these rates to equal values. Each rate has a maximum burst size associated with it, peak burst size (PBS) and committed burst size (CBS) respectively. You cannot configure the burst sizes. These values ensure maximum traffic fairness between the ports; the CBS value is lower than the PBS value. Depending on the traffic pattern, this configuration can result in a small percentage of traffic qualified as yellow or above CIR, but not red or above PIR, even if the rates are equal.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the policing limit:

```
qos if-policer [port {slot/port[-slot/port] [,...]}] peak-rate
<64-100000000> svc-rate <64-100000000>
```

## Example

Configure the policing limit to a peak-rate of 10000 and the service rate limit to 5000 for port 4/10:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 4/10
Switch:1(config-if)#qos if-policer port 4/10 peak-rate 10000 svc-rate 5000
```

## Variable Definitions

Use the data in the following table to use the **qos if-policer** command.

Variable	Value
<code>peak-rate&lt;64-100000000&gt;</code>	Specifies the peak rate limit in Kbps.
<code>port {slot/port[-slot/port] [,...]}</code>	Identifies the slot and the port.
<code>svc-rate&lt;64-100000000&gt;</code>	Specifies the service rate limit in Kbps.

## View Ingress Policer Statistics

Use this procedure to view the ingress policer statistics. The system displays individual policer statistics for specific ports to manage network performance.

### Note

This procedure only applies to VSP 8600 Series, VSP 4450 Series and XA1400 Series.

## Procedure

1. Enter Privileged EXEC mode:

```
enable
```

## 2. View the policer statistics:

```
show interfaces gigabitethernet statistics policer {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

### Example

```
Switch:1# show interfaces gigabitethernet statistics policer 1/3
```

QoS Ingress Port Policer Stats				
PORT NUM	TOTAL PKTS	TOTAL BYTES	YELLOW BYTES	RED BYTES
1/3	420	31628	0	0

### Variable Definitions

Use the data in the following table to use the **show interfaces gigabitethernet statistics policer** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Configuring the ingress port-rate limiter

Use the ingress port-rate limiter to limit the traffic rate accepted by the specified ingress port. The port drops or re-marks violating traffic.

### Procedure

#### 1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

#### 2. Configure the ingress port-rate limit:

```
qos if-rate-limiting [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]] rate <1000-40000000>
```

## 3. Disable the ingress port-rate limit:

```
no qos if-rate-limiting [port {slot/port[/sub-port] [-slot/port[/sub-
port]] [,...]]
```

*Variable definitions*

Use the data in the following table to use the **qos if-rate-limiting** command.

Variable	Value
<i>1000-40000000</i>	Specifies the ingress rate limit in Kbps. The range is 1000–40000000.
<i>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</i>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

[View the Ingress Port-Rate Limit Information](#)

Use this procedure to view the ingress port-rate limit information. The system displays the port, rate limit in Kbps, and rate limit status.

**Procedure**

## 1. Enter Privileged EXEC mode:

```
enable
```

## 2. View the ingress port-rate limit information:

```
show qos rate-limiting interface gigabitEthernet [{slot/port[/sub-
port] [-slot/port[/sub-port]] [,...]]
```

**Example**

```
Switch:1# show qos rate-limiting interface gigabitEthernet 1/1
```

```

=====
                                Port Ingress Rate-Limiting
=====
-----
PORT      RATE (kbps)      ENABLED/DISABLED
-----
1/1       0                 DISABLED

```

*Variable definitions*

Use the data in the following table to use the **show qos rate-limiting interface gigabitEthernet** command.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Viewing Ingress Port-rate Limit Statistics

Use this procedure to view the ingress port-rate limit statistics. The system displays the statistics of the dropped packets and bytes.

**Note**

This procedure is not supported on VSP 4450 Series and VSP 8600 Series.

**Procedure**

1. Enter Privileged EXEC mode:

```
enable
```

2. View the ingress port-rate limit statistics:

```
show interfaces gigabitethernet statistics rate-limiting [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

**Example**

```
Switch:1# show interfaces gigabitethernet statistics rate-limiting 1/1
```

```

=====
                        QOS Interface Ingress Rate-Limiting Stats
=====
PORT      DROPPING          DROPPING          DROPPING          DROPPING
          PKTS RATE      BYTES RATE        PKTS              BYTES
-----
1/1       9224              1436481032        9260507
1430758

```

### Variable Definitions

Use the data in the following table to use the **show interfaces gigabitethernet statistics rate-limiting** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Configuring ingress mappings

You can modify the ingress mappings to change traffic priorities. However, as a best practice, use the default mappings.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure 802.1p bit to QoS ingress mappings:
 

```
qos ingressmap 1p <0-7> <0-6>
```
3. Configure DSCP to QoS ingress mappings:
 

```
qos ingressmap ds <0-63> <0-6>
```
4. Ensure the configuration is correct:
 

```
show qos ingressmap [1p <0-7>]

show qos ingressmap [ds <0-63>]
```

### Variable Definitions

Use the data in the following table to use the `qos ingressmap` command.

Variable	Value
<code>1p &lt;0-7&gt; &lt;0-6&gt;</code>	<p>Maps the IEEE 802.1p bit to QoS level. Each QoS level has a default IEEE 1P value:</p> <ul style="list-style-type: none"> <li>• level 0—1</li> <li>• level 1—0</li> <li>• level 2—2</li> <li>• level 3—3</li> <li>• level 4—4</li> <li>• level 5—5</li> <li>• level 6—6</li> </ul> <p>The system reserves level 7 for Network Control. To use the default configuration, use the default option in the command:  <code>default qos ingressmap 1p</code></p>
<code>ds &lt;0-63&gt; &lt;0-6&gt;</code>	<p>Maps the DS byte to QoS level. The system reserves level 7 for Network Control. To use the default configuration, use the default option in the command:  <code>default qos ingressmap ds</code></p>

## Configuring egress mappings

You can modify the egress mappings to change traffic priorities. However, as a best practice, use the default mappings.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure QoS to 802.1p bit egress mappings:
 

```
qos egressmap 1p <0-6> <0-7>
```
3. Configure QoS to DSCP egress mappings:
 

```
qos egressmap ds <0-7> WORD<1-6>
```
4. Ensure the configuration is correct:
 

```
show qos egressmap [1p <0-7>]

show qos egressmap [ds <0-7>]
```

### Variable Definitions

Use the data in the following table to use the `qos egressmap` command.

Variable	Value
<code>1p &lt;0-6&gt; &lt;0-7&gt;</code>	<p>Maps the QoS level to IEEE 802.1p bit. Each QoS level has a default IEEE 1P value:</p> <ul style="list-style-type: none"> <li>• level 0—1</li> <li>• level 1—0</li> <li>• level 2—2</li> <li>• level 3—3</li> <li>• level 4—4</li> <li>• level 5—5</li> <li>• level 6—6</li> </ul> <p>The system reserves level 7 for Network Control. To use the default configuration, use the default option in the command: <code>default qos egressmap 1p</code></p>
<code>ds &lt;0-7&gt; WORD&lt;1-6&gt;</code>	<p>Maps the QoS level to DS byte. You can specify the DSCP in either hexadecimal, binary, or decimal format. To use the default configuration, use the default option in the command: <code>default qos egressmap ds</code></p>

## View Port Egress CoS Queue Statistics

View the port egress CoS queue statistics. The system displays the statistics of the forwarded packets and bytes, and the dropped packets and bytes.

### About This Task

If you disable rate limiting on queue 6, bandwidth is shared based on the weights from queues 0 through 6. Based on equal weights assigned for queues 4 through 6, equal amounts of traffic egress queues 4 through 6. The system displays Queue 6 to provide much lower throughput than 50% of port bandwidth.

#### Note

On VOSS devices, if there is egress congestion when you enable the `boot config flags flow-control-mode` command, then the system does not drop the packets at egress, and does not increment the counters under the `show qos cosq-stats interface {slot/port[/sub-port]}[-slot/port[/sub-port]][, ...]` command output. Instead, the system drops the packets at the ingress port and the system counts them under the `INDISCARD` column of `show interfaces gigabitEthernet error {slot/port[/sub-port]}[-slot/port[/sub-port]][, ...]` command output.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the port egress CoS queue statistics:  
show qos cosq-stats interface <PT\_PORT>

#### Note

The show command output varies based on your hardware platform. On all VSP platforms except the VSP 8600 Series, the show command output displays Out Packets and Out Bytes per interface which shows the number of unicast packets sent out on each queue for an egress port. VSP 8600 Series uses VoQ queuing architecture which enables to read the Accepted Packets and Accepted Bytes on each queue. The Accepted Packets and Accepted Bytes show the number of packets and bytes that enter the VoQ for a particular queue on the egress port. The Drop Packets and Drop Bytes show the number of packets and bytes that are dropped when the VoQ is full.

#### Variable Definitions

Use the data in the following table to use the **show qos cosq-stats interface <PT\_PORT>** command.

Variable	Value
<PT_PORT>	PT indicates the slot number; PORT indicates the port number.

### Clearing port egress CoS queue statistics

Clear the port egress CoS queue statistics in the hardware.

#### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Clear the port egress CoS queue statistics:  
clear qos cosq-stats interface <PT\_PORT>

#### Variable Definitions

Use the data in the following table to use the **clear qos cosq-stats interface <PT\_PORT>** command.

Variable	Definition
<PT_PORT>	PT indicates the slot number; PORT indicates the port number.

## View CPU Queue Statistics

View the statistics of the forwarded packets and bytes, and the dropped packets and bytes for the traffic sent toward CP. The queue assignment is based on the protocol types, not on the internal CoS value. These statistics are useful for debugging purposes.

When a neighbor transitions to the STALE state, to initiate Neighbor Unreachability detection (NUD), a duplicate copy of the traffic destined to this neighbor is sent to the switch Control Processor (CP) on a low priority queue (queue 0). The original packet is forwarded to this neighbor. Once NUD is initiated, the hardware records are updated and the traffic is no longer sent to the CP. When a high rate of such traffic is sent to CP, the switch can drop some of these packets due to the in built CP rate limiting feature, which protects the CP from DOS attacks.

Use the command **show qos cosq-stats cpu-port** to view drop statistics on the CPU queue. This design does not result in loss of traffic.

Use the command **ipv6 nd reachable-time <0-3600000>** to increase the default value of 3000 milliseconds which in turn delays the scenario of data path sending STALE neighbor destined packets to the CP.

### About This Task

#### Note

If you disable rate limiting on queue 6, bandwidth is shared based on the weights from queues 0 through 6. Based on equal weights assigned for queues 4 through 6, equal amounts of traffic egress queues 4 through 6. The system displays Queue 6 to provide much lower throughput than 50% of port bandwidth.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. View the CPU queue statistics:  
`show qos cosq-stats cpu-port`

#### Note

Product Notice: The show command output varies based on your hardware platform. On all platforms except VSP 8600 Series, the show command output displays Out Packets and Out Bytes per interface which shows the number of unicast packets sent out on each queue for an egress port. VSP 8600 Series uses VoQ queuing architecture which supports an increased number of available queues, hence the output displays the number of packets accepted and dropped on each protocol type going to the CPU.

## Clearing CPU queue statistics

Clear the CPU queue statistics.

## Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Clear CPU queue statistics:
 

```
clear qos cosq-stats cpu-port
```

## Display CPU COSQ Counters

### Note

This procedure only applies to XA1400 Series.

Use the following procedure to display the CPU COSQ statistics and counters.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display CPU COSQ counter statistics:
 

```
show io cpu-cosq-counters
```

## Example

```
Switch:1# show io cpu-cosq-counters

===== PORT 1 COSQ STATS =====

bash-4.3# tc -s filter show dev veth101 ingress | grep 'match\|Sent'
match 00008902/0000ffff at -4

```

## Configure an Egress QoS Queue Profile

Configure a queue profile to apply the configured egress queue parameters to queues and ports.

### About This Task

After you make a configuration change to a queue profile, you must apply the profile before the changes take effect.

#### Note

The switch supports six queue profiles. The default queue profile, with the name default and ID 1, is automatically created during system startup and cannot be deleted.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the minimum weight for a specific queue:
 

```
qos queue-profile queue <1-6> <0-7> min-weight <1-100>
```
3. Enable rate limiting on a weighted queue:
 

```
qos queue-profile queue <1-6> <0-7> rate-limit-enable
```
4. Add a queue-profile port member:
 

```
qos queue-profile <1-6> member add {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```
5. Add a queue-profile name:
 

```
qos queue-profile <1-6> name WORD<0-64>
```
6. Apply the queue profile:
 

```
qos queue-profile <1-6> apply
```
7. Verify the egress queue configuration:
 

```
show qos queue-profile [<1-6> queue <0-7>|all]
```

## 8. (Optional) Configure the default settings for an egress queue:

- Configure the default minimum weight using one of the following commands:

```
default qos queue-profile queue <1-6> <0-7> min-weight
```

```
no qos queue-profile queue <1-6> <0-7> min-weight
```

- Configure the default rate limiting on a weighted queue using one of the following commands:

```
default qos queue-profile queue <1-6> <0-7> rate-limit-enable
```

```
no qos queue-profile queue <1-6> <0-7> rate-limit-enable
```

*Examples*

Configure the queue profile for queue 6 to use a weight of 20.

```
Switch:1(config)#qos queue-profile 6
Switch:1(config)#qos queue-profile queue 6 1 min-weight 20
Switch:1(config)#qos queue-profile 6 apply
```

View the queue profile configuration.

```
Switch:1#show qos queue-profile
```

```
=====
                        Qos Queue Profile
=====
```

Profile ID	Profile Name	Profile Port List
1	default	1/1-1/42,2/1-2/42
6	profile-6	

The value in the `Weight Applied` column is the maximum bandwidth for Strict Priority queues (Rate Limit Enabled) and the weight in the WRR scheduling algorithm applied per queue. Strict Priority queues are serviced first and limited to the configured percentage of bandwidth. WRR queues (no rate limit applied) have no upper boundary, other than the delta between the available bandwidth per port and the one consumed by Strict Priority queues. For WRR queues, there is no association with the bandwidth percentage servicing this queue; the bandwidth that can be served is relative to the available bandwidth at a certain moment and the load of other queues.

```
Switch:1(config)#show qos queue-profile 1 queue 1
```

```
=====
                        Qos Queue Profile Table
=====
```

Profile ID	Profile Name	Queue ID	Weight Applied	Weight Configured	Rate-limit Applied	Rate-limit Configured
1	default	1	0	20	ENABLE	DISABLE

```
Switch:1(config)#show qos queue-profile 1 queue all
```

Qos Queue Profile Table						
Profile ID	Profile Name	Queue ID	Weight Applied	Weight Configured	Rate-limit Applied	Rate-limit Configured
1	default	0	10	10	DISABLE	DISABLE
1	default	1	20	20	DISABLE	DISABLE
1	default	2	30	30	DISABLE	DISABLE
1	default	3	40	40	DISABLE	DISABLE
1	default	4	50	50	DISABLE	DISABLE
1	default	5	50	50	DISABLE	DISABLE
1	default	6	50	50	DISABLE	ENABLE
1	default	7	5	5	ENABLE	ENABLE

Variable Definitions

The following table defines parameters for the `qos queue-profile queue` command.

Variable	Value
<1-6>	Specifies the queue profile ID.  <b>Note:</b> The switch supports six queue profiles. The default queue is 1.
<0-7>	Specifies the egress queue to configure.
<i>min-weight</i> <1-100>	Configures the queue weight for weighted round robin (WRR), or the rate-limit in percentage of the link rate for queue shaping enabled on the queue. For rate-limit-enabled queues, 50 indicates 50% bandwidth. The overall rate-limit-enabled queues cannot sum higher than 100 min-weight. If rate-limiting is not enabled, this parameter configures the weight in the WRR scheduler. These values are not associated with bandwidth percentage. The following list identifies the default minimum weight for each queue: <ul style="list-style-type: none"> <li>• Queue 0 — 10</li> <li>• Queue 1 — 20</li> <li>• Queue 2 — 30</li> <li>• Queue 3 — 40</li> <li>• Queue 4 — 50</li> <li>• Queue 5 — 50</li> <li>• Queue 6 — Rate limited to 50% of configured shaper rate</li> <li>• Queue 7 — Rate limited to 5% of configured shaper rate</li> </ul>
<i>member add</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Specifies a port member of the queue-profile to add or remove.

Variable	Value
<i>name</i> WORD<0-64>	Specifies a profile name.
<i>rate-limit-enable</i>	Enables rate limiting on the queue. By default, rate limiting is enabled for queues 6 and 7 only; it is disabled for queues 0 through 5.

The following table defines parameters for the **show qos queue-profile** command.

Variable	Value
<1-6>	Specifies the queue profile ID. If you do not include a queue profile ID, the command output displays all configured profiles.  <b>Note:</b> The switch supports six queue profiles. The default queue is 1.
<0-7>	Specifies the egress queue. Displays configuration settings of the specified egress queue.
<i>all</i>	The command output displays the configuration settings of all eight egress queues of the queue profile.

## Configure Egress Tunnel Shaping

### About This Task

Perform this procedure to configure Egress Tunnel Shaping on a logical interface.

### Procedure

- To enter User EXEC mode, log on to the switch.
- Enter Global Configuration mode:  
enable  
  
configure terminal
- Enable SPBM globally:  
spbm
- Enter IS-IS Router Configuration mode:  
router isis
- Create a global SPBM instance:  
spbm <1-100>
- Create a nickname for the global SPBM instance:  
spbm <1-100> nick-name x.xx.xx
- Add the backbone VLANs to the SPBM instance and set the primary VLAN:  
spbm <1-100> b-vid {vlan-id[-vlan-id][, ...]} primary <1-4059>
- Exit IS-IS Router Configuration mode:  
exit

9. Enter IS-IS Router Configuration mode:

```
router isis
```

10. Configure the IS-IS system name:

```
sys-name WORD<0-255>
```

11. Configure the global router type:

```
is-type l1
```

12. Configure the manual area:

```
manual-area xx.xxx.xxx...xxxx
```

13. Exit IS-IS Router Configuration mode:

```
exit
```

14. Create two SPBM Backbone VLANs that correspond to those configured in the previous step using the following command twice:

```
vlan create <1-4059> type spbm-bvlan
```

15. Enable IS-IS globally:

```
router isis enable
```

16. Remove the brouter port from all VLANs:

```
vlan members remove <1-4059> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} {
```

17. Enter Interface Configuration mode:

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]} {
```

18. Configure a brouter port:

```
brouter port {slot/port[/sub-port]} vlan <1-4059> subnet {A.B.C.D/X} mac-offset <MAC-offset>
```

19. Exit Interface Configuration mode:

```
exit
```

20. Enter IS-IS Router Configuration mode:

```
router isis
```

21. Configure the IP tunnel source address:

```
ip-tunnel-source-address {A.B.C.D}
```

22. Exit IS-IS Router Configuration mode:

```
exit
```

23. Create a logical IS-IS interface and enter Logical Interface Configuration mode:

```
logical-intf isis <1-255> dest-ip {A.B.C.D} name WORD <1-64> [mtu <750-9000>]
```

24. Create an IS-IS circuit and interface:

```
isis
```

25. Enable the SPBM instance:

```
isis spbm <1-100>
```

26. Enable the IS-IS circuit and interface:

```
isis enable
```

## 27. Configure the Egress Tunnel Shaper:

```
egress-shaping-rate <1-1000>
```

## 28. Exit Logical Interface Configuration mode:

```
exit
```

## Variable Definitions

Use the data in the following table to use the **vlan members** command.

Variable	Value
remove <1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Use the data in the following table to use the **spbm** command.

Variable	Value
<1-100>	Specifies the Shortest Path Bridging MAC (SPBM) instance ID. Creates the SPBM instance. Only one SPBM instance is supported.

Use the data in the following table to use the **spbm** command to create a system nickname for an SPBM instance.

Variable	Value
<1-100>	Specifies the Shortest Path Bridging MAC (SPBM) instance ID. Creates the SPBM instance. Only one SPBM instance is supported.
nick-name x.xx.xx	Specifies the system nickname (2.5 bytes in the format ).

Use the data in the following table to use the **spbm** command to assign Backbone VLANs to the SPBM instance.

Variable	Value
<code>&lt;1-100&gt;</code>	Specifies the Shortest Path Bridging MAC (SPBM) instance ID. Creates the SPBM instance. Only one SPBM instance is supported.
<code>b-vid {vlan-id[-vlan-id][, ...]}</code>	Specifies the VLANs to add to the Shortest Path Bridging MAC (SPBM) instance as Backbone VLANs (B-VLANs). Sets the IS-IS SPBM instance data VLANs.
<code>primary &lt;1-4059&gt;</code>	Specifies the primary B-VLAN by VLAN ID.

Use the data in the following table to use the **sys-name** command.

Variable	Value
<code>WORD&lt;0-255&gt;</code>	Specifies the system name.

Use the data in the following table to use the **is-type** command.

Variable	Value
<code>11</code>	Configures the router type as Level 1 Intermediate-System-to-Intermediate-System (IS-IS).

Use the data in the following table to use the **manual-area** command.

Variable	Value
<code>xx.xxxx.xxxx...xxxx</code>	Configures the manual area in a size up to 13 octets. The current release supports one area. For Intermediate-System-toIntermediate-System (IS-IS) to operate, you must configure at least one area.

Use the data in the following table to use the **vlan create** command.

Variable	Value
<code>&lt;1-4059&gt;</code>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<code>type spbm-bvlan</code>	Specifies the VLAN type as the backbone VLAN (B-VLAN) for Shortest Path Bridging MAC (SPBM).

Use the data in the following table to use the **interface GigabitEthernet** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Use the data in the following table to use the **router port** command.

Variable	Value
<code>{slot/port[/sub-port]}</code>	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>vlan &lt;1-4059&gt;</code>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

Variable	Value
<code>subnet &lt;A.B.C.D/X&gt;</code>	Assigns an IP address and mask for the port.
<code>mac-offset &lt;MAC-offset&gt;</code>	Specifies a number by which to offset the MAC address from the chassis MAC address. This ensures that each IP address has a different MAC address. If you omit this variable, a unique MAC offset is automatically generated. Different hardware platforms support different ranges. To see which range is available on the switch, use the CLI command completion Help.

Use the data in the following table to use the **ip-tunnel-source-address** command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the IS-IS IPv4 tunnel source address.

The following table defines parameters for the **logical-intf** command.

Variable	Value
<code>isis &lt;1-255&gt;</code>	Specifies the ISIS logical interface ID.
<code>dest-ip {A.B.C.D}</code>	Specifies the destination IP address for the logical interface.
<code>name WORD &lt;1-64&gt;</code>	Specifies the administratively-assigned name of this logical interface, which can be up to 64 characters.
<code>mtu &lt;750-9000&gt;</code> <b>Note:</b> Exception: only supported onXA1400 Series	Specifies the Maximum Transmission Unit (MTU) size for each packet. Default mtu value is 1950.

Use the data in the following table to use the **egress-shaping-rate** command.

Variable	Value
<code>&lt;1-1000&gt;</code>	Specifies the shaper bandwidth in Mbps.

### Egress Tunnel Shaping Configuration Example

The following is an example of an Egress Tunnel Shaping configuration.

#### SPBM Configuration

```
Switch> enable
Switch# config terminal
Switch(config)# vlan members remove 1 1/8
```

```

Switch(config)# spbm
Switch(config-isis)# router isis
Switch(config-isis)# spbm 1
Switch(config-isis)# spbm 1 nick-name 1.11.40
Switch(config-isis)# spbm 1 b-vid 2,3 primary 2
Switch(config-isis)# exit
Switch(config)# router isis
Switch(config-isis)# sys-name XA1400
Switch(config-isis)# is-type ll
Switch(config-isis)# manual-area c0.2000.0000.00
Switch(config-isis)# exit
Switch(config)# vlan create 2 type spbm-bvlan
Switch(config)# vlan create 3 type spbm-bvlan

```

### Fabric Extend Configuration

```

Switch(config)# router isis enable
Switch(config)# interface GigabitEthernet 1/8
Switch(config-if)# brouter port 1/8 vlan 2500 subnet 192.0.2.1/255.255.255.0 mac-offset 0
Switch(config-if)# exit
Switch(config)# router isis
Switch(config-isis)# ip-tunnel 192.0.2.1
Switch(config-isis)# exit

```

### Egress Tunnel Shaping Configuration

```

Switch(config)# logical-intf isis 1 dest-ip 192.0.2.2 name "bang"
Switch(config-isis-1)# isis
Switch(config-isis-1)# isis spbm 1
Switch(config-isis-1)# isis enable
Switch(config-isis-1)# egress-shaping-rate 500
Switch(config-isis-1)# exit

```

## Viewing Logical Interface CoS Queue Statistics

View the QoS CoS queue statistics for IS-IS logical interfaces. These statistics are useful for debugging purposes.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. View the logical interface queue statistics:  
show qos cosq-stats logical-intf [isis <1-255>]

## Clearing Logical Interface CoS Queue Statistics

Clear the QoS CoS queue statistics for IS-IS logical interfaces.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Clear the logical interface queue statistics:  
clear qos cosq-stats logical-intf [isis <1-255>]

## QoS configuration using EDM

---

Configure Quality of Service (QoS) to allocate network resources where you need them most.

### Configuring port-based shaping

Configure egress port-based shaping to bind the maximum rate at which traffic leaves the port.

#### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Click **General**.
4. Click the **Interface** tab.
5. From **EgressRateLimitState**, select **enable**.
6. In the **EgressRateLimit** box, type an egress rate limit in kilobits per second (Kb/s).
7. Click **Apply**.

### Configure Port-Based Policing

Use a port-based policer to bandwidth-limit ingress traffic. The system drops or re-marks violating traffic.

#### Procedure

1. In the Device Physical View tab, select a port.
2. In the navigation tree, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **Interface** tab.
5. From **IngressRatePeak**, type the value for the peak rate in Kbps.  
The peak rate must be greater than or equal to the service rate.
6. From **IngressRateSvc**, type the value for the service rate in Kbps.
7. Select **Apply**.

### View Port Policer Statistics

#### Note

This procedure only applies to VSP 4450 Series.

View port policer statistics to manage network performance.

#### Procedure

1. In the navigation pane, expand **Configuration > Graph**.
2. Select **Port**.
3. Select the **Policer** tab.

**Policer** Field Descriptions

Use the data in the following table to use the **Policer** tab.

Name	Description
<b>TotalPkts</b>	Shows the total number of packets received on the port.
<b>TotalBytes</b>	Shows the total number of bytes received on the port.
<b>YellowBytes</b>	Shows the total number of bytes received on the port that were above the committed rate but below the peak rate.
<b>RedBytes</b>	Shows the total number of bytes received on the port that were above the peak rate.

## Configuring ingress port-rate limiter

Use the ingress port-rate limiter to limit the traffic rate accepted by the specified ingress port. The system drops or re-marks violating traffic.

**Procedure**

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand the **Configuration > Edit > Port** folders.
3. Click **General**.
4. Click the **Interface** tab.
5. From **IngressRateLimit** , type the value in Kbps to set the traffic rate limit.  
The ingress rate limit must be between 1000 and 40000000.
6. Click **Apply**.

## Graphing Stat Rate Limit Statistics for a Port

View stat rate limit statistics to view the total dropped packets and bytes.

**Procedure**

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Port**.
4. Click the **Stat Rate Limit** tab.
5. Select one or more values.
6. Click the type of graph to create.

**Stat Rate Limit** *Field Descriptions*

Use the data in the following table to use the **Stat Rate Limit** tab.

Name	Description
<b>DropPktRate</b>	Indicates the drop packet rate.
<b>DropByteRate</b>	Indicates the drop byte rate.
<b>DropTotalBytes</b>	Indicates the total bytes dropped.
<b>DropTotalPkts</b>	Indicates the total packets dropped.

## Modifying ingress 802.1p to QoS mappings

Modify the ingress mappings to change traffic priorities. As a best practice, use the default mappings.

**About This Task**

Do not change the default values. If you change the values, make sure that the values are consistent on all other devices in the network. Inconsistent mapping of table values can result in unpredictable service levels.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **Mapping Tables**.
3. Click the **Ingress 8021p to QoS** tab.
4. Double-click a QosLevel field to change the value.
5. Click **Apply**.

**Ingress 8021p To QoS** *field descriptions*

Use the data in the following table to use the **Ingress 8021p to QoS** tab.

Name	Description
<b>InIeee8021P</b>	Specifies the value of the IEEE 802.1p bit of the incoming packet.
<b>QosLevel</b>	Specifies the equivalent egress QoS level (0–7).

## Modifying ingress DSCP to QoS mappings

Modify the ingress Differentiated Services Code Point (DSCP) to QoS mappings to change traffic priorities. As a best practice, use the default mappings. Changes to the mapping table take effect after you restart the system.

### About This Task

Do not change the default values. If you change the values, make sure that the values are consistent on all other devices in the network. Inconsistent mapping of table values can result in unpredictable service levels.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > QoS**.
2. Click **Mapping Tables**.
3. Click the **Ingress Dscp To QoS** tab.
4. Double-click a QoSLevel field to change the value.
5. Click **Apply**.

### *Ingress Dscp To QoS field descriptions*

Use the data in the following table to use the **Ingress Dscp To QoS** tab.

Name	Description
<b>InDscp</b>	Specifies the value of the DiffServ codepoint (in decimal format) in the IP header of the incoming packet.
<b>InDscpBinaryFormat</b>	Specifies the value of the DiffServ codepoint (in binary format) in the IP header of the incoming packet.
<b>QoSLevel</b>	Specifies the equivalent QoS level.

## Modifying egress QoS to 802.1p mappings

Modify the egress mappings to change the mappings between the QoS levels and the IEEE 802.1p bits.

### About This Task

Do not change the default values. If you change the values, make sure that the values are consistent on all other devices in the network. Inconsistent mapping of table values can result in unpredictable service levels.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > QoS**.
2. Click **Mapping Tables**.
3. Click the **Egress QoS to 8021p** tab.
4. Double-click the Outleee8021P field to change the value.
5. Click **Apply**.

**Egress QoS to 8021p** field descriptions

Use the data in the following table to use the **Egress QoS to 8021p** tab.

Name	Description
<b>QosLevel</b>	Specifies the QoS level of the outgoing packet.
<b>Outleeee8021P</b>	Specifies the equivalent value of the IEEE 802.1p bit.

## Modifying egress QoS to DSCP mappings

Modify the egress QoS to DSCP mappings to change traffic priorities. As a best practice, use the default mappings.

**About This Task**

Do not change the default values. If you change the values, make sure that the values are consistent on all other devices in the network. Inconsistent mapping of table values can result in unpredictable service levels.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **Mapping Tables**.
3. Click the **Egress QoS To Dscp** tab.
4. Double-click the OutDscp file to change the value.
5. Click **Apply**.

**Egress QoS To Dscp** field descriptions

Use the data in the following table to use the **Egress QoS To Dscp** tab.

Name	Description
<b>QosLevel</b>	Specifies the QoS level of the outgoing packet.
<b>OutDscp</b>	Specifies the equivalent value of the DiffServ code point (in decimal format).
<b>OutDscpBinaryFormat</b>	Specifies the equivalent value of the DiffServ code point (in binary format).

## Viewing port egress CoS queue statistics

Use the following procedure to retrieve the port egress CoS queue statistics. The system displays the statistics of the forwarded packets and bytes, and the dropped packets and bytes.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > QOS**.

2. Click **CoS Queue Stats**.
3. Select the **Interface** tab.

#### *Interface Field Descriptions*

The following table describes the fields from the CoS Queue Stats **Interface** tab.

Name	Description
<b>Index</b>	Indicates the loopback port number from 192(1/1) to 241(1/50).
<b>ClearStat</b>	Clears the port egress statistics.
<b>Que&lt;0-7&gt;OutPackets</b>	Indicates the out packets by CoS queue number 0-7.
<b>Que&lt;0-7&gt;OutBytes</b>	Indicates the out bytes by CoS queue number 0-7.
<b>Que&lt;0-7&gt;DropPackets</b>	Indicates the drop packets by CoS queue number 0-7.
<b>Que&lt;0-7&gt;DropBytes</b>	Indicates the drop bytes by CoS queue number 0-7.

## Clearing CPU statistics for the chassis

Use the following procedure to clear the CPU statistics for the chassis.

#### **Procedure**

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **CoS Queue Stats**.
3. Select the **CPU-Stats-Clear** tab.
4. Select the **CpuStatsClear** check box.
5. Click **Apply**.

## Viewing CPU queue statistics

Use the following procedure to retrieve the statistics of the forwarded packets and bytes, and the dropped packets and bytes for the traffic sent toward CP. The queue assignment is based on the protocol types, not on the internal CoS value. These statistics are useful for debugging purposes.

#### **Procedure**

1. In the navigation tree, expand the following folders: **Configuration > QOS**.
2. Click **CoS Queue Stats**.
3. Select the **CPU-Port** tab.

#### **CPU-Port** *Field Descriptions*

Use the data in the following table to use the **CPU-Port** tab.

Name	Description
Index	Indicates the CoS queue number.
OutPackets	Indicates the out packets for the CPU port.
OutBytes	Indicates the out bytes for the CPU port.
DropPackets	Indicates the drop packets for the CPU port.
DropBytes	Indicates the drop bytes for the CPU port.

## View Tunnel CoS Queue Statistics

### Note

This procedure only applies to XA1400 Series.

Use the following procedure to retrieve the tunnel CoS queue statistics. The system opens the statistics of the forwarded packets and bytes and the dropped packets and bytes.

### Procedure

1. In the navigation tree, expand: **Configuration** > **QOS**.
2. Select **CoS Queue Stats**.
3. Select the **Tunnel** tab.

### Tunnel Field Descriptions

The following table describes the fields from the CoS Queue Stats **Tunnel** tab.

Name	Description
<b>Index</b>	Indicates the loopback port number from 192(1/1) to 241(1/50).
<b>Que&lt;0-7&gt;OutPackets</b>	Indicates the out packets by CoS queue number 0-7.
<b>Que&lt;0-7&gt;OutBytes</b>	Indicates the out bytes by CoS queue number 0-7.
<b>Que&lt;0-7&gt;DropPackets</b>	Indicates the drop packets by CoS queue number 0-7.
<b>Que&lt;0-7&gt;DropBytes</b>	Indicates the drop bytes by CoS queue number 0-7.

## Configuring an egress QoS queue profile

Configure a queue profile to apply the configured egress queue parameters to queues and ports. You must apply the profile before the changes take effect.

### About This Task

The switch supports six queue profiles. The default queue profile, with the name default and ID 1, is automatically created during system startup and cannot be deleted.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > QoS**.
2. Click **Queue Profile**.
3. Click the **Queue Profile** tab.
4. Click **Insert**.
5. In the **Id** field, type the queue profile value.
6. In the **Name** field, specify a name for the queue profile.
7. To add a port to this queue, click the **PortList** ellipsis (...), choose a port or ports, and then click **Ok**.
8. Select the **Apply** check box.
9. Click **Insert**.

### Queue Profile field descriptions

Use the data in the following table to use the **Queue Profile** tab.

Field	Description
<b>Id</b>	Specifies the ID for the queue profile.
<b>Name</b>	Specifies the queue profile name.
<b>Apply</b>	Applies the queue profile.
<b>PortList</b>	Indicates the port members of the queue profile.

## Editing queue profile information

### About This Task

Use the following procedure to edit queues of a queue profile, to configure a queue weight or enable rate limiting on the queue.

#### Note

After you make the configuration changes, you must apply the queue profile before the changes take effect.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > QoS**.
2. Click **Queue Profile**.
3. Update a queue to configure queue weight or rate limiting.
  - a. Click the **Queue** tab.
  - b. Edit the **AdminWeight** and **AdminRateLimitStatus** fields by double-clicking on them, and then selecting or typing the new value.

- c. Click **Apply**.
4. Apply the queue profile for the queue configuration to take effect.
  - a. Click the **Queue Profile** tab.
  - b. In the **Apply** field, double-click and select **true**.
  - c. Click **Apply**.
5. Click the **Queue** tab again, to verify updates to the **OperWeight** and the **OperRateLimitStatus** fields, for the respective queue.

#### Queue field descriptions

Use the data in the following table to use the **Queue** tab.

Field	Description
PId	Displays the queue profile ID.
Id	Displays the queue ID.
AdminWeight	<p>Configures the queue weight for weighted round robin (WRR), or the rate-limit in percentage of the link rate for queue shaping enabled on the queue. For rate-limit-enabled queues, 50 indicates 50% bandwidth. The overall rate-limit-enabled queues cannot sum higher than 100 min-weight. If rate-limiting is not enabled, this field configures the weight in the WRR scheduler. These values are not associated with bandwidth percentage. The following list identifies the default minimum weight for each queue:</p> <ul style="list-style-type: none"> <li>• Queue 0 — 10</li> <li>• Queue 1 — 20</li> <li>• Queue 2 — 30</li> <li>• Queue 3 — 40</li> <li>• Queue 4 — 50</li> <li>• Queue 5 — 50</li> <li>• Queue 6 — Rate limited to 50% of configured shaper rate</li> <li>• Queue 7 — Rate limited to 5% of configured shaper rate</li> </ul>
OperWeight	Displays the operational weight of the profile, described as a percentage.
AdminRateLimitStatus	Enables rate limiting on the queue. By default, rate limiting is enabled (true) for queues 6 and 7 only; it is disabled (false) for queues 0 through 5.
OperRateLimitStatus	Displays the operational status of the queue rate limit.

## Configure Port Rate Limits

### Note

This procedure does not apply to XA1400 Series.

Configure broadcast, unknown unicast, and multicast bandwidth limiting to limit the amount of ingress traffic on a port. The switch drops traffic that violates the bandwidth limit.

### About This Task

### Note

VSP 8600 Series does not support this feature for unknown unicast traffic.

### Procedure

1. On the Device Physical View, select a port or multiple ports.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Select **General**.
4. Select the **Rate Limiting** tab.
5. In the row for the required traffic type, configure the bandwidth limit in **AllowedRatePps**.
6. In the row for the required traffic type, select true for **Enable**.
7. Select **Apply**.

### **Rate Limiting** Field Descriptions

Use the data in the following table to use the **Rate Limiting** tab.

Name	Description
<b>Index</b>	Displays the port number.
<b>TrafficType</b>	Displays the type of traffic being rate limited, either broadcast/unknown unicast or multicast traffic. The default is broadcast, which means both broadcast and unknown unicast traffic.
<b>AllowedRatePps</b>	Specifies the allowed traffic rate limit for the port in packets per second (pps). 1–65535 configures the limit in packets for each second. The default is 25.
<b>Enable</b>	Enables or disables rate limiting. The default is false or disabled.

## Configuring Rate Limits on an Extreme Integrated Application Hosting Port

### Note

This procedure only applies to VSP 4900 Series and VSP 7400 Series.

### About This Task

Perform this procedure to configure the rate limit of broadcast or multicast packets and determine the total bandwidth limit on the Extreme Integrated Application Hosting (IAH) port.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > Insight Port**.
2. Select the IAH port you want to configure.
3. Select the **Rate Limiting** tab.
4. In the **AllowedRatePps** column, enter a time duration for the specific Extreme Integrated Application Hosting port.
5. In the **Enable** column, select **true** to enable rate limiting for the specific IAH port.
6. Select **Apply**.

### **Rate Limiting** *Field Descriptions*

Name	Description
<b>Index</b>	Specifies the Extreme Integrated Application Hosting (IAH) port.
<b>TrafficType</b>	Shows the traffic type.
<b>AllowedRatePps</b>	Specifies the allowed traffic rate limit for the IAH port in packets per second (pps).
<b>Enable</b>	Enables or disables rate limiting for the specific IAH port. The default is false (disabled).

**Note**

DEMO FEATURE - Secure AAA server communication, which includes RADIUS secure communication using IPSec for IPv4 and IPv6, is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [Fabric Engine and VOSS Feature Support Matrix](#).

## RADIUS Fundamentals

---

Remote Access Dial-In User Services (RADIUS) is a distributed client/server system that assists in securing networks against unauthorized access, allowing a number of communication servers and clients to authenticate users identity through a central database. The database within the RADIUS server stores information about clients, users, passwords, and access privileges including the use of shared secret.

RADIUS is a fully open and standard protocol, defined by two Requests for Comments (RFC) (Authentication: RFC2865, Accounting: RFC2866). You use RADIUS authentication to get secure access to the system (console/Telnet/SSH/EDM), and RADIUS accounting to track the management sessions (CLI only).

### RADIUS Server Support for IPv6

RADIUS supports both IPv4 and IPv6 with no differences in functionality or configuration in all but the following case. When you add or update a RADIUS server in

Enterprise Device Manager (EDM) you must specify if the address type is an IPv4 or an IPv6 address.

## How RADIUS Works

A RADIUS application has two components:

<ul style="list-style-type: none"> <li>• RADIUS server</li> </ul>	<p>A computer equipped with server software (for example, a UNIX workstation) that is located at a central office or campus. The server has authentication and access information in a form that is compatible with the client. Typically, the database in the RADIUS server stores client information, user information, password, and access privileges, including the use of a shared secret. A network can have one server for both authentication and accounting, or one server for each service.</p>
<ul style="list-style-type: none"> <li>• RADIUS client</li> </ul>	<p>A device, router, or a remote access server, equipped with client software, that typically resides on the same local area network (LAN) segment as the server. The client is the network access point between the remote users and the server.</p>

The two RADIUS processes are

- RADIUS authentication—Identifies remote users before you give them access to a central network site.
- RADIUS accounting—Performs data collection on the server during a remote user's dial-in session with the client.

## Configuration of the RADIUS Server and Client

For more information about how to configure a RADIUS server, see the documentation that came with the server software.

The switch software supports BaySecure Access Control (BSAC) and the Merit Network servers. To use these servers, you must first obtain the software for the server you will use. Also, you must make changes to one or more configuration files for these servers.

## RADIUS Authentication

You can use RADIUS authentication to use a remote server to authenticate logons. The RADIUS server also provides access authority. RADIUS assists network security and authorization by managing a database of users. The device uses this database to verify user names and passwords as well as information about the type of access priority available to the user.

When the RADIUS client sends an authentication request requesting additional information such as a SecurID number, it sends it as a challenge-response. Along with the challenge-response, it sends a reply-message attribute. The reply-message is a text

string, such as `Please enter the next number on your SecurID card:`. The RFC defined maximum length of each reply-message attribute is 253 characters. If you have multiple instances of reply-message attributes that together form a large message that displays to the user, the maximum length is 2000 characters.

You can use additional user names to access the device, in addition to the six existing user names of `ro`, `L1`, `L2`, `L3`, `rw`, and `rwa`. The RADIUS server authenticates the user name and assigns one of the existing access priorities to that name. Unauthenticated user names are denied access to the device. You must add user names `ro`, `L1`, `L2`, `L3`, `rw`, and `rwa` to the RADIUS server if you enable authentication. Users not added to the server are denied access.

The limitation on the number of characters in a username for users logging into CLI or EDM configured with RADIUS authentication is 64 characters.

**Note**

RADIUS server used-by snmp does not support authentication.

The following list shows the user configurable options of the RADIUS feature:

- Up to 10 RADIUS servers in each device for fault tolerance (each server is assigned a priority and is contacted in that order).
- A secret key for each server to authenticate the RADIUS client
- The server UDP port
- Maximum retries allowed
- Time-out period for each attempt

**Note**

If you enable enhanced secure mode with the **boot config flags** **enhancedsecure-mode** command, you enable different access levels, along with stronger password complexity, length, and minimum change intervals. With enhanced secure mode enabled, the switch supports the following access levels for RADIUS authentication:

- Administrator
- Privilege
- Operator
- Auditor
- Security

The switch associates each username with a certain role and appropriate authorization rights to view and configure commands. For more information on system access fundamentals and configuration, see [System Access](#) on page 3611.

## Use of RADIUS to Modify User Access to CLI Commands

The switch provides CLI command access based on the configured access level of a user. However, you can use RADIUS to override CLI command access provided by the switch.

To override user access to CLI commands, you must configure the `command-access-attribute` on the switch and on the RADIUS server. (The switch uses decimal value 194 as the default for this parameter.) On the RADIUS server, you can then define the commands that the user can or cannot access.

### Important

When you enable RADIUS on the switch and configure a RADIUS server to be used by CLI or EDM, the server authenticates the connection, whether it is FTP, HTTPs, SSH, or TELNET. However, in the event that the RADIUS server is unresponsive or is unreachable, the switch falls back to the local authentication, so that you can access the switch using your local login credentials.

Regardless of the RADIUS server configuration, you must configure the user's access on the switch based on the six platform access levels.

## RADIUS Accounting

RADIUS accounting logs all of the activity of each remote user in a session on the centralized RADIUS accounting server.

Session-IDs for each RADIUS account generate as 12-character strings. The first four characters in the string form a random number in hexadecimal format. The last eight characters in the string indicate the number of user sessions started since the last restart, in hexadecimal format.

The Network Address Server (NAS) IP address for a session is the address of the device interface to which the remote session is connected over the network. For a console session, modem session, and sessions running on debug ports, this value is set to 0.0.0.0, as is the case with RADIUS authentication.

The following table summarizes the events and associated accounting information logged at the RADIUS accounting server.

**Table 211: Accounting Events and Logged Information**

Event	Accounting information logged at server
Accounting is turned on at router	<ul style="list-style-type: none"> <li>Accounting on request: NAS IP address</li> </ul>
Accounting is turned off at router	<ul style="list-style-type: none"> <li>Accounting off request: NAS IP address</li> </ul>
User logs on	<ul style="list-style-type: none"> <li>Accounting start request: NAS IP address</li> <li>Session ID</li> <li>User name</li> </ul>

**Table 211: Accounting Events and Logged Information (continued)**

Event	Accounting information logged at server
More than 40 CLI commands are executed	<ul style="list-style-type: none"> <li>• Accounting interim request: NAS IP address</li> <li>• Session ID</li> <li>• CLI commands</li> <li>• User name</li> </ul>
User logs off	<ul style="list-style-type: none"> <li>• Accounting stop request: NAS IP address</li> <li>• Session ID</li> <li>• Session duration</li> <li>• User name</li> <li>• Number of input octets for session</li> <li>• Number of octets output for session</li> <li>• Number of packets input for session</li> <li>• Number of packets output for session</li> <li>• CLI commands</li> </ul>

When the device communicates with the RADIUS accounting server, the following actions occur:

1. If the server sends an invalid response, the response is silently discarded and the server does not make an attempt to resend the request.
2. User-specified number of attempts are made if the server does not respond within the user-configured timeout interval. If a server does not respond to any of the retries, requests are sent to the next priority server (if configured). You can configure up to 10 RADIUS servers for redundancy.

**Note**

RADIUS server used-by endpoint-tracking does not support accounting.

## RFC 4675 RADIUS Attributes: Egress VLAN

Egress VLAN controls egress traffic. Egress VLAN supports two standard RADIUS attributes as defined in RFC 4675:

- Egress-VLANID
- Egress-VLAN-Name

RADIUS attributes control the 802.1Q tagging for traffic egressing a port where RADIUS authentication is performed for a connected EAP or NEAP client.

Egress VLANs are standard attributes, therefore the RADIUS server supports the attributes by default and offer the ability to configure the attributes. Each attribute has two parts:

1. Indicates if the frames on the VLAN egress must be tagged or untagged
2. Specifies the VLAN name or VLAN ID

The switch applies the VLAN received in the Egress-VLAN attributes to the port where the client is authenticated through RADIUS and then sets the tagging rules (tagged or untagged) accordingly.

The switch processes the Egress-VLAN attributes when decoding the RADIUS packet, therefore the switch adds the port to the VLANs first and then sets the proper tagging for the VLANs. You must create VLANs in advance on the switch.

In the MultiVlan operation mode, the EAP applies ingress hardware rules to ensure untagged traffic from each authenticated client goes into its own VLAN. The unauthenticated clients send traffic to the Guest VLAN, which matches the default VLAN ID.

For more information, see [VLAN RADIUS Attributes](#) on page 3041.

## RADIUS Server Reachability

Configure up to 10 EAP RADIUS servers on the switch to manage fault tolerance. Each server is assigned a priority and is contacted in the priority order. If the first server is unavailable, the switch tries the second server, and so on, until the switch establishes a successful connection. Higher priority means lower integer value.

RADIUS server reachability prevents clients from trying to establish a connection with non-reachable servers. RADIUS server reachability runs a periodic check in the background to identify the available servers. The switch is aware of the first available EAP RADIUS server without going through each of the servers and wait for time-outs.

Use RADIUS server reachability to configure the switch to use RADIUS requests to determine the reachability of the RADIUS server. The switch regularly performs the reachability test to determine if the switch should fail over to the secondary RADIUS server or activate the Fail Open VLAN, if configured on the switch.

Use one of the following modes to configure RADIUS reachability:

- **status-server mode:** Status-Server packets provide a standard-compliant alternative to configuring dummy RADIUS requests. You can configure the switch to send status-server packets when the keep-alive timer or the unreachable timer expires. In order to use status-server mode, the configured RADIUS servers must support RFC5997.
- **use-radius mode:** Configure user-radius mode if any of the RADIUS servers do not support RFC5997. In user-radius mode, the switch regularly generates a dummy RADIUS request with the username `reachme` and password `reachme`. The switch interprets either Request Accept or Request Reject responses as a confirmation for server reachability, therefore it is not necessary to add the credentials on the server to test server reachability. You can configure the username and password for the dummy account through CLI. Use-radius is the default mode for RADIUS reachability.

You can configure the RADIUS reachability mode in either CLI or EDM.

**Note**

RADIUS server reachability is enabled on the switch and is not a configurable option. The reachability process starts when at least one RADIUS server used by EAP is configured, and RADIUS is enabled globally.

Based on the number of EAP RADIUS servers configured, the switch performs the following:

- If the highest priority EAP RADIUS server is reachable, the server status is updated to reachable and further authentication will use this server. As long as the highest priority EAP RADIUS server is reachable, the rest of the EAP RADIUS servers are not tested for reachability.
- If the highest priority EAP RADIUS server is not reachable, then the switch tests the rest of the EAP RADIUS servers for reachability. The servers are checked one by one for reachability based on their priority from highest to lowest. The first server that is reachable is used for authentication and the rest of the lower priority EAP RADIUS servers if any, are skipped from the reachability test.
- If all the EAP RADIUS servers are unreachable, then no further authentication occurs until the next successful reachability check.

The intervals between two consecutive reachability checks can be configured. The default values are as follows:

- one minute, if the last check result was unreachable
- three minutes, if the last check result was reachable

A server is marked as unreachable after a number of retries and time-outs. The default number of retries is 1 and the default time-out value is 8 seconds, but you can also configure these values in CLI.

## RFC 3580 RADIUS Attributes: IEEE 802.1X Remote Authentication Dial In User Service

RFC 3580 provides support for EAP and NEAP clients for the following RADIUS attributes:

- Called-Station ID attribute: For IEEE 802.1X authenticators, the Called-Station ID stores the bridge or access point MAC address in upper case ASCII format, with octet values separated by a hyphen (-). For example: 00-10-A4-23-19-C0.

In IEEE 802.11, where the SSID is known, the SSID must be appended to the access point MAC address and separated from the MAC address with a colon (:). For example: 00-10-A4-23-19-C0:AP1.

- Calling-Station ID: For IEEE 802.1X authenticators, the Calling-Station ID is used to store the supplicant MAC address in upper case ASCII format, with octet values separated by a hyphen (-). For example: 00-10-A4-23-19-C0.
- NAS-Port ID: The NAS-Port ID is used to identify the IEEE 802.1X Authenticator port which authenticates the Supplicant. The NAS-Port-Id differs from the NAS-Port in that it is a string of variable length whereas the NAS-Port is a 4 octet value.

## RFC 5176 — Dynamic Session Change

RFC 5176 allows you to dynamically change the following user session characteristics:

- You can disconnect an authenticated user on a port and remove all associated session context.

If the RADIUS server issues a disconnect command to the switch and the switch identifies a user (that satisfies all attributes of the RADIUS server request) on a port that has enabled RADIUS dynamic extensions commands, the switch performs the following actions:

- Notify the user of the disconnect by sending an 802.1x disconnect message to the client.
  - Remove all session context from the port.
  - Remove the port from the RADIUS-assigned VLAN, if applicable.
  - Send the disconnect response Disconnect-ACK to the RADIUS server if the user session is disconnected and all steps successfully performed.
  - Send the Disconnect-NAK response to the RADIUS server if the user session is not found or if the Network Access Server (NAS) cannot disconnect the session and discard the session context.
- You can use the Change of Authorization command to dynamically change the VLAN used by the RADIUS server.

If the RADIUS server issues a Change of Authorization command to the switch and the switch identifies a user (that satisfies all attributes of the RADIUS server request) on a port that has enabled RADIUS dynamic extensions commands, the switch performs the following actions:

- If the Change of Authorization command specifies a valid VLAN ID for a port, the port is removed from the VLAN specified by RADIUS and added to the VLAN specified in the request.
  - A CoA-ACK response is sent to the RADIUS server.
  - If the user session is not found or an error is encountered in processing the Change of Authorization command, then a CoA-NAK response is sent to the RADIUS server.
  - If the Change of Authorization request specifies a VLAN that is not port-based, a CoA-NAK response is sent to the RADIUS server.
- You can dynamically initiate client re-authentication.

Re-authenticate requests can be made with Change of Authorization or Disconnect packet IDs, but they must have the Re-authentication Request Vendor-Specific Attributes (VSA) set to True.

Dynamic session changes are directed to specific user sessions, as identified by RADIUS attributes.

To enable dynamic session changes, configure the following:

- You must enable EAP or Endpoint Tracking globally and at the port level.
- You must enable RADIUS dynamic extensions commands at the port level.

You can use the **show radius dynamic-server statistics** command to view statistics about dynamic session changes.

```
Switch:1#enable
Switch:1#show radius dynamic-server statistics

=====
                        RADIUS Dynamic Authorization Global Statistics
=====
Disconnects From Invalid Client Addresses:      0
CoAs From Invalid Client Addresses:             0
-----
```

## RADSec

Remote Access Dial-In User Services (RADIUS) Security (RADSec) provides secure communication between RADIUS peers using Transport Layer Security (TLS) encryption over Transmission Control Protocol (TCP), or Datagram Transport Layer Security (DTLS) encryption over User Datagram Protocol (UDP).

RADSec peers use certificates to establish trust relationships. Certificates are specified in the RADSec profile on the switch, which can be the default profile or a profile that you configure. You must configure the client and secure server with the same certificate authority (CA) certificate file, server certificate, certificate key file and password to establish a RADSec connection. The password is used for packet encryption and decryption.

You can configure the RADSec security mode to use the TLS protocol or DTLS protocol. Both TLS and DTLS modes support IPv4 addresses, but IPv6 addresses are supported only by TLS mode.

### Important

To avoid TLS handshake issues if the switch and RADSec proxy server run different versions of OpenSSL, manually force TLS version 2 negotiation through the RADSec proxy by adding the following text to the `radsecproxy.conf` configuration file:

```
tls default{
    ...
    TlsVersion TLS1_2
}
```

RADSec uses `radsecproxy` to encrypt packets sent between RADIUS clients and a secure server. A `radsecproxy` process starts when RADIUS and secure-mode are enabled both globally and for the current server. `Radsecproxy` uses multiple instances on the switch, one for each security-configured RADIUS server. The maximum number of `radsecproxy` instances is 10, which is equivalent to the maximum number of RADIUS servers you can configure on the switch.

### Note

As a best practice, use `radsecproxy` version 1.9.1 or later. Using an earlier version of `radsecproxy` can result in authentication failures.

The following events cause all radsecproxy processes to restart:

- A Segmented Management Instance interface is deleted, enabled, or disabled.
- An IPv4 address or route is changed.
- An IPv6 address or route is changed.
- RADIUS global enable and secure-enable change.

The following changes only affect a radsecproxy instance and result only in the associated process restarting:

- Enabling or disabling the RADIUS server state or secure state.
- Modifying the RADIUS server secure mode, associated profile, or secure log level.

A RADSec profile configuration change causes all processes associated with the profile to restart.

A RADSec process automatically stops when the corresponding RADIUS server entry is deleted, or if RADIUS or secure mode is disabled for the server.

If one of the global RADIUS flags (radius state, radius secure state) is disabled, all radsecproxy instances stop.

## RADIUS configuration using CLI

---

You can configure Remote Access Dial-In User Services (RADIUS) to secure networks against unauthorized access, and allow communication servers and clients to authenticate users identity through a central database.

The database within the RADIUS server stores client information, user information, password, and access privileges, including the use of shared secret.

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration using CLI.

RADIUS is a fully open and standard protocol, defined by RFCs (Authentication: RFC2865, accounting RFC2866). With the switch, you use RADIUS authentication to secure access to the device (console/Telnet/SSH), and RADIUS accounting to track the management sessions for Command Line Interface (CLI) only.

RADIUS authentication allows the remote server to authenticate logons. RADIUS accounting logs all of the activity of each remote user in a session on the centralized RADIUS accounting server.

### Configure RADIUS Attributes

Configure RADIUS to authenticate user identity through a central database.

## Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Configure RADIUS access priority:  
`radius access-priority-attribute <192-240>`
3. Configure RADIUS accounting:  
`radius accounting {attribute-value <192-240>|enable|include-cli-commands}`
4. Configure the RADIUS authentication info attribute value:  
`radius auth-info-attr-value <0-255>`
5. Clear RADIUS statistics:  
`radius clear-stat`
6. Configure the value of the CLI commands:  
`radius cli-commands-attribute <192-240>`
7. Configure the value of the command access attribute:  
`radius command-access-attribute <192-240>`
8. Configure the maximum number of servers allowed:  
`radius maxserver <1-10>`
9. Configure the multicast address attribute:  
`radius mcast-addr-attr-value <0-255>`
10. Enable RADSec globally:  
`radius secure-flag`
11. Configure the RADSec profile:  
`radius secure-profile WORD<1-16> [ca-cert-file | cert-file | key-file | key-pwd]`

## Example

Configure RADIUS access priority:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#radius access-priority-attribute 192
```

Configure RADIUS accounting to include CLI commands:

```
Switch:1(config)#radius accounting include-cli-commands
```

### Variable Definitions

The following table defines parameters for the **radius** command.

Variable	Value
<i>access-priority-attribute</i> <192-240>	Specifies the value of the access priority attribute. The default is 192.
<i>accounting</i> { <i>attribute-value</i> <192-240>  <i>enable</i>   <i>include-cli-commands</i> }	Configures the accounting attribute value, enable accounting, or configure if accounting includes CLI commands. The default is false.
<i>auth-info-attr-value</i> <0-255>	Specifies the value of the authentication information attribute. The default is 91.
<i>clear-stat</i>	Clears RADIUS statistics.
<i>cli-cmd-count</i> <1-40>	Specifies how many CLI commands before the system sends a RADIUS accounting interim request. The default value is 40.
<i>cli-commands-attribute</i> <192-240>	Specifies the value of CLI commands attribute. The default is 195.
<i>cli-profile</i>	Enable RADIUS CLI profiling. CLI profiling grants or denies access to users being authenticated by way of the RADIUS server. You can add a set of CLI commands to the configuration on the RADIUS server, and you can specify the command-access more for these commands. The default is false.
<i>command-access-attribute</i> <192-240>	Specifies the value of the command access attribute. The default is 194.
<i>enable</i>	Enable RADIUS authentication globally on the switch.
<i>maxserver</i> <1-10>	Specific to RADIUS authentication, configures the maximum number of servers allowed for the device. The default is 10.
<i>mcast-addr-attr-value</i> <0-255>	Specifies the value of the multicast address attribute. The default is 90.
<i>secure-flag</i>	Specifies whether RADIUS Security (RADSec) is globally enabled. The default is disabled.

Variable	Value
<i>secure-profile</i>	Specifies the RADSec profile name.
<pre>server host WORD&lt;0-46&gt; key WORD&lt;0-32&gt; [used- by {cli snmp web} [acct- enable] [acct-port &lt;1- 65536&gt;] [enable] [port &lt;1-65536&gt;] [priority &lt;1- 10&gt;] [retry &lt;0-6&gt;secure- enablesecure-log-level {critical   debug   error   info   warning}secure- mode{dtls   tls}secure- profileWORD&lt;1-16&gt;] [timeout &lt;1-60&gt;]</pre>	<ul style="list-style-type: none"> <li>• <i>host WORD&lt;0-46&gt;</i> Creates a host server. WORD&lt;0-46&gt; signifies an IP address.</li> <li>• <i>key WORD&lt;0-32&gt;</i> Specifies a secret key in the range of 0-32 characters.</li> <li>• <i>used-by {cli eapol  endpoint-tracking  snmp web}</i> Specifies how the server functions. Configures the server for: <ul style="list-style-type: none"> <li>◦ cli authentication</li> <li>◦ eapol authentication</li> <li>◦ endpoint-tracking authentication</li> <li>◦ snmp accounting</li> <li>◦ web authentication</li> </ul> </li> <li>• <i>acct-enable</i> Enables RADIUS accounting on this server. The system enables RADIUS accounting by default.</li> <li>• <i>acct-port &lt;1-65536&gt;</i> Specifies a UDP port of the RADIUS accounting server. The default value is 1816. The UDP port value set for the client must match the UDP value set for the RADIUS server.</li> <li>• <i>enable</i> Enables the server. The default is true.</li> <li>• <i>port &lt;1-65536&gt;</i> Specifies a UDP port of the RADIUS server. The default value is 1812.</li> <li>• <i>priority &lt;1-10&gt;</i> Specifies the priority value for this server. The default is 10.</li> <li>• <i>retry &lt;0-6&gt;</i> Specifies the maximum number of authentication retries. The default is 3.</li> <li>• <i>secure-enable</i> Enable secure mode on the server.</li> <li>• <i>secure-log-level {critical   debug   error   info   warning}</i></li> </ul>

Variable	Value
	<p>Specifies the RADIUS secure server log severity level.</p> <ul style="list-style-type: none"> <li><code>secure-mode{dtls   tls}</code></li> </ul> <p>Specifies the protocol for establishing the secure connection with the server. IPv4 supports both dtls and tls modes. IPv6 only supports tls mode.</p> <ul style="list-style-type: none"> <li><code>secure-profileWORD&lt;1-16&gt;</code></li> </ul> <p>Specifies the secure profile name.</p> <ul style="list-style-type: none"> <li><code>timeout &lt;1-60&gt;</code></li> </ul> <p>Specifies the number of seconds before the authentication request times out. The default is 3.</p>

## Configuring RADIUS profile

Use RADIUS CLI profiling to grant or deny CLI command access to users being authenticated by way of the RADIUS server. You can add a set of CLI commands to the configuration file on the radius server, and you can specify the command-access mode for these commands. The default is false.

### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Enable RADIUS CLI profiling:  
radius cli-profile

### Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# radius cli-profile
```

## Enabling RADIUS authentication

### About This Task

Enable or disable RADIUS authentication globally on the device to allow further configuration to take place. Use the no option to disable RADIUS authentication globally. The default is false or disabled.

### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal

2. Enable RADIUS authentication globally on the switch:

```
radius enable
```

## Enabling RADIUS accounting

### Before You Begin

- You must configure a RADIUS server before you can enable RADIUS accounting.

### About This Task

Enable Remote Access Dial-in User Services (RADIUS) accounting to log all of the activity of each remote user in a session on the centralized RADIUS accounting server.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable RADIUS accounting globally:

```
radius accounting enable
```

3. Include or exclude CLI commands in RADIUS accounting updates:

```
radius accounting include-cli-commands
```

4. Specify the integer value of the CLI commands attribute:

```
radius accounting attribute-value <192-240>
```

### Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# radius accounting enable
Switch:1(config)# radius accounting include-cli-commands
```

### Variable Definitions

The following table defines parameters for the **radius accounting** command.

Variable	Value
<i>enable</i>	Enable RADIUS globally.
<i>include-cli-commands</i>	Include CLI commands in RADIUS accounting updates.
<i>attribute-value</i> <192-240>	Specify the integer value of the CLI commands attribute.

## Enabling RADIUS-SNMP accounting

### Before You Begin

- You must configure a RADIUS server before you can enable RADIUS-SNMP accounting.

## About This Task

Enable Remote Access Dial-in User Services (RADIUS) Simple Network Managing Protocol (SNMP) accounting globally. Use SNMP to remotely collect management data. An SNMP agent is a software process that monitors the UDP port 161 for SNMP messages. Each SNMP message sent to the agent contains a list of management objects.

## Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enable RADIUS Simple Network Management Protocol (SNMP) accounting globally:
 

```
radius-snmp acct-enable
```
3. Set a timer to send a stop accounting message for RADIUS Simple Network Management Protocol (SNMP):
 

```
radius-snmp abort-session-timer <30-65535>
```
4. Set the timer for re-authentication of the SNMP session:
 

```
radius-snmp re-auth-timer <30-65535>
```
5. Specify the user name for SNMP access:
 

```
radius-snmp user WORD <0-20>
```

## Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# radius-snmp acct-enable
Switch:1(config)# radius-snmp abort-session-timer 30
```

## Variable Definitions

The following table defines parameters for the **radius-snmp** command.

Variable	Value
<i>acct-enable</i>	Enables RADIUS accounting globally. You cannot enable RADIUS accounting before you configure a valid server. The system disables RADIUS accounting by default. The default is false. Use the no option to disable RADIUS accounting globally: <b>no radius-snmp acct-enable</b>
<i>abort-session-timer</i> <30-65535>	Set the timer, in seconds, to send a stop accounting message. The default is 180.
<i>re-auth-timer</i> <30-65535>	Sets timer for re-authentication of the SNMP session. The timer value ranges from 30 to 65535 seconds. The default is 180.
<i>user</i> WORD <0-20>	Specifies the user name for SNMP access. WORD <0-20> specifies the user name in a range of 0 to 20 characters. The default is snmp_user.

## Configuring RADIUS accounting interim request

### About This Task

Configure RADIUS accounting interim requests to create a log whenever a user executes more than the number of CLI commands you specify.

If the packet size equals or exceeds 1.8 KB, an interim request packet is sent even if the configured limit is not reached. Therefore, the trigger to send out the interim request is either the configured value or a packet size greater than, or equal to 1.8 KB, whichever happens first.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure RADIUS accounting interim requests:
 

```
radius cli-cmd-count <1-40>
```
3. Include or exclude CLI commands in RADIUS accounting:
 

```
radius accounting include-cli-commands
```

### Important

You must configure the **radius accounting include-cli-commands** command for accounting interim requests to function.

### Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# radius cli-cmd-count 30
Switch:1(config)# radius accounting include-cli-commands
```

### Variable Definitions

The following table defines parameters for the **radius cli-cmd-count** command.

Variable	Value
<1-40>	Specifies how many CLI commands, from 1 to 40, before the system sends a RADIUS accounting interim request. The default value is 40.

## Configure RADIUS Authentication and RADIUS Accounting Attributes

### About This Task

Configure RADIUS authentication and RADIUS accounting attributes to determine the size of the packets received.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the RADIUS authentication attribute value:
 

```
radius command-access-attribute <192-240>
```
3. Configure the RADIUS accounting attribute value:
 

```
radius accounting attribute-value <192-240>
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#radius command-access-attribute 192
Switch:1(config)#radius accounting attribute-value 192
```

### Variable Definitions

The following table defines parameters for the **radius** command.

Variable	Value
<i>access-priority-attribute</i> <192-240>	Specifies the value of the access priority attribute. The default is 192.
<i>accounting</i> { <i>attribute-value</i> <192-240>  <i>enable</i>   <i>include-cli-commands</i> }	Configures the accounting attribute value, enable accounting, or configure if accounting includes CLI commands. The default is false.
<i>auth-info-attr-value</i> <0-255>	Specifies the value of the authentication information attribute. The default is 91.
<i>clear-stat</i>	Clears RADIUS statistics.
<i>cli-cmd-count</i> <1-40>	Specifies how many CLI commands before the system sends a RADIUS accounting interim request. The default value is 40.
<i>cli-commands-attribute</i> <192-240>	Specifies the value of CLI commands attribute. The default is 195.
<i>cli-profile</i>	Enable RADIUS CLI profiling. CLI profiling grants or denies access to users being authenticated by way of the RADIUS server. You can add a set of CLI commands to the configuration on the RADIUS server, and you can specify the command-access more for these commands. The default is false.
<i>command-access-attribute</i> <192-240>	Specifies the value of the command access attribute. The default is 194.
<i>enable</i>	Enable RADIUS authentication globally on the switch.
<i>maxserver</i> <1-10>	Specific to RADIUS authentication, configures the maximum number of servers allowed for the device. The default is 10.

Variable	Value
<i>mcast-addr-attr-value</i> <0-255>	Specifies the value of the multicast address attribute. The default is 90.
<i>secure-flag</i>	Specifies whether RADIUS Security (RADSec) is globally enabled. The default is disabled.

Variable	Value
<i>secure-profile</i>	Specifies the RADSec profile name.
<pre>server host WORD&lt;0-46&gt; key WORD&lt;0-32&gt; [used- by {cli snmp web} [acct- enable] [acct-port &lt;1- 65536&gt;] [enable] [port &lt;1-65536&gt;] [priority &lt;1- 10&gt;] [retry &lt;0-6&gt;secure- enablesecure-log-level {critical   debug   error   info   warning}secure- mode{dtls   tls}secure- profileWORD&lt;1-16&gt;] [timeout &lt;1-60&gt;]</pre>	<ul style="list-style-type: none"> <li>• <i>host WORD&lt;0-46&gt;</i> Creates a host server. WORD&lt;0-46&gt; signifies an IP address.</li> <li>• <i>key WORD&lt;0-32&gt;</i> Specifies a secret key in the range of 0-32 characters.</li> <li>• <i>used-by {cli eapol  endpoint-tracking  snmp web}</i> Specifies how the server functions. Configures the server for: <ul style="list-style-type: none"> <li>◦ cli authentication</li> <li>◦ eapol authentication</li> <li>◦ endpoint-tracking authentication</li> <li>◦ snmp accounting</li> <li>◦ web authentication</li> </ul> </li> <li>• <i>acct-enable</i> Enables RADIUS accounting on this server. The system enables RADIUS accounting by default.</li> <li>• <i>acct-port &lt;1-65536&gt;</i> Specifies a UDP port of the RADIUS accounting server. The default value is 1816. The UDP port value set for the client must match the UDP value set for the RADIUS server.</li> <li>• <i>enable</i> Enables the server. The default is true.</li> <li>• <i>port &lt;1-65536&gt;</i> Specifies a UDP port of the RADIUS server. The default value is 1812.</li> <li>• <i>priority &lt;1-10&gt;</i> Specifies the priority value for this server. The default is 10.</li> <li>• <i>retry &lt;0-6&gt;</i> Specifies the maximum number of authentication retries. The default is 3.</li> <li>• <i>secure-enable</i> Enable secure mode on the server.</li> <li>• <i>secure-log-level {critical   debug   error   info   warning}</i></li> </ul>

Variable	Value
	<p>Specifies the RADIUS secure server log severity level.</p> <ul style="list-style-type: none"> <li><code>secure-mode{dtls   tls}</code></li> </ul> <p>Specifies the protocol for establishing the secure connection with the server. IPv4 supports both dtls and tls modes. IPv6 only supports tls mode.</p> <ul style="list-style-type: none"> <li><code>secure-profileWORD&lt;1-16&gt;</code></li> </ul> <p>Specifies the secure profile name.</p> <ul style="list-style-type: none"> <li><code>timeout &lt;1-60&gt;</code></li> </ul> <p>Specifies the number of seconds before the authentication request times out. The default is 3.</p>

## Add a RADIUS Server

### About This Task

Add a RADIUS server to provide RADIUS service on the switch.

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration using CLI.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Add a RADIUS server:

```
radius server host WORD <0-46> key WORD<0-32> [used-by {cli|
eapol|endpoint-tracking|snmp|web}] [acct-enable][acct-port <1-65536>]
[enable] [port <1-65536>][priority <1-10>][retry <0-6>] [secure-
enable] [secure-log-level] [secure-mode] [secure-profile] [timeout
<1-60>]
```

### Example

Add a RADIUS server:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#radius server host 4717:0000:0000:0000:0000:7933:0001 key testkey1
used-by snmp port 12 retry 5 timeout 10 enable
```

### Variable Definitions

The following table defines parameters for the **radius server host** command.

Variable	Value
<i>used-by</i> { <i>cli</i>   <i>eapol</i>   <i>endpoint-tracking</i>   <i>snmp</i>   <i>web</i> }	Configures how the server functions: <ul style="list-style-type: none"> <li>• <i>cli</i>—configure the server for CLI authentication.</li> <li>• <i>eapol</i>—configure the server for EAPoL authentication.</li> <li>• <i>endpoint-tracking</i>—configure the server for Endpoint Tracking authentication.</li> <li>• <i>snmp</i>—configure the server for SNMP accounting.</li> <li>• <i>web</i>—configure the server for HTTP(s) authentication.</li> </ul> The default is <i>cli</i> .
<i>host</i> WORD <0-46>	Configures a host server. WORD <0-46> signifies an IPv4 address in the format A.B.C.D or an IPv6 address in the format x:x:x:x:x:x. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration using CLI.
<i>acct-enable</i>	Enables RADIUS accounting on this server. The system enables RADIUS accounting by default.
<i>acct-port</i> <1-65536>	Configures the UDP port of the RADIUS accounting server. The default value is 1813.  <b>Important:</b> The UDP port value set for the client must match the UDP value set for the RADIUS server.
<i>enable</i>	Enables the RADIUS server. The default is true.
<i>key</i> WORD<0-32>	Configures the secret key of the authentication client.
<i>port</i> <1-65536>	Configures the UDP port of the RADIUS authentication server. The default value is 1812.
<i>priority</i> <1-10>	Configures the priority value for this server. The default is 10.
<i>retry</i> <0-6>	Configures the number of authentication retries the server will accept. The default is 3.
<i>secure-enable</i>	Enable RADIUS Security (RADSec).
<i>secure-log-level</i>	Specifies the log severity level. Possible values are : <ul style="list-style-type: none"> <li>• critical</li> <li>• debug</li> <li>• error</li> <li>• info</li> <li>• warning</li> </ul>
<i>secure-mode</i>	Specifies the protocol used for secure connection to the server.
<i>secure-profile</i>	Configures the secure profile for the server.
<i>timeout</i> <1-180>	Configures the number of seconds before the authentication request times out. The default is 8.

## Modify RADIUS Server Settings

### About This Task

Change a specified RADIUS server value without having to delete the server and recreate it again.

RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration using CLI.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Modify a RADIUS server:

```
radius server host WORD <0-46> used-by {cli|eapol|endpoint-tracking|
snmp|web} [key WORD<0-32>] [port 1-65536] [priority <1-10>] [retry
<0-6>] [timeout <1-180>] [enable] [acct-port <1-65536>] [acct-enable]
```

### Example

Modify a RADIUS server:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#radius server host 4717:0000:0000:0000:0000:0000:7933:0001 used-by snmp
port 12 retry 5 timeout 10 enable
```

### Variable Definitions

The following table defines parameters for the **radius server host** command.

Variable	Value
<i>used-by</i> {cli eapol endpoint-tracking snmp web}	Configures how the server functions: <ul style="list-style-type: none"> <li>• cli—configure the server for CLI authentication.</li> <li>• eapol—configure the server for EAPoL authentication.</li> <li>• endpoint-tracking—configure the server for Endpoint Tracking authentication.</li> <li>• snmp—configure the server for SNMP accounting.</li> <li>• web—configure the server for HTTP(s) authentication.</li> </ul> The default is cli.
<i>host</i> WORD <0-46>	Configures a host server. WORD <0-46> signifies an IPv4 address in the format A.B.C.D or an IPv6 address in the format x:x:x:x:x:x. RADIUS supports IPv4 and IPv6 addresses, with no difference in functionality or configuration using CLI.
<i>acct-enable</i>	Enables RADIUS accounting on this server. The system enables RADIUS accounting by default.

Variable	Value
<i>acct-port</i> <1-65536>	Configures the UDP port of the RADIUS accounting server. The default value is 1813.  <b>Important:</b> The UDP port value set for the client must match the UDP value set for the RADIUS server.
<i>enable</i>	Enables the RADIUS server. The default is true.
<i>key</i> WORD<0-32>	Configures the secret key of the authentication client.
<i>port</i> <1-65536>	Configures the UDP port of the RADIUS authentication server. The default value is 1812.
<i>priority</i> <1-10>	Configures the priority value for this server. The default is 10.
<i>retry</i> <0-6>	Configures the number of authentication retries the server will accept. The default is 3.
<i>secure-enable</i>	Enable RADIUS Security (RADSec).
<i>secure-log-level</i>	Specifies the log severity level. Possible values are : <ul style="list-style-type: none"> <li>• critical</li> <li>• debug</li> <li>• error</li> <li>• info</li> <li>• warning</li> </ul>
<i>secure-mode</i>	Specifies the protocol used for secure connection to the server.
<i>secure-profile</i>	Configures the secure profile for the server.
<i>timeout</i> <1-180>	Configures the number of seconds before the authentication request times out. The default is 8.

## View RADIUS Information

View the global status of RADIUS information to ensure you configured the RADIUS feature according to the needs of the network.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the global status of RADIUS information:

```
show radius
```

### Example

```
Switch:1>show radius
  acct-attribute-value : 193
      acct-enable      : false
  acct-include-cli-commands : false
  access-priority-attribute : 192
      auth-info-attr-value : 91
  command-access-attribute : 194
```

```
cli-commands-attribute : 195
  cli-cmd-count : 40
  cli-profile-enable : false
    enable : false
  igap-passwd-attr : standard
igap-timeout-log-fsize : 512
  maxserver : 10
mcast-addr-attr-value : 90
supported-vendor-ids : 1584, 562, 1916
  secure-flag : false
```

### Note

The Extreme Networks vendor ID 1916 in the *supported-vendor-ids* field does not apply to VSP 4450 Series or XA1400 Series.

## View RADIUS Server Information

If your system is configured with a RADIUS server you can display the RADIUS server information.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. To view the RADIUS server information enter the following command:

```
show radius-server
```

### Note

If no RADIUS server is configured, the system displays the following message:

```
no RADIUS server configured
```

### Example

```
=====
                        Radius Server Entries
=====
```

NAME	USED BY	SECRET	PORT	PRIO	RETRY	TIMEOUT	ENABLED	SECURE ENABLED	SECURE MODE	SECURE INSTANCE	SECURE PROFILE	SECURE LOG-LEVEL	ACCT PORT	ACCT ENABLED
---														
192.0.2.14	cli	*****	1812	10	1	8	true	true	tls	0	radsecp	error	1813	true
192.0.2.15	cli	*****	1812	10	1	8	true	false	tls	-1	default	error	1813	true

## Showing RADIUS Server Statistics

### About This Task

You cannot collect the following network statistics from a console port: the number of input and output packets, and the number of input and output bytes. All other statistics from console ports are available to assist with debugging.

## Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display RADIUS server statistics:  
show radius-server statistics
3. Clear server statistics:  
clear radius statistics

## Example

```
Switch:1#show radius-server statistics

Responses with invalid server address: 0

  Radius Server(UsedBy) : 192.0.2.58 (cli)
-----
    Access Requests : 52
    Access Accepts  : 0
    Access Rejects  : 0
    Bad Responses   : 52
    Client Retries  : 52
    Pending Requests : 0
    Acct On Requests : 1
    Acct Off Requests : 0
    Acct Start Requests : 47
    Acct Stop Requests : 46
    Acct Interim Requests : 0
    Acct Bad Responses : 94
    Acct Pending Requests : 0
    Acct Client Retries : 94
    Access Challenges : 0
    Round-trip Time :
    Nas Ip Address : 192.0.2.32

  Radius Server(UsedBy) : 192.0.2.58 (snmp)
-----
    Access Requests : 0
    Access Accepts  : 0
    Access Rejects  : 0
    Bad Responses   : 0
    Client Retries  : 0
    Pending Requests : 0
    Acct On Requests : 0
    Acct Off Requests : 0
    Acct Start Requests : 0
    Acct Stop Requests : 0
    Acct Interim Requests : 0
    Acct Bad Responses : 0
    Acct Pending Requests : 0
    Acct Client Retries : 0
    Access Challenges : 0
    Round-trip Time :
    Nas Ip Address : 192.0.2.32

--More-- (q = quit)
```

## Configuring RADIUS server reachability

### About This Task

Use this procedure to configure the RADIUS server reachability settings.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Configure the RADIUS keep-alive timer:  
`radius reachability keep-alive-timer <30-600>`
3. Configure the RADIUS reachability mode:  
`radius reachability mode <status-server | use-radius>`
4. If you selected `use-radius` as the RADIUS reachability mode, configure the RADIUS request username and password:  
`radius reachability username WORD<1-16> password WORD<1-16>`
5. Configure the RADIUS reachability unreachable timer:  
`radius reachability unreachable-timer <30-600>`

### Example

Configure values for RADIUS server reachability:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

Configure the RADIUS keep-alive timer:

```
Switch:1(config)#radius reachability keep-alive-timer 30
```

Configure the RADIUS reachability mode:

```
Switch:1(config)#radius reachability mode status-server
```

Configure the RADIUS reachability unreachable timer:

```
Switch:1(config)#radius reachability unreachable-timer 30
```

## Variable Definitions

The following table defines parameters for the **radius reachability** command.

Variable	Value
keep-alive-timer <30-600>	Specifies, in seconds, the interval between checks when radius server is reachable. The default is 180 seconds.
mode <status-server   use-radius>	Specifies status-server mode or use-radius mode. Status-server mode provides a standard-compliant method for RADIUS reachability. Use-radius mode requires the configuration of dummy packets that are sent to RADIUS servers. The default is use-radius mode.
password <i>WORD</i> <1-16>	Configures the RADIUS request password. The default is extremenetworks.
unreachable-timer <30-600>	Specifies, in seconds, the interval between checks when radius server is unreachable. The default is 60 seconds.
username <i>WORD</i> <1-16>	Configures the RADIUS request username. The default is extremenetworks.

## Displaying RADIUS server reachability

### About This Task

Use this procedure to display the RADIUS server reachability settings.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the RADIUS server reachability settings:

```
show radius reachability
```

### Example

Display the RADIUS server reachability settings.

```
Switch:1#show radius reachability
EAP RADIUS reachability mode      : use-radius
EAP RADIUS reachability status    : RADIUS is disabled globally
EAP RADIUS reachable server       : none
Time until next check             : N/A
RADIUS username                   : reachme
RADIUS password                   : reachme
RADIUS keep-alive-timer           : 180
RADIUS unreachable-timer          : 60
```

## Showing RADIUS SNMP configurations

Display current RADIUS SNMP configurations.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the current RADIUS server SNMP configurations:

```
show radius snmp
```

**Example**

```
Switch:1>show radius snmp
      abort-session-timer : 180
      acct-enable : false
      user : snmp_user
      enable : false
      re-auth-timer : 180
```

## Displaying RADIUS dynamic server information

**About This Task**

Use the following procedure to display information about the configuration of RADIUS dynamic session changes.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display information about dynamic change configuration:

```
show radius dynamic-server [client | statistics]
```

**Example**

```
Switch:1#show radius dynamic-server
```

```
=====
                        RADIUS Dynamic Authorization General Info
=====
CLIENT                UDP        CLIENT    SECRET
ADDRESS              PORT        ENABLED    KEY
-----
192.0.2.15            1026        Disabled  *****
192.0.2.16            1027        Disabled  *****
-----

All 2 out of 2 Total Num of RADIUS Dynamic Authorization clients displayed
```

Display dynamic server statistics:

```
Switch:1#show radius dynamic-server statistics
```

```
=====
                        RADIUS Dynamic Authorization Global Statistics
=====
Disconnects From Invalid Client Addresses:    0
CoAs From Invalid Client Addresses:          0
-----
```

*Variable Definitions*

The following table defines parameters for the **show radius dynamic-server** command.

Variable	Value
client WORD<0-46>	Display RADIUS Dynamic Authorization configuration values for the specified client.
statistics	Display statistics for RADIUS Dynamic Authorization clients.

## Configuring a RADIUS dynamic-server client

### About This Task

Configure a client to allow processing of dynamic session changes.

### Before You Begin

You must enable EAPOL globally and at the port level.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure values for client IP address, port, and secret key:  

```
Switch:1(config)#radius dynamic-server client WORD<0-46> port
```

```
<1024-65535> secret WORD<0-32> enable
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#radius dynamic-server client 192.0.2.15 port 1025 secret 123 enable
```

*Variable Definitions*

The following table defines parameters for the **radius dynamic-server** command.

Variable	Value
client WORD<0-46>	Specifies the client address.
enable	Enable processing of dynamic session changes.
port <1024-65535>	Specifies the port value.
secret WORD<0-32>	Specifies a value for secret key.

## RADSec Configuration Using CLI

This section contains procedures for configuring RADSec using Command Line Interface (CLI).

## Create and Configure a RADIUS Secure Profile

You configure RADIUS secure profiles with certificate information, certificate key information, and password information, which enables RADSec peers to establish connections.

### About This Task

#### Note

- All the files (certificates and keys) must be in .pem format and copy it to flash /intflash directory.
- A new profile directory is created for each new profile in the flash/intflash/.radsec/profile/.radsec directory.
- Profile configuration file “profile\_info.cfg” is available in /intflash/.radsec/profile directory.
- You can configure a maximum of 10 RADSec profiles.

### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Configure a name for the RADIUS profile:  
radius secure-profile WORD<1-16>
3. Configure the full file path of the certificate authority (CA) certificate for the RADIUS secure profile:  
radius secure-profile WORD<1-16> CA-cert-file WORD<0-128>  
[WORD<1-128>]
4. Configure the full path of the server certificate for the RADIUS secure profile:  
radius secure-profile WORD<1-16> cert-file WORD<0-128> [WORD<1-128>]
5. Configure the full path of the private key file for the RADIUS secure profile:  
radius secure-profile WORD<1-16> key-file WORD<0-128> [WORD<1-128>]
6. Configure the private key password for the RADIUS secure profile:  
radius secure-profile WORD<1-16> key-pwd WORD<0-255>

#### Variable Definitions

The following table defines parameters for the **radius secure-profile** command.

Variable	Value
WORD<1-16>	Specifies the RADIUS secure profile name.
CA-cert-file WORD<0-128>	Specifies the full file path of the certificate authority (CA) certificate.

Variable	Value
cert-file WORD<0-128>	Specifies the full file path of the server certificate.
key-file WORD<0-128>	Specifies the full file path of the private key file.
WORD<1-128>	Specifies the file name.
key-pwd WORD<0-255>	Specifies the private key password.

## Display RADIUS Secure Profile information

### About This Task

Use the following procedure to display information about the configuration of RADIUS secure profiles.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display information about RADIUS secure profile configuration:  
show radius secure-profile

### Example

```
Switch:1>enable
Switch:1#show radius secure-profile
```

```
=====
                        Secure RADIUS profile
=====
Profile default:
  Name : default
  RootCert : n/a
  Cert : n/a
  Key : n/a
  Password : *****
```

## Associate a RADSec Profile with a RADIUS Server

### Before You Begin

Add a RADIUS Server. For more information, see [Add a RADIUS Server](#) on page 2987.

### About This Task

RADSec peers use certificates to establish trust relationships. You must associate a RADSec profile with a RADIUS server in order to use certificates.

### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal

- Associate a RADSec profile with a RADIUS server:

```
radius server host WORD<0-46> used-by {cli | eapol | endpoint-tracking
| snmp | web} secure-profile WORD<1-16>
```

### Variable Definitions

The following table defines parameters for the **radius server host** command.

Variable	Value
WORD<0-46>	Specifies the IPv4 address or the IPv6 address of the RADIUS server.
used-by	Specifies how the server functions. Configures the server for one of the following: <ul style="list-style-type: none"> <li>cli authentication</li> <li>eapol authentication</li> <li>endpoint-tracking authentication</li> <li>snmp accounting</li> <li>web authentication</li> </ul>
secure-enable	Enables RADSec on the RADIUS server.

## Configure RADSec Secure Mode

Configure the secure mode for RADSec as either Transport Layer Security (TLS) protocol or Datagram Transport Layer Security (DTLS) protocol.

### Before You Begin

To avoid TLS handshake issues if the switch and RADsec proxy server run different versions of OpenSSL, manually force TLS version 2 negotiation through the RADsec proxy by adding the following text to the `radsecproxy.conf` configuration file:

```
tls default{
    ...
    TlsVersion TLS1_2
}
```

### Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Configure the secure mode:

```
radius server host WORD<0-46> used-by {cli | eapol | endpoint-tracking
| snmp | web} secure-mode {tls | dtls}
```

## Variable Definitions

The following table defines parameters for the **radius server host** command.

Variable	Value
<i>WORD&lt;0-46&gt;</i>	Specifies the IPv4 address or the IPv6 address.
<i>used-by</i>	Specifies how the server functions. Configures the server for one of the following: <ul style="list-style-type: none"> <li>cli authentication</li> <li>eapol authentication</li> <li>endpoint-tracking authentication</li> <li>snmp accounting</li> <li>web authentication</li> </ul>
<i>secure-mode</i>	Specifies the RADSec security mode. Possible values are: <ul style="list-style-type: none"> <li>tls - Transport Layer Security (TLS) encryption over Transmission Control Protocol (TCP)</li> <li>dtls - Datagram Transport Layer Security (DTLS) encryption over User Datagram Protocol (UDP)</li> </ul> <p>The default is tls.</p>

## Enable RADSec

### About This Task

You must enable RADSec globally and at the RADIUS server level in order for RADSec to be enabled for a RADIUS server.

### Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Enable RADSec globally:

```
radius secure-flag
```
- Enable RADSec on the RADIUS server:

```
radius server host WORD<0-46> used-by {cli | eapol | endpoint-tracking
| snmp | web} secure-enable
```

## Change the logging level for RADSec secure profile

### About This Task

Use the following procedure to change the logging level for a RADSec secure profile.

**Procedure**

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Change the logging level of the RADIUS secure profile:  
radius server host WORD<0-46> used-by cli secure-log-level debug

*Variable Definitions*

The following table defines parameters for the **radius server host WORD<0-46> used-by cli secure-log-level debug** command.

Variable	Value
WORD<0-46>	Specifies the IPv4 address or the IPv6 address.

## Display Log Information for Secure RADIUS Instance

**About This Task**

Use the following procedure to display log information for secure instance of RADIUS.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Display log information for a secure instance of RADIUS:  
show radius secure-server log <0-9>.

*Variable Definitions*

The following table defines parameters for the **show radius secure-server** command.

Variable	Value
log<0-9>	Specifies the log for a secure RADIUS instance.

## RADIUS configuration using Enterprise Device Manager

You can configure Remote Access Dial-In User Services (RADIUS) to assist in securing networks against unauthorized access, and allow communication servers and clients to authenticate the identity of users through a central database.

The database within the RADIUS server stores client information, user information, password, and access privileges, including the use of shared secret.

RADIUS supports IPv4 and IPv6 addresses with no difference in functionality or configuration in all but the following case. When adding a RADIUS server in Enterprise

Device Manager (EDM) or modifying a RADIUS configuration in EDM, you must specify if the address type is an IPv4 or an IPv6 address.

RADIUS is a fully open and standard protocol, defined by RFCs (Authentication: RFC2865, accounting RFC2866). With the switch, you use RADIUS authentication to secure access to the device (console/Telnet/SSH), and RADIUS accounting to track the management sessions for Command Line Interface (CLI) only.

RADIUS authentication allows the remote server to authenticate logons. RADIUS accounting logs all of the activity of each remote user in a session on the centralized RADIUS accounting server.

## Enable RADIUS Authentication

### About This Task

Enable RADIUS authentication globally to allow all features and functions of RADIUS to operate with the RADIUS server.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **RADIUS**.
3. Select the **RADIUS Global** tab.
4. Select **Enable**.
5. In the **MaxNumberServer** field, type a value for the maximum number of servers.
6. In the **AccessPriorityAttrValue** field, type an access policy value (by default, this value is 192).
7. Configure the rest of the parameters in the RADIUS global tab.
8. Select **Apply**.

### *RADIUS Global* Field Descriptions

Use the data in the following table to use the **RADIUS Global** tab.

Name	Description
<b>Enable</b>	Enables the RADIUS authentication feature globally.
<b>MaxNumberServer</b>	Specifies the maximum number of servers to be used inclusive.
<b>AccessPriorityAttrValue</b>	Specific to RADIUS authentication. Specifies the vendor-specific attribute value of the access-priority attribute to match the type value set in the dictionary file on the RADIUS server. The default is 192.
<b>AcctEnable</b>	Enables RADIUS accounting.

Name	Description
<b>AcctAttriValue</b>	Specific to RADIUS accounting. Specifies the vendor-specific attribute value of the CLI-command attribute to match the type value set in the dictionary file on the RADIUS server. This value must be different from the access-priority attribute value configured for authentication. The default value is 193.
<b>AcctIncludeCli</b>	Specifies whether you want CLI commands included in RADIUS accounting requests.
<b>ClearStat</b>	Clears RADIUS statistics from the device.
<b>McastAttributeValue</b>	Specifies the value of the Mcast attribute. The default value is 90.
<b>AuthInfoAttrValue</b>	Specifies the value of the authentication information attribute. The default value is 91.
<b>CommandAccessAttrValue</b>	Specifies the value of the command access attribute. The default value is 194.
<b>CliCommandAttrValue</b>	Specifies the value of the CLI command attribute. The default value is 195.
<b>AuthInvalidServerAddress</b>	Displays the number of access responses from unknown or invalid RADIUS servers.
<b>CliCmdCount</b>	Gives the value for the CLI command count. The default is 40.
<b>CliProfEnable</b>	Enables RADIUS CLI profiling.
<b>SupportedVendorIds</b>	Shows the vendor IDs that the software supports for RADIUS.
<b>RadiusReachability</b>	Specifies the mode for RADIUS reachability. Status-server mode provides a standard-compliant method for RADIUS reachability. Use-radius mode requires the configuration of dummy packets that are sent to RADIUS servers. The default is use-radius mode.
<b>SecureEnable</b>	Enable RADIUS Security (RADSec).
<b>UserName</b>	Specifies the username for RADIUS server reachability. The default is extremenetworks.
<b>Password</b>	Specifies the password for RADIUS server reachability. The default is extremenetworks.
<b>Confirm Password</b>	Confirms the password for RADIUS server reachability.
<b>Unreachable Timer</b>	Specifies, in seconds, the interval between checks when radius server is unreachable. The default is 60 seconds.
<b>Keep Alive Timer</b>	Specifies, in seconds, the interval between checks when radius server is reachable. The default is 180 seconds.

## Enable RADIUS Accounting

### Before You Begin

- You must set up a RADIUS server and add it to the configuration file of the device before you can enable RADIUS accounting on the device. Otherwise, the system displays an error message.

### About This Task

Enable RADIUS accounting to log all of the activity of each remote user in a session on the centralized RADIUS accounting server.

### Procedure

- In the navigation pane, expand **Configuration > Security > Control Path**.
- Click **RADIUS**.
- In the **RADIUS Global** tab, select the **AcctEnable** check box.
- In the **AcctAttrValue** field, type an access policy value (by default, this value is 193).
- Click **Apply**.

### *RADIUS Global* Field Descriptions

Use the data in the following table to use the **RADIUS Global** tab.

Name	Description
<b>Enable</b>	Enables the RADIUS authentication feature globally.
<b>MaxNumberServer</b>	Specifies the maximum number of servers to be used inclusive.
<b>AccessPriorityAttrValue</b>	Specific to RADIUS authentication. Specifies the vendor-specific attribute value of the access-priority attribute to match the type value set in the dictionary file on the RADIUS server. The default is 192.
<b>AcctEnable</b>	Enables RADIUS accounting.
<b>AcctAttriValue</b>	Specific to RADIUS accounting. Specifies the vendor-specific attribute value of the CLI-command attribute to match the type value set in the dictionary file on the RADIUS server. This value must be different from the access-priority attribute value configured for authentication. The default value is 193.
<b>AcctIncludeCli</b>	Specifies whether you want CLI commands included in RADIUS accounting requests.
<b>ClearStat</b>	Clears RADIUS statistics from the device.
<b>McastAttributeValue</b>	Specifies the value of the Mcast attribute. The default value is 90.
<b>AuthInfoAttrValue</b>	Specifies the value of the authentication information attribute. The default value is 91.
<b>CommandAccessAttrValue</b>	Specifies the value of the command access attribute. The default value is 194.

Name	Description
<b>CliCommandAttrValue</b>	Specifies the value of the CLI command attribute. The default value is 195.
<b>AuthInvalidServerAddress</b>	Displays the number of access responses from unknown or invalid RADIUS servers.
<b>CliCmdCount</b>	Gives the value for the CLI command count. The default is 40.
<b>CliProfEnable</b>	Enables RADIUS CLI profiling.
<b>SupportedVendorIds</b>	Shows the vendor IDs that the software supports for RADIUS.
<b>RadiusReachability</b>	Specifies the mode for RADIUS reachability. Status-server mode provides a standard-compliant method for RADIUS reachability. Use-radius mode requires the configuration of dummy packets that are sent to RADIUS servers. The default is use-radius mode.
<b>SecureEnable</b>	Enable RADIUS Security (RADSec).
<b>UserName</b>	Specifies the username for RADIUS server reachability. The default is extremenetworks.
<b>Password</b>	Specifies the password for RADIUS server reachability. The default is extremenetworks.
<b>Confirm Password</b>	Confirms the password for RADIUS server reachability.
<b>Unreachable Timer</b>	Specifies, in seconds, the interval between checks when radius server is unreachable. The default is 60 seconds.
<b>Keep Alive Timer</b>	Specifies, in seconds, the interval between checks when radius server is reachable. The default is 180 seconds.

## Disable RADIUS Accounting

### Before You Begin

- You cannot globally disable RADIUS accounting unless a server entry exists.

### About This Task

Disabling RADIUS accounting removes the accounting function from the RADIUS server.

### Procedure

- In the navigation pane, expand **Configuration > Security > Control Path**.
- Click **RADIUS**.
- In the **RADIUS Global** tab, disable RADIUS accounting by clearing the **AcctEnable** check box.
- Click **Apply**.

## Enable RADIUS Accounting Interim Request

### About This Task

Enable the RADIUS accounting interim request feature to create a log whenever more than the specified number of CLI commands are executed.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS**.
3. In the **RADIUS Global** tab, type the number of CLI commands in the **CliCmdCount** field.
4. Click **Apply**.

### *RADIUS Global* Field Descriptions

Use the data in the following table to use the **RADIUS Global** tab.

Name	Description
<b>Enable</b>	Enables the RADIUS authentication feature globally.
<b>MaxNumberServer</b>	Specifies the maximum number of servers to be used inclusive.
<b>AccessPriorityAttrValue</b>	Specific to RADIUS authentication. Specifies the vendor-specific attribute value of the access-priority attribute to match the type value set in the dictionary file on the RADIUS server. The default is 192.
<b>AcctEnable</b>	Enables RADIUS accounting.
<b>AcctAttriValue</b>	Specific to RADIUS accounting. Specifies the vendor-specific attribute value of the CLI-command attribute to match the type value set in the dictionary file on the RADIUS server. This value must be different from the access-priority attribute value configured for authentication. The default value is 193.
<b>AcctIncludeCli</b>	Specifies whether you want CLI commands included in RADIUS accounting requests.
<b>ClearStat</b>	Clears RADIUS statistics from the device.
<b>McastAttributeValue</b>	Specifies the value of the Mcast attribute. The default value is 90.
<b>AuthInfoAttrValue</b>	Specifies the value of the authentication information attribute. The default value is 91.
<b>CommandAccessAttrValue</b>	Specifies the value of the command access attribute. The default value is 194.
<b>CliCommandAttrValue</b>	Specifies the value of the CLI command attribute. The default value is 195.
<b>AuthInvalidServerAddress</b>	Displays the number of access responses from unknown or invalid RADIUS servers.
<b>CliCmdCount</b>	Gives the value for the CLI command count. The default is 40.

Name	Description
<b>CliProfEnable</b>	Enables RADIUS CLI profiling.
<b>SupportedVendorIds</b>	Shows the vendor IDs that the software supports for RADIUS.
<b>RadiusReachability</b>	Specifies the mode for RADIUS reachability. Status-server mode provides a standard-compliant method for RADIUS reachability. Use-radius mode requires the configuration of dummy packets that are sent to RADIUS servers. The default is use-radius mode.
<b>SecureEnable</b>	Enable RADIUS Security (RADSec).
<b>UserName</b>	Specifies the username for RADIUS server reachability. The default is extremenetworks.
<b>Password</b>	Specifies the password for RADIUS server reachability. The default is extremenetworks.
<b>Confirm Password</b>	Confirms the password for RADIUS server reachability.
<b>Unreachable Timer</b>	Specifies, in seconds, the interval between checks when radius server is unreachable. The default is 60 seconds.
<b>Keep Alive Timer</b>	Specifies, in seconds, the interval between checks when radius server is reachable. The default is 180 seconds.

## Add a RADIUS Server

### About This Task

Add a RADIUS server to allow RADIUS service on the switch.

Remote Dial-In User Services (RADIUS) supports both IPv4 and IPv6 addresses, with no differences in functionality or configuration in all but the following case. When adding a RADIUS server or updating a RADIUS server in Enterprise Device Manager (EDM) you must specify if the address type is an IPv4 or an IPv6 address.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **RADIUS**.
3. Select the **RADIUS Servers** tab.
4. Select **Insert**.
5. Configure the server as required.
6. Select **Insert**.

**RADIUS Servers** *Field Descriptions*

Use the data in the following table to use the **RADIUS Servers** tab.

Name	Description
<b>AddressType</b>	Specifies either an IPv4 or an IPv6 address. RADIUS supports IPv4 and IPv6 addresses.
<b>Address</b>	Specifies the IP address of the RADIUS server. RADIUS supports IPv4 and IPv6 addresses.
<b>UsedBy</b>	Configures how the server functions: <ul style="list-style-type: none"> <li>• cli—configure the server for CLI authentication.</li> <li>• eapol—configure the server for EAPoL authentication.</li> <li>• endpointTracking—configure the server for Endpoint Tracking authentication.</li> <li>• snmp—configure the server for SNMP accounting.</li> <li>• web—configure the server for HTTP(s) authentication.</li> </ul> The default is cli.
<b>Priority</b>	Specifies the priority of each server, or the order of servers to send authentication. The default is 10.
<b>TimeOut</b>	Specifies the time interval in seconds before the client retransmits the packet. The default is 8.
<b>Enable</b>	Enables or disables authentication on the server. The default is true.
<b>MaxRetries</b>	Specifies the maximum number of retransmissions allowed. The default is 1.
<b>UdpPort</b>	Specifies the UDP port that the client uses to send requests to the server. The default value is 1812. The UDP port value set for the client must match the UDP value set for the RADIUS server.
<b>SecretKey</b>	Specifies the RADIUS server secret key, which is the password used by the client to be validated by the server.
<b>AcctEnable</b>	Enables or disable RADIUS accounting. The default is true.
<b>AcctUdpPort</b>	Specifies the UDP port of the RADIUS accounting server. The default value is 1813. The UDP port value configured for the client must match the UDP value configured for the RADIUS server.
<b>SecureEnable</b>	Enable RADIUS Security (RADSec).

Name	Description
<b>SecureMode</b>	<p>Specifies the RADSec security mode. Possible values are:</p> <ul style="list-style-type: none"> <li>• <b>tls</b> - Transport Layer Security (TLS) encryption over Transmission Control Protocol (TCP)</li> <li>• <b>dtls</b> - Datagram Transport Layer Security (DTLS) encryption over User Datagram Protocol (UDP)</li> </ul> <p>The default is <b>tls</b>.</p> <p><b>Important:</b> To avoid TLS handshake issues if the switch and RADsec proxy server run different versions of OpenSSL, manually force TLS version 2 negotiation through the RADsec proxy by adding the following text to the <code>radsecproxy.conf</code> configuration file:</p> <pre> tls default{     ...     TlsVersion TLS1_2 } </pre>
<b>SecureProfile</b>	Specifies the name of the secure profile.
<b>SecureLogLevel</b>	<p>Specifies the log severity level. Possible values are :</p> <ul style="list-style-type: none"> <li>• <b>critical</b></li> <li>• <b>error</b></li> <li>• <b>warning</b></li> <li>• <b>info</b></li> <li>• <b>debug</b></li> </ul>

## Showing RADIUS Server Statistics

### About This Task

Use the server statistics feature to display the number of input and output packets and the number of input and output bytes. Statistics from console ports are available to assist with debugging.

### Procedure

1. In the navigation pane, expand the **Configuration > Security > Control Path** folders.
2. Click **RADIUS**.
3. Click the **RADIUS Servers Stats** tab.

### **RADIUS Server Stats** Field Descriptions

Use the data in the following table to use the **RADIUS Server Stats** tab.

Name	Description
<b>AddressType</b>	Specifies the type of IP address. RADIUS supports IPv4 addresses only.
<b>Address</b>	Shows the IP address of the RADIUS server.

Name	Description
<b>Used by</b>	Identifies the client.
<b>AccessRequests</b>	Shows the number of access-response packets sent to the server; does not include retransmissions.
<b>AccessAccepts</b>	Shows the number of access-accept packets, valid or invalid, received from the server.
<b>AccessRejects</b>	Shows the number of access-reject packets, valid or invalid, received from the server.
<b>BadResponses</b>	Shows the number of invalid access-response packets received from the server.
<b>PendingRequests</b>	Shows the access-request packets sent to the server that have not yet received a response or that have timed out.
<b>ClientRetries</b>	Shows the number of authentication retransmissions to the server.
<b>AcctOnRequests</b>	Shows the number of accounting on requests sent to the server.
<b>AcctOffRequests</b>	Shows the number of accounting off requests sent to the server.
<b>AcctStartRequests</b>	Shows the number of accounting start requests sent to the server.
<b>AcctStopRequests</b>	Shows the number of accounting stop requests sent to the server.
<b>AcctInterimRequests</b>	Number of Accounting Interim requests sent to the server.  <b>Important:</b> The AcctInterimRequests counter increments only if you select AcctIncludeCli from the RADIUS Global tab.
<b>AcctBadResponses</b>	Shows the number of Invalid responses discarded from the server.
<b>AcctPendingRequests</b>	Shows the number of requests waiting to be sent to the server.
<b>AcctClientRetries</b>	Shows the number of retries made to this server.
<b>RoundTripTime</b>	Shows the time difference between the instance when a RADIUS request is sent and the corresponding response is received.
<b>AccessChallenges</b>	Shows the number of RADIUS access-challenges packets sent to this server. This does not include retransmission.
<b>NasIpAddress</b>	Shows the RADIUS client NAS Identifier for this server.

## Reauthenticate the RADIUS SNMP Server Session

### About This Task

Specify the number of challenges that you want the RADIUS SNMP server to send to authenticate a given session.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS**.
3. Click the **RADIUS SNMP** tab.  
The system displays RADIUS SNMP tab.
4. Select the **Enable** check box.
5. In the **ReauthenticateTimer** field, enter a value to specify the interval between RADIUS SNMP server reauthentications.

The timer for reauthentication of the RADIUS SNMP server session is enabled.

### Important

To end the RADIUS SNMP server session, enter a value for the `AbortSessionTimer`, and then select **Enable**.

6. Select the **AcctEnable** check box if desired.
7. Select **Apply**.

### *RADIUS SNMP* field descriptions

Use the data in the following table to use the **RADIUS SNMP** tab.

Name	Description
<b>Enable</b>	Enables or disables timer authentication on the server. The default is true.
<b>AbortSessionTimer</b>	Specifies the allowable time, in seconds, before aborting the RADIUS SNMP server session (30 to 65535). The default is 180.
<b>ReAuthenticateTimer</b>	Specifies the time, in seconds, between reauthentications of the RADIUS SNMP server (30 to 65535). The default is 180.
<b>AcctEnable</b>	Enables or disables the RADIUS SNMP session timer.
<b>UserName</b>	Specifies the user name for the RADIUS SNMP accounting.

## Configure RADIUS SNMP

### About This Task

Configure RADIUS SNMP parameters for authentication and session times.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.

2. Click **RADIUS**.
3. Select the **RADIUS SNMP** tab.
4. Select the **Enable** check box to enable RADIUS SNMP.
5. In the **AbortSessionTimer** field, enter the period after which the session expires in seconds.
6. In the **ReAuthenticateTimer** field, enter the period of time the system waits before reauthenticating in seconds.
7. Select the **AcctEnable** check box to enable RADIUS accounting for SNMP.
8. In the **UserName** field, type the RADIUS SNMP user name.
9. Click **Apply**.

### **RADIUS SNMP** field descriptions

Use the data in the following table to use the **RADIUS SNMP** tab.

Name	Description
<b>Enable</b>	Enables or disables timer authentication on the server. The default is true.
<b>AbortSessionTimer</b>	Specifies the allowable time, in seconds, before aborting the RADIUS SNMP server session (30 to 65535). The default is 180.
<b>ReAuthenticateTimer</b>	Specifies the time, in seconds, between reauthentications of the RADIUS SNMP server (30 to 65535). The default is 180.
<b>AcctEnable</b>	Enables or disables the RADIUS SNMP session timer.
<b>UserName</b>	Specifies the user name for the RADIUS SNMP accounting.

## Modify a RADIUS Configuration

### About This Task

Use this procedure to modify an existing RADIUS configuration or single function such as retransmissions and RADIUS accounting.

RADIUS supports IPv4 and IPv6 addresses with no difference in functionality or configuration in all except the following case. When modifying a RADIUS configuration in Enterprise Device Manager (EDM), you must specify if the address type is an IPv4 or an IPv6 address.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS**.
3. Click the **RADIUS Servers** tab.
4. In the row and field to modify, type the information or use the lists to make a selection. Access the lists by double-clicking in a field.
5. When you are done with modifying the RADIUS configuration, click **Apply**.

**RADIUS Servers** *Field Descriptions*

Use the data in the following table to use the **RADIUS Servers** tab.

Name	Description
<b>AddressType</b>	Specifies either an IPv4 or an IPv6 address. RADIUS supports IPv4 and IPv6 addresses.
<b>Address</b>	Specifies the IP address of the RADIUS server. RADIUS supports IPv4 and IPv6 addresses.
<b>UsedBy</b>	Configures how the server functions: <ul style="list-style-type: none"> <li>• cli—configure the server for CLI authentication.</li> <li>• eapol—configure the server for EAPoL authentication.</li> <li>• endpointTracking—configure the server for Endpoint Tracking authentication.</li> <li>• snmp—configure the server for SNMP accounting.</li> <li>• web—configure the server for HTTP(s) authentication.</li> </ul> The default is cli.
<b>Priority</b>	Specifies the priority of each server, or the order of servers to send authentication. The default is 10.
<b>TimeOut</b>	Specifies the time interval in seconds before the client retransmits the packet. The default is 8.
<b>Enable</b>	Enables or disables authentication on the server. The default is true.
<b>MaxRetries</b>	Specifies the maximum number of retransmissions allowed. The default is 1.
<b>UdpPort</b>	Specifies the UDP port that the client uses to send requests to the server. The default value is 1812. The UDP port value set for the client must match the UDP value set for the RADIUS server.
<b>SecretKey</b>	Specifies the RADIUS server secret key, which is the password used by the client to be validated by the server.
<b>AcctEnable</b>	Enables or disable RADIUS accounting. The default is true.
<b>AcctUdpPort</b>	Specifies the UDP port of the RADIUS accounting server. The default value is 1813. The UDP port value configured for the client must match the UDP value configured for the RADIUS server.
<b>SecureEnable</b>	Enable RADIUS Security (RADSec).

Name	Description
<b>SecureMode</b>	<p>Specifies the RADSec security mode. Possible values are:</p> <ul style="list-style-type: none"> <li>• <b>tls</b> - Transport Layer Security (TLS) encryption over Transmission Control Protocol (TCP)</li> <li>• <b>dtls</b> - Datagram Transport Layer Security (DTLS) encryption over User Datagram Protocol (UDP)</li> </ul> <p>The default is <b>tls</b>.</p> <p><b>Important:</b> To avoid TLS handshake issues if the switch and RADsec proxy server run different versions of OpenSSL, manually force TLS version 2 negotiation through the RADsec proxy by adding the following text to the <code>radsecproxy.conf</code> configuration file:</p> <pre> tls default{     ...     TlsVersion TLS1_2 } </pre>
<b>SecureProfile</b>	Specifies the name of the secure profile.
<b>SecureLogLevel</b>	<p>Specifies the log severity level. Possible values are :</p> <ul style="list-style-type: none"> <li>• <b>critical</b></li> <li>• <b>error</b></li> <li>• <b>warning</b></li> <li>• <b>info</b></li> <li>• <b>debug</b></li> </ul>

## Delete a RADIUS Configuration

### About This Task

Delete an existing RADIUS configuration.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS**.
3. Click the **RADIUS Servers** tab.
4. Identify the configuration to delete by clicking anywhere in the row.
5. Click **Delete**.

## Configure RADIUS Server Reachability

### About This Task

Use this procedure to configure the RADIUS server reachability settings.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.

2. Click **RADIUS**.
3. Click the **RADIUS Global** tab.
4. In **RadiusReachability**, select either **useStatusServerPackets** or **useDummyRadiusRequests**.
5. In the **UserName** field, type the reachability user name.
6. In the **Password** field, type the reachability password.
7. In the **Confirm Password** field, retype the reachability password.
8. In the **Unreachable Timer** field, type the interval in seconds between checks when the RADIUS server is unreachable.
9. In the **KeepAlive Timer** field, type the interval in seconds between checks when the RADIUS server is reachable.
10. Click the **Apply**.

### **RADIUS Global** Field Descriptions

Use the data in the following table to use the **RADIUS Global** tab.

Name	Description
<b>Enable</b>	Enables the RADIUS authentication feature globally.
<b>MaxNumberServer</b>	Specifies the maximum number of servers to be used inclusive.
<b>AccessPriorityAttrValue</b>	Specific to RADIUS authentication. Specifies the vendor-specific attribute value of the access-priority attribute to match the type value set in the dictionary file on the RADIUS server. The default is 192.
<b>AcctEnable</b>	Enables RADIUS accounting.
<b>AcctAttriValue</b>	Specific to RADIUS accounting. Specifies the vendor-specific attribute value of the CLI-command attribute to match the type value set in the dictionary file on the RADIUS server. This value must be different from the access-priority attribute value configured for authentication. The default value is 193.
<b>AcctIncludeCli</b>	Specifies whether you want CLI commands included in RADIUS accounting requests.
<b>ClearStat</b>	Clears RADIUS statistics from the device.
<b>McastAttributeValue</b>	Specifies the value of the Mcast attribute. The default value is 90.
<b>AuthInfoAttrValue</b>	Specifies the value of the authentication information attribute. The default value is 91.
<b>CommandAccessAttrValue</b>	Specifies the value of the command access attribute. The default value is 194.
<b>CliCommandAttrValue</b>	Specifies the value of the CLI command attribute. The default value is 195.
<b>AuthInvalidServerAddress</b>	Displays the number of access responses from unknown or invalid RADIUS servers.

Name	Description
<b>CliCmdCount</b>	Gives the value for the CLI command count. The default is 40.
<b>CliProfEnable</b>	Enables RADIUS CLI profiling.
<b>SupportedVendorIds</b>	Shows the vendor IDs that the software supports for RADIUS.
<b>RadiusReachability</b>	Specifies the mode for RADIUS reachability. Status-server mode provides a standard-compliant method for RADIUS reachability. Use-radius mode requires the configuration of dummy packets that are sent to RADIUS servers. The default is use-radius mode.
<b>SecureEnable</b>	Enable RADIUS Security (RADSec).
<b>UserName</b>	Specifies the username for RADIUS server reachability. The default is extremenetworks.
<b>Password</b>	Specifies the password for RADIUS server reachability. The default is extremenetworks.
<b>Confirm Password</b>	Confirms the password for RADIUS server reachability.
<b>Unreachable Timer</b>	Specifies, in seconds, the interval between checks when radius server is unreachable. The default is 60 seconds.
<b>Keep Alive Timer</b>	Specifies, in seconds, the interval between checks when radius server is reachable. The default is 180 seconds.

## Configure a RADIUS Dynamic-server Client

### About This Task

Use this procedure to configure a client to allow processing of dynamic session changes.

### Before You Begin

You must enable EAPOL globally and at the port level.

You must enable RADIUS dynamic extensions commands processing at the port level.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **RADIUS CoA**.
3. Click **Global**.
4. Click **Insert**.
5. In the **Address** field type a client address.
6. (Optional) In the **UdpPort** field, type a value for client port.
7. (Optional) In the **Secret** field, type a value for the secret key.
8. Select the **Enable** checkbox to enable dynamic session processing for the client.

9. Click **Insert**.

*Global field descriptions*

Use the data in the following table to use the **Global** tab.

Name	Description
<b>AddressType</b>	Specifies the type of address contained in the corresponding instance of a RADIUS Dynamic Authorization Client configured in this entry.
<b>Address</b>	Specifies the internet address of a RADIUS Dynamic Authorization Client configured in this entry.
<b>UdpPort</b>	Specifies the UDP port number the server/NAS listens on for requests from the RADIUS Dynamic Authorization Client configured in this entry.
<b>Secret</b>	Specifies the secret key shared between the RADIUS Dynamic Authorization Client and Server. Note that when this object is retrieved, its value will always be a zero-length octet string.
<b>Enable</b>	Enable processing of dynamic session changes.

## Displaying RADIUS CoA Disconnect Statistics

### About This Task

Use this procedure to display RADIUS CoA Disconnect statistics.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **Security** > **Control Path**.
2. Click **RADIUS CoA**.
3. Click the **Disconnect Stats** tab.

*Disconnect Stats Field Descriptions*

Use the data in the following table to use the **Disconnect Stats** tab.

Name	Description
<b>DisconRequests</b>	Specifies the number of RADIUS disconnect requests received from this Dynamic Authorization Client. This also includes the RADIUS disconnect requests that have a Service-Type attribute with a value of Authorize Only.
<b>DisconAuthOnlyRequests</b>	Specifies the number of RADIUS disconnect requests that include a Service-Type attribute with a value of Authorize Only received from this Dynamic Authorization Client.
<b>DupDisconRequests</b>	Specifies the number of duplicate RADIUS Disconnect-Request packets received from this Dynamic Authorization Client.
<b>DisconAcks</b>	Specifies the number of RADIUS Disconnect-ACK packets sent to this Dynamic Authorization Client.
<b>DisconNaks</b>	Specifies the number of RADIUS Disconnect-NAK packets sent to this Dynamic Authorization Client. This includes the RADIUS Disconnect-NAK packets sent with a Service-Type attribute with a value of Authorize Only and the RADIUS Disconnect-NAK packets sent because no session context was found.
<b>DisconNakAuthOnlyRequests</b>	Specifies the number of RADIUS Disconnect-NAK packets that include a Service-Type attribute with a value of Authorize Only sent to this Dynamic Authorization Client.
<b>DisconNakSessNoContext</b>	Specifies the number of RADIUS Disconnect-NAK packets sent to this Dynamic Authorization Client because no session context was found.
<b>DisconUserSessRemoved</b>	Specifies the number of user sessions removed for the disconnect requests received from this Dynamic Authorization Client. Depending on site-specific policies, a single disconnect request can remove multiple user sessions. In cases where this Dynamic Authorization Server has no knowledge of the number of user sessions that are affected by a single request, each such disconnect request counts as a single affected user session only.

Name	Description
<b>MalformedDisconRequests</b>	Specifies the number of malformed RADIUS Disconnect-Request packets received from this Dynamic Authorization Client. Bad authenticators and unknown types are not included as malformed disconnect requests
<b>DisconBadAuthenticators</b>	Specifies the number of RADIUS Disconnect-Request packets that contain an invalid Authenticator field received from this Dynamic Authorization Client.
<b>DisconPacketsDropped</b>	Specifies the number of incoming disconnect requests from this Dynamic Authorization Client silently discarded by the server application for some reason other than malformed packets, bad authenticators, or unknown types.
<b>UnknownTypes</b>	Specifies the number of incoming requests that have an invalid ID type.

## Displaying RADIUS CoA Reauthenticate Statistics

### About This Task

Use this procedure to display RADIUS CoA Reauthenticate statistics.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Control Path**.
2. Click **RADIUS CoA**.
3. Click the **Reauthenticate Stats** tab.

### *Reauthenticate Stats Field Descriptions*

Use the data in the following table to use the **Reauthenticate Stats** tab.

Name	Description
<b>Requests</b>	Specifies the number of RADIUS Reauthentication-Requests received from this Dynamic Authorization Client. This also includes the Reauthentication requests that have a Service-Type attribute with a value of Authorize Only.
<b>AuthOnlyRequests</b>	Specifies the number of RADIUS Reauthentication-Requests that include a Service-Type attribute with value Authorize Only received from this Dynamic Authorization Client.

Name	Description
<b>DupRequests</b>	Specifies the number of duplicate RADIUS Reauthentication-Request packets received from this Dynamic Authorization Client.
<b>Acks</b>	Specifies the number of incoming Reauthentication packets from this Dynamic Authorization Client silently discarded by the server application for some reason other than malformed, bad authenticators, or unknown types.
<b>Nacks</b>	Specifies the number of RADIUS Reauthentication-NAK packets sent to this Dynamic Authorization Client. This includes the RADIUS Reauthentication-NAK packets sent with a Service-Type attribute value of Authorize Only, and the RADIUS Reauthentication-NAK packets sent because no session context was found.
<b>NacksAuthOnlyRequests</b>	Specifies the number of RADIUS Reauthentication-NAK packets that include a Service-Type attribute with a value of Authorize Only sent to this Dynamic Authorization Client.
<b>NacksNoSess</b>	Specifies the number of RADIUS Reauthentication-NAK packets sent to this Dynamic Authorization Client because no session context was found.
<b>SessReauthenticated</b>	Specifies the number of user sessions reauthenticated for the Reauthentication-Requests received from this Dynamic Authorization Client. Depending on site-specific policies, a single Reauthentication-Request can change the authorization of multiple user sessions. In cases where the Dynamic Authorization Server has no knowledge of the number of user sessions that are affected by a single request, each CoA-Request counts as a single affected user session.
<b>Malformed</b>	Specifies the number of malformed RADIUS Reauthentication-Request packets received from the Dynamic Authorization Client. Bad authenticators and unknown types are not included as malformed Reauthentication-Requests.

Name	Description
<b>Dropped</b>	Specifies the number of incoming Reauthentication packets from the Dynamic Authorization Client silently discarded by the server application for some reason other than malformed, bad authenticators, or unknown types.
<b>BadAuths</b>	Specifies the number of RADIUS Reauthentication-Request packets that contained an invalid Authenticator field received from the Dynamic Authorization Client.
<b>UnknownTypes</b>	Specifies the number of incoming requests that have an invalid ID type.

## Displaying RADIUS CoA Statistics

### About This Task

Use this procedure to display information about RADIUS CoA statistics.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **Security** > **Control Path**.
2. Click **RADIUS CoA**.
3. Click the **CoA Stats** tab.

### CoA Stats Field Descriptions

Use the data in the following table to use the **CoA Stats** tab.

Name	Description
<b>AddressType</b>	Specifies the RADIUS Dynamic Authorization Client IP address type.
<b>Address</b>	Specifies the RADIUS Dynamic Authorization Client IP address.
<b>DisconRequests</b>	Specifies the number of RADIUS Disconnect-Requests received from this Dynamic Authorization Client. This also includes the Disconnect requests that have a Service-Type attribute with a value of Authorize Only.
<b>DisconAuthOnlyRequests</b>	Specifies the number of RADIUS Disconnect-Requests that include a Service-Type attribute with value Authorize Only received from this Dynamic Authorization Client.

Name	Description
<b>DupDisconRequests</b>	Specifies the number of duplicate RADIUS Disconnect-Request packets received from this Dynamic Authorization Client.
<b>DisconAcks</b>	Specifies the number of RADIUS Disconnect-ACK packets sent to this Dynamic Authorization Client.
<b>DisconNaks</b>	Specifies the number of RADIUS Disconnect-ACK packets sent to this Dynamic Authorization Client. This includes the RADIUS Disconnect-ACK packets sent with a Service-Type attribute value of Authorize Only, and the RADIUS Disconnect-ACK packets sent because no session context was found.
<b>DisconNakAuthOnlyRequests</b>	Specifies the number of RADIUS Disconnect-NAK packets that include a Service-Type attribute with a value of Authorize Only sent to this Dynamic Authorization Client.
<b>DisconNakSessNoContext</b>	Specifies the number of RADIUS Disconnect-NAK packets sent to this Dynamic Authorization Client because no session context was found.
<b>DisconUserSessRemoved</b>	Specifies the number of user sessions removed for the Disconnect-Requests received from this Dynamic Authorization Client. Depending on site-specific policies, a single Disconnect-Request can change the authorization of multiple user sessions. In cases where the Dynamic Authorization Server has no knowledge of the number of user sessions that are affected by a single request, each Disconnect-Request counts as a single affected user session.
<b>MalformedDisconRequests</b>	Specifies the number of malformed RADIUS Disconnect-Request packets received from the Dynamic Authorization Client. Bad authenticators and unknown types are not included as malformed Disconnect-Requests.
<b>UnknownTypes</b>	Specifies the number of incoming requests that have an invalid ID type.

## RADSec Configuration Using EDM

This section contains procedures for configuring RADSec with Enterprise Device Manager (EDM).

## Configure a RADIUS Secure Profile

Configure a RADIUS Security (RADSec) profile to specify certificate information used by RADSec to develop trust between peers. You can also specify a password used for RADSec encryption.

### About This Task

All the files (certificates and keys) must be in .pem format and copy it to flash /intflash directory.

A new profile directory is created for each new profile in the flash/intflash/.radsec/profile/radsec directory.

Profile configuration file “profile\_info.cfg” is available in /intflash/.radsec/profile directory.

You can configure a maximum of 10 RADsec profiles.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **RADIUS**.
3. Select the **Secure Certificate Profile**
4. Select **Insert**.
5. For **Name**, enter the name for the profile.
6. For **RootCert**, enter the full path for the profile root certificate.
7. For **Cert**, enter the full path for the profile certificate.
8. For **Key**, enter the full path for the profile private key.
9. For **Password**, enter the full path to decrypt the profile private key.
10. For **RootCertDestFile**, enter the file name to use when installing the root certificate.
11. For **CertDestFile**, enter the file name to use when installing the certificate.
12. For **KeyDestFile**, enter the file name to use when installing the key.
13. Select **Insert**.

### Secure Certificate Profile Field Descriptions

Use the data in the following table to use the **Secure Certificate Profile** tab.

Name	Description
<b>Name</b>	Specifies the profile name.
<b>RootCert</b>	Specifies the full path of the profile root certificate.
<b>Cert</b>	Specifies the full path of the profile certificate.
<b>Key</b>	Specifies the full path of the profile private key.
<b>Password</b>	Specifies the password used to decrypt the profile private key.

Name	Description
<b>RootCertDestFile</b>	Specifies the file name to use when installing the root certificate.
<b>CertDestFile</b>	Specifies the file name to use when installing the certificate.
<b>KeyDestFile</b>	Specifies the file name to use when installing the key.

# RADIUS Attributes

---

[Vendor Specific Attributes](#) on page 3025

[IETF Attributes](#) on page 3041

The following topics list RADIUS attributes for EAP.

## Vendor Specific Attributes

---

### RADIUS Vendor Specific Frame Format

The following figure shows the frame format for RADIUS vendor specific attributes (VSA).

**Figure 222: RADIUS vendor-specific frame format**

### FA-VLAN-ISID

On EAP-enabled Flex-UNI ports, the context for the authenticating MAC is the association using the FA-VLAN-ISID attribute. This attribute provides one VLAN:ISID binding.

- defined under vendor IDs 562 and 1584 and uses the value 171
- I-SID values are 0-15999999
- VLAN values are 0 - 4096 to create untagged S-UNIs in MHSA mode and MAC-BasedS-UNIs in MHMV mode
- RADIUS server provides up to 94 bindings
- for MHMV with multiple bindings, only the last binding is created

### FA-Client-Type

This attribute is used in packets transmitted to the RADIUS server to inform that the current authenticated MAC is associated to a FA Client of type x. This attribute is defined under Nortel vendor id (562) and uses the value 182.

Only one FA Client per port is supported.

The following values are defined for FA Client type:

- 0: FA Element Not Found
- 1: FA Element Type Other
- 2: FA Server
- 3: FA Proxy
- 4: FA Server No Authentication
- 5: FA Proxy No Authentication
- 6: FA Client Wireless AP Type 1 [clients direct network attachment]
- 7: FA Client Wireless AP Type 2 [clients tunneled to controller]
- 8: FA Client Switch
- 9: FA Client Router
- 10: FA Client IP Phone
- 11: FA Client Camera
- 12: FA Client IP Video
- 13: FA Client Security Device
- 14: FA Client Virtual Switch
- 15: FA Client Server Endpoint
- 16: FA Client ONA SDN mode
- 17: FA Client ONA SPBOIP mode
- 63: FA Client Unknown

Any integer value provided by the FA is sent to the RADIUS server without any check from the EAP application.

### Extreme-Dynamic-MHSA

On EAP-enabled Flex UNI ports, this attribute changes the current interface EAPoL operating mode from MHMV to MHSA.

- defined under Extreme Networks vendor ID 1916 and uses the value 250
- parsed only on ports with Flex-UNI enabled
- value contained in this attribute must be 1

### Extreme-Dynamic-ACL

On EAP-enabled ports, this attribute assigns a dynamic ACL for an EAP-enabled port. The dynamic behavior of the ACL depends on the EAP port state (MHMV or MHSA).

- defined under Extreme Networks vendor ID 1916 and uses the value 251

For more information, see [RADIUS Dynamic User-Based Policies](#) on page 849.

### Examples

The following examples provide the RADIUS configuration for the corresponding CLI filter configuration. This example is for MAC 0a:0a:0a:0a:0a:0a on port 1/1 and EAP is in MHMV mode.

```
filter acl 1 type inPort
filter acl port 1 1/1

filter acl ace 1 1 name RadiusGuest-Rule01
filter acl ace ethernet 1 1 src-mac eq 0a:0a:0a:0a:0a:0a
filter acl ace ethernet 1 1 ether-type eq 0x800
filter acl ace ip 1 1 ip-protocol-type eq 17
filter acl ace protocol 1 1 dst-port eq 53
filter acl ace 1 1 action permit
filter acl ace 1 1 enable

filter acl ace 1 2 name RadiusGuest-Rule02
filter acl ace ethernet 1 2 src-mac eq 0a:0a:0a:0a:0a:0a
filter acl ace ethernet 1 2 ether-type eq 0x800
filter acl ace ip 1 2 dst-ip mask 192.0.2.1 24
filter acl ace 1 2 action permit
filter acl ace 1 2 enable

filter acl ace 1 3 name RadiusGuest-Rule03
filter acl ace ethernet 1 3 src-mac eq 0a:0a:0a:0a:0a:0a
filter acl ace 1 3 action deny
filter acl ace 1 3 enable
```

The RADIUS VSA does not specify the MAC or the port number because they are already known at the EAP level.

```
Extreme-Dynamic-ACL = "CLIENT RadiusGuest",
Extreme-Dynamic-ACL += "acl inPort",
Extreme-Dynamic-ACL += "ace 1 sec ethernet ether-type eq 0x800 & ip ip-protocol-type eq
17 & protocol dst-port eq 53 action permit",
Extreme-Dynamic-ACL += "ace 2 sec ethernet ether-type eq 0x800 & ip dst-ip mask 192.0.2.1
24 action permit",
Extreme-Dynamic-ACL += "ace 3 sec action deny"
```

The following example provides the ability to remark DSCP value for IP traffic (0x800):

```
Extreme-Dynamic-ACL = "ace 1 qos action permit internal-qos 5 remark-dot1p 5 remark-
dscp phbaf41 & ethernet ether-type eq 0x800",
Extreme-Dynamic-ACL += "acl set default-action permit"
```

The following examples provide both the list and expanded syntax for the same port configuration.

```
Extreme-Dynamic-ACL += 'ace 1 ethernet ether-type equal ip & ip ip-protocol-type eq tcp &
protocol dst-port equal list 37, 38, 1427 & action permit',
Extreme-Dynamic-ACL += 'ace 1 ethernet ether-type equal ip & ip ip-protocol-type eq tcp &
protocol dst-port equal 37 & action permit',
Extreme-Dynamic-ACL += 'ace 2 ethernet ether-type equal ip & ip ip-protocol-
type eq tcp & protocol dst-port equal 38 & action permit',
Extreme-Dynamic-ACL += 'ace 3 ethernet ether-type equal ip & ip ip-protocol-
type eq tcp & protocol dst-port equal 1427 & action permit',
```

The following examples provide both the list and expanded syntax for the same mask configuration.

```
Extreme-Dynamic-ACL += 'ace 1 ethernet ether-type equal ip & ip-protocol-type equal tcp
& protocol source mask list 9100 0xFFFFC, 9220 0xFFFFE, 9290 0xFFFFE, 49152 0xC000, 800
0xFFFF8, 808 0xFFFFE & ip dst mask 172.16.0.0 12 & action permit',
Extreme-Dynamic-ACL += 'ace 1 ethernet ether-type equal ip & ip-protocol-type equal tcp &
protocol source mask 9100 0xFFFFC & ip dst mask 172.16.0.0 12 & action permit',
Extreme-Dynamic-ACL += 'ace 2 ethernet ether-type equal ip & ip-protocol-type equal tcp &
protocol source mask 9220 0xFFFFE & ip dst mask 172.16.0.0 12 & action permit',
Extreme-Dynamic-ACL += 'ace 3 ethernet ether-type equal ip & ip-protocol-type equal tcp &
protocol source mask 9290 0xFFFFE & ip dst mask 172.16.0.0 12 & action permit',
Extreme-Dynamic-ACL += 'ace 4 ethernet ether-type equal ip & ip-protocol-type equal tcp &
protocol source mask 49152 0xC000 & ip dst mask 172.16.0.0 12 & action permit',
Extreme-Dynamic-ACL += 'ace 5 ethernet ether-type equal ip & ip-protocol-type equal tcp &
protocol source mask 800 0xFFFF8 & ip dst mask 172.16.0.0 12 & action permit',
Extreme-Dynamic-ACL += 'ace 6 ethernet ether-type equal ip & ip-protocol-type equal tcp &
protocol source mask 808 0xFFFFE & ip dst mask 172.16.0.0 12 & action permit',
```

## Extreme-Dynamic-Config

### Note

This VSA is not supported on XA1400 Series.  
VSP 4450 Series does not support EAP on Flex UNI ports.

This VSA configures port and VLAN based attributes.

- Name: Extreme-Dyn-Config
- Value: 252
- Type: String
- Vendor: Extreme
- Extreme Vendor ID is 1916

The following features can be configured using Extreme-Dynamic-Config RADIUS VSA:

- VLAN-based features:
  - DHCP Snooping
  - Dynamic ARP Inspection (DAI)
  - IGMP Snooping
- Port-based features:
  - Custom Auto-Negotiation Advertisements (CANA)
  - Bridge Protocol Data Unit (BPDU) Guard
  - IP Source Guard (IPSG)
  - Port bounce
  - Reauthentication

- Simple Loop Prevention Protocol (SLPP) Guard
- Traffic Control (Wake on LAN - WoL)

**Note**

If you use the Extreme-Dynamic-Config RADIUS VSA, then Dynamic ARP Inspection and DHCP Snooping are only enabled on the default VLAN if IPSP is present in the RADIUS attributes.

*AN-ADVERTISEMENTS:100Half or AN-ADVERTISEMENTS:100H*

AN-ADVERTISEMENTS:100Half or AN-ADVERTISEMENTS:100H settings configure CANA speed and duplex to the following supported values:

- 10Half
- 100Full
- 100Half
- 100Full
- 1000Full

*BPDU*

This attribute enables BPDU Guard on the port where the client resides.

*DAI*

This attribute enables DAI on the VLAN received from the RADIUS server. For a Flex-UNI port, DAI is enabled on the platform VLAN associated with the I-SID received from the RADIUS server.

DAI is also enabled on the default VLAN of the port to prepare for IPSP, which requires DAI and DHCP Snooping enabled on all VLANs. If the RADIUS server does not return a VLAN of I-SID, DAI is enabled on the default VLAN. For Flex-UNI ports, DAI is enabled on the platform VLAN associated with the untagged I-SID.

**Note**

If you use the Extreme-Dynamic-Config RADIUS VSA, then DAI is only enabled on the default VLAN if IPSP is present in the RADIUS attributes.

*DHCP Snooping*

This attribute enables DHCP Snooping on the VLAN received from the RADIUS server. For a Flex-UNI port, DHCP Snooping is enabled on the platform VLAN associated with the I-SID received from the RADIUS server.

DHCP Snooping is also enabled on the default VLAN of that port to prepare for IPSP, which requires DAI and DHCP Snooping enabled on all VLANs. If the RADIUS server does not return a VLAN of I-SID, DHCP Snooping is enabled on the default VLAN. For

Flex-UNI ports, DHCP Snooping is enabled for the platform VLAN associated with the untagged I-SID.

**Note**

If you use the Extreme-Dynamic-Config RADIUS VSA, then DHCP Snooping is only enabled on the default VLAN if IPSP is present in the RADIUS attributes.

*IGMPSNOOP*

This attribute enables IGMP Snooping on the VLAN received from the RADIUS server. For a Flex-UNI port, IGMP Snooping is enabled on the platform VLAN associated with the I-SID received from the RADIUS server.

*IPSG*

This attribute enables IPSG on the port where the client resides.

In order to apply IPSG, DHCP Snooping and DAI must be configured on the RADIUS server. DHCP Snooping and DAI must be enabled on all VLANs.

The following is an example of a log message that displays if a setting is not configured correctly:

```
GlobalRouter EAP WARNING Cannot apply Radius IP Source Guard attribute
on port 3/15 without DHCP Snooping and DAI attributes.
```

*PORTBOUNCE*

This attribute runs a port bounce on an EAP port including Power over Ethernet (PoE), if capable. Current EAP sessions are preserved during the port bounce process.

Use this attribute for on-demand re-authentication, for example, to use a power cycle to trigger a port bounce for a PC behind a phone, which is being rebooted, as in the following use cases:

- To ensure a PC behind a phone acquires an IP address from the VLAN or I-SID assigned by the RADIUS server, the PC triggers a new DHCP negotiation if it receives the port-bounce attribute in the RADIUS-Accept packet.
- To force a client to renew its DHCP IP address by using a RADIUS dynamic Change-of-Authorization (CoA) or Disconnect request.

CLI and EDM output that displays the interface state indicates if a port is down because of a RADIUS VSA port bounce.

*REAUTH or REAUTH:100*

This attribute enables EAPOL reauthentication on a port either manually using CLI or dynamically through RADIUS. The origin identifies how reauthentication was configured, either CONFIG or RADIUS.

*SLPPGUARD*

This attribute enables SLPP Guard on the port where the client resides.

*WOL*

This attribute enables EAP traffic-control (Wake On LAN) on the port where the client resides.

*Session Timeout and Reauthentication VSA Behavior*

Session	REAUTH status	Cause
EAP Session	Without REAUTH VSA	On MAC ageout.  <b>Note:</b> Session timeouts if the client is not connected.
	With REAUTH VSA	On periodically timer and MAC ageout.
NEAP Session	Without REAUTH VSA	On MAC Ageout.
	With REAUTH VSA	Useful for silent devices, session stays active despite MAC ageout. Session is removed only by manual intervention or RADIUS reject/timeout.  <b>Note:</b> The same command activates both EAP and NEAP reauthentication. If reauthentication is needed for EAP, NEAP reauthentication for silent devices is automatically activated.

Command	Level	Processing	Configuration	Prerequisites
<b>Session-timeout</b>	per session basis.	Changes the reauth interval for a particular session.	none.	Enable port level reauthentication.
<b>VSA (REAUTH: 300 or REAUTH)</b>	per port basis.	Changes the port configuration.	Enable reauthentication and configure interval.	none.

*Expected Behavior for DHCP Snooping and DAI Vendor Specific Attributes*

The following table shows the behavior for Dynamic Host Configuration Protocol Snooping (DHCP Snooping) and Dynamic ARP Inspection (DAI) Vendor Specific Attributes (VSA) for each authentication scenario, depending on Extensible

Authentication Protocol (EAP) Operational mode, Flex-UNI mode, and IP Source Guard (IPSG) VSA or RADIUS VLAN/ISID.

**Table 212: Expected Behavior for DHCP Snooping and DAI VSAs**

EAP Operational Mode	IPSG VSA received	Flexi-UNI	RADIUS VLAN/I-SID	DHCP Snooping and DAI VSA received
Mutiple Host Single Authentication (MHSA)	Yes	Yes	Yes	DHCP, DAI, and IPSG enabled on all associated Platform VLANs.
MHSA	Yes	Yes	No	DHCP, DAI, and IPSG enabled on all associated Platform VLANs.
MHSA	Yes	No	Yes	DHCP, DAI, and IPSG enabled on all associated Platform VLANs.
MHSA	Yes	No	No	DHCP, DAI, and IPSG enabled on all associated Platform VLANs.
MHSA	No	Yes	Yes	DHCP and DAI enabled on Platform VLAN associated with RADIUS I-SIDs.
MHSA	No	Yes	No	DHCP and DAI enabled on all static Platform VLANs.
MHSA	No	No	Yes	DHCP and DAI enabled on received RADIUS VLAN.
MHSA	No	No	No	DHCP and DAI enabled on default VLAN.
Mutiple Host Multiple VLAN (MHMV)	Yes	Yes	Yes	DHCP, DAI, and IPSG enabled on Platform VLAN associated with RADIUS I-SID and Platform VLAN associated with untagged I-SID.
MHMV	Yes	Yes	No	DHCP, DAI, and IPSG enabled on Platform VLAN associated with untagged I-SID.
MHMV	Yes	No	Yes	DHCP, DAI, and IPSG enabled on RADIUS VLAN and default VLAN.
MHMV	Yes	No	No	DHCP, DAI, and IPSG enabled on default VLAN.
MHMV	No	Yes	Yes	DHCP and DAI enabled on Platform VLAN associated with RADIUS I-SID.

**Table 212: Expected Behavior for DHCP Snooping and DAI VSAs (continued)**

EAP Operational Mode	IPSG VSA received	Flexi-UNI	RADIUS VLAN/I-SID	DHCP Snooping and DAI VSA received
MHSA	No	Yes	No	DHCP and DAI enabled on Platform VLAN associated with untagged I-SID.
MHSA	No	No	Yes	DHCP and DAI enabled on received RADIUS VLAN.
MHSA	No	No	No	DHCP and DAI enabled on default VLAN.
<p><b>Note:</b> If no RADIUS VLAN or Platform VLAN is associated with RADIUS I-SID, DHCP Snooping and DAI are enabled on the default VLAN or Platform VLAN associated with static untagged I-SID.</p>				

### Operational Considerations

Consider the following when you use port and VLAN based attributes:

- Configuring Custom Auto-Negotiation Advertisements (CANA) on a port triggers a port bounce, which generates new client authentication.
- DHCP Snooping Option 82 is not supported.
- IGMP Snooping is not supported on a DvR Leaf.
- Disconnect requests execute a disconnect command for the client. If the PORTBOUNCE attribute is included, then it only performs a port bounce.
- Reauthenticate requests execute a reauthentication of the client. These requests can include all attributes.
- Change-of-Authorization (CoA) requests perform the change of authorized configuration for the supported attributes. If the PORTBOUNCE attribute is included, then it only performs a port bounce.
- On Flex-UNI ports, if the I-SID received from the RADIUS server does not have a platform VLAN associated with it, attributes are not applied. When a platform VLAN is associated with the I-SID, EAP reauthentication is generated to apply the attribute by bouncing a port, bouncing EAP on a port, or by using CoA Reauthenticate.
- If you configure a port in Multiple Host Single Association (MHSA) mode and VLAN based attributes are received from the RADIUS server, features are enabled on the default VLAN and on all VLANs that contain the authentication port.

This consideration only applies if IP Source Guard is received from the RADIUS server. Otherwise DHCP Snooping and Dynamic ARP Inspection (DAI) is enabled based on the behavior described in [Expected Behavior for DHCP Snooping and DAI Vendor Specific Attributes](#) on page 3031.

- Only attributes that can be configured manually can be configured dynamically using EAP.

- IP Source Guard restrictions apply even if the feature is configured on the RADIUS server.
  - Maximum 10 entries per port
  - Maximum 1000 entries per server
  - DHCP Snooping and DAI must be enabled on all VLAN members of the RADIUS configured port.
- If multiple client authentication is permitted in MHMV mode, you can apply RADIUS attributes incrementally as subsequent clients authenticate.

If a client authenticates with DHCP Snooping, DAI, and IP Source Guard attributes on the VLAN and a second client attempts to authenticate with the same attributes, consider the following:

- If the second client uses the same VLAN as the first client, only IP Source Guard applies on the RADIUS configuration port.
- If the second client uses a different VLAN, DHCP Snooping and DAI apply on the VLAN and the IP Source Guard applies on the RADIUS configuration port.
- If you configure a Guest VLAN on a port and the RADIUS server returns IP Source Guard as a result of EAP or NEAP authentication, then you should manually remove static VLANs from that port. Alternatively, you can enable DHCP Snooping and DAI on static VLANs.
- If you configure a port with multiple platform VLANs and the RADIUS server returns IP Source Guard as a result of EAP/NEAP authentication, then you must manually configure DHCP Snooping and DAI on static platform VLANs.
- The reauthentication flag and reauthentication period attributes origin can be either CONFIG or RADIUS. Different origins for reauthentication flag and reauthentication period attributes are valid.
  - You can configure the reauthentication flag with or without a time interval in CLI or RADIUS VSA. If you do not specify a time interval when you enable reauthentication on a port from RADIUS, the reauthentication period origin does not change.
  - If a RADIUS client specifies the same value as the one that already exists in static configuration through CLI, the origin remains as CONFIG.
  - If you enable reauthentication through CLI and you configure a specific period using the command `re-authentication-period <60-65535>` the origin is CONFIG.

The following message displays to indicate that RADIUS clients use the configuration:

```
WARNING: Setting used by Radius Client. Are you sure you want to
continue? (y/n)?
```

If the reauthentication period attribute was configured with the reauthentication flag through RADIUS VSA, the origin is RADIUS.

When you change the reauthentication period attribute in CLI, the following message displays to indicate that the origin of this parameter is RADIUS.

WARNING: Current port reauth period has RADIUS origin. Are you sure you want to continue? (y/n)?

Changing a parameter in CLI that was originally configured using RADIUS, changes the origin to CONFIG.

- Dynamic cleanup is supported. When the last client to authenticate using a dynamic attribute is removed, the following dynamic attributes are also removed:
  - Dynamic ARP Inspection (DAI)
  - DHCP Snooping
  - IGMP Snooping
  - IP Source Guard
  - Reauthentication

However, the following attributes can only be removed by disabling EAP:

- SLPP Guard
- BPDU Guard
- Traffic Control (Wake on LAN)
- Custom Auto-Negotiation Advertisements

For more information, see [Extreme-Dynamic-Config](#) on page 3028.

### Examples

The following example enables DHCP Snooping and Dynamic ARP Inspection (DAI) on VLAN 100 and IP Source Guard on authentication port:

```
Auth-Type := Local
User-Password == "0000000000001"
Service-Type = Administrative-User
Tunnel-Type = VLAN
Tunnel-Medium-Type = IEEE-802
Tunnel-Private-Group-Id = 100
Extreme-Dynamic-Config = "DHCP Snooping"
Extreme-Dynamic-Config += "DAI"
Extreme-Dynamic-Config += "IPSG"
```

The following example configures the Custom Auto-Negotiation Advertisements (CANA) to 100Half on authentication port:

```
Auth-Type := Local
User-Password == "0000000000008"
Service-Type = Administrative-User
Extreme-Dynamic-Config = "AN-ADVERTISEMENTS:100H"
```

The following example enables BPDU Guard on authentication port:

```
Auth-Type := Local
User-Password == "0000000000006"
Service-Type = Administrative-User
Extreme-Dynamic-Config = "BPDU"
```

The following example enables DHCP Snooping and DAI on the platform VLAN associated with I-SID 10000 and IP Source Guard on authentication port:

```
Auth-Type := Local
User-Password == "0000000000002"
Service-Type = Administrative-User
Fabric-Attach-ISID = "0:10000"
Extreme-Dynamic-Config = "DHCP Snooping"
Extreme-Dynamic-Config += "DAI"
Extreme-Dynamic-Config += "IPSG"
```

The following example enables IGMP Snooping on VLAN 100:

```
Auth-Type := Local
User-Password == "0000000000003"
Service-Type = Administrative-User
Tunnel-Type = VLAN
Tunnel-Medium-Type = IEEE-802
Tunnel-Private-Group-Id = 100
Extreme-Dynamic-Config = "IGMP Snooping"
```

The following example enables IGMP Snooping platform VLAN associated with I-SID 10000:

```
Auth-Type := Local
User-Password == "0000000000004"
Service-Type = Administrative-User
Fabric-Attach-ISID = "0:10000"
Extreme-Dynamic-Config = "IGMP Snooping"
```

The following example enables reauthentication on a port without a configured time interval:

```
Auth-Type := Local
User-Password == "0000000000007"
Service-Type = Administrative-User
Extreme-Dynamic-Config = "REAUTH"
```

The following example enables reauthentication on a port with a configured time interval:

```
Auth-Type := Local
User-Password == "0000000000007"
Service-Type = Administrative-User
Extreme-Dynamic-Config = "REAUTH:1230"
```

The following example enables SLPP Guard on authentication port:

```
Auth-Type := Local
User-Password == "0000000000007"
Service-Type = Administrative-User
Extreme-Dynamic-Config = "SLPPGUARD"
```

The following example enables EAP traffic-control on authentication port:

```
Auth-Type := Local
User-Password == "0000000000005"
Service-Type = Administrative-User
Extreme-Dynamic-Config = "WOL"
```

The following example triggers a PORTBOUNCE on the port that authenticates the user.:

```
Auth-Type := Local, User-Password == "0000000000001"  
Extreme-Dynamic-Client-Assignments += "create=vlan, pv=300, vni=100300",  
Extreme-Dynamic-Config += "PORTBOUNCE"
```

## Extreme-Dynamic-Client-Assignments

The Extreme-Dynamic-Client-Assignments Vendor Specific Attribute (VSA) is a RADIUS VSA for dynamic VLAN and Private VLAN (PVLAN) creation. You can also configure VLAN parameters, such as VLAN name, I-SID to VLAN association, and I-SID name.

### Note

Product Notice: This section does not apply to XA1400 Series, VSP 8600 Series, or VSP 4450 Series (flex-uni ports).

- Name: Extreme-Dynamic-Client-Assignments
- Value: 253
- Type: String
- Vendor: Extreme
- Extreme Vendor ID is 1916

The Extreme-Dynamic-Client-Assignments VSA supports the following VLAN-based features:

- IGMP Snooping
- DHCP Snooping
- Dynamic ARP Inspection (DAI)

You configure these features through the Extreme-Dynamic-Config RADIUS VSA before you use the VSA Extreme-Dynamic-Client-Assignments.

RADIUS Change of Authorization (CoA) is supported also. With CoA, a RADIUS server can remove a client device from a network and force it to re-authenticate.

Note the following points regarding VLAN creation with the Extreme-Dynamic-Client-Assignments VSA:

- **Platform VLAN manual configuration**—This maps the Extreme-Dynamic-Client-Assignments Radius VSA without `create`. Only the options used to define the existing functionality of mapping clients to VLAN on regular ports or `vlan:isid` on flex-uni ports are used—Primary VLAN (PV), Virtual Network Identifier (VNI), and Egress VLAN (EV). The Secondary VLAN (SV), VLAN Name (VN), and VNIN attributes for dynamic VLAN are ignored.
- **Regular VLAN configuration**—This maps the VSA with the option `create=vlan`. The Multiple Spanning Tree Protocol (MSTP) instance is 0. When platform VLAN is dynamically created, all VLAN parameters are also dynamically applied; a static VLAN setting is not allowed. Dynamic platform VLANs and dynamic I-SIDs names will exist as long as EAP clients reference them. If clients do not use them, then they are deleted and are not saved in the configuration file.

- **PVLAN configuration**—This maps with the usage of Extreme-Dynamic-Client-Assignments Radius VSA with the `create=pvlan` option. The EAP and Private VLANs on regular ports are not supported. But they are supported on flex-uni ports. The MSTP instance is 0. When you dynamically create a private VLAN, all VLAN parameters are also dynamically created; this is no static setting allowed. Dynamic PVLANS and dynamic I-SIDs names will exist as long as EAP clients reference them. If clients do not use them, then they are deleted and are not saved in the configuration file.

Use the information in the following tables and this string format to create a dynamic VLAN—`create=vlan|pvlan,pv=Primary VLANID, sv=secondary VLANID, vni=ISID, ev=EGRESS-VLAN-tag, vn=vlan-name, vnin=isid-name`.

#### Note

If `ev` is missing, it will default to 0. You can also use `U` or `T` (case-sensitive). When `ev` is set to `U`, it is untagged or 0. When `ev` is set to `T`, it takes the value of `pv` or tagged. If `pv` is not specified, then an error occurs and the VSA is ignored.

**Table 213: String Options for Dynamic VLAN Creation**

Option	Note
<code>create=vlan   pvlan</code>	<p>If <code>create</code> is missing, the assumption is that a manually created VLAN exists. Note the following two examples:</p> <ul style="list-style-type: none"> <li>• <code>create=vlan</code>—dynamically creates a platform VLAN.</li> <li>• <code>create=pvlan</code>—dynamically creates a private VLAN.</li> </ul> <p>This option is ignored on DVR Leafs.</p>
<code>pv=Primary VLANID</code>	<p>The platform VLAN that the client is assigned.</p> <p>This option is valid for any combination of the <code>create</code> command.</p>
<code>sv=Secondary VLANID</code>	<p>This option is only valid for a private VLAN and if the <code>create</code> option is also used.</p>
<code>vni=ISID</code>	<p>If you did not use <code>create</code> then you can use <code>vni</code> on flex-uni ports with <code>ev</code> to assign a client to a Switched UNI (S-UNI). The <code>vni</code> command also has the role of mapping the dynamic created VLAN to the VNI.</p>
<code>ev=EGRESS-VLAN-tag</code>	<p>Use this option on regular ports to tag or untag the egress for the PV.</p> <p>Use this option on flex-uni ports as <code>c-vid</code> in S-UNI creation.</p>

**Table 213: String Options for Dynamic VLAN Creation (continued)**

Option	Note
vn=Vlan name	Valid only if you use <code>create</code> .
vnin=ISID name	Valid only if you use <code>create</code> .

**Table 214: VSA Equivalency with Radius Attributes**

Port Type	RADIUS Attribute	Extreme-Dynamic-Client-Assignments Radius VSA	Comment
Regular port.	Tunnel Private GroupID.	Without <code>create</code> . pv=Primary VLANID.	This adds the port to the primary VLAN; tag is the port tag.
	Egress-VLANID.	Without <code>create</code> . pv=Primary VLANID. ev= EGRESS-VLAN-tag.	Untagged: ev = 0. Tagged: ev = pv. This adds the port to the primary VLAN; The VLAN egress tag is dictated by the ev.
	Egress-VLAN-Name.	Not Supported.	-
Flex-Uni ports.	FA VLAN:ISID.	Without <code>create</code> . vni=[ISID] ev= [EGRESS-VLAN-tag].	Untagged: ev = 0. Tagged: ev != 0. A S-UNI is created, either MAC-based or regular, depending on MHMV/MHSA setting; uses i-sid (vni) and c-vid (ev) values.
	Egress-VLANID + FA VLAN:I-SID.	Supported by the same combination for FA VLAN:ISID.	-
	Egress-VLANID + Tunnel Private GroupID + autoIsidOffset.	Without <code>create</code> . pv=Primary VLANID. ev= EGRESS-VLAN-tag.	Untagged: ev = 0. Tagged: ev != 0. A S-UNI is created, either MAC-based or regular, depending on MHMV/MHSA setting; uses auto configured i-sid from pv value and c-vid (ev) values.

**Table 214: VSA Equivalency with Radius Attributes (continued)**

Port Type	RADIUS Attribute	Extreme-Dynamic-Client-Assignments Radius VSA	Comment
	Egress-VLAN-Name + FA VLAN:I-SID >	Not supported.	-
	Egress-VLAN-Name + Tunnel Private GroupId + autoIsidOffset.	Not supported.	-

The dynamic VLAN is deleted after you disconnect all of the clients across the Extensible Authentication Protocol (EAP) ports. The port is removed when the last client is disconnected and the saved I-SID name is restored.

You cannot delete a static VLAN if EAP ports are assigned to it. But the VLAN can be deleted if you have added EAP FlexUNI ports to it. When you do this action, all MAC addresses are flushed, and any Non-EAP (NEAP) sessions are deleted. The MAC address is re-learned in I-SID and a new RADIUS authentication can now create a dynamic VLAN. For EAP sessions, the session goes to the re-authentication state, and the new RADIUS authentication can create a dynamic VLAN.

In Multiple Host Multiple VLAN (MHMV), if there are multiple assignments received for one session, the rule is to process only the last one and ignore the rest.

### Operational Considerations

#### Note

Product Notice: This section does not apply to XA1400 Series, VSP 8600 Series, or VSP 4450 Series (flex-uni ports).

Keep in mind the following operational considerations when you use the Extreme-Dynamic-Client-Assignments Vendor Specific Attribute (VSA):

- Extreme-Dynamic-Client-Assignments takes precedence over FA-VLAN-ISID, EGRESS-VLAN-ID, EGRESS-VLAN-Name, and RAD\_ATTR\_TUNNEL\_PRI\_GROUP\_ID.
- The RADIUS packet is limited to 4096 bytes, but can carry any VSA combination that does not exceed 4096 bytes. The Extreme-Dynamic-Client-Assignments VSA has a variable length and combinations can scale up to 94 VSAs in a packet. To reach 94 VSAs in a packet, each VSA should be about 40 bytes long.
- You cannot manually modify dynamic VLANs.
- You cannot use this VSA to dynamically create VLANs on a DvR Leaf node.
- The Extreme-Dynamic-Client-Assignments VSA does not support static configuration.
- As with all Extensible Authentication Protocol (EAP) enhancements, the Extreme-Dynamic-Client-Assignments VSA is not supported on the MultiLink Trunk (MLT) and Split MultiLink Trunk (SMLT) ports.

## EAP-Port-Priority

### Important

Configure these attributes only if you require dynamic port priority.

Port priority (vendor-specific) attributes:

- Vendor ID: value 562 (Nortel)

### Note

Vendor ID 1916 (Extreme) does not support port priority.

- Attribute Number: value 1, Port Priority
- Attribute Value: value 0 (zero) to 6 (this value indicates the port priority value assigned to the specified user)

The following list provides the switch Port Priority frame format:

- vendor specific type = 26
- length = 12
- vendor-id = 562
- string = vendor type = 1 + vendor length = 6 + attribute specific = priority

The following figure shows an example of the port priority frame format.

26	12	562	01	06	(0..6)
----	----	-----	----	----	--------

**Figure 223: Port priority frame format**

## IETF Attributes

### VLAN RADIUS Attributes

To control the tagging for traffic egressing a port, configure the preferred tagging option and one of the following attributes on the RADIUS server:

- EGRESS-VLAN-ID
- EGRESS-VLAN-NAME

VLAN attributes are defined by RFC 4675.

#### *EGRESS-VLAN-ID*

Functionality is combined with other RADIUS attributes and EAPoL configurations to create untagged S-UNIs.

This attribute supports the following combinations:

- untagged EGRESS-VLAN-ID + VLAN:ISID -> VLAN from S-UNI becomes untagged

- untagged EGRESS-VLAN-ID + vid[NEW\_RADIUS\_VID] + autolsidOffset -> create S-UNI for I-SID (VLAN+autolsidOffset)

### Examples

From the RADIUS attributes, for untagged VLAN 15. The VLAN from S-UNI becomes untagged:

```
Egress-VLANID = "838860815" (untagged vlan 15)
Fabric-Attach-ISID += "15:23513"
```

The following example results in the value 0:1015 for creating an untagged S-UNI.

From the RADIUS attributes, for untagged VLAN 15 and RADIUS-assigned VLAN. Creates S-UNI for I-SID (VLAN+autolsidOffset):

```
Egress-VLANID = "838860815"
Tunnel-Private-Group-Id = "15"
```

From the EAP configuration:

```
eapol auto-isid-offset 1000
eapol auto-isid-offset enable
```

### Considerations

Consider the following when using this attribute:

- Any combinations with EGRESS-VLAN-ID for a tagged VLAN are ignored.
- When EGRESS-VLAN-ID and VLAN:ISID binding attributes are used, the VLAN must have the same value.
- The RADIUS server can provide more than one VLAN:ISID binding but one must match the VLAN used in EGRESS-VLAN-ID to create an untagged S-UNI.
- Only one EGRESS-VLAN-ID attribute is used. If more than one is found in the packet, only the first one is used.
- If the untagged S-UNI is derived from EGRESS-VLAN-ID + VLAN-ID + VLAN attribute + auto-isid-offset, the packet must not contain any S-UNI bindings.

### *EGRESS-VLAN-NAME*

Functionality is combined with other RADIUS attributes and EAPoL configurations to create untagged S-UNIs.

This attribute supports the following combinations:

- EGRESS-VLAN-ID + VLAN:I-SID
- EGRESS-VLAN-ID + VLAN + autolsidOffset

This attribute includes the following information:

- Egress-VLAN-Name = "1VLAN\_NAME" for tagged VLAN
- Egress-VLAN-Name = "2VLAN\_NAME" for untagged VLAN
- VLAN\_NAME is the name of the VLAN on the switch

### Example

The following example creates an untagged Switched UNI with I-SID 1000. VLAN 10 is named "Dummy\_VLAN".

```
b0adaa41b830 Cleartext-Password :="b0adaa41b830"  
                Service-Type = Framed-User,  
                Framed-Protocol = PPP,  
                Auth-Type := Accept,  
                Fabric-Attach-ISID = "10:1000",  
                Egress-VLAN-name = "2Dummy_VLAN"
```

## RADIUS Tunnel Attributes

The switch uses the RADIUS tunnel attributes to place a port into a particular VLAN to support dynamic VLAN switching based on authentication. The server must send these attributes together in the same RADIUS packet. If one attribute is missing, the switch ignores the others.

The RADIUS server indicates the desired VLAN by including the tunnel attribute within the Access-Accept message. RADIUS uses the following tunnel attributes for VLAN membership:

- RAD\_ATTR\_TUNNEL\_TYPE(64)  
Tunnel-Type: value 13, Tunnel-Type-VLAN
- RAD\_ATTR\_TUNNEL\_MEDIUM\_TYPE(65)  
Tunnel-Medium-Type: value 6, Tunnel-Medium-Type-802
- RAD\_ATTR\_TUNNEL\_PRI\_GROUP\_ID  
Tunnel-Private-Group-ID: ASCII value 1-4094 (this value identifies the specified VLAN)

Tunnel attributes are defined by RFC 2868.

#### Important

Configure these attributes only if you require Dynamic VLAN membership.

The VLAN ID is 12 bits, uses a value from  $\langle 1-4094 \rangle$ , and is encoded as a string.

In addition, you can configure the RADIUS server to send a vendor-specific attribute (VSA) to configure port priority. You can assign the switch Supplicant port a QoS value from 0 to 6.

For more information, see [EAP-Port-Priority](#) on page 3041.

## Note

Product Notice: Using RESTCONF on VSP4900-48P or VSP4900-24S reduces the number of supported port-based VLANs on those platforms. For known issues, see [VOSS Release Notes](#).

## Representational State Transfer Configuration Protocol (RESTCONF) Fundamentals

---

Representational State Transfer Configuration Protocol (RESTCONF) is a next generation northbound interface that provides an additional way to configure and monitor the switch. RESTCONF is an HTTP-based protocol that provides a programmatic interface to access data defined in a YANG model using the datastore concepts defined in NETCONF. RESTCONF uses a client-server model. The server acts as an entry point to a datastore, a conceptual place to store and access information. Clients use HTTP or HTTPS to interface with the server to configure and monitor devices.

### RESTCONF Client and Server

A typical RESTCONF interaction consists of an HTTP/HTTPS request sent by a RESTCONF client and an HTTP/HTTPS response sent by the server. The HTTP/HTTPS request and response contain a required set of expected HTTP headers and can also contain a request or response message body. The message body is encoded in JSON.

An HTTP request consists of the HTTP method (such as GET or POST) identifier, resource identifier, HTTP protocol version, HTTP headers, and HTTP body. The HTTP resource identifier is the string that identifies a service or resource that the server makes available to the client. The RESTCONF request contains the Universal Resource Identifier or URI which starts with `/rest/restconf/data/` or `/rest/restconf/operations/`.

### YANG Model

YANG is the data modeling language used for modeling configuration and state data for manipulation by using remote procedure calls (RPCs). The RESTCONF interface is generated with YANG Data Model. The YANG model is based on Open config model, which is a non vendor specific model that captures the key components found in multiple vendor solutions. RESTCONF is described by the Internet Engineering Task Force (IETF) in RFC 8040.

### RESTCONF Authentication

RESTCONF uses the CLI user account and supports both local and remote authentication. Local authentication uses the local CLI user account while remote authentication can use either a RADIUS or TACACS+ server.

You can only use a CLI account with the RWA access level.

With RADIUS or TACACS+ enabled, if the remote server is not available, authentication falls back to local authentication and uses the local CLI user on the switch.

When the RESTCONF client posts for authentication, the HTTP server validates the login username and password if you have not enabled CLI remote authentication. If the remote server is not reachable, the HTTP server uses the local user for login validation.

For HTTPS access to the RESTCONF server, you must enable TLS and install a certificate. For the certificate, first you need to create a leaf certificate in .pem format and convert the private key to PKCS8 format. Then you need to create a .pem container that contains both the leaf certificate and the PCKS8 private key. The container will be used in the RESTCONF configuration and will have the following format:

```
-----BEGIN CERTIFICATE-----
-----END CERTIFICATE-----
-----BEGIN PRIVATE KEY-----
-----END PRIVATE KEY-----
```

To install the certificate, copy your certificate and private key into the container between the appropriate BEGIN and END lines.

## RESTCONF APIs

You can access the RESTCONF API documentation on your switch using the following URL:

*http(s)://<IP>:<tcp-port>/apps/restconfdoc/*

Replace <IP> with the management IP address of your switch and <tcp-port> with the TCP port configured for RESTCONF. For example, <http://192.0.2.16:8080/apps/restconfdoc/>.

The on-switch URL works only if you enable the RESTCONF feature on the switch.

You can also access the RESTCONF API documentation online through the Developer Center (<https://www.extremenetworks.com/support/documentation-api/>).

## Server Support

The RESTCONF server in the network operating system (NOS) supports the following actions:

HTTP Action	VOSS Instrumentation
GET	Corresponds to SHOW
POST	Corresponds to SET for creation
PATCH	Corresponds to SET for modification
DELETE	Corresponds to SET for deletion

The following table details modules supported by RESTCONF:

Modules	
OpenConfig	Extreme Network Service
OpenConfig	Relay Agent (DHCP support)

Modules	
OpenConfig	Interfaces Port: POE, port attributes, such as auto-sense, default-vlan-id, flex-uni, qos, untag-port-default-vlan
OpenConfig	Interfaces LAG: attributes, such as flex-uni
OpenConfig	Platform: ports, CPU, fans, power supply, optical devices - GET operations only
OpenConfig	Network Instance: VLAN interface - VRF association, CVLAN I-SID, IS-IS redistribute direct, IPVPN, I-SID, and IP DHCP relay forward path)
OpenConfig	STP: STP global information and port interface bpduguard state, RSTP global and port level information, MSTP global, MST instance level state - GET operations only
OpenConfig	System (aaa)
OpenConfig	LLDP
OpenConfig	VLAN

The RESTCONF feature is disabled by default. The RESTCONF server uses the same management IP address as the other applications and TCP port. The default TCP port that RESTCONF server listens to is port 8080. The TCP port delivers the message to the HTTP server for RESTCONF.

## RESTCONF configuration using CLI

This section provides procedures to configure Representational State Transfer Configuration Protocol (RESTCONF) using the command line interface (CLI).

### Enable the RESTCONF Server

#### About This Task

Use the following procedure to enable the RESTCONF server.

#### Before You Begin

Run the **show application restconf conflict-ifname** command to see if any conflict in interface names exist. To enable RESTCONF, the interface names (VLAN name, MLT name, and Port interface name) must be unique.

Run the **show application restconf invalid-name mlt** and **show application restconf invalid-name vlan** commands to see if any MLT or VLAN names contain special characters. To enable RESTCONF, VLAN and MLT names cannot contain special characters other than underscore (\_) and en dash (-).

### Procedure

1. Enter Application Configuration mode:

```
enable
```

```
configure terminal
```

```
application
```

2. Enable the RESTCONF server:

```
restconf enable
```

### Note

If the interface names (VLAN, MLT, and Port) are not unique, or if VLAN or MLT names contain prohibited special characters, an error occurs indicating that you cannot enable RESTCONF. You must change the interface names before you enable RESTCONF.

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CTRL/Z.
Switch:1(config)#application
Switch:1(config-app)#restconf enable
```

## Configure HTTPS Access to the RESTCONF Server

### About This Task

By default, the RESTCONF server uses HTTP. If you need to use HTTPS, generate a certificate file and transfer the certificate file to the `/intflash` directory on the switch.

For more information on generating certificate files, see [Manage an SSL Certificate](#) on page 3254.

### Before You Begin

Ensure that you have the certificate file in the `/intflash` directory on the switch.

### Procedure

1. Enter Application Configuration mode:

```
enable
```

```
configure terminal
```

```
application
```

2. If RESTCONF is enabled, disable RESTCONF:

```
no restconf enable
```

3. Install the certificate file for the RESTCONF server:

```
restconf install-cert-file WORD<1-128>
```

4. Enable HTTPS:  

```
restconf tls
```
5. Enable RESTCONF:  

```
restconf enable
```

**Example**

```
Switch:1>enable
Switch:1# configure terminal
Enter configuration commands, one per line. End with CTRL/Z.
Switch:1(config)#application
Switch:1(config-app)#no restconf enable
Switch:1(config-app)#restconf install-cert-file /intflash/.cert/restconf-cert.pem
Switch:1(config-app)#restconf tls
Switch:1(config-app)#restconf enable
```

*Variable Definitions*

The following table defines parameters for the **restconf** command.

Variable	Value
<i>enable</i>	Enables the RESTCONF Server.
<i>install-cert-file WORD&lt;1-128&gt;</i>	Installs the certificate file for the RESTCONF server.
<i>tcp-port &lt;1-49151&gt;</i>	Set RESTCONF Server TCP port number.
<i>tls</i>	Enables TLS for the RESTCONF server. The default is disabled.
<i>trap-notification</i>	Enables trap notification.

**Modifying the RESTCONF Server Settings**

**About This Task**

Use this procedure to modify the RESTCONF server settings.

**Note**

These steps are considered optional and RESTCONF can operate with the default configuration of these values.

**Procedure**

1. Enter Application Configuration mode:  

```
enable
```

```
configure terminal
```

```
application
```
2. Disable trap notification when the RESTCONF server is not available:  

```
no restconf trap-notification
```

3. Modify the TCP port number for the RESTCONF server:
  - a. Disable RESTCONF: `no restconf enable`
  - b. Change the value of the TCP port: `restconf tcp-port <1-49151>`
  - c. Enable RESTCONF: `restconf enable`
4. Disable TLS for the RESTCONF server:
  - a. Disable RESTCONF: `no restconf enable`
  - b. Disable TLS: `no restconf tls`
  - c. Enable RESTCONF: `restconf enable`

### Variable Definitions

Use the data in the following table to modify the RESTCONF server settings.

Variable	Value
<code>enable</code>	Enables or disables the RESTCONF server. The default is disabled.
<code>tcp-port &lt;1-49151&gt;</code>	Specifies the TCP port to use for the RESTCONF server. The default is 8080.
<code>trap-notification</code>	Enables or disables trap notification when the RESTCONF server is not available. The default is enabled.

## Showing the RESTCONF Configuration Information

### About This Task

Use this procedure to show the RESTCONF configuration information and operation status.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the RESTCONF configuration:
 

```
show application restconf
```

### Example

```
Switch:1>show application restconf
=====
                                RESTCONF Info
=====
Admin State           : true
TCP Port              : 8080
Certificate File Status : install
TLS Enable            : false
Trap Notification     : true
Oper State            : up
Web Server Version    : 1.0.1.11
RESTCONF Server Version : 1.0.1.39
=====
```

## Show Conflicting Interface Name Information

### About This Task

To enable RESTCONF, the interface name (VLAN name, MLT name, and Port interface name) must be unique. Use this procedure to display conflicting interface name information.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the RESTCONF conflicting interface name information:

```
show application restconf conflict-ifname
```

### Example

```
Switch:1>show application restconf conflict-ifname
-----
Conflicting Interface IfName - Port, VLAN Name and MLT Name
-----
Mlt 1 name is same as Vlan 1001 name - "Interface-1"
Mlt 2 name is same as Vlan 1002 name - "VLAN-1002"
Vlan 1003 name is Mlt 1 Default Name - "MLT-1"
-----
Total Conflict Count: 3
```

### What to Do Next

If a conflict exists, change the conflicting interface name to a unique name.

## Show Special Characters in VLAN or MLT Names

### About This Task

To enable RESTCONF, VLAN and MLT names cannot contain special characters other than underscore (\_) and en dash (-). Use this procedure to display VLAN or MLT names that contain prohibited special characters.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show the RESTCONF VLAN or MLT names that contain prohibited special characters:

```
show application restconf invalid-name vlan
```

```
show application restconf invalid-name mlt
```

### Example

```
Switch:1>show application restconf invalid-name mlt
-----
Invalid MLT names - Only "-" and "_" special characters are allowed
-----
Mlt 3 name has special characters - "gigi#g"
Mlt 4 name has special characters - "my%mlt"
Mlt 5 name has special characters - "isa.text"
-----
Total Invalid Names Count: 3
```

## What to Do Next

If any of the names contain prohibited special characters, change the names to remove the special characters.

## RESTCONF Configuration using EDM

This section contains procedures for configuring RESTCONF with Enterprise Device Manager (EDM).

### Configuring the RESTCONF Server

#### About This Task

To configure the server, you must enable RESTCONF. RESTCONF is disabled by default.

After RESTCONF is enabled, you must disable RESTCONF to modify some of the RESTCONF parameters.

#### Procedure

1. In the navigation pane, expand **Configuration > Serviceability**.
2. Click **RESTCONF**.
3. Click the **RESTCONF** tab.
4. Select the **GlobalEnable** check box to enable the RESTCONF server.
5. Configure optional parameters as required.
6. Click **Apply**.

#### *RESTCONF Field Descriptions*

Use the data in the following table to use the RESTCONF tab.

Name	Description
<b>GlobalEnable</b>	Enables or disables the RESTCONF server. The default is disabled (cleared).
<b>TcpPort</b>	Specifies the TCP port to use for the RESTCONF server. The default is 8080. The RESTCONF status must be disabled before you can modify this field.
<b>TlsEnable</b>	Enables or disables TLS/SSL if you require HTTPS access to the RESTCONF server. The default is disabled. The RESTCONF status must be disabled before you can modify this field.
<b>CertificateFilename</b>	If HTTPS access is required, specifies the file name and path of the TLS/SSL certificate. The certificate file must be in the /intflash directory on the switch.

Name	Description
<b>CertificateAction</b>	Installs or uninstalls the TLS/SSL certificate file. It also shows the current status of the certificate installation.
<b>NotificationEnable</b>	Enables or disables trap notification when the RESTCONF server is not available. The default is enabled.
<b>OperStatus</b>	Shows the operational status of the RESTCONF server.
<b>WebServerVersion</b>	Shows the RESTCONF web server version that is running on the server.
<b>RestConfServerVersion</b>	Shows the RESTCONF server version that is running on the server.

## Use Representational State Transfer Configuration Protocol (RESTCONF) to Configure a Switch

The documentation does not include information about how to use RESTCONF clients. This example documents some common tasks using Python.

For additional details, see [Extreme API with Python](#).

### Before You Begin

Configure the RESTCONF server on the switch.

### Procedure

1. Import classes, define variables, and prepare the session object:

```
#!/usr/bin/env python
import sys
import json
import requests
from requests import Request, Session
from requests.auth import HTTPBasicAuth
from requests.packages.urllib3.exceptions import InsecureRequestWarning
requests.packages.urllib3.disable_warnings(InsecureRequestWarning)
#####
Host = '192.0.2.1'
TcpPort = '8080'
UserName = 'rwa'
PassWord = 'rwa'
LoginUrl = 'https://%s:%s/auth/token' % (Host, TcpPort)
QueryUrl = 'https://%s:%s/rest/restconf/data/' % (Host, TcpPort)
vlan = 123
#####
session = Session()
session.verify = False
session.timeout = 5

session.headers.update({
    'Accept': 'application/json',
    'Accept-Encoding': 'gzip, deflate, br',
    'Connection': 'keep-alive',
    'Cache-Control': 'no-cache',
    'Pragma': 'no-cache', })
```

## 2. Learn the authentication token:

**Note**

The token expires after 24 hours.

```
body = '{"username": "%s", "password" : "%s" }' % (UserName,PassWord)

response = session.put( LoginUrl, body )

if response.status_code != 200:
    print "ERROR: Login failed"
    sys.exit(1)
else:
    session.headers.update({
        'X-Auth-Token': response.headers['X-Auth-Token']
    })
    print "INFO: login passed"
```

## 3. Query all VLANs:

```
response = session.get( QueryUrl + 'openconfig-vlan:vlan' )
if response.status_code != 200:
    print 'ERROR: can't fetch VLANs'
```

## 4. Query specific VLANs:

```
response = session.get( QueryUrl + 'openconfig-vlan:vlan/vlan=%s' % vlan )

if response.status_code != 200:
    print 'INFO: VLAN %s doesn't exists' % vlan
else:
    print 'INFO: VLAN %s exists' % vlan
```

## 5. Access data:

```
inbound_data = json.loads( response.text )

for vlan in inbound_data['openconfig-vlan:vlan']['vlan']:
    print 'VLAN: %s [%s]' % ( vlan['state']['name'], vlan['vlan-id'] )
```

## 6. Present data:

```
inbound_data = json.loads( response.text )

for dataVlan in inbound_data[ dataObject ]['vlan']:
    print ''
    print 'VLAN: ' + dataVlan['state']['name'] + '[' + dataVlan['vlan-id'] + ']'
    interfaces = ' '
    if 'members' in dataVlan :
        for interface in dataVlan['members']['member ']:
            interfaces = interfaces + interface['interface-ref']['state']['interface']
    + ','

    print interfaces
```

## 7. Add a VLAN:

```
dataObject = 'openconfig-vlan:vlan'

data = { "openconfig-vlan:vlan": [
    { "config":
        { "name": "Test-VLAN",
          "extreme-mod-oc-vlan:stg-id": 1,
          "vlan-id": vlan
        }
    }
]
```

```

    }

    response = session.post( QueryUrl + dataObject, json=data )

    if response.status_code != 201:
        print "ERROR: add VLAN %s failed" % vlan
    else:
        print "INFO: VLAN %s added " % vlan

```

#### 8. Update a VLAN:

```

dataObject = 'openconfig-vlan:vlans/vlan=%s/config' % vlan

data = { "openconfig-vlan:config":
        { "name": "New-VLAN-Name" }
        }

response = session.patch( QueryUrl + dataObject )

if response.status_code != 204:
    print "ERROR: update VLAN %s fails" % vlan
else:
    print "INFO: VLAN %s updated" % vlan

```

#### 9. Delete a VLAN:

```

dataObject = 'openconfig-vlan:vlans/vlan=%s' % vlan

response = session.delete( QueryUrl + dataObject )

if response.status_code != 204:
    print "ERROR: delete VLAN %s fails" % vlan
else:
    print "INFO: VLAN %s deleted" % vlan

```

## RESTCONF Operational Behavior Examples

This section provides an example of RESTCONF operational behavior.

In the following example, RESTCONF sends a request that involves multiple commands where one command operation fails and other command operations proceed.

#### Example:

```

POST http://{{vossip}}:8080/rest/restconf/data/extreme-network-service:network-services
{
  "extreme-network-service:network-services": [
    {
      "network-service": {
        "id": "990099",
        "type": "elanTransparent",
        "name": "isid-990099",
        "interfaces": {
          "interface": [
            {
              "name": "1/8"
            }
          ]
        }
      }
    }
  ]
}

```

```

    "ietf-restconf:errors": {
      "error": [
        {
          "error-message": "Unable to push data - Manual configuration not allowed on Auto-
Sense port",
          "error-tag": "operation-failed",
          "error-type": "protocol"
        }
      ]
    }
  }
}

```

The following sample output displays the configured I-SID and the created ELAN-transparent based service. The port does not display because the command operation failed.

```

Switch:1(config)#i-sid name 990099 isid-990099
Switch:1(config)#i-sid 990099 elan-transparent
Switch:1(elan-tp:990099)#port 1/8

Switch:1>show i-sid
*****
=====
=====
ISID      ISID      PORT      MLT
ORIGIN    ISID
ID        TYPE      VLANID    INTERFACES
INTERFACES      NAME
-----
99999     ELAN_TR   N/A       -          -          C  ---  -  ---  -
-         isid-99999
990099    ELAN_TR   N/A       -          -          C  ---  -  ---  -

## RIP fundamentals

Use the information in these sections to help you understand the Routing Information Protocol (RIP). For more information about the Border Gateway Protocol (BGP), see [BGP](#) on page 430.

### Routing Information Protocol

In routed environments, routers communicate with one another to track available routes. Routers can dynamically learn about available routes using the RIP. The switch software implements standard RIP to exchange IP route information with other routers.

RIP uses broadcast User Datagram Protocol (UDP) data packets to exchange routing information. Each router advertises routing information by sending a routing information update every 30 seconds (one interval). If RIP does not receive information about a network for 180 seconds, the metric associated with the network rises to infinity (U); that is, the metric resets to 16, which means the network becomes unreachable. If RIP does not receive information about a network for 120 seconds, it removes the network from the routing table.

RIP is a distance vector protocol. The vector is the network number and next hop, and the distance is the cost associated with the network number. RIP identifies network reachability based on cost, and cost is defined as hop count. One hop is the distance from one router to the next. This cost or hop count is the metric (see the following figure).

**Figure 224: Hop count or metric in RIP**

RIP version 1 (RIPv1) advertises default class addresses without subnet masking. RIP version 2 (RIPv2) advertises class addresses explicitly, based on the subnet mask.

The switch supports RIPv2, which supports variable length subnet masks (VLSM) and triggered router updates. RIPv2 sends mask information. If RIP does not receive

information about a network for 90 seconds, the metric associated with the network rises to infinity (U); that is, the metric resets to 16, which means the network becomes unreachable. If RIP does not receive information about a network for 180 seconds (six update intervals), it removes the network from the routing table. You can change the default timers by configuring the RIP interface timeout timer and the holddown timer.

A directly connected network has a metric of zero. An unreachable network has a metric of 16. Therefore, the highest metric between two networks can be 15 hops or 15 routers.

## RIP and route redistribution

Redistribution imports routes from one protocol to another. Redistribution sends route updates for a protocol-based route through another protocol. For example, if RIP routes exist in a router and they must travel through a BGP network, configure redistribution of RIP routes through BGP. Redistribution sends RIP routes to a router that uses BGP.

You can redistribute routes

- on an interface basis
- on a global basis between protocols on a single VRF instance (intraVRF)
- between the same or different protocols on different VRF instances (interVRF)

To configure interface-based redistribution, configure a route policy, and then apply it to the interface. Configure the match parameter to the protocol from which to learn routes.

You can redistribute routes on a global basis, rather than for every interface. The switch adds support for global RIP redistribution. Use the **ip rip redistribute** command to accomplish the (intraVRF) redistribution of routes through RIP, so that RIP redistribution occurs globally on all RIP-enabled interfaces. This redistribution does not require a route policy, but you can use one for more control.

If you configure redistribution globally and on an interface, redistribution through the route policy takes precedence.

You can redistribute routes from a protocol in one VRF to RIP in another VRF. You can use a route policy for redistribution control. If you enable route redistribution between VRF instances, ensure that IP addresses do not overlap.

## RIPng fundamentals

Routing Information Protocol next generation (RIPng) allows routers to exchange information for computing routes through an IPv6-based network. You should implement RIPng only on routers. IPv6 provides neighbor router information required by RIPng protocol to function as intended. A RIPng router is assumed to have interfaces in several networks and the protocol relies primarily on the metric of each network to compute routes using the distance vector algorithm.

RIP identifies network reachability based on cost, and cost is defined as hop count. One hop is the distance from one router to the next. This cost, or hop count, is the metric.

RIPng-enabled routers use UDP port 521 (the RIPng port) to exchange routing information. RIPng responds to a request by sending a message to the port from which the request originates. Specific queries can be sent from ports other than the RIPng port, but they must be directed to the RIPng port on the target machine.

Each router advertises routing information by sending an update every 30 seconds (one interval). If RIPng does not receive information about a network for 180 seconds, the metric associated with the network rises to infinity (U); that is, the metric resets to 16, which means the network becomes unreachable. If RIP does not receive information about a network for 120 seconds, it removes the network from the routing table.

**Note**

These time interval values are default values which are configurable by the user.

Each router that implements RIPng contains a routing table. This table contains one entry for every destination that is reachable throughout the system operating RIPng. At a minimum, each routing table entry contains the following information:

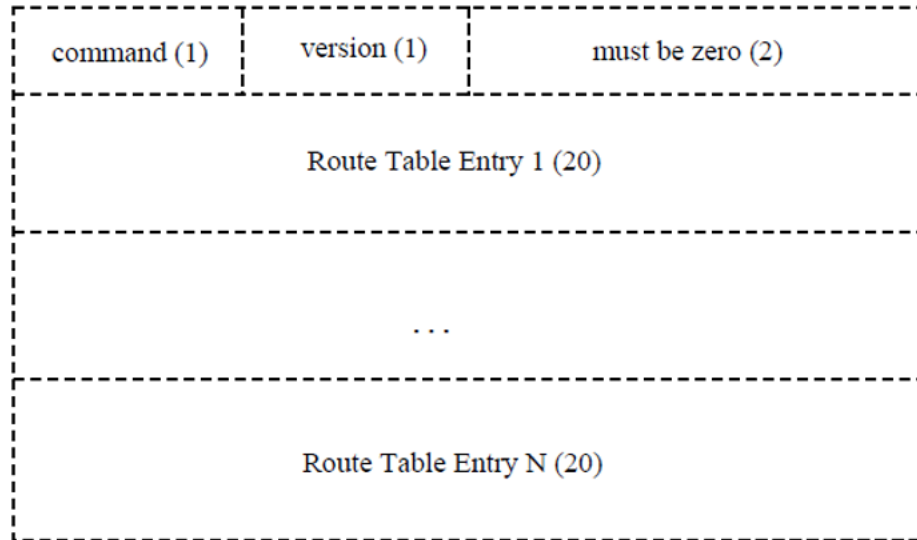

- The IPv6 prefix of the destination.
- A metric that represents the total cost of getting a datagram from the router to that destination. The metric is the sum of the costs of traversing the networks to arrive at the destination.
- The IPv6 address of the next router in the path to the destination (the next hop). The next-hop IPv6 address is a linklocal address.
- The VLAN or brouter port on which the RIPng routes were learned.
- The age of the RIPng route.

RIPng protocol implementation is specified in IETF document RFC 2080.

## RIPng messages and packet format

RIPng-enabled routers use UDP port 521 (the RIPng port) to send and receive datagrams.

The following figure shows the RIPng packet format:

**Figure 225: RIPng packet format**

A RIPng packet header consists of the following components:

- **command:** Specifies the purpose of the message.
- **version:** The version of RIPng.

## Originate Default route

Generally you use a default route when it is not convenient to list every possible network in RIPng updates, and one or more routers in the system are able to handle traffic to networks that RIPng does not explicitly list.

RIPng is enabled with the default route only option. When you enable default route only on an interface, it suppresses all other routes in the update sent for the interface, and advertises only the default route.

## Timers

RIPng states four different timer intervals for protocol operation:

- **Update timer:** The RIPng process sends a complete routing table to each neighboring router every 30 seconds. To prevent collisions on broadcast networks, the process adds an offset value to the timer.
- **Timeout time interval:** This is a 180 second time interval associated with every route. If the time interval expires, the metric for this route updates to the value of infinity (16) and the route is no longer valid. However, the routing table retains the value for another 120 seconds.
- **Garbage collection time interval:** After the timeout time interval expires and the route becomes invalid, it remains in the routing table until the garbage collection time interval expires. The garbage collection time interval is 120 seconds. Until the garbage collection time interval expires all updates sent by this router include the

invalid route. When the garbage collection timer expires, the process removes the route from the routing table.

- **Triggered update time interval:** The triggered update time interval is set to a random value between 1 and 5 seconds after a triggered update is sent. A single update is sent even if multiple triggered updates occur before the timer expires.

Configuration of timers or time intervals is supported only at the CLI/SNMP/EDM level. Configuration of timers or time intervals is not supported at the interface/port level.

## RIP configuration using CLI

---

Use Routing Information Protocol (RIP) to perform dynamic routing within an autonomous system. This section describes how you use the command line interface (CLI) to configure and manage RIP.

### Configuring RIP globally

Configure RIP parameters on the switch so you can control RIP behavior on the system.

#### Before You Begin

- You configure RIP on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode and the prefix **ip rip**. The VRF must have an RP Trigger of RIP. Not all parameters are configurable on non0 VRFs.

#### About This Task

All router interfaces that use RIP use the RIP global parameters. Both router ports and VLAN virtual routing interfaces use the same RIP global parameters.

You can configure RIP on interfaces while RIP is globally disabled. This way, you can configure all interfaces before you enable RIP for the switch.

#### Procedure

1. Enter RIP Router Configuration mode:  

```
enable  
  
configure terminal  
  
router rip
```
2. Define the default-import-metric for the switch:  

```
default-metric <0-15>
```
3. (Optional) Configure one or more timer values:  

```
timers basic timeout <15-259200> [holddown <0-360>] [update <1-360>]
```
4. Enable RIP on an IP network:  

```
network {A.B.C.D}
```
5. Exit to Global Configuration mode:  

```
exit
```

6. After the configuration is complete, enable RIP globally:

```
router rip enable
```

7.

8. Check that your configuration is correct:

```
show ip rip [vrf WORD<1-16>] [vrfsids WORD<0-512>]
```

### Example

Define the default-import-metric as 1, the timeout interval as 180, the holddown time as 120, and the update time as 30. Enable RIP on an IP network, and ensure your configuration is correct.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1#router rip
Switch:1(config-rip)#default-metric 1
Switch:1(config-rip)#timers basic timeout 180 holddown 120 update 30
Switch:1(config-rip)#network 192.0.2.11
Switch:1(config-rip)#exit
Switch:1(config)#router rip enable
Switch:1(config)#show ip rip
=====
                        RIP Global - GlobalRouter
=====
Default Import Metric : 1
      HoldDown Time   : 120
      Queries         : 0
          Rip         : Enabled
      Route Changes   : 0
      Timeout Interval : 180
      Update Time     : 30
```

### Variable definitions

The following table defines parameters for the RIP commands.

Variable	Value
<i>default-metric</i> <0-15>	Configures the value of default import metric to import a route into a RIP domain. To announce OSPF internal routes into RIP domain, if the policy does not specify a metric value, the default is used. For OSPF external routes, the external cost is used. The default is 8.
<i>domain</i> <0-39321>	Specifies the RIP domain from 0–39321. The default is 0.
<i>holddown</i> <0-360>	Configures the RIP hold-down timer value, the length of time (in seconds) that RIP continues to advertise a network after it determines that the network is unreachable. The default is 120.
<i>network</i> {A.B.C.D}	Enables RIP on an IP network.
<i>timeout</i> <15-259200>	Configures the RIP timeout interval. The default is 180.
<i>update</i> <1-360>	Configures the RIP update timer. The update time is the time interval, in seconds, between RIP updates. The default is 30.

The following table defines parameters for the **show ip rip** command.

Variable	Value
<code>vrf WORD&lt;1-16&gt;</code>	Specifies a VRF by name.
<code>vrfids WORD&lt;0-512&gt;</code>	Specifies a range of VRF IDs.

## Configuring RIP on an interface

Configure RIP on Ethernet ports and VLANs so that they can participate in RIP routing.

### Before You Begin

- Assign an IP address to the port or VLAN.
- Configure RIP and enable it globally.
- Configure in and out policies.

### About This Task

RIP does not operate on a port or VLAN until you enable it both globally and on the port or VLAN.

To configure RIP on a VRF instance for a port or VLAN, you configure RIP on the port or VLAN, and then associate the port or VLAN with the VRF.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Define the cost:

```
ip rip cost <1-15>
```

3. Specify an in policy for filtering inbound RIP packets:

```
ip rip in-policy WORD<0-64>
```

4. Specify an out policy for filtering outbound RIP packets:

```
ip rip out-policy WORD<0-64>
```

5. Enable RIP:

```
ip rip enable
```

6. Specify the send mode:

```
ip rip send version <notsend|rip1|rip1comp|rip2>
```

7. Specify the receive mode:

```
ip rip receive version <rip1|rip2|rip1orrip2>
```

8. Change other RIP parameters from their default values as required.

### Example

The following configuration example shows how to configure the switch (labeled R1) to operate only in RIP version 2 mode.

**Figure 226: Configuration example-RIPv2 only**

Enable RIPv2 send mode on VLAN 2:

```
Switch:1(config-if)# ip rip send version rip2
```

Enable RIPv2 receive mode on VLAN 2:

```
Switch:1(config-if)# ip rip receive version rip2
```

Repeat these commands on VLAN 3 and the port interfaces.

### Variable definitions

The following table defines parameters for the `ip rip` command.

Variable	Value
<code>advertise-when-down enable</code>	Enables or disables AdvertiseWhenDown. If enabled, RIP advertises the network on this interface as up, even if the port is down. The default is disabled. If you configure a port with no link and enable advertise-when-down, it does not advertise the route until the port is active. RIP advertises the route even when the link is down. To disable advertising based on link status, you must disable this parameter.
<code>auto-aggregation enable</code>	Enables or disables automatic route aggregation on the port. If enabled, the switch automatically aggregates routes to their natural mask when an interface in a different class network advertises them. The default is disable.
<code>cost &lt;1-15&gt;</code>	Configures the RIP cost for this port (link).

Variable	Value
<code>default-listen enable</code>	Enables DefaultListen. The switch accepts the default route learned through RIP on this interface. The default is disabled.
<code>default-supply enable</code>	Enables DefaultSupply. If enabled, this interface must advertise a default route. The default is false. RIP advertises the default route only if it exists in the routing table.
<code>enable</code>	Enables RIP routing on the port.
<code>holddown &lt;0-360&gt;</code>	Configures the RIP holddown timer value, the length of time (in seconds) that RIP continues to advertise a network after it determines that the network is unreachable. The default is 120.
<code>in-policy WORD&lt;0-64&gt;</code>	Configures the policy name for inbound filtering on this RIP interface. This policy determines whether to learn a route on this interface and specifies the parameters of the route when RIP adds it to the routing table.
<code>listen enable</code>	Specifies that the routing switch learns RIP routes through this interface. If enabled, the switch listens for a default route without listening for all routes. The default is enable.
<code>out-policy WORD&lt;0-64&gt;</code>	Configures the policy name for outbound filtering on this RIP interface. This policy determines whether to advertise a route from the routing table on this interface. This policy also specifies the parameters of the advertisement. <i>WORD&lt;0-64&gt;</i> is a string of length 0–64 characters.
<code>poison enable</code>	Enables Poison Reverse. If you disable Poison Reverse ( <code>no poison enable</code> ), Split Horizon is enabled. By default, Split Horizon is enabled. If you enable Split Horizon, the interface does not advertise IP routes learned from an immediate neighbor back to the neighbor. If you enable Poison Reverse, the RIP updates sent to a neighbor from which a route is learned are poisoned with a metric of 16. Therefore, the receiver neighbor ignores this route because the metric 16 indicates infinite hops in the network. These mechanisms prevent routing loops.
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>receive version &lt;rip1 rip2 rip1orrip2&gt;</code>	Indicates which RIP update version to accept on this interface. The default is rip1orrip2.

Variable	Value
<code>send version &lt;notsend rip1 rip1comp rip2&gt;</code>	Indicates which RIP update version the router sends from this interface. <code>ripVersion1</code> implies sending RIP updates that comply with RFC1058. <code>rip1comp</code> implies broadcasting RIP2 updates using RFC1058 route subassumption rules. The default is <code>rip1Compatible</code> .
<code>supply enable</code>	Specifies that the switch advertises RIP routes through the port. The default is <code>enable</code> .
<code>timeout &lt;15-259200&gt;</code>	Configures the RIP timeout interval in seconds. The default is 180.
<code>triggered enable</code>	Enables automatic triggered updates for RIP.

## Configuring route redistribution to RIP

Configure a redistribute entry to announce certain routes into the RIP domain, including static routes, direct routes, RIP, Open Shortest Path First (OSPF), IS-IS, or Border Gateway Protocol (BGP). Optionally, use a route policy to control the redistribution of routes.

### Before You Begin

- Enable RIP globally.
- Configure a route policy.

### Procedure

1. Enter RIP Router Configuration mode:
 

```
enable

configure terminal

router rip
```
2. Create the redistribution instance:
 

```
redistribute <bgp|direct|isis|ospf|rip|static> [vrf-src WORD<1-16>]
```
3. Apply a route policy, if required:
 

```
redistribute <bgp|direct|isis|ospf|rip|static> route-map WORD<0-64>
[vrf-src WORD<1-16>]
```
4. Configure other parameters.
5. Enable the redistribution:
 

```
redistribute <bgp|direct|isis|ospf|rip|static> enable [vrf-src
WORD<1-16>]
```
6. Ensure that the configuration is correct:
 

```
show ip rip redistribute [vrf WORD<1-16>] [vrfids WORD<0-512>]
```
7. Exit to Global Configuration mode:
 

```
exit
```
8. Apply the redistribution:
 

```
ip rip apply redistribute <bgp|direct|isis|ospf|rip|static> [vrf
WORD<1-16>] [vrf-src WORD<1-16>]
```

## Example

Create the redistribution instance, apply a route policy, enable the redistribution, and apply the redistribution.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router rip
Switch:1(config-rip)#redistribute rip
Switch:1(config-rip)#redistribute rip route-map test1
Switch:1(config-rip)#redistribute rip enable
Switch:1(config-rip)#exit
Switch:1(config)#ip rip apply redistribute rip
```

### Variable definitions

The following table defines parameters for the **redistribute** command.

Variable	Value
<i>metric</i> <0-65535>	Configures the metric to apply to redistributed routes.
<i>route-map</i> WORD<0-64>	Configures the route policy to apply to redistributed routes.
[ <i>vrf-src</i> WORD<1-16>]	Specifies the optional source VRF instance. You can use this variable with the other command variables.
WORD<0-32>	Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, rip, ospf, or static.

The following table defines parameters for the **show ip rip redistribute** command.

Variable	Value
<i>vrf</i> WORD<1-16>	Specifies the VRF instance.
<i>vrfids</i> WORD<1-512>	Specifies a range of VRF IDs.

The following table defines parameters for the **ip rip apply redistribute** command.

Variable	Value
<i>vrf</i> WORD<1-16>	Specifies the VRF instance.
<i>vrf-src</i> WORD<1-16>	Specifies the source VRF instance. You do not need to configure this parameter for redistribution within the same VRF.
< <i>bgp</i>   <i>direct</i>   <i>isis</i>   <i>ospf</i>   <i>rip</i>   <i>static</i> >	Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, rip, ospf, or static.

## Configuring interVRF route redistribution for RIP

Configure a redistribute entry to announce certain routes into the RIP domain, including static routes, direct routes, RIP, OSPF, IS-IS, or BGP. Use a route policy to control the redistribution of routes.

### Before You Begin

- Enable RIP globally.
- Configure a route policy.
- Configure the VRFs.

### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Create the redistribution instance:

```
ip rip redistribute <bgp|direct|isis|ospf|rip|static>
```

3. Apply a route policy, if required:

```
ip rip redistribute <bgp|direct|isis|ospf|rip|static> route-map
WORD<0-64> [vrf-src WORD<1-16>]
```

4. Configure other parameters.

5. Enable the redistribution:

```
ip rip redistribute <bgp|direct|isis|ospf|rip|static> enable [vrf-src
WORD<1-16>]
```

6. Ensure that the configuration is correct:

```
show ip rip redistribute [vrf WORD<1-16>] [vrfids WORD<1-512>]
```

7. Exit to Global Configuration mode:

```
exit
```

8. Apply the redistribution:

```
ip rip apply redistribute <bgp|direct|isis|ospf|rip|static> [vrf
WORD<1-16>] [vrf-src WORD<1-16>]
```

### Example

Create the redistribution instance, apply a route policy, enable the redistribution, and apply the redistribution.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1#router vrf red
Switch:1(router-vrf)#ip rip redistribute ospf
Switch:1(router-vrf)#ip rip redistribute ospf route-map test1
Switch:1(router-vrf)#ip rip redistribute ospf enable
Switch:1(router-vrf)#exit
Switch:1(config)#ip rip apply redistribute ospf
```

### Variable definitions

The following table defines parameters for the **ip rip redistribute** `<bgp|isis|ospf|static|direct|rip>` command.

Variable	Value
<code>&lt;bgp direct isis ospf rip static&gt;</code>	Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, rip, ospf, or static.
<code>vrf-src WORD&lt;1-16&gt;</code>	Specifies the source VRF instance. You do not need to configure this parameter for redistribution within the same VRF.
<code>metric &lt;0-65535&gt;</code>	Configures the metric to apply to redistributed routes.
<code>route-map WORD&lt;0-64&gt;</code>	Configures the route policy to apply to redistributed routes.

The following table defines parameters for the **show ip rip redistribute** command.

Variable	Value
<code>vrf WORD&lt;1-16&gt;</code>	Specifies the VRF instance.
<code>vrfids WORD&lt;1-512&gt;</code>	Specifies a range of VRF IDs.

The following table defines parameters for the **ip rip apply redistribute** command.

Variable	Value
<code>vrf WORD&lt;1-16&gt;</code>	Specifies the VRF instance.
<code>vrf-src WORD&lt;1-16&gt;</code>	Specifies the source VRF instance. You do not need to configure this parameter for redistribution within the same VRF.
<code>&lt;bgp direct isis ospf rip static&gt;</code>	Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, rip, ospf, or static.

## Forcing a RIP Update for a Port or VLAN

Force RIP to update the routing table so that the port or VLAN uses the latest routing information.

### About This Task

If you perform this procedure, you also update the tables for all VRFs associated with the port or VLAN.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable the triggered-update flag:

```
ip rip triggered enable
```

#### Note

You can enable this flag in either the GigabitEthernet or VLAN Interface Configuration mode. However, you can update the RIP routes in the GigabitEthernet Interface Configuration mode only.

3. Update the routing table:

```
action triggerRipUpdate
```

### Example

Update the routing table:

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#interface vlan 1  
Switch:1(config-if)#ip rip triggered enable
```

## Viewing the RIP redistribution configuration information

Displays the RIP redistribution configuration information.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View the RIP redistribution configuration information:

```
show ip rip redistribute [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

View the RIP redistribution configuration information:

```
Switch(config-ospf)#show ip rip redistribute
```

```
=====
```

```
RIP Redistribute List - GlobalRouter
```

```
=====
```

```

SRC-VRF          SRC  MET  ENABLE  RPOLICY
-----
GlobalRouter    ISIS  0    FALSE

```

### Variable definitions

The following table defines parameters for the **show ip rip redistribute** command or the **show ipv6 rip redistribute** command.

Variable	Value
<code>vrf WORD&lt;1-16&gt;</code>	Specifies a VRF by name.
<code>vrfids WORD&lt;0-512&gt;</code>	Specifies a range of VRF IDs.

## RIPng Configuration using CLI

Use the procedures in this section to configure RIPng using CLI.

### Configuring RIPng globally

Configure RIPng parameters on the router so you can control RIPng behavior on the system.

#### Before You Begin

You can configure RIPng only on a global router. You cannot configure RIPng on a VRF instance.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable
configure terminal
```
2. Enable RIPng globally:
 

```
router rip ipv6-enable
```

### Configuring RIPng on an interface

Configure RIPng on Ethernet ports and VLANs so that they can participate in RIPng routing.

#### About This Task

RIPng does not operate on a port or VLAN until you enable it both globally and on the port or VLAN.

#### Before You Begin

- Assign an IP address to the port or VLAN.

- Configure RIPng and enable it globally.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Create a RIPng interface:

```
ipv6 rip
```

3. Enable the RIPng interface:

```
ipv6 rip enable
```

4. Verify the operational status of the RIPng interface:

```
show ipv6 rip interface
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface vlan 22
Switch:1(config-if)#ipv6 rip
Switch:1(config-if)#ipv6 rip enable
Switch:1(config-if)#show ipv6 rip interface
```

```
Total RIPng interfaces: 2
```

```
=====
                        RIPng Interface - GlobalRouter
=====

### Variable Definitions

The following table defines parameters for the **ipv6 rip** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. This variable applies only to VLAN interfaces, not ports.
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Configuring RIPng custom values

Configure custom values for RIPng parameters to replace default values.

### Before You Begin

- Configure RIPng and enable it globally.

### Procedure

1. Enter Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]} or interface vlan <1-4059>
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable RIPng poison:

```
ipv6 rip poison enable
```

3. Specify the RIPng cost:

```
ipv6 rip cost <1-15 Cost>
```

4. Access router RIPng configuration mode:

```
router rip
```

5. Specify the RIPng holddown timer value:  
`ipv6 timers basic holddown <0-360>`
6. Specify the RIPng timeout timer value:  
`ipv6 timers basic timeout <15-259200>`
7. Specify the RIPng update timer value:  
`ipv6 timers basic update <1-360>`
8. Specify the default route metric value:  
`ipv6 default-information metric <1-15>`
9. Enable default information globally:  
`ipv6 default-information enable`
10. Ensure the configuration is correct:  
`show ipv6 rip`

## Example

Configure custom values for RIPng.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#router rip
Switch:1(config-rip)#ipv6 default-information metric 1
Switch:1(config-rip)#ipv6 default-information enable
Switch:1(config-rip)#ipv6 timers basic update 30
Switch:1(config-rip)#ipv6 timers basic timeout 180
Switch:1(config-rip)#ipv6 timers basic holddown 120
Switch:1(config-rip)#router rip ipv6-enable
Switch:1(config)#show ipv6 rip
```

```
=====
                                RIPng Global - GlobalRouter
=====
      Rip : Enabled
      HoldDown Time : 120
      Timeout Interval : 180
      Update Time : 30
      Default Info Metric : 1
      Default Info State : Enabled
      Default Import Metric : 1
```

### Variable definitions

Use the data in the following table to use the **ipv6 rip poison**, **ipv6 default-information** and **ipv6 timers basic** commands.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. This variable applies only to VLAN interfaces, not ports.
port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
poison enable	Enables Poison Reverse. If you disable Poison Reverse (no poison enable), Split Horizon is enabled. By default, Split Horizon is enabled. If you enable Split Horizon, the interface does not advertise IP routes learned from an immediate neighbor back to the neighbor. If you enable Poison Reverse, the RIP updates sent to a neighbor from which a route is learned are poisoned with a metric of 16. Therefore, the receiver neighbor ignores this route because the metric 16 indicates infinite hops in the network. These mechanisms prevent routing loops.
<1-15 Cost>	Configures the RIPng cost for this port (link).
holddown <0-360>	Configures the RIPng holddown timer value, the length of time (in seconds) that RIPng continues to advertise a network after it determines that the network is unreachable. The default is 120.
timeout <15-259200>	Configures the RIPng timeout interval. The default is 180.
update <1-360>	Configure the RIPng update timer. The update time is the time interval between RIPng updates.
default-information <1-15>	Configure the default route metric value.

## Configuring RIPng route distribution

Configure a redistribute entry to announce certain routes into the RIPng domain, including static routes, direct routes, Open Shortest Path First (OSPFv3), IS-IS, or Border Gateway Protocol (BGP+).

### Before You Begin

- Enable RIPng globally.

### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Access router RIP configuration mode:  
router rip
3. Enable the redistribution:  
ipv6 redistribute {direct|isis|static|ospf|bgp} enable
4. Ensure the configuration is correct:  
show ipv6 rip redistribute

### Example

Enable the redistribution instance.

```
Switch:1#enable
Switch:1#configure terminal
Switch:1(config)#router rip
Switch:1(config-rip)#ipv6 redistribute bgp enable
Switch:1(config-rip)#ipv6 redistribute direct enable
Switch:1(config-rip)#ipv6 redistribute isis enable
Switch:1(config-rip)#ipv6 redistribute ospf enable
Switch:1(config-rip)#ipv6 redistribute static enable
Switch:1(config-rip)#show ipv6 rip redistribute

=====
                        RIPng Redistribute List
=====
      direct                : enabled
      static                : enabled
      ospf                  : enabled
      bgp                   : enabled
      isis                  : enabled
=====
```

#### Variable definitions

Use the data in the following table to use the **ipv6 redistribute** command.

Variable	Value
<bgp direct isis ospf static>	Specifies the type of routes to redistribute (the protocol source). Valid options are bgp, isis, direct, ospf, or static.

## RIP configuration using EDM

Use Routing Information Protocol (RIP) to perform dynamic routing within an autonomous system. This section describes how you use Enterprise Device Manager (EDM) to configure and manage RIP.

## Configuring RIP globally

Configure RIP global parameters on the switch so you can control RIP behavior on the system.

### Before You Begin

- Change the VRF instance as required to configure RIP on a specific VRF instance. The VRF must have an RP trigger of RIP. Not all parameters are configurable on non-default VRFs.

### About This Task

All router interfaces that use RIP use the RIP global parameters. Both brouter ports and VLAN virtual routing interfaces use the same RIP global parameters.

You can configure RIP on interfaces while RIP is globally disabled. This way, you can configure all interfaces before you enable RIP for the switch.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **RIP**.
3. Click the **Globals** tab.
4. Select the **enable** option button.
5. Configure other global RIP parameters as required.
6. Click **Apply**.

### *Globals* field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
<b>Operation</b>	Enables or disables RIP on all interfaces. The default is disabled.
<b>UpdateTime</b>	Specifies the time interval between RIP updates for all interfaces. The default is 30 seconds, and the range is 0–360.
<b>RouteChanges</b>	Specifies the number of route changes RIP made to the IP route database. RouteChanges does not include the refresh of a route age.
<b>Queries</b>	Specifies the number of responses sent to RIP queries received from other systems.
<b>HoldDownTime</b>	Configures the length of time that RIP continues to advertise a network after the network is unreachable. The range is 0–360 seconds. The default is 120 seconds.

Name	Description
<b>TimeOutInterval</b>	Configures the RIP timeout interval. The range is 15–259200 seconds. The default is 180 seconds.
<b>DeflImportMetric</b>	Configures the default import metric used to import a route into a RIP domain. To announce OSPF internal routes into a RIP domain, if the policy does not specify a metric, you must use the default import metric. OSPF external routes use the external cost. The range is 0–15 and the default is 8.

## Viewing RIP status

View RIP status.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **RIP**.
3. Click the **Status** tab.

### Status field description

The following table defines parameters for the **RIP Status** tab.

Name	Description
<b>Address</b>	Specifies the IP address of the router interface.
<b>RcvBadPackets</b>	Specifies the number of RIP response packets received by the RIP process which were subsequently discarded; for example, version 0 packet, or an unknown command type.
<b>RcvBadRoutes</b>	Specifies the number of routes, in valid RIP packets, that are ignored; for example, unknown address family, or invalid metric.
<b>SentUpdates</b>	Specifies the number of triggered RIP updates sent on this interface, that do not include full updates sent containing new information.

## Configuring RIP interface compatibility

Configure RIP parameters on an interface so you can control RIP behavior on the interface. You can specify the RIP version to use on interfaces that you configure to send (supply) or receive (listen to) RIP updates.

### Before You Begin

- Configure a routing interface (either a router port or a virtual routing interface).
- Assign an IP address to the interface.
- Enable RIP globally.
- Change the VRF instance as required to configure RIP on a specific VRF instance. The VRF must have an RP trigger of RIP. Not all parameters are configurable on non-default VRFs.

## About This Task

On an interface, RIP does not operate until you enable it globally and on the interface.

Although visible, the switch does not support the AuthType and AuthKey parameters.

## Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **RIP**.
3. Click the **Interface** tab.
4. Double-click the **Send** value to edit it, and then select the RIP version datagrams the router sends.
5. Double-click the **Receive** value to edit it, and then select the RIP version datagrams for which the router listens.
6. Click **Apply**.

### *Interface Field Descriptions*

Use the data in the following table to use the **Interface** tab.

Name	Description
<b>Address</b>	Specifies the IP address of the router interface.
<b>Domain</b>	Specifies the value inserted into the routing domain parameter of all RIP packets sent on this interface.
<b>AuthType</b>	Specifies the type of authentication to use on this interface.
<b>AuthKey</b>	Specifies the authentication key whenever AuthType is not noAuthentication.
<b>Send</b>	<p>Specifies the update version the router sends on this interface:</p> <ul style="list-style-type: none"> <li>• DoNotSend—no RIP updates sent on this interface</li> <li>• ripVersion1—RIP updates compliant with RFC1058</li> <li>• rip1Compatible—broadcast RIPv2 updates using RFC1058 route subassumption rules</li> <li>• ripVersion2—multicast RIPv2 updates</li> </ul> <p>The default is rip1compatible.</p>
<b>Receive</b>	<p>Indicates which versions of RIP updates to accept:</p> <ul style="list-style-type: none"> <li>• rip1</li> <li>• rip2</li> <li>• rip1OrRip2</li> </ul> <p>The default is rip1OrRip2. Rip2 and rip1OrRip2 imply receipt of multicast packets.</p>

### *Job Aid*

Choose one of three options for receiving RIP updates:

- rip1OrRip2—accepts RIPv1 or RIPv2 updates

- rip1—accepts RIPv1 updates only
- rip2—accepts RIPv2 updates only

The following table describes the four RIP send modes that the switch supports. You can configure RIP send modes on all router interfaces.

**Table 218: RIP send modes**

Send mode	Description	Result
rip1Compatible	Broadcasts RIPv2 updates using RFC1058 route consumption rules. This is the default mode.	<ul style="list-style-type: none"> <li>• Destination MAC is a broadcast, ff-ff-ff-ff-ff-ff</li> <li>• Destination IP is a broadcast for the network (for example, 192.0.2.255)</li> <li>• RIP update is formed as a RIP-2 update, including network mask</li> <li>• RIP version = 2</li> </ul>
ripVersion1	Broadcasts RIP updates that are compliant with RFC1058	<ul style="list-style-type: none"> <li>• Destination MAC is a broadcast, ff-ff-ff-ff-ff-ff</li> <li>• Destination IP is a broadcast for the network (for example, 198.0.2.255)</li> <li>• RIP update is formed as a RIP-1 update, no network mask included</li> <li>• RIP version = 1</li> </ul>
ripVersion2	Broadcasts multicast RIPv2 updates	<ul style="list-style-type: none"> <li>• Destination MAC is a multicast, 01-00-5e-00-00-09</li> <li>• Destination IP is the RIP-2 multicast address, 224.0.0.9</li> <li>• RIP update is formed as a RIP-2 update including network mask</li> <li>• RIP version = 2</li> </ul>
doNotSend	Does not send RIP updates on the interface	None

## Configuring RIP on an interface

Configure RIP parameters to control and optimize RIP routing for the interface.

### Before You Begin

- Change the VRF instance as required to configure RIP on a specific VRF instance. The VRF must have an RP trigger of RIP. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **RIP**.
3. Click the **Interface Advance** tab.
4. Double-click a RIP parameter to edit it, as required.

5. Click **Apply**.

### **Interface Advance** field descriptions

Use the data in the following table to use the RIP **Interface Advance** tab.

Name	Description
<b>Address</b>	Shows the address of the entry in the IP RIP interface table.
<b>Interface</b>	Indicates the index of the RIP interface.
<b>Enable</b>	Shows if the RIP interface is enabled or disabled.
<b>Supply</b>	Enables (true) or disables (false) the ability to send RIP updates on this interface.
<b>Listen</b>	Configures whether the switch learns routes on this interface.
<b>Poison</b>	Configures whether to advertise RIP routes learned from a neighbor back to the neighbor. If disabled, the interface invokes Split Horizon and does not advertise IP routes learned from an immediate neighbor back to the neighbor. If enabled, RIP poisons the RIP updates, sent to the neighbor from which a route is learned, with a metric of 16. Therefore, the receiver neighbor ignores this route because the metric 16 indicates infinite hops in the network.
<b>DefaultSupply</b>	Enables (true) or disables (false) an advertisement of a default route on this interface. This command takes effect only if a default route exists in the routing table.
<b>DefaultListen</b>	Enables (true) or disables (false) the switch to accept the default route learned through RIP on this interface. The default is disabled. Enable DefaultListen to add a default route to the route table if another route advertises it.
<b>TriggeredUpdate</b>	Enables (true) or disables (false) the switch to send RIP updates from this interface.
<b>AutoAggregate</b>	Enables (true) or disables (false) automatic route aggregation on this interface. If enabled, the switch automatically aggregates routes to their natural mask when an interface advertises them. The default is disabled.
<b>InPolicy</b>	Determines if RIP can learn routes on this interface. This variable also specifies the parameters of the route when RIP adds it to the routing table.
<b>OutPolicy</b>	Determines if RIP advertises a route from the routing table on this interface. This policy also specifies the parameters of the advertisement.
<b>Cost</b>	Indicates the RIP cost for this interface. The range is 1–15. The default is 1.

*Job aid*

The following table indicates the relationship between switch action and the RIP supply and listen settings.

**Table 219: RIP supply and listen settings and switch action**

RIP supply settings		RIP listen settings		Switch action
Supply	Default supply	Listen	Default listen	
Disabled (false)	Disabled (false)			Sends no RIP updates.
Enabled (true)	Disabled (false)			Sends RIP updates except the default.
Disabled (false)	Disabled (false)			Sends only the default (default route must exist in routing table).
Enabled (true)	Enabled (true)			Sends RIP updates including the default route (if it exists).
		Disabled (false)	Disabled (false)	Does not listen to RIP updates.
		Enabled (true)	Disabled (false)	Listens to all RIP updates except the default.
		Disabled (false)	Enabled (true)	Listens only to the default.
		Enabled (true)	Enabled (true)	Listens to RIP updates including the default route (if it exists).

## Configuring RIP on a port

Configure RIP on a port so that the port can participate in RIP routing.

### Before You Begin

- Assign an IP address to the port.
- Configure RIP and enable it globally.

Both brouter ports and VLAN virtual routing interfaces use the same RIP global parameters.

- Enable RIP on the interface.

### About This Task

On an interface, RIP does not operate until you enable it globally and on the interface.

### Procedure

1. In the Device Physical View tab, select a port.

2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **RIP** tab.
5. Configure the RIP parameters as required.
6. Click **Apply**.

### *RIP field descriptions*

Use the data in the following table to use the **RIP** tab.

Name	Description
<b>Enable</b>	Enables or disables RIP on the port.
<b>Supply</b>	Specifies that the routing switch advertises RIP routes through the interface. The default is enable.
<b>Listen</b>	Specifies that the routing switch learns RIP routes through this interface. The default is enable.
<b>Poison</b>	If disabled, the interface invokes Split Horizon and does not advertise IP routes learned from an immediate neighbor back to the neighbor. If enabled, the RIP update sent to a neighbor from which a route is learned is poisoned with a metric of 16. In this manner, the route entry is not passed to the neighbor, because 16 is infinity in terms of hops on a network. The default is disable.
<b>DefaultSupply</b>	Enables or disables DefaultSupply. Enable DefaultSupply if a default route exists in the routing table. The default is false. RIP advertises the default route only if it exists in the routing table.
<b>DefaultListen</b>	Enables or disables DefaultListen. Enable DefaultListen if this interface must learn a default route after another router that connects to the interface advertises it. The default is false (disabled). Enable DefaultListen to add a default route to the route table if another router advertises it.
<b>TriggeredUpdateEnable</b>	Enables or disables triggered RIP updates. The default is false (disabled).
<b>AutoAggregateEnable</b>	Enables or disables RIP automatic aggregation. RIPv2 automatically aggregates routes to their natural mask. You can enable automatic aggregation only in RIPv2 mode or RIPv1 compatibility mode. The default is false.
<b>AdvertiseWhenDown</b>	Enables or disables AdvertiseWhenDown. If true, RIP advertises the network on this interface as up, even if the port is down. The default is false. If you configure a port with no link and enable AdvertiseWhenDown, the port does not advertise the route until the port is active. RIP advertises the route even when the link is down. To disable advertising based on link-states, disable AdvertiseWhenDown.

Name	Description
<b>InPolicy</b>	Determines whether the RIP can learn a route on this interface. This variable also specifies the parameters of the route when RIP adds it to the routing table.
<b>OutPolicy</b>	Determines if this interface advertises a route from the routing table on this interface. This policy also specifies the parameters of the advertisement.
<b>Cost</b>	Indicates the RIP cost for this interface. The default is 1, and the range is 1–15.
<b>HolddownTime</b>	Configures the length of time that RIP continues to advertise a network after determining it is unreachable. The range is 0–360 seconds. The default is 120 seconds
<b>TimeOutInterval</b>	Configures the RIP timeout interval in seconds. The range is 15–259200 seconds. The default is 180 seconds.

## Configuring RIP on a VLAN

Configure RIP on a VLAN so that the VLAN acts as a routed VLAN (a virtual router).

### Before You Begin

- Configure the VLAN.
- Assign an IP address to the VLAN.
- Enable RIP globally.
- Enable RIP on the interface.
- Change the VRF instance as required to configure RIP on a specific VRF instance. The VRF must have an RP trigger of RIP. Not all parameters are configurable on non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Click the **RIP** tab.
7. Configure the VLAN RIP parameters as required.
8. Click **Apply**.

**RIP** field descriptions

Use the data in the following table to use the **RIP** tab.

Name	Description
<b>Enable</b>	Enables or disables RIP on the VLAN.
<b>Supply</b>	Specifies that the routing switch advertises RIP routes through the interface. The default is enable.
<b>Listen</b>	Specifies that the routing switch learns RIP routes through this interface. The default is enable.
<b>Poison</b>	If disabled, the interface invokes Split Horizon and does not advertise IP routes learned from an immediate neighbor back to the neighbor. If enabled, the RIP update sent to a neighbor from which a route is learned is poisoned with a metric of 16. In this manner, the route entry is not passed to the neighbor, because 16 is infinity in terms of hops on a network. The default is disable.
<b>DefaultSupply</b>	Enables or disables DefaultSupply. Enable DefaultSupply if a default route exists in the routing table. The default is false. RIP advertises the default route only if it exists in the routing table.
<b>DefaultListen</b>	Enables or disables DefaultListen. Enable DefaultListen if this interface must learn a default route after another router that connects to the interface advertises it. The default is false (disabled). Enable DefaultListen to add a default route to the route table if another router advertises it.
<b>TriggeredUpdateEnable</b>	Enables or disables triggered RIP updates. The default is false (disabled).
<b>AutoAggregateEnable</b>	Enables or disables RIP automatic aggregation. RIPv2 automatically aggregates routes to their natural mask. You can enable automatic aggregation only in RIPv2 mode or RIPv1 compatibility mode. The default is false.
<b>AdvertiseWhenDown</b>	Enables or disables AdvertiseWhenDown. If true, RIP advertises the network on this interface as up, even if the interface is down. The default is false. If you configure a VLAN with no link and enable AdvertiseWhenDown, the VLAN does not advertise the route until the VLAN is active. RIP advertises the route even when the link is down. To disable advertising based on link-states, disable AdvertiseWhenDown.
<b>InPolicy</b>	Determines whether the RIP can learn a route on this interface. This variable also specifies the parameters of the route when RIP adds it to the routing table.
<b>OutPolicy</b>	Determines if this interface advertises a route from the routing table. This policy also specifies the parameters of the advertisement.
<b>Cost</b>	Indicates the RIP cost for this interface. The default is 1, and the range is 1–15.

Name	Description
<b>HolddownTime</b>	Configures the length of time that RIP continues to advertise a network after determining it is unreachable. The range is 0–360 seconds. The default is 120 seconds
<b>TimeOutInterval</b>	Configures the RIP timeout interval in seconds. The range is 15–259200 seconds. The default is 180 seconds.

## Configuring route redistribution to RIP

Configure a redistribute entry to announce routes of a certain source protocol type into the RIP domain, for example, static, RIP, or direct. Use a route policy to control the redistribution of routes.

### Before You Begin

- Enable RIP globally.
- Configure a route policy.
- Change the VRF instance as required to configure RIP on a specific VRF instance. The VRF must have an RP trigger of RIP. Not all parameters are configurable on non-default VRFs.

### About This Task

#### Important

Changing the RIP redistribute context is a process-oriented operation that can affect system performance and network reachability while you perform the procedures. As a best practice, change default preferences for a RIP redistribute context, you must do so before you enable the protocols.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **RIP**.
3. Click the **Redistribute** tab.
4. Click **Insert**.
5. Configure the source of the routes to redistribute.
6. Select **enable**.
7. Select the route policy to apply to redistributed routes.
8. Configure a metric value.
9. Click **Insert**.

**Redistribute** field descriptions

Use the data in the following table to use the **Redistribute** tab.

Name	Description
<b>DstVrfId</b>	Specifies the destination VRF instance. You cannot configure this variable.
<b>Protocol</b>	Specifies the dynamic routing protocol that receives the external routing information.
<b>SrcVrfId</b>	Specifies the source VRF instance. You cannot configure this variable.
<b>RouteSource</b>	Specifies the route source protocol for the redistribution entry.
<b>Enable</b>	Enables (or disables) a RIP redistribute entry for a specified source type.
<b>RoutePolicy</b>	Configures the route policy (by name) that redistributes external routes from a specified source into an RIP domain. Click the ellipsis (...) button and choose from the list in the Route Policy dialog box.
<b>Metric</b>	Configures the RIP route redistribution metric for basic redistribution. The value can be in the range 0–65535. A value of 0 indicates to use the original cost of the route.

## RIPng Configuration using EDM

Use the procedures in this section to configure RIPng using EDM.

### Configuring RIPng globally

Configure RIPng global parameters on the switch so you can control RIPng behavior on the system.

#### About This Task

All router interfaces that use RIPng use the RIPng global parameters. Both router ports and VLAN virtual routing interfaces use the same RIPng global parameters.

You can configure RIPng on interfaces while RIPng is globally disabled. This way, you can configure all interfaces before you enable RIPng for the switch

#### Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **IPv6**.
2. Click **IPv6 RIPng**.
3. Click the **Globals** tab.
4. Select the **enable** option button.
5. Configure other global RIPng parameters as required.
6. Click **Apply**.

*Globals field descriptions*

Use the data in the following table to use the **Globals** tab.

Name	Description
<b>AdminState</b>	Enables or disables RIPng globally. The default is disabled.
<b>UpdateTime</b>	Specifies the time interval between RIPng updates for all interfaces. The default is 30 seconds, and the range is 1–360.
<b>GlobalHoldDownTime</b>	Configures the length of time that RIPng continues to advertise a network after the network is unreachable. The range is 0–360 seconds. The default is 120 seconds.
<b>GlobalTimeOutInterval</b>	Configures the RIPng timeout interval. The range is 15–259200 seconds. The default is 180 seconds.
<b>DefaultInfoMetric</b>	RIPng default-information metric.
<b>DefaultInfoState</b>	Default-information enable or disable at the global level
<b>DefaultImportMetric</b>	Specifies the RIPng default import metric.

## Configuring an IPv6 RIPng interface

Configure RIPng parameters on an interface so you can control RIPng behavior on the interface.

### About This Task

RIPng does not operate on an interface until you enable it globally and on the interface.

You can also configure an IPv6 RIPng interface for a brouter port by selecting **Device Physical View**, selecting a port, and following the **Edit > Port > IPv6** navigation path. You can configure an IPv6 RIPng interface for a VLAN through the **VLAN > VLANs > Basic > IPv6** navigation path. This procedure uses the main IPv6 RIPng navigation path where you can create both types of interfaces.

### Before You Begin

- Configure a routing interface (either a brouter port or a virtual routing interface).
- Assign an IP address to the interface.
- Enable RIPng globally.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 RIPng**.
3. Click the **Interfaces** tab.
4. Click **Insert**.
5. In the **IfIndex** box, type a value to identify the IPv6 interface.
6. In the **RipAdminStatus** option box, select **enable**.
7. Configure other parameters as required.

8. Click **Insert**.

*Interfaces field descriptions*

Use the data in the following table to use the **Interfaces** tab.

Name	Description
<b>IfIndex</b>	RIPng interface index.
<b>RipAdminStatus</b>	Enable or disable RIPng on an interface.
<b>DefaultInfoState</b>	Enable or disable default information at the interface level.
<b>Cost</b>	Specifies the RIPng metric cost.
<b>Poison</b>	Enable or disable poison reverse on an RIPng interface.
<b>RipOperStatus</b>	Enable or disable the RIPng operational state on an interface.

## Configuring an IPv6 RIPng VLAN interface

Configure RIPng parameters on a VLAN interface so you can control RIPng behavior on the interface.

### About This Task

RIPng does not operate on an interface until you enable it globally and on the interface.

You can also configure an IPv6 RIPng interface for a brouter port by selecting **Device Physical View**, selecting a port, and following the **Edit > Port > IPv6** navigation path.

### Before You Begin

- Configure a routing interface (either a brouter port or a virtual routing interface).
- Assign an IP address to the interface.
- Enable RIPng globally.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration >VLAN**.
2. Click **VLANS**.
3. Click the **Basic** tab.
4. Select a row, and click **IPv6**.
5. Click **Insert**.
6. Configure other parameters, as required.
7. Click **Insert**.
8. Click **Apply**.

**IPv6 Interfaces** VLAN Field Descriptions

Use the data in the following table to use the **IPv6 Interfaces** tab.

Name	Description
<b>Interface</b>	Specifies the port or VLAN.
<b>Identifier</b>	Shows the IPv6 address interface identifiers. This value is a binary string of up to 8 octets in network byte-order.
<b>IdentifierLength</b>	Shows the length of the identifier, in bits.
<b>Descr</b>	Specifies a description of the interface. The network management system also configures this string.
<b>VlanId</b>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. This value corresponds to the lower 12 bits of the IEEE 802.1Q VLAN tag.
<b>Type</b>	Shows the interface type.
<b>ReasmMaxSize(MTU)</b>	Specifies the maximum size of the MTU of this IPv6 interface. This value must be the same for all the IP addresses defined on this interface. The default value is 1500.
<b>PhysAddress</b>	Specifies the media-dependent physical address. For Ethernet, this is a MAC address.
<b>AdminStatus</b>	Specifies if IPv6 is active on this interface. The default is false (disabled).
<b>OperStatus</b>	Specifies the current operational status of the interface.
<b>ReachableTime</b>	Specifies the time, in milliseconds, that a neighbor is considered reachable after receiving a reachability confirmation. The default is 30000.
<b>RetransmitTimer</b>	Specifies the time, in milliseconds, between retransmissions of neighbor solicitation messages to a neighbor when resolving the address, or when probing the reachability of a neighbor. The default is 1000.
<b>CurHopLimit</b>	Specifies the current hop limit field sent in router advertisements from this interface. The value must be the current diameter of the Internet. A value of zero indicates that the advertisement does not specify a value for CurHopLimit. The default is 64.
<b>MulticastAdminStatus</b>	The option to select <b>MulticastAdminStatus</b> is disabled. You cannot configure the administrative status for multicast in this context.

Name	Description
<b>MacOffset</b>	Requests a particular MAC for an IPv6 VLAN. You can specify a MAC offset when you configure IPv6 on a VLAN, or the system can assign a MAC address from within the available range. Different hardware platforms support different MAC offset ranges.
<b>ForwardingEnabled</b>	Indicates whether IPv6 forwarding is enabled. The default is enabled.
<b>RSMLTEnable</b>	Shows whether RSMLT is enabled on the interface. The default value is disabled (false).

## Configuring an IPv6 RIPng router port interface

Configure RIPng parameters on an interface so you can control RIPng behavior on the interface.

### About This Task

RIPng does not operate on an interface until you enable it globally and on the interface.

### Before You Begin

- Configure a routing interface (either a router port or a virtual routing interface).
- Assign an IP address to the interface.
- Enable RIPng globally and on the interface.

### Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration** > **EditPort** folders.
3. Click **IPv6**.
4. Click the **RIPng** tab.
5. In the **RipAdminStatus** option box, select **enable**.
6. Configure other parameters as required.
7. Click **Apply**.

### *RIPng Field Descriptions*

Use the data in the following table to use the **RIPng** tab.

Name	Description
<b>RipAdminStatus</b>	Enable or disable RIPng on an interface.
<b>DefaultInfoState</b>	Enable or disable default information at the interface level. The default is disable.
<b>Cost</b>	Specifies the RIPng metric cost. The default is 1.

Name	Description
<b>Poison</b>	Enable or disable poison reverse on an RIPng interface. The default is disable.
<b>RipOperStatus</b>	Shows the RIPng operational state on an interface.

## Graphing IPv6 RIPng statistics

Use the following procedure to graph RIPng statistics for monitoring RIPng behavior on the interface.

### About This Task

RIPng does not operate on an interface until you enable it globally and on the interface.

### Before You Begin

- Configure a routing interface (either a brouter port or a virtual routing interface).
- Assign an IP address to the interface.
- Enable RIPng globally and on the interface.

### Procedure

1. In the navigation pane, expand the **Configuration > Ipv6** folders.
2. Click the **IPv6 RIPng**.
3. Click the **Stats** tab.
4. Select an interface row.
5. Click **Graph**.
6. Click **Apply**.

## Configuring route redistribution to RIPng

Configure a redistribute entry to announce routes of a certain source protocol type into the RIPng domain, for example, static, RIP, or direct. Use a route policy to control the redistribution of routes.

### Before You Begin

- Enable RIP globally.
- Configure a route policy.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 RIPng**.
3. Click the **Redistribute** tab.
4. Double-click the value in the **Enable** column that corresponds with the source protocol type you want to enable or disable.
5. Select **enable** or **disable** from the list.
6. Click **Apply**.

*Redistribute field descriptions*

Use the data in the following table to use the **Redistribute** tab.

Name	Description
<b>DstVrfiled</b>	Specifies the destination VRF ID used in the redistribution.
<b>Protocol</b>	Specifies the dynamic routing protocol that receives the external routing information.
<b>SrcVrfiled</b>	Specifies the source VRF ID used in the redistribution.
<b>RouteSource</b>	Specifies the route source protocol for the redistribution entry.
<b>Enable</b>	Enables (or disables) a RIPng redistribute entry for a specified source type.

## Viewing stats for RIPng interfaces

View statistics for RIPng interfaces.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > IPv6**.
2. Click **IPv6 RIPng**.
3. Click the **Stats** tab.

*Stats field descriptions*

Use the data in the following table to use the **Stats** tab.

Name	Description
<b>IfIndex</b>	Shows the unique value to identify an IPv6 interface.
<b>RcvBadPackets</b>	The number of RIPng response packets received by the RIP process that were subsequently discarded for any reason (examples: a version 0 packet or an unknown command type).
<b>RcvBadRoutes</b>	The number of routes, in valid RIPng packets, that were ignored for any reason (examples: unknown address family or invalid metric).
<b>SentUpdates</b>	The number of triggered RIPng updates actually sent on this interface.
<b>RcvUpdates</b>	The number of triggered RIPng updates actually received on this interface. This explicitly does not include full updates received containing new information.

## Remote Monitoring

Remote Monitoring (RMON) is a management information base (MIB) or a group of management objects that you use to obtain or configure values using the Simple Network Management Protocol (SNMP). Use CLI, or EDM, to globally enable RMON on the system. After you globally enable RMON, you enable monitoring for individual devices on a port-by-port basis.

RMON1 is the original version of the protocol, which collects information for OSI Layer 1 and Layer 2 in Ethernet networks. RMON1 provides traffic statistics at the MAC layer, and provides statistics on Ethernet segments for packets and bytes received and transmitted.

You can use RMON1 to:

- Configure alarms for user-defined events.
- Collect Ethernet statistics.
- Log events.
- Send traps for events.

Within EDM, you can configure RMON1 alarms that relate to specific events or variables. You can also specify events associated with alarms to trap or log-and-trap. In turn, the system traps or logs tripped alarms.

You can view all RMON1 information using CLI or EDM. Alternatively, you can use any management application that supports SNMP traps to view RMON1 trap information.

This section describes RMON1 alarms, RMON1 history, RMON1 events, and RMON1 statistics.

## RMON1 alarms

You can configure alarms to alert you if the value of a variable goes out of range. You can define RMON1 alarms on any MIB variable that resolves to an integer value. You cannot use string variables (such as system description) as alarm variables.

You can use RMON1 alarm to monitor anything that has a MIB OID associated with it and a valid instance.

All alarms share the following characteristics:

- A defined upper and lower threshold value.
- A corresponding rising and falling event.
- An alarm interval or polling period.

After you activate alarms, you can:

- View the activity in a log and/or a trap.
- Create a script directing the system to sound an audible alert at a console.
- Create a script directing the system to send an e-mail.
- Create a script directing the system to call a pager.

The system polls the alarm variable and the system compares the result against upper and lower limit values you select when you create the alarm. If the system reaches or crosses the alarm variable during the polling period, the alarm fires and generates an event that you can view in the event log or the trap log. You can configure the alarm to either create a log, or have the alarm send a Simple Network Management Protocol (SNMP) trap to a Network Management System (NMS). You can view the activity in a log or a trap log, or you can create a script to cause a console to beep, send an e-mail, or call a pager.

The upper limit of the alarm is the rising value, and the lower limit is the falling value. RMON1 periodically samples data based upon the alarm interval. During the first interval that the data passes above the rising value, the alarm fires as a rising event. During the first interval that the data drops below the falling value, the alarm fires as a falling event.

The following figure shows how alarms fire:

**Figure 227: How alarms fire**

The alarm fires during the first interval that the sample goes out of range. No additional events generate for that threshold until the system crosses the opposite threshold. Therefore, you must carefully define the rising and falling threshold values for alarms. Incorrect thresholds cause an alarm to fire at every alarm interval, or never at all.

You can define one threshold value to an expected, baseline value, and then define the opposite threshold as the out-of-bounds limit. Because of sample averaging, the value is equal to  $\pm 1$  baseline unit. For example, assume you define an alarm with octets leaving a port as the variable. The intent of the alarm is to notify you if excessive traffic occurs on that port. You enable spanning tree, and then 52 octets transmit from the port every 2 seconds, which is equivalent to baseline traffic of 260 octets every 10 seconds. This alarm notifies you if you define the lower limit of exiting octets at 260 and you define the upper limit at 320 (or at any value greater than  $260 + 52 = 312$ ).

The rising alarm fires the first time outbound traffic, other than spanning tree Bridge Protocol Data Units (BPDUs), occurs. The falling alarm fires after outbound traffic, other than spanning tree, ceases. This process provides the time intervals of any nonbaseline outbound traffic.

If you define the alarm with a falling threshold of less than 260 and the alarm polling interval is at 10 seconds, for example, 250, then the rising alarm can fire only once, as shown in the following example. The falling alarm (the opposite threshold) must fire for the rising alarm to fire a second time. The falling alarm cannot fire unless the port becomes inactive or you disable spanning tree, which causes the value for outbound octets to drop to zero, because the baseline traffic is always greater than the value of the falling threshold. By definition, the failure of the falling alarm to fire prevents the rising alarm from firing a second time.

The following figure shows an example of the alarm threshold:

**Figure 228: Alarm example, threshold less than 260**

When you create an alarm, you select a variable from the variable list and a port, or another system component to which it connects. Some variables require port IDs, card IDs, or other indexes, for example, spanning tree group IDs. You then select a rising and a falling threshold value. The rising and falling values compare to the actual value of the variable that you choose. If the variable falls outside of the rising or falling value range, an alarm triggers, and the system logs an event or trap.

When you create an alarm, you also select a sample type, which can be either absolute or delta. Define absolute alarms for alarms based on the cumulative value of the alarm variable. An example of an absolute alarm value is card operating status. Because this value is not cumulative, but instead represents states, such as card up (value 1) and card down (value 2), you configure the value as the absolute value. Therefore, you can create an alarm with a rising value of 2 and a falling value of 1 to alert you whether the card is up or down.

Configure most alarm variables related to Ethernet traffic as a delta value. Define delta alarms for alarms based on the difference in the value of the alarm variable between the start of the polling period and the end of the polling period.

**Note**

If you create an alarm that monitors a variable that does not exist, you will receive an error message and the creation will fail. Also, if the variable you are monitoring is no longer valid at the time of sampling, the switch removes the alarm automatically. For example, if you create an alarm that monitors some information about a VLAN, and that VLAN is later removed, then the switch silently removes the associated alarm at the next sampling interval.

## RMON1 history

The RMON1 history group records periodic statistical samples from a network. A sample is a history and the system gathers the sample in time intervals referred to as buckets.

You can use RMON1 history for the MAC layer in the network. You cannot use RMON1 history for application and network layer protocols.

You enable and create histories to establish a time-dependent method to gather RMON1 statistics on a port. The following are the default values for history:

- Buckets are gathered at 30-minute intervals.
- The number of buckets gathered is 50.

You can configure both the time interval and the number of buckets. However, after the system reaches the last bucket, the system dumps bucket 1 and recycles the bucket to hold a new bucket of statistics. Then the system dumps bucket 2, and so forth.

## RMON1 events

RMON1 events and alarms work together to notify you when values in your network go out of a specified range. After a value passes the specified range, the alarm fires. The event specifies how the system records the activity.

You can use RMON1 events to monitor anything that has a MIB OID associated with it and a valid instance.

An event specifies whether a trap, a log, or both a trap and a log generates to view alarm activity.

You must create an event before associating it with an alarm, otherwise an error occurs. Also, you cannot delete an event as long as there are alarms associated with it. If you try to do so, an error message displays.

## RMON1 statistics

You can use EDM to gather and graph statistics in a variety of formats, or you can save the statistics to a file and export the statistics to a third-party presentation or graphing application.

## RMON1 scaling limits

The following tables shows the scaling limits for RMON1 elements.

### Note

When the log table reaches the maximum 500 log limit, the oldest third of the logs per event is removed to make room for new events. For all other elements, a message displays when you reach the maximum limit and no other element can be added.

Alarms	100
Events	100
History (entries in the history control table with 2000 buckets shared between them)	20
Logs	500
Statistics (entries in stats table)	100

## RMON 2

Remote Monitoring (RMON) is a management information base (MIB) or a group of management objects that you use to obtain or configure values using the Simple Network Management Protocol (SNMP).

Use CLI or EDM to globally enable RMON on the system.

After you globally enable RMON, you enable monitoring for individual devices on a port-by-port basis.

RMON1 is the original version of the protocol, which collects information for OSI Layer 1 and Layer 2 in Ethernet networks. RMON1 provides traffic statistics at the MAC layer, and provides statistics on Ethernet segments for packets and bytes received and transmitted.

RMON2 monitors and counts network layer and application layer protocol packets on configured network hosts, either VLAN or port interfaces, that you enable for monitoring. RMON2 monitors Segmented Management Instances at the mgmt configuration level for out-of-band (OOB), circuitless IP (CLIP), and VLAN interfaces.

**Note**

RMON2 monitoring of Segmented Management Instances at the mgmt configuration level is not supported on VSP 8600 Series.

**Note**

RMON2 counters on Segmented Management Instance interfaces are cleared only when a Segmented Management Instance interface is newly enabled, or when RMON2 is newly enabled on a previously enabled Segmented Management Instance interface.

The following figure shows which form of RMON monitors which layers in the OSI model:

**Figure 229: OSI model and RMON**

The RMON2 feature is a management information base (MIB) or a group of management objects that you use to obtain or configure values using the Simple Network Management Protocol (SNMP). The switch supports a partial implementation of RMON2. The RMON2 feature adds the following MIBs: protocol directory, protocol distribution, address map, network-layer host and application layer host for the traffic passing through the (Control Processor) CP for these MIB tables.

The system only collects statistics for IP packets that pass through the CP. RMON2 does not monitor packets on other interfaces processed on the switch that do not

pass through the CP. However, RMON2 monitors packets for applications listed in the RMON2 MIB, whether or not the application is enabled or supported on the switch.

After you globally enable RMON2, enable monitoring for individual devices. Identify the network hosts for the system to monitor with a manual configuration on the interfaces you want to monitor.

The RMON2 feature monitors a list of predefined protocols. The system begins to collect protocol statistics immediately after you enable RMON.

The RMON2 feature collects statistics on:

- Protocols predefined by the system.
- Address mapping between physical and network address on particular network hosts that you configure for monitoring.
- Network host statistics for particular hosts on a network layer protocol (IP) that you configure for monitoring.
- Application host statistics for a particular host on an application layer protocol that you configure for monitoring.

## RMON2 MIBs

This section describes the following MIBs, on which RMON2 can collect statistics: protocol directory, protocol distribution, address map, network-layer host, and application layer host.

### Protocol Directory MIB

The protocol directory lists all of the protocols RMON2 can monitor. The protocols include network layer, transport layer, and application layer protocols, under the OSI model. The system only monitors statistics for the predefined protocols. You cannot delete or add additional protocols to this table. The protocol directory MIB is enabled by default for the predefined protocols.

The predefined protocols include:

- Internet Protocol (IP)
- Secure Shell version 2 (SSHv2)
- Transmission Control Protocol (TCP)
- User Datagram Protocol (UDP)
- File Transfer Protocol (FTP)
- Hypertext Transfer Protocol (HTTP)
- Telnet
- Remote login (rlogin)

#### Note

RMON2 can count application packets received on a platform, even if the application is not enabled or supported, before dropping them.

- Trivial File Transfer Protocol (TFTP)
- Simple Network Management Protocol (SNMP)

## Protocol distribution MIB

The protocol distribution MIB collects traffic statistics that each protocol generates by local area network (LAN) segment. The switch acts as the probe and the system collects protocol statistics for the entire switch as part of the group for all of the protocols predefined in the protocol directory table. The protocol distribution control table is part of this group. The protocol distribution control table is predefined with an entry for the management IP for the switch to represent the network segment where the system collects the statistics.

No CLI or EDM support exists to add or delete entries in this table.

## Address map MIB

The address map MIB maps the network layer IP to the MAC layer address.

The system populates the address map control table MIB with an entry for each host interface that you enable for monitoring on the switch.

## Network layer host MIB

The network layer host MIB monitors the Layer 3 traffic statistics for each host. The network layer host MIB monitors traffic packets in and out of hosts based on the network layer address. The network layer host controls the network and application layer host tables.

The system populates an entry for the management IP of the switch to represent the network segment where the system collects the statistics. You have to enable each host interface that you want to monitor on the switch.

The system only collects statistics for this group from packets that go to the CP.

## Application layer host MIB

The application layer host MIB monitors traffic statistics by application protocol for each host.

The system populates an entry for the management IP of the switch to represent the network segment where the system collects the statistics. You have to enable each host interface that you want to monitor on the switch.

The system only collects statistics for this group from packets that go to the CP.

## RMON2 Considerations

The following considerations apply to RMON2:

- You must enable RMON globally before you enable RMON2 monitoring for a Segmented Management Instance interface.
- You must configure an IPv4 address for the Segmented Management Instance management interface before you enable RMON2 monitoring.
- You can enable RMON on a maximum of 30 IP interfaces on a host.
- You cannot directly configure RMON for a routing VLAN that is an underlying management VLAN. In this case, RMON must be configured at the mgmt vlan configuration level.
- RMON2 is not available if DHCP Client is configured on a Management Instance. DHCP Client is not available if RMON2 is configured on a Management Instance.
- You cannot delete the IPv4 manual address from a Segmented Management Instance management interface that is RMON enabled. If the only IPv4 address is deleted outside of the normal configuration process, RMON is administratively disabled on the Segmented Management Instance management interface.

## RMON Configuration Using CLI

This section contains procedures to configure RMON using Command Line Interface (CLI).

For information about RMON statistics, see the following sections:

- [Displaying RMON Statistics for Specific Ports](#) on page 3114
- [View RMON Statistics](#) on page 3114

## Configuring RMON

Enable RMON1 and RMON2 globally, and configure RMON1 alarms, events, history, statistics, and whether port utilization is calculated in half or full duplex. By default, RMON1 and RMON2 are disabled globally.

For RMON1, you enable RMON globally, and then you can use RMON1 alarm, history, events, and statistics for the MAC layer in the network. You cannot use RMON1 history or statistics for application and network layer protocols.

For RMON2, you enable RMON globally, and then you enable RMON on the host interfaces you want to monitor.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable RMON1 and RMON2 globally:  

```
rmon
```

## 3. Configure an RMON1 alarm:

```
rmon alarm <1-65535> WORD <1-1536> <1-3600> {absolute|delta} [falling-
threshold <-2147483647-2147483647> event <1-65535>] [owner WORD<1-
127>] [rising-threshold <-2147483647-2147483647> event <1-65535>]
```

## 4. Configure an RMON1 event:

```
rmon event <1-65535> [community WORD<1-127>] [description WORD<0-127>]
[log] [owner WORD<1-127>] [trap] [trap_dest [{A.B.C.D}]] [trap_src
[{A.B.C.D}]]
```

## 5. Configure RMON1 history:

```
rmon history <1-65535> {slot/port [/sub-port] [-slot/port[/sub-port]
[,...]} [buckets <1-65535>] [interval <1-3600>] [owner WORD<1-127>]
```

## 6. Configure RMON1 statistics:

```
rmon stats <1-65535> {slot/port [/sub-port] [-slot/port[/sub-port]
[,...]} [owner <1-127>]
```

## 7. Configure whether the system calculates port utilization in half or full duplex:

```
rmon util-method [half|full]
```

**Example**

Configure RMON globally, an RMON1 alarm, and RMON1 event:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#rmon
Switch:1(config)#rmon event 60534 community public description "Rising Event" log trap
Switch:1(config)#rmon alarm 4 rcCliNumAccessViolations.0 10 absolute rising-threshold 2
event 60000
```

*Variable Definitions*

Use the data in this table to use the **rmon** command.

Variable	Value
<pre>alarm &lt;1-65535&gt; WORD &lt;1-1536&gt; &lt;1-3600&gt; {absolute  delta} [falling-threshold &lt;-2147483647-2147483647&gt; event &lt;1-65535&gt; ] [owner WORD&lt;1-127&gt; ] [rising-threshold &lt;- 2147483647-2147483647&gt; event &lt;1-65535&gt;]</pre>	<p>Creates an alarm interface.</p> <ul style="list-style-type: none"> <li>• <i>&lt;1-65535&gt;</i>— Specifies the interface index number from 1 to 65535. Each entry defines a diagnostics sample at a particular interval for an object on the device. The default is 1.</li> <li>• <i>WORD &lt;1-1536&gt;</i>— Specifies the variable name or OID. The entry is case sensitive and can have a string length of 1 to 1536.</li> <li>• <i>{absolute   delta}</i>— Specifies the sample type.</li> <li>• <i>rising-threshold &lt;-2147483648-2147483647&gt; [<i>&lt;event:1-65535&gt;</i>]</i> — Specifies the rising threshold from -2147483648 to 2147483647, which is a threshold for the sampled statistic. After the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval was less than this threshold, the system generates a single event. The system also generates a single event if the first sample after this entry that becomes valid is greater than or equal to the rising alarm, or the rising or falling alarm. After the system generates a rising event, the system does not generate another such event until the sampled value falls below this threshold and reaches the alarm falling threshold. You cannot modify this object if the associated alarm status is equal to valid.</li> </ul> <p><i>&lt;1-65535&gt;</i>— Specifies the rising event index, which the system uses after the system crosses a rising threshold. The event entry identified by a particular value of this index is the same as identified by the same value of the event index object. If no corresponding entry exists in the event table, no association exists. In particular, if this value is zero, the system does not generate an associated event, as zero is not a valid event index. You cannot modify this object if the associated alarm status is equal to valid.</p> <ul style="list-style-type: none"> <li>• <i>falling-threshold &lt;-2147483648-2147483647&gt; [<i>&lt;event:1-65535&gt;</i>]</i> — Specifies the falling threshold from -2147483648 to 2147483647, which specifies a threshold for the sampled statistic. If the current sampled value is less than or equal to this threshold, and the value at the last sampling interval was greater than this threshold, the system generates a single event. The system also generates a single event if the first sample after this entry that becomes valid is less than or equal to this threshold and the</li> </ul>

Variable	Value
	<p>associated alarm startup alarm is equal to falling alarm or rising or falling alarm. After the system generates a falling event, the system does not generate another such event until the sampled value rises above this threshold, and reaches the alarm rising threshold. You cannot modify this object if the associated alarm status is equal to valid.</p> <p>&lt;1-65535&gt; – Specifies the index of the event entry that the system uses after a falling threshold is crossed. The event entry identified by a particular value of this index is the same as identified by the same value of the event index object. If no corresponding entry in the event table exists, no association exists. In particular, if this value is zero, the system does not generate an event, as zero is not a valid event index. You cannot modify this object if the associated alarm status is equal to valid. The default is 60535.</p> <ul style="list-style-type: none"> <li>• <i>owner WORD&lt;1-127&gt;</i> — Specifies the name of the owner, with a string length 1 to 127.</li> </ul> <p>Use the <b>default</b> operator to reset the RMON alarms to their default configuration: <code>default rmon alarm &lt;65535&gt;</code></p> <p><b>Note:</b> When configuring from CLI, the default owner is <b>cli</b>; when configuring with SNMP, the default owner is <b>snmp</b>. The default command only sets the owner to default. No other parameters can be changed after you create the alarm.</p> <p>Use the <b>no</b> operator to disable RMON alarms: <code>no rmon alarm [&lt;1-65535&gt;]</code></p>
<pre>event &lt;1-65535&gt; [community WORD&lt;1-127&gt;] [description WORD&lt;0-127&gt;] [log] [owner WORD&lt;1-127&gt; ] [trap]</pre>	<p>Create an event.</p> <ul style="list-style-type: none"> <li>• &lt;1-65535&gt;— Specifies the event index number. Each entry defines one event that the system generates after the appropriate conditions occur. The default is 1.</li> <li>• <i>log</i>— Specifies if this event stores a log when the event is triggered by the alarm.</li> <li>• <i>trap</i>— Specifies if this event sends a trap when the event is triggered by the alarm. The trap will be sent to all the snmp-server hosts configured in the snmp table.</li> <li>• <i>description WORD&lt;0-127&gt;</i>— Specifies the event description, with a string length of 0 to 127.</li> </ul>

Variable	Value
	<ul style="list-style-type: none"> <li>• <i>owner</i> <i>WORD</i>&lt;1-127&gt; — Specifies the name of the owner, with a string length of 1 to 127.</li> <li>• <i>community</i> <i>WORD</i>&lt;1-127&gt; — Specifies the SNMP community where you can send SNMP traps, with a string length 1 to 127.</li> </ul> <p>You can set the community, but the trap is not filtered out. The trap is sent to all configured snmp-server hosts, regardless of the value of this field.</p> <p>Use the <b>no</b> operator to delete a RMON event: <code>no rmon event [&lt;1-65535&gt;] [log]</code></p>
<pre>history &lt;1-65535&gt; {slot/port [/sub-port] [- slot/port [/sub-port] [,...]} [buckets &lt;1-65535&gt;] [interval &lt;1-3600&gt;] [owner WORD&lt;1-127&gt;]</pre>	<p>Configures RMON history.</p> <ul style="list-style-type: none"> <li>• &lt;1-65535&gt; — Specifies the history index number that uniquely identifies an entry in the history control table. Each entry defines a set of samples at a particular interval for an interface on the default. The default value is 1.</li> <li>• {slot/port [/sub-port] [-slot/port [/sub-port] [,...]} — Specifies the single port interface. Identifies the source for which the system collects and places historical data in a media-specific table on behalf of this history control entry. The source is an interface on this device. The statistics in this group reflect all packets on the local network segment that attaches to the identified interface.</li> <li>• <i>buckets</i> &lt;1-65535&gt; — Specifies the requested number of discrete time intervals where the system saves data in the part of the media-specific table associated with this history control entry. The default value is 50.</li> <li>• <i>interval</i> &lt;1-3600&gt; — Specifies the time interval in seconds over which the system samples the data for each bucket in the part of the media-specific table associated with this history control entry. Because the counters in a bucket can overflow at their maximum value with no indication, you must take into account the possibility of overflow in all the associated counters. Consider the minimum time in which a counter can overflow on a particular media type, and then set the history control interval to a value less than this interval, which is typically most important for the octets counter in a media-specific table. The default value is 1800.</li> <li>• <i>owner</i> <i>WORD</i>&lt;1-127&gt; — Specifies the name of the owner.</li> </ul>

Variable	Value
<pre>stats &lt;1-65535&gt; {slot/ port [/sub-port] [-slot/ port [/sub-port] [, ...]} owner WORD&lt;1-127&gt;</pre>	<p>Configures RMON statistics.</p> <ul style="list-style-type: none"> <li>• &lt;1-65535&gt;— Specifies the control Ether statistics entry index number.</li> <li>• {slot/port [/sub-port] [-slot/port [/sub-port] [, ...]}— Specifies the single port interface.</li> <li>• owner WORD&lt;1-127&gt; — Specifies the name of the owner.</li> </ul> <p>Use the <b>no</b> operator to delete a RMON Ether stats control interface: <code>no rmon stats [&lt;1-65535&gt;]</code></p>
<pre>util-method [half full]</pre>	<p>Configures whether port utilization is calculated in half or full duplex to calculate port usage.</p> <ul style="list-style-type: none"> <li>• half—Configures the string to half duplex.</li> <li>• full—Configures the string to full duplex.</li> </ul> <p>After you select half for half duplex, RMON uses InOctets and the speed of the port to calculate port usage (this is the standard RMON RFC 1271 convention). After you select full for full duplex, RMON uses InOctets and OutOctets, and 2X the speed of the port to calculate port usage. If you select full, but the port operates in half-duplex mode, the calculation defaults to the RFC1271 convention. The default is half.</p>

## Enable Remote Monitoring on an Interface

Use the following procedure to enable Remote Monitoring (RMON) on an interface.

### Before You Begin

- Enable RMON globally.

### Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable RMON on a particular VLAN:

```
vlan rmon <1-4059>
```

## 3. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## 4. Enable RMON on a particular port:

```
rmon
```

*Examples*

## Enable RMON on VLAN 2:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#vlan rmon 2
```

## Enable RMON on port 3/8:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface gigabitethernet 3/8
Switch:1(config-if)#rmon
```

*Variable Definitions*

Use the data in this table to use the **vlan rmon** command.

Variable	Value
<1-4059>	Specifies the VLAN ID on which to configure RMON.

## Enable RMON2 on a Segmented Management Instance Interface

**Before You Begin**

You must enable RMON globally before you enable RMON2 monitoring for a Segmented Management Instance interface.

**Procedure**

## 1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

## 2. Enter the configuration mode for the Management Instance:

```
mgmt <clip | oob | vlan>
```

### 3. Enable RMON2 on the Segmented Management Instance:

```
rmon
```

## View RMON Information

View RMON1 and RMON2 information on the switch. You can view information about RMON1 alarms, events, history, logs, and statistics. You can also view RMON2 information about application host statistics, control tables, network host statistics, and protocol distribution statistics.

### Procedure

#### 1. View RMON1 information:

```
show rmon {alarm|event|history|log|stats}
```

#### 2. View RMON2 information:

```
show rmon {address-map|application-host-stats WORD<1-64>|application
protocols|ctl-table|protocol-dist-stats|network-host-stats}
```

### Example

View RMON event, log, and statistics information:

```
Switch:1(config)#show rmon event

=====
                        Rmon Event
=====

INDEX DESCRIPTION          TYPE          COMMUNITY OWNER      LAST_TIME_SENT
-----

                        "Falling Event"
60535. 2 8 day(s), 19:14:45 1.3.6.1.4.1.2272.1.19.14.0 (absValue = 0, Falling
                        Threshold = 1, interval = 10)[alarmIndex.2][trap]
                        "Falling Event"

Switch:1(config)#show rmon stats

=====
                        Rmon Ether Stats
=====

INDEX PORT   OWNER
-----
1     1/10   monitor
```

### Variable Definitions

The following table defines parameters for the **show rmon** command.

Variable	Value
<i>address-map</i>	Displays the RMON2 address map. This RMON2 parameter expands RMON capacity to display information on network, transport, and application layers.
<i>alarm</i>	Displays the RMON1 alarm table.
<i>application-host-stats WORD&lt;1-64&gt;</i>	Displays RMON2 application host statistics from monitored protocols. This RMON2 parameter expands RMON capacity to display network, transport, and application layer information.  <b>Note:</b> RMON2 can count application packets received on a platform, even if the application is not enabled or supported, before dropping them.
<i>ctl-table</i>	Displays the RMON2 control tables. This RMON2 parameter expands RMON capacity to display network, transport, and application layers.
<i>event</i>	Displays the RMON1 event table.
<i>history</i>	Displays the RMON1 history table. This RMON1 parameter displays and is limited to link layer information, including as MAC information.
<i>log</i>	Displays the RMON1 log table.
<i>network-host-stats</i>	Displays RMON2 network-host statistics. This RMON2 parameter expands RMON capacity to display network, transport, and application layers.
<i>protocol-dist-stats</i>	Displays RMON2 protocol distribution statistics. This RMON2 parameter expands RMON capacity to display network, transport, and application layers.
<i>stats</i>	Displays the RMON1 statistics table. This RMON1 parameter displays and is limited to link layer information, including as MAC information.

## Displaying RMON Address Maps

View the maps of network layer address to physical address to interface.

The probe adds entries based on the source MAC and network addresses in packets without MAC-level errors.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON address maps:  

```
show rmon address-map
```

**Example**

```
Switch:1# show rmon address-map
=====
                        Rmon Address Map Table
=====
PROTOIDX  HOSTADDR      SOURCE  PHYADDR      LASTCHANGE
-----
1         192.0.2.11   2060   b0:ad:aa:42:a5:03  10/09/15 17:30:41
```

## View RMON Statistics

**About This Task**

View RMON statistics to manage network performance.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. View RMON statistics:

```
show rmon stats
```

**Example**

```
Switch:1#show rmon stats
=====
                        Rmon Ether Stats
=====
INDEX  PORT  OWNER
-----
1      1/10  monitor
```

## Displaying RMON Statistics for Specific Ports

Display individual RMON statistics for specific ports to manage network performance.

**Note**

Slot and port information can differ depending on hardware platform.

**Procedure**

1. Enter Privileged EXEC mode:
 

```
enable
```
2. View statistics for specific ports:
 

```
show interfaces GigabitEthernet statistics rmon {slot/port[/sub-port]}
[-slot/port[/sub-port]][, ...]
```

**Example**

View RMON statistics:

```
Switch:1>enable
Switch:1#show interfaces gigabitEthernet statistics rmon 1/13
=====
```

Port Stats Rmon									
PORT NUM	OCTETS	PKTS	MULTI CAST	BROAD CAST	CRC ALIGN	UNDER SIZE	OVER SIZE	FRAG MENT	COLLI SION
1/13	1943	21	8	13	0	0	0	0	0

### Variable Definitions

Use the data in the following table to use the **show interfaces GigabitEthernet statistics rmon** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## View RMON Application Host Statistics

View application host statistics to see traffic statistics by application protocol for each host.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON application host statistics:  

```
show rmon application-host-stats WORD<1-64>
```

### Example

```
Switch:1# show rmon application-host-stats ?
WORD<1-64> Select one of these application protocols
             {TCP|UDP|FTP|TELNET|HTTP|RLOGIN|SSH|TFTP|SNMP|HTTPS}
Switch:1# show rmon application-host-stats FTP
```

Rmon Application Host Stats					
HOSTADDR	INPKT	OUTPKT	INOC	OUTOC	CREATETIME
192.0.2.10	0	0	0	0	10/09/15 17:29:54

### Note

Protocol support can vary across platforms.

### Variable Definitions

The following table defines parameters for the **show rmon application-host-stats** command.

Variable	Value
WORD<1-64>	<p>Specifies one of the following application protocols: TCP, UDP, FTP, TELNET, HTTP, rlogin, SSH, TFTP, SNMP, HTTPS.</p> <p><b>Note:</b> RMON2 can count application packets received on a platform, even if the application is not enabled or supported, before dropping them.</p>

## View RMON Control Tables

View RMON control tables to see the data source for both network layer and application layer host statistics.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON control tables:  

```
show rmon ctl-table
```

### Example

#### Note

RMON2 can count application packets received on a platform, even if the application is not enabled or supported, before dropping them.

```
Switch:1# show rmon ctl-table

=====
                        Rmon Control Table

```

## Displaying RMON Network Host Statistics

View network host statistics to see Layer 3 traffic statistics for each host. The network layer host MIB monitors traffic packets in and out of hosts based on the network layer address.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON network host statistics:

```
show rmon network-host-stats
```

## View RMON Protocol Distribution Statistics

View protocol distribution statistics to see traffic statistics that each protocol generates by local area network (LAN) segment.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON protocol distribution statistics:

```
show rmon protocol-dist-stats
```

### Example

#### Note

RMON2 can count application packets received on a platform, even if the application is not enabled or supported, before dropping them.

```
Switch:1# show rmon protocol-dist-stats
```

```
=====
                                Rmon Protocol Dist Stats

```

```

=====

HTTPS     0         0
=====

```

## Displaying RMON Status

View the current RMON status on the switch.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RMON status:

```
show rmon
```

### Example

```

Switch:1# show rmon

RMON Info :
Status      : enable

```

## View the RMON2 Configuration State of Management Interfaces

### About This Task

#### Note

This procedure does not apply to VSP 8600 Series.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View information about the RMON2 configuration state:

```
show mgmt rmon
```

### Example

```

Switch:1>show mgmt rmon
=====
Mgmt Rmon Information
=====
INST  DESCR  RMON-ADMIN-ENABLE  RMON-OPER-ENABLE  RMON-IP-ADDR
-----
1 Mgmt-oob1  disable  disable  0.0.0.0
3 Mgmt-clip  enable   enable  192.0.2.72
4 Mgmt-vlan  enable   enable  198.51.100.72

```

## RMON Configuration Using EDM

This section contains procedures to configure RMON using Enterprise Device Manager (EDM).

For information about RMON statistics, see the following sections:

- [Enabling RMON Statistics](#) on page 3130
- [Viewing RMON Statistics](#) on page 3131

### Enabling RMON Globally

#### About This Task

You must globally enable RMON before you can use RMON2 functions. If you attempt to enable an RMON2 function before the global flag is disabled, EDM informs you that the flag is disabled and prompts you to enable the flag. You can configure RMON1 while RMON is globally disabled.

If you want to use nondefault RMON parameter values, you can configure them before you enable RMON, or as you configure the RMON functions.

#### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Options**.
3. Click the **Options** tab.
4. Select the **Enable** check box.
5. In the **UtilizationMethod** option, select a utilization method.
6. Click **Apply**.

#### *Options* Field Descriptions

Use the data in the following table to use the **Options** tab.

Name	Description
<b>Enable</b>	Enables RMON. If you select the <b>Enable</b> check box, the RMON agent starts immediately. To disable RMON, clear the <b>Enable</b> check box and click <b>Apply</b> to save the new setting to NVRAM, and then restart the device. The default is disabled.
<b>UtilizationMethod</b>	Controls whether RMON uses a half-duplex or full-duplex formula to calculate port usage. After you select halfDuplex, RMON uses InOctets and the speed of the port to calculate port usage (this is the standard RMON RFC1271 convention). After you select fullDuplex, RMON uses InOctets and OutOctets and 2X the speed of the port to calculate port usage. If you select fullDuplex, but the port operates in half-duplex mode, the calculation defaults to the RFC1271 convention. The default is halfDuplex.

## Enabling RMON on a Port or VLAN

Use the following procedure to enable RMON on an interface.

### Before You Begin

- Enable RMON globally.

### Procedure

1. Enable RMON on a VLAN:
  - a. In the navigation pane, expand the **Configuration > VLAN** folders.
  - b. Click **VLANs**.
  - c. Click the **Advanced** tab.
  - d. In the row for the VLAN, double-click the **RmonEnable** field, and then select **enable**.
  - e. Click **Apply**.
2. Enable RMON on a port:
  - a. In the Device Physical View, select a port.
  - b. In the navigation pane, expand the **Configuration > Edit > Port** folders.
  - c. Click **General**.
  - d. Click the **Interface** tab.
  - e. For the **RmonEnable** field, select **enable**.
  - f. Click **Apply**.

## Enabling RMON1 History

### About This Task

Use RMON1 to establish a history for a port and configure the bucket interval. For example, to gather RMON statistics over the weekend, you must have enough buckets to cover two days. Configure the history to gather one bucket every hour, and cover a 48-hour period. After you configure the history characteristics, you cannot modify them; you must delete the history and create another one.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Control**.
3. In the **History** tab, click **Insert**.
4. In the **Port** box, click the ellipsis (...) button.
5. Select a port.
6. Click **OK**.
7. In the **Buckets Requested** box, type the number of discrete time intervals to save data.
8. In the **Interval** box, type the interval in seconds.
9. In the **Owner** box, type the owner information.
10. Click **Insert**.

**History Field Descriptions**

Use the data in the following table to use the **History** tab.

Name	Description
<b>Index</b>	Specifies an index that uniquely identifies an entry in the historyControl table. Each entry defines a set of samples at a particular interval for an interface on the device. Index value ranges from 1–65535. The default value is 1.
<b>Port</b>	Identifies the source for which the system collects and places historical data in a media-specific table on behalf of this historyControlEntry. The source is an interface on this device. To identify a particular interface, the object identifies the instance of the ifIndex object, defined in (4,6), for the desired interface. For example, if an entry receives data from interface 1, the object is ifIndex 1. The statistics in this group reflect all packets on the local network segment attached to the identified interface. You cannot modify this object if the associated historyControlStatus object is equal to valid(1).
<b>BucketsRequested</b>	Specifies the requested number of discrete time intervals over which the system save data in the part of the media-specific table associated with this historyControlEntry. After this object is created or modified, the probe configures historyControlBucketsGranted as closely to this object as possible for the particular probe implementation and available resources. Values range from 1–65535. The default value is 50.
<b>BucketsGranted</b>	Specifies the number of discrete sampling intervals over which the system save data in the part of the media-specific table associated with this historyControlEntry. After the associated BucketsRequested object is created or modified, the probe sets this object as closely to the requested value as possible for the particular probe implementation and available resources. The probe must not lower this value except as a result of a modification to the associated BucketsRequested object. Occasionally, the actual number of buckets associated with this entry is less than the value of this object. In this case, at the end of each sampling interval, the system adds a new bucket to the media-specific table. After the number of buckets reaches the value of this object and the system is going to add a new bucket to the media-specific table, the agent deletes the oldest bucket associated with this entry so the system can added the new bucket. After the value of this object changes to a value less than the current value, entries are deleted from the media-specific table associated with this entry. The agent deletes the oldest of these entries so that their number remains less than or equal to the new value of this object. After the value of this object changes to a value greater than the current value, the system allows the number of associated media-specific entries to grow.

Name	Description
<b>Interval</b>	Specifies the interval in seconds over which the system samples data for each bucket in the part of the media-specific table associated with this historyControlEntry. You can set this interval between 1–3600 seconds (1 hour). Because the counters in a bucket can overflow at their maximum value with no indication, you must take into account the possibility of overflow in all of the associated counters. Consider the minimum time in which a counter can overflow on a particular media type, and then set the historyControlInterval object to a value less than this interval, which is typically most important for the octets counter in a media-specific table. For example, on an Ethernet network, the etherHistoryOctets counter can overflow in approximately 1 hour at the maximum utilization. You cannot modify this object if the associated historyControlStatus object is equal to valid. The default value is 1800.
<b>Owner</b>	Specifies the entity that configured this entry and uses the assigned resources.

## Disabling RMON1 History

### About This Task

Disable RMON1 history on a port if you do not want to record a statistical sample from that port.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Control**.
3. In the **History** tab, select the row that contains the port ID to delete.
4. Click **Delete**.

## Viewing RMON1 History Statistics

View RMON1 history statistics when you want to see a statistical sample from the switch. You can create a graph of the statistics in a bar, pie, chart, or line format.

### Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Port**.
4. Click the **RMON History** tab.
5. Select the statistics you want to graph.
6. Click the button for the type of graph you require (bar, pie, chart, or line).

**RMON History** *Field Descriptions*

Use the data in the following table to use the **RMON History** tab.

Parameter	Description
<b>SampleIndex</b>	Identifies the particular sample this entry represents among all samples associated with the same history control entry. This index starts at one and increases by one as each new sample is taken.
<b>Utilization</b>	Specifies the best estimate of the mean physical layer network utilization on this interface during the sampling interval, in hundredths of a percent.
<b>Octets</b>	Specifies the total number of octets of data (including those in bad packets) received on the network (excluding framing bits but including FCS octets)
<b>Pkts</b>	Specifies the number of packets (including bad packets) received during this sampling interval.
<b>BroadcastPkts</b>	Specifies the number of good packets received during this sampling interval that were directed to the broadcast address.
<b>MulticastPkts</b>	Specifies the number of good packets received during this sampling interval that the system directs to a multicast address. This number does not include packets addressed to the broadcast address.
<b>DropEvents</b>	Specifies the total number of events in which the probe dropped packets due to lack of resources during this sampling interval. This number is not necessarily the number of packets dropped; it is only the number of times the system detects this condition.
<b>CRCAAlignErrors</b>	The number of packets the system receives during this sampling interval that had a length (excluding framing bits but including FCS octets) from 64–1518 octets, inclusive, but had either a bad Frame Check Sequence (FCS) with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error).
<b>UndersizePkts</b>	Specifies the number of packets the system receives during this sampling interval that were less than 64 octets (excluding framing bits but including FCS octets), and were otherwise well formed.
<b>OversizePkts</b>	Specifies the number of packets the system receives during this sampling interval that were longer than 1518 octets (excluding framing bits but including FCS octets), but were otherwise well formed.

Parameter	Description
<b>Fragments</b>	Specifies the total number of packets received during this sampling interval that were less than 64 octets in length (excluding framing bits but including FCS octets) and had either a bad Frame Check Sequence (FCS) with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error). It is entirely normal for Fragments to increment because it counts both runts (which are normal occurrences due to collisions) and noise hits.
<b>Collisions</b>	Specifies the best estimate of the total number of collisions on this Ethernet segment during this sampling interval. The value returned depends on the location of the RMON probe. Section 8.2.1.3 (10BASE-5) and section 10.3.1.3 (10BASE-2) of IEEE standard 802.3 states that a station must detect a collision in the receive mode if three or more stations transmit simultaneously. A repeater port must detect a collision when two or more stations transmit simultaneously. Thus, a probe placed on a repeater port can record more collisions than a probe connected to a station on the same segment. Probe location plays a small role when 10BASE-T. 14.2.1.4 (10BASE-T) of IEEE standard 802.3 defines a collision as the simultaneous presence of signals on the DO and RD circuits (transmitting and receiving at the same time). A 10BASE-T station can detect only collisions when it transmits. Thus, probes placed on a station and a repeater can report the same number of collisions. An RMON probe inside a repeater can ideally report collisions between the repeater and one or more other hosts (transmit collisions as defined by IEEE 802.3k) plus receiver collisions observed on any coax segments to which the repeater is connected.

## Creating an RMON Alarm

After you enable RMON globally, you also create a default rising and falling event. The default for the events is log-and-trap, which means that you receive notification through a trap as well as through a log entry.

### Before You Begin

- You must globally enable RMON.

### Procedure

- In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
- Click **Alarms**.
- Click the **Alarms** tab.
- Click **Insert**.
- In the **Variable** option, select a variable for the alarm.  
If you select some variables, the system will prompt you for a port (or other object) on which you want to set an alarm.
- In the **SampleType** option, select a sample type.

7. In the **Interval** box, type a sample interval in seconds.
8. In the **Index** box, type an index number.
9. In the **RisingThreshold** box, type a rising threshold value.
10. In the **RisingEventIndex** box, type a rising threshold event index.
11. In the **FallingThreshold** box, type a falling threshold value.
12. In the **FallingEventIndex** box, type a falling threshold event index.
13. In the **Owner** box, type the owner of the alarm.
14. Click **Insert**.

### **Alarms** Field Descriptions

Use the data in the following table to use the **Alarms** tab.

Name	Description
<b>Index</b>	Uniquely identifies an entry in the alarm table. Each entry defines a diagnostic sample at a particular interval for an object on the device. The default is 1.
<b>Interval</b>	Specifies the interval, in seconds, over which the data is sampled and compared with the rising and falling thresholds. <b>deltaValue</b> sampling—Configures the interval short enough that the sampled variable is unlikely to increase or decrease by more than $2^{31}-1$ during a single sampling interval.
<b>Variable</b>	<p>Specifies the object identifier of the particular variable to be sampled. Only variables that resolve to an ASN.1 primitive type of INTEGER (INTEGER, Counter, Gauge, or TimeTicks) can be sampled.</p> <p>Alarm variables exist in three formats, depending on the type:</p> <ul style="list-style-type: none"> <li>• A chassis, power supply, or fan-related alarm ends in x where the x index is hard-coded. No further information is required.</li> <li>• A card, spanning tree group (STG), or EtherStat alarm ends with a dot (.). You must enter a card number, STG ID, IP address, or EtherStat information.</li> <li>• A port alarm ends with no dot or index and requires that you use the port shortcut menu. An example of a port alarm is <code>ifInOctets</code> (interface incoming octet count).</li> </ul> <p>Because the system articulates SNMP access control entirely in terms of the contents of MIB views, no access control mechanism exists to restrict the value of this object to identify only those objects that exist in a particular MIB view. Because no acceptable means of restricting the read access that is obtained through the alarm mechanism exists, the probe must grant only write access to this object in those views that have read access to all objects on the probe.</p> <p>After you configure a variable, if the supplied variable name is not available in the selected MIB view, the system returns a <code>badValue</code> error. After the variable name of an established <code>alarmEntry</code> is no longer available in the selected MIB view, the probe changes the status of this <code>alarmEntry</code> to <code>invalid</code>. You cannot modify this object if the associated <code>alarmStatus</code> object is equal to <code>valid</code>.</p>

Name	Description
<b>SampleType</b>	Specifies the method of sampling the selected variable and calculating the value to be compared against the thresholds. If the value of this object is <code>absoluteValue</code> , the value of the system compares the selected variable directly with the thresholds at the end of the sampling interval. If the value of this object is <code>deltaValue</code> , the system subtracts the value of the selected variable at the last sample from the current value, and the system compares the difference with the thresholds. You cannot modify this object if the associated <code>alarmStatus</code> object is equal to <code>valid</code> . The default is <code>deltaValue</code> .
<b>Value</b>	Specifies the value of the statistic during the last sampling period. For example, if the sample type is <code>deltaValue</code> , this value is the difference between the samples at the beginning and end of the period. If the sample type is <code>absoluteValue</code> , this value is the sampled value at the end of the period. This system compares the value with the rising and falling thresholds. The value during the current sampling period is not made available until the period is completed and remains available until the next period is complete.
<b>StartupAlarm</b>	Specifies the alarm that is sent after this entry is first set to <code>valid</code> . If the first sample after this entry becomes <code>valid</code> is greater than or equal to the <code>risingThreshold</code> and <code>alarmStartupAlarm</code> is equal to the <code>risingAlarm</code> or the <code>risingOrFallingAlarm</code> , then the system generates a single rising alarm. If the first sample after this entry becomes <code>valid</code> is less than or equal to the <code>fallingThreshold</code> and <code>alarmStartupAlarm</code> is equal to the <code>fallingAlarm</code> or the <code>risingOrFallingAlarm</code> , then the system generates a single falling alarm. You cannot modify this object if the associated <code>alarmStatus</code> object is equal to <code>valid</code> .
<b>RisingThreshold</b>	Specifies a threshold for the sampled statistic. After the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval was less than this threshold, the system generates a single event. The system also generates a single event if the first sample after this entry becomes <code>valid</code> is greater than or equal to this threshold and the associated <code>alarmStartupAlarm</code> is equal to <code>risingAlarm</code> or <code>risingOrFallingAlarm</code> . After a rising event is generated, another such event is not generated until the sampled value falls below this threshold and reaches the <code>alarmFallingThreshold</code> . You cannot modify this object if the associated <code>alarmStatus</code> object is equal to <code>valid</code> .
<b>RisingEventIndex</b>	Specifies the index of the <code>eventEntry</code> that is used after a rising threshold is crossed. The <code>eventEntry</code> identified by a particular value of this index is the same as identified by the same value of the <code>eventIndex</code> object. If no corresponding entry exists in the <code>eventTable</code> , no association exists. In particular, if this value is zero, the system generates no associated event, as zero is not a valid event index. You cannot modify this object if the associated <code>alarmStatus</code> object is equal to <code>valid</code> .  <b>Note:</b> You must create the event prior to associating it to an alarm.

Name	Description
<b>FallingThreshold</b>	Specifies a threshold for the sampled statistic. If the current sampled value is less than or equal to this threshold, and the value at the last sampling interval was greater than this threshold, the system generates a single event. The system also generates a single event if the first sample after this entry becomes valid is less than or equal to this threshold and the associated alarmStartupAlarm is equal to fallingAlarm or risingOrFallingAlarm. After the system generates a falling event, the system does not generate another similar event until the sampled value rises above this threshold and reaches the alarmRisingThreshold. You cannot modify this object if the associated alarmStatus object is equal to valid.
<b>FallingEventIndex</b>	Specifies the index of the eventEntry that the system uses after a falling threshold is crossed. The eventEntry identified by a particular value of this index is the same as identified by the same value of the eventIndex object. If there is no corresponding entry in the eventTable, no association exists. In particular, if this value is zero, the system generates no associated event, as zero is not a valid event index. You cannot modify this object if the associated alarmStatus object is equal to valid.  <b>Note:</b> You must create the event prior to associating it to an alarm.
<b>Owner</b>	Specifies the entity that configured this entry and is therefore using the resources assigned to it.
<b>Status</b>	Specifies the status of this alarm entry.

## Viewing RMON1 Alarms

View the RMON1 alarm information to see alarm activity.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Alarms**.
3. Click the **Alarm** tab.

## Deleting an RMON1 Alarm

Delete an RMON1 alarm if you no longer display it in the log.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Alarms**.
3. Select the alarm you must delete.
4. Click **Delete**.

## Creating an RMON Event

Create a custom rising and falling RMON event to specify if alarm information is sent to a trap, a log, or both.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Alarms**.
3. Click the **Events** tab.
4. Click **Insert**.
5. In the **Description** box, type an event name.
6. In the **Type** option, select an event type.

The default configuration is log-and-trap. To save memory, configure the event type to log. To reduce traffic from the system, configure the event type to snmp-log.

If you select snmp-trap or log, you must configure trap receivers.

7. In the **Community** box, type an SNMP community.
8. In the **Owner** box, type the owner of this event.
9. Click **Insert**.

### Events Field Descriptions

Use the data in the following table to use the **Events** tab.

Name	Description
<b>Index</b>	Uniquely identifies an entry in the event table. Each entry defines one event that the system generates after the appropriate conditions occur. The default is 1.
<b>Description</b>	Specifies a comment that describes this event entry.
<b>Type</b>	Specifies the type of notification that the probe makes about this event. In the case of a log, the system makes an entry in the log table for each event. In the case of SNMP traps, the system sends an SNMP trap to one or more management stations.
<b>Community</b>	Specifies the SNMP community where you can send SNMP traps.
<b>LastTimeSent</b>	Specifies the value of sysUpTime at the time this event entry last generated an event. If this entry has not generated events, this value is zero.
<b>Owner</b>	Specifies the entity that configured this entry and is therefore using the assigned resources. If this object contains a string starting with monitor and has associated entries in the log table, all connected management stations retrieve those log entries, as they have significance to all management stations connected to this device.

## Viewing RMON Events

View RMON events to see how many events occurred.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Alarms**.
3. Click the **Events** tab.

### Events Field Descriptions

Use the data in the following table to use the **Events** tab.

Name	Description
<b>Index</b>	Uniquely identifies an entry in the event table. Each entry defines one event that the system generates after the appropriate conditions occur. The default is 1.
<b>Description</b>	Specifies a comment that describes this event entry.
<b>Type</b>	Specifies the type of notification that the probe makes about this event. In the case of a log, the system makes an entry in the log table for each event. In the case of SNMP traps, the system sends an SNMP trap to one or more management stations.
<b>Community</b>	Specifies the SNMP community where you can send SNMP traps.
<b>LastTimeSent</b>	Specifies the value of sysUpTime at the time this event entry last generated an event. If this entry has not generated events, this value is zero.
<b>Owner</b>	Specifies the entity that configured this entry and is therefore using the assigned resources. If this object contains a string starting with monitor and has associated entries in the log table, all connected management stations retrieve those log entries, as they have significance to all management stations connected to this device.

## Deleting an Event

Delete an event after you no longer require the alarm information.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Alarms**.
3. Click the **Events** tab.
4. Select the event you must delete.
5. Click **Delete**.

## Viewing the RMON Log

### About This Task

View the trap log to see which activity occurred.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Alarms**.
3. Click the **Log** tab.

### Log Field Descriptions

Use the data in the following table to use the **Log** tab.

Name	Description
<b>EventIndex</b>	Specifies an index that uniquely identifies an entry in the event table. Each entry defines one event that is generated under appropriate conditions.
<b>Index</b>	Specifies an index that uniquely identifies an entry in the log table generated by the same event entries.
<b>Time</b>	Specifies the creation time for this log entry.
<b>Description</b>	Specifies an implementation dependent description of the event that activated this log entry.

## Enabling RMON Statistics

### About This Task

Enable Ethernet statistics collection for RMON.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Control**.
3. Click the **Ethernet Statistics** tab.
4. Click **Insert**.
5. Next to the **Port** box, click the ellipsis (...) button.
6. Select a port.
7. Click **OK**.
8. In the **Owner** box, type the name of the owner entity.
9. Click **OK**.
10. Click **Insert**.

### **Ethernet Statistics** Field Descriptions

Use the data in the following table to use the **Ethernet Statistics** tab.

Name	Description
<b>Index</b>	Uniquely identifies an entry in the Ethernet Statistics table. The default is 1.
<b>Port</b>	Identifies the source of the data that this etherStats entry is configured to analyze.
<b>Owner</b>	Specifies the entity that configured this entry and therefore uses the assigned resources.

## Viewing RMON Statistics

### Before You Begin

- You must enable RMON statistics collection.

### About This Task

Use the following procedure to view RMON statistics for each port.

### Procedure

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration > Graph** folders.
3. Click **Port**.
4. Click the **RMON** tab.
5. Select the statistics you want to graph.
6. Select a graph type:
  - bar
  - pie
  - chart
  - line

**RMON** Field Descriptions

The following table describes fields on the **RMON** tab.

Name	Description
<b>Octets</b>	<p>Specifies the number of octets of data (including those in bad packets) received on the network (excluding framing bits but including FCS octets).</p> <p>You can use this object as a reasonable estimate of Ethernet utilization. If additional precision is desired, sample the Pkts and Octets objects before and after a common interval. The differences in the sampled values are Pkts and Octets, and the number of seconds in the interval is Interval. These values are used to calculate the Utilization as follows:</p> $\text{Pkts} * (9.6+6.4) + (\text{Octets} * .8)$ <p>Utilization = ..... Interval * 10,000</p> <p>The result of this equation is the value Utilization, which is the percent utilization of the Ethernet segment on a scale of 0 to 100 percent.</p>
<b>Pkts</b>	Specifies the number of packets (including bad packets, broadcast packets, and multicast packets) received.
<b>BroadcastPkts</b>	Specifies the number of good packets received that were directed to the broadcast address. This number does not include multicast packets.
<b>MulticastPkts</b>	Specifies the number of good packets received that were directed to a multicast address. This number does not include packets directed to the broadcast address.
<b>CRCAAlignErrors</b>	Specifies the number of packets received that had a length (excluding framing bits, but including FCS octets) between 64 and 1518 octets, inclusive, but had either a bad Frame Check Sequence (FCS) with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error).
<b>UndersizePkts</b>	Specifies the number of packets received that were less than 64 octets long (excluding framing bits, but including FCS octets) and were otherwise well formed.
<b>OversizePkts</b>	Specifies the number of packets received that were longer than 1518 octets (excluding framing bits, but including FCS octets) and were otherwise well formed.

Name	Description
<b>Fragments</b>	Specifies the number of packets received that were less than 64 octets in length (excluding framing bits but including FCS octets) and had either a bad Frame Check Sequence (FCS) with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error). It is entirely normal for Fragments to increment because it counts both runs (which are normal occurrences due to collisions) and noise hits.
<b>Collisions</b>	Specifies the best estimate of the number of collisions on this Ethernet segment. The value returned depends on the location of the RMON probe. Section 8.2.1.3 (10BASE-5) and section 10.3.1.3 (10BASE-2) of IEEE standard 802.3 states that a station must detect a collision in the receive mode if three or more stations are transmitting simultaneously. A repeater port must detect a collision when two or more stations transmit simultaneously. Thus, a probe placed on a repeater port can record more collisions than a probe connected to a station on the same segment. Probe location plays a much smaller role when considering 10BASE-T. 14.2.1.4 (10BASE-T) of IEEE standard 802.3 defines a collision as the simultaneous presence of signals on the DO and RD circuits (transmitting and receiving at the same time). A 10BASE-T station can only detect collisions when it is transmitting. Thus, probes placed on a station and a repeater reports the same number of collisions. An RMON probe inside a repeater reports collisions between the repeater and one or more other hosts (transmit collisions as defined by IEEE 802.3k) plus receiver collisions observed on any coax segments to which the repeater is connected.

## View the Protocol Directory

View the protocol directory to see the list of protocols that RMON2 can monitor. You cannot change the list of protocols.

### About This Task

The protocol directory MIB is enabled by default for the predefined protocols.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Protocol Directory**.
3. Click the **Protocol Directories** tab.

### **Protocol Directories** Field Descriptions

The following table defines parameters for the **Protocol Directories** tab.

Name	Description
<b>Index</b>	Shows a unique identifier for the entry in the table.
<b>Protocol</b>	<p>Shows the protocols RMON2 can monitor:</p> <ul style="list-style-type: none"> <li>• Internet Protocol (IP)</li> <li>• Secure Shell version 2 (SSHv2)</li> <li>• Transmission Control Protocol (TCP)</li> <li>• User Datagram Protocol (UDP)</li> <li>• File Transfer Protocol (FTP)</li> <li>• Hypertext Transfer Protocol (HTTP)</li> <li>• Telnet</li> <li>• Remote login (rlogin)</li> <li>• Trivial File Transfer Protocol (TFTP)</li> <li>• Simple Networking Management Protocol (SNMP)</li> </ul> <p><b>Note:</b> RMON2 can count application packets received on a platform, even if the application is not enabled or supported, before dropping them.</p>
<b>AddressMapConfig</b>	<p>Describes and configures the probe support for the network layer and application layer host tables for this protocol. The value can be one of the following:</p> <ul style="list-style-type: none"> <li>• notSupported</li> <li>• supportedOff</li> <li>• supportedOn</li> </ul> <p>If the value is supportedOn, the probe adds entries to the Address Map tab that maps the network layer address to the MAC layer address.</p>
<b>HostConfig</b>	<p>Describes and configures the probe support for the network layer and application layer host tables for this protocol. The value can be one of the following:</p> <ul style="list-style-type: none"> <li>• notSupported</li> <li>• supportedOff</li> <li>• supportedOn</li> </ul> <p>If the value is supportedOn, the probe adds entries to the Host Control tab to collect statistics for network layer and application layer hosts.</p>

Name	Description
<b>MatrixConfig</b>	Describes and configures the probe support for the network layer and application layer host tables for this protocol. The value can be one of the following: <ul style="list-style-type: none"> <li>notSupported</li> <li>supportedOff</li> <li>supportedOn</li> </ul>
<b>Owner</b>	Shows the entity that configured this entry.

## Viewing the Data Source for Protocol Distribution Statistics

View the Distribution Control tab to see the network segment data source on which the protocol distribution statistics are measured. The management IP mentioned as a data source represents the IP that the SNMP agent uses to access the switch.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Protocol Distribution**.
3. Click the **Distribution Control** tab.

### *Distribution Control Field Descriptions*

Use the data in the following table to use the **Distribution Control** tab.

Name	Description
<b>Index</b>	Shows a unique identifier for the entry in the table.
<b>DataSource</b>	Specifies the source of data for this protocol distribution.
<b>DroppedFrames</b>	Shows the total number of frames that the probe receives and drops but does not include in the StatsDropEvents value. This event can occur if the probe is out of resources and sheds the load from this collection. This value does not include packets that were not counted because they had MAC-layer errors.
<b>CreateTime</b>	Shows the value of the sysUpTime when the entry was last activated.
<b>Owner</b>	Shows the entity that configured this entry.

## Viewing Protocol Distribution Statistics

View protocol distribution statistics to see traffic statistics that each protocol generates by local area network (LAN) segment.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Protocol Distribution**.
3. Click the **Distribution Stats** tab.

### *Distribution Stats Field Descriptions*

Use the data in the following table to use the **Distribution Stats** tab.

Name	Description
<b>LocalIndex</b>	Identifies the protocol distribution an entry is part of, as well as the particular protocol that it represents.
<b>Pkts</b>	Shows the number of packets without errors received for this protocol type. This value is the number of link-layer packets so a single, fragmented network-layer packet can increment the counter several times.
<b>Octets</b>	Shows the number of octets in packets received for this protocol type since it was added to the table. This value does not include octets in packets that contained errors. This value counts octets in the entire packet that contained the protocol, not just the particular protocol frames.

## Viewing the Host Interfaces Enabled for Monitoring

View the entries in the address map control tab to see which host interfaces are enabled for monitoring on the switch. Each entry in this table enables the discovery of addresses on a new interface.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Address Map**.
3. Click the **Address Map Control** tab.

### *Address Map Control Field Descriptions*

Use the data in the following table to use the **Address Map Control** tab.

Name	Description
<b>Index</b>	Shows a unique identifier for the entry in the table.
<b>DataSource</b>	Shows the source of data for the entry.
<b>DroppedFrames</b>	Shows the total number of frames that the probe receives and drops but does not include in the StatsDropEvents value. This event can occur if the probe is out of resources and sheds the load from this collection. This value does not include packets that were not counted because they had MAC-layer errors.
<b>Owner</b>	Shows the entity that configured this entry.

## Viewing Address Mappings

View the mappings of network layer address to physical address to interface.

### About This Task

The probe adds entries on this tab based on the source MAC and network addresses in packets without MAC-level errors.

The probe populates this table for all protocols on the **Protocol Directories** tab with a value of **AddressMapConfig** equal to **supportedOn**.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Address Map**.
3. Click the **Address Map** tab.

### Address Map Field Descriptions

Use the data in the following table to use the **Address Map** tab.

Name	Description
<b>LocalIndex</b>	Shows a unique identifier for the entry in the table.
<b>HostAddress</b>	Shows the network address for this entry. The format of the value depends on the protocol portion of the local index.
<b>Source</b>	Shows the interface or port on which the network address was most recently seen.

Name	Description
<b>PhysicalAddress</b>	Shows the physical address on which the network address was most recently seen.
<b>LastChange</b>	Shows the value of the sysUpTime when the entry was created or last changed. If this value changes frequently, it can indicate duplicate address problems.

## Viewing the Data Source for Host Statistics

View the Host Control tab to see the data source for both network layer and application layer host statistics.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Network Layer Host**.
3. Click the **Host Control** tab.

### Host Control Field Descriptions

Use the data in the following table to use the **Host Control** tab.

Name	Description
<b>Index</b>	Shows a unique identifier for the entry in the table.
<b>DataSource</b>	Shows the source of data for the associated host table. The statistics in this group reflect all packets on the local network segment that attaches to the identified interface.
<b>NHDropFrames</b>	Shows the total number of frames that the probe receives and drops but does not include in the StatsDropEvents value. This event can occur if the probe is out of resources and sheds the load from this collection. This value does not include packets that were not counted because they had MAC-layer errors.
<b>AHDropFrames</b>	Shows the total number of frames that the probe receives and drops but does not include in the StatsDropEvents value. This event can occur if the probe is out of resources and sheds the load from this collection. This value does not include packets that were not counted because they had MAC-layer errors.
<b>Owner</b>	Shows the entity that configured this entry.

## Viewing Network Host Statistics

View network host statistics to see Layer 3 traffic statistics for each host. The network layer host MIB monitors traffic packets in and out of hosts based on the network layer address.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Network Layer Host**.
3. Click the **Network Host Stats** tab.

### Network Host Stats Field Descriptions

Use the data in the following table to use the **Network Host Stats** tab.

Name	Description
<b>LocalIndex</b>	Shows a unique identifier for the entry in the table.
<b>HostAddress</b>	Shows the host address for this entry.
<b>InPkts</b>	Shows the number of packets without errors transmitted to this address. This value is the number of link-layer packets so a single, fragmented network-layer packet can increment the counter several times.
<b>OutPkts</b>	Shows the number of packets without errors transmitted by this address. This value is the number of link-layer packets so a single, fragmented network-layer packet can increment the counter several times.
<b>InOctets</b>	Shows the number of octets transmitted to this address, excluding octets in packets that contained errors. This value counts octets in the entire packet that contained the protocol, not just the particular protocol frames.
<b>OutOctets</b>	Shows the number of octets transmitted by this address, excluding octets in packets that contained errors. This value counts octets in the entire packet that contained the protocol, not just the particular protocol frames.
<b>CreateTime</b>	Shows the value of the sysUpTime when the entry was last activated.

## Viewing Application Host Statistics

View application host statistics to see traffic statistics by application protocol for each host.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability > RMON** folders.
2. Click **Application Layer Host**.
3. Click the **Application Host Stats** tab.

### *Application Host Stats Field Descriptions*

Use the data in the following table to use the **Application Host Stats** tab.

Name	Description
<b>Index</b>	Shows a unique identifier for the entry in the table.
<b>HostAddress</b>	Identifies the network layer address of this entry.
<b>LocalIndex</b>	Identifies the network layer protocol of the address.
<b>InPkts</b>	Shows the number of packets for this protocol type, without errors, transmitted to this address. This value is the number of link-layer packets so a single, fragmented network-layer packet can increment the counter several times.
<b>OutPkts</b>	Shows the number of packets for this protocol type, without errors, transmitted by this address. This value is the number of link-layer packets so a single, fragmented network-layer packet can increment the counter several times.
<b>InOctets</b>	Shows the number of octets transmitted to this address, excluding octets in packets that contained errors. This value counts octets in the entire packet that contained the protocol, not just the particular protocol frames.
<b>OutOctets</b>	Shows the number of octets transmitted by this address, excluding octets in packets that contained errors. This value counts octets in the entire packet that contained the protocol, not just the particular protocol frames.
<b>CreateTime</b>	Shows the value of the sysUpTime when the entry was last activated.

## RMON Alarm Variables

RMON alarm variables are divided into three categories. Each category has subcategories.

The following table lists the alarm variable categories and provides a brief variable description.

**Table 221: RMON alarm variables**

Category	Subcategory	Variable	Definition
Security		rcCliNumAccessViolations.0	The number of CLI access violations detected by the system.
		rcWebNumAccessBlocks.0	The number of accesses the web server blocked.
		snmpInBadCommunityNames.0	The total number of SNMP messages delivered to the SNMP protocol entity that represented an SNMP operation not allowed by the SNMP community named in the message.
Errors	Interface	ifInDiscards	The number of inbound packets discarded even though no errors were detected to prevent the packets being deliverable to a higher-layer protocol. One possible reason for discarding a packet is to free buffer space.
		ifInErrors	For packet-oriented interfaces, the number of inbound packets that contained errors preventing them from being deliverable to a higher-layer protocol. For character-oriented or fixed-length interfaces, the number of inbound transmission units that contained errors, preventing them from being deliverable to a higher-layer protocol.
		ifOutDiscards	The number of outbound packets discarded even though no errors were detected to prevent the packets being transmitted. One possible reason for discarding such a packet is to free buffer space.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		ifOutErrors	For packet-oriented interfaces, the number of outbound packets that were not transmitted because of errors. For character-oriented or fixed-length interfaces, the number of outbound transmission units that were not transmitted because of errors.
	Ethernet	dot3StatsAlignmentErrors	A count of frames received on a particular interface that are not an integral number of octets in length and do not pass the Frame Check Sequence (FCS) check. The count represented by an instance of this object increments when the alignmentError status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions exist are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		dot3StatsFCSErrors	A count of frames received on a particular interface that are an integral number of octets in length but do not pass the FCS check. The count represented by an instance of this object increments when the frameCheckError status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions occur are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.
		dot3StatsSingleCollisionFrames	A count of successfully transmitted frames on a particular interface where transmission is inhibited by exactly one collision. A frame that is counted by an instance of this object is also counted by the corresponding instance of either the ifOutUcastPkts object, the ifOutMulticastPkts object, or the ifOutBroadcastPkts object, and is not counted by the corresponding instance of the dot3StatsMultipleCollisionFrames object.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		dot3StatsMultipleCollisionFrames	A count of successfully transmitted frames on a particular interface where transmission is inhibited by more than one collision. A frame that is counted by an instance of this object is also counted by the corresponding instance of either the ifOutUcastPkts, ifOutMulticastPkts, or ifOutBroadcastPkts object, and is not counted by the corresponding instance of the dot3StatsSingleCollisionFrames object.
		dot3StatsSQETestErrors	A count of times that the SQE TEST ERROR message is generated by the PLS sublayer for a particular interface. The SQE TEST ERROR message is defined in section 7.2.2.2.4 of ANSI/IEEE 802.3-1985 and its generation is described in section 7.2.4.6 of the same document.
		dot3StatsDeferredTransmissions	A count of frames for which the first transmission attempt on a particular interface is delayed because the medium is busy. The count represented by an instance of this object does not include frames involved in collisions.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		dot3StatsLateCollisions	The number of times that a collision is detected on a particular interface later than 512 bit-times into the transmission of a packet; 512 bit-times corresponds to 51.2 microseconds on a 10 Mb/s system. A (late) collision included in a count represented by an instance of this object is also considered as a (generic) collision for purposes of other collision-related statistics.
		dot3StatsExcessiveCollisions	A count of frames where the transmission on a particular interface fails due to excessive collisions.
		dot3StatsInternalMacTransmitErrors	A count of frames where the transmission on a particular interface fails due to an internal MAC sublayer transmit error. A frame is only counted by an instance of this object if it is not counted by the corresponding instance of either the dot3StatsLateCollisions object, the dot3StatsExcessiveCollisions object, or the dot3StatsCarrierSenseErrors object. The precise meaning of the count represented by an instance of this object is implementation specific. In particular, an instance of this object can represent a count of transmission errors on a particular interface that are not otherwise counted.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		dot3StatsCarrierSenseErrors	The number of times the carrier sense condition was lost or never asserted when the switch attempted to transmit a frame on a particular interface. The count represented by an instance of this object increments at most once for each transmission attempt, even if the carrier sense condition fluctuates during a transmission attempt.
		dot3StatsFrameTooLongs	A count of frames received on a particular interface that exceeds the maximum permitted frame size. The count represented by an instance of this object increments when the frameTooLong status is returned by the MAC service to the LLC (or other MAC user). Received frames for which multiple error conditions obtained are, according to the conventions of IEEE 802.3 Layer Management, counted exclusively according to the error status presented to the LLC.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		dot3StatsInternalMacReceiveErrors	A count of frames where the transmission on a particular interface fails due to an internal MAC sublayer transmit error. A frame is counted by an instance of this object only if it is not counted by the corresponding instance of either the dot3StatsLateCollisions object, the dot3StatsExcessiveCollisions object, or the dot3StatsCarrierSenseErrors object. The precise meaning of the count represented by an instance of this object is implementation-specific. In particular, an instance of this object can represent a count of transmission errors on a particular interface that are not otherwise counted.
	IP	ipInHdrErrors.0	The number of input datagrams discarded due to errors in the datagram IP headers, including bad checksums, version number mismatch, other format errors, time-to-live exceeded, and errors discovered in processing IP options.
		ipInDiscards.0	The number of discarded input IP datagrams where no problems were encountered to prevent continued processing. An example of why they were discarded can be lack of buffer space. This counter does not include any datagrams discarded while awaiting reassembly.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		ipOutDiscards.0	The number of output IP datagrams where no problems were encountered to prevent transmission to the destination, but that were discarded (for example, for lack of buffer space). This counter includes datagrams counted in ipForwDatagrams if packets meet this (discretionary) discard criterion.
		ipFragFails.0	The number of IP datagrams discarded because they needed to be fragmented at this entity but were not, for example, because the Don't Fragment flag was set.
		ipReasmFails.0	The number of failures detected by the IP reassembly algorithm (for whatever reason: timed out, errors, and so forth). This is not necessarily a count of discarded IP fragments because some algorithms (notably the algorithm in RFC 815) can lose track of the number of fragments by combining them as they are received.
		icmpInParmProbs.0	The number of ICMP In parameter problem messages received.
		icmpOutParmProbs.0	The number of ICMP Out parameter problem messages received.
	MLT	rcStatMltEtherAlignmentErrors	The number of frames received on an MLT that are not an integral number of octets in length, but do not pass the FCS check.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		rcStatMltEtherFCSErrors	The number of frames received on an MLT that are an integral number of octets in length, but do not pass the FCS check.
		rcStatMltEtherSingleCollFrames	The number of successfully transmitted frames on a particular MLT where transmission is inhibited by exactly one collision.
		rcStatMltEtherMultipleCollFrames	The number of successfully transmitted frames on a particular MLT where transmission is inhibited by more than one collision.
		rcStatMltEtherSQETestError	A count of times that the SQE TEST ERROR message is generated by the PLS sublayer for a particular MLT.
		rcStatMltEtherDeferredTransmiss	A count of frames where the first transmission attempt on a particular MLT is delayed because the medium is busy. The count represented by an instance of this object.
		rcStatMltEtherLateCollisions	The number of times that a late collision is detected on a particular MLT later than 512 bit-times into the transmission of a packet; 512-bit-times corresponds to 51.2-microseconds on a 10 Mb/s system.
		rcStatMltEtherExcessiveCollis	The number of times that excessive collisions are detected on a particular MLT later than 512 bit-times into the transmission of a packet; 512 bit-times corresponds to 51.2 microseconds on a 10-Mb/s system.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		rcStatMltEtherMacTransmitError	A count of frames where the transmission on a particular MLT fails due to an internal MAC sublayer transmit error. A frame is only counted by an instance of this object if it is not counted by the corresponding instance of either the LateCollisions object, the ExcessiveCollisions object, or the CarrierSenseErrors object.
		rcStatMltEtherCarrierSenseError	The number of times the carrier sense condition was lost or never asserted when attempting to transmit a frame on a particular MLT. The count represented by an instance of this object increments at most once for each transmission attempt, even if the carrier sense condition fluctuates during a transmission attempt.
		rcStatMltEtherFrameTooLong	A count of frames received on a particular MLT that exceeds the maximum permitted frame size. The count represented by an instance of this object increments when the frameTooLong status is returned by the MAC service to the LLC (or other MAC user).
		rcStatMltEtherMacReceiveError	A count of frames for which reception on a particular MLT fails due to an internal MAC sublayer receive error. A frame is only counted by an instance of this object if it is not counted by the corresponding instance of either the FrameTooLongs object, the AlignmentErrors object, or the FCSErrors object.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
	Other	rcTblArNoSpace	The number of entries not added to the address translation table due to lack of space.
		snmpInAsnParseErrs.0	The total number of ASN.1 or BER errors encountered by the SNMP protocol entity when it decodes received SNMP messages.
		rcStgPortInBadBpdus	The number of bad BPDUs received by this port.
		dot1dTpPortInDiscards	Count of valid frames received that were discarded (that is, filtered) by the forwarding process.
Traffic	Interface	ifInOctets	The total number of octets received on the interface, including framing characters.
		ifInMulticastPkts	The number of packets, delivered by this sublayer to a higher sublayer, that are addressed to a multicast address at this sublayer. For a MAC layer protocol, this number includes both Group and Functional addresses.
		ifInBroadcastPkts	The number of packets, delivered by this sublayer to a higher (sub) layer, that are addressed to a broadcast address at this sublayer.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		ifInUnkownProtos	For packet-oriented interfaces, the number of packets received through the interface that are discarded because of an unknown or unsupported protocol. For character-oriented or fixed-length interfaces that support protocol multiplexing, the number of transmission units received through the interface that are discarded because of an unknown or unsupported protocol. For any interface that does not support protocol multiplexing, this counter is always 0.
		ifOutOctets	The total number of octets transmitted from the interface, including framing characters.
		ifOutMulticastPkts	The total number of packets that higher-level protocols requested be transmitted, and that are addressed to a multicast address at this sublayer, including those that are discarded or not sent. For a MAC layer protocol, this includes both Group and Functional addresses.
		ifoutBroadcastPkts	The total number of packets that higher level protocols requested transmitted, and that were addressed to a broadcast address at this sublayer, including those discarded or not sent.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		ifLastChange	The value of sysUpTime at the time the interface entered its current operational state. If the current state was entered prior to the last reinitialization of the local network management subsystem, this object contains a value of zero.
	RmonEther Stats	etherStatsOctets	The total number of octets of data (including those in bad packets) received on the network (excluding framing bits but including FCS octets). Use this object as a reasonable estimate of Ethernet utilization. For greater precision, sample the etherStatsPkts and etherStatsOctets objects before and after a common interval.
		etherStatsPkts	The total number of packets (including bad packets, broadcast packets, and multicast packets) received.
		etherStatsBroadcastPkts	The total number of good packets received that are directed to the broadcast address. This number does not include multicast packets.
		etherStatsMulticastPkts	The total number of good packets received that are directed to a multicast address. This number does not include packets directed to the broadcast address.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		etherStatsCRCAAlignErrors	The total number of packets received that had a length (excluding framing bits, but including FCS octets) of 64 to 1518 octets, inclusive, but had either a bad Frame Check Sequence (FCS) with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error).
		etherStatsUndersizePkts	The total number of packets received that are less than 64 octets long (excluding framing bits, but including FCS octets) and were otherwise well formed.
		etherStatsOversizePkts	The total number of packets received that are longer than 1518 octets (excluding framing bits, but including FCS octets) and were otherwise well formed.
		etherStatsFragments	The total number of packets received that are less than 64 octets in length (excluding framing bits but including FCS octets) and had either a bad Frame Check Sequence (FCS) with an integral number of octets (FCS Error) or a bad FCS with a nonintegral number of octets (Alignment Error). It is entirely normal for etherStatsFragments to increment because it counts both runts (which are normal occurrences due to collisions) and noise hits.
		etherStatsCollisions	The best estimate of the total number of collisions on this Ethernet segment.
	IP	ipInReceives.0	All incoming IP packets.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		ipInAddrErrors.0	The number of bad IP destination addresses.
		ipForwDatagrams.0	IP packets forwarded.
		ipInUnknownProtos.0	Number of unsupported IP protocols.
		ipInDelivers.0	The number of IP In packets delivered.
		ipOutRequests.0	The total number of IP datagrams that local IP user protocols supplied to IP in request for transmission.
		ipOutNoRoutes.0	The number of IP datagrams discarded because no route was found to transmit to the destination.
		ipFragOKs.0	The number of IP datagrams successfully fragmented.
		ipFragCreates.0	The number of IP datagram fragments generated as a result of fragmentation.
		ipReasmReqds.0	The number of requests to reassemble fragments.
		ipReasmOKs.0	The number of fragments reassembled successfully.
	ICMP	icmplnSrcQuenchs.0	The number of ICMP Source Quench messages received.
		icmplnRedirects.0	The number of ICMP redirect messages.
		icmplnEchos.0	The number of ICMP Echo requests messages received.
		icmplnEchosReps.0	The number of ICMP Echo reply messages received.
		icmplnTimeStamps.0	The number of ICMP timestamp request messages received.
		icmplnTimeStampsReps.0	The number of ICMP timestamp reply messages received.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		icmpInAddrMasks.0	The number of ICMP mask request messages reviewed.
		icmpInAddrMasksReps.0	The number of ICMP mask reply messages reviewed.
		icmpInDestUnreachs.0	The number of ICMP destinations unreachable messages received.
		icmpInTimeExcds.0	The number of ICMP Time Exceeded messages received.
		icmpOutSrcQuenchs.0	The number of ICMP Source Quench messages sent.
		icmpOutRedirects.0	The number of ICMP redirect messages sent.
		icmpOutEchos.0	The number of ICMP Echo request messages sent.
		icmpOutEchosReps.0	The number of ICMP Echo reply messages sent.
		icmpOutTimeStamps.0	The number of ICMP Timestamp request messages sent.
		icmpOutTimeStampsReps.0	The number of ICMP Timestamp reply messages sent.
		icmpOutAddrMasks.0	The number of ICMP Address mask messages sent.
		icmpOutAddrMasksReps.0	The number of ICMP Address mask reply messages sent.
		icmpOutDestUnreachs.0	The number of ICMP destination unreachable messages sent.
		icmpOutTimeExcds.0	The number of ICMP time exceeded messages sent.
	Snmp	snmpInPkts.0	The total number of messages delivered to the SNMP entity from the transport service.
		snmpOutPkts.0	The total number of SNMP messages passed from the SNMP protocol entity to the transport service.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		snmpInBadVersions.0	The total number of SNMP messages delivered to the SNMP protocol entity that were intended for an unsupported SNMP version.
		snmpInBadCommunityUses.0	The total number of SNMP messages delivered to the SNMP protocol entity that represented an SNMP operation that was not allowed by the SNMP community named in the message.
		snmpInTooBigs.0	The total number of SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is tooBig.
		snmpInNoSuchNames.0	The total number of SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is noSuchName.
		snmpInBadValues. 0	The total number of SNMP PDUs received that were generated by the SNMP protocol entity and for which the value of the error-status field is badValue.
		snmpInReadOnlys.0	The total number of valid SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is readOnly. It is a protocol error to generate an SNMP PDU that contains the value readOnly in the error-status field; as such, this object is provided as a means of detecting incorrect implementations of the SNMP.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		snmpInGenErrs.0	The total number of SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is genErr.
		snmpInTotalReqVars.0	The total number of MIB objects retrieved successfully by the SNMP protocol entity as the result of receiving valid SNMP Get-Request and Get-Next PDUs.
		snmpInTotalSetVars.0	The total number of MIB objects altered successfully by the SNMP protocol entity as the result of receiving valid SNMP Set-Request PDUs.
		snmpInGetRequests.0	The total number of SNMP Get-Request PDUs accepted and processed by the SNMP protocol entity.
		snmpInGetNexts.0	The total number of SNMP Get-Next PDUs accepted and processed by the SNMP protocol entity.
		snmpInSetRequests.0	The total number of SNMP Set-Request PDUs accepted and processed by the SNMP protocol entity.
		snmpInGetResponses.0	The total number of SNMP Get-Response PDUs accepted and processed by the SNMP protocol entity.
		snmpInTraps.0	The total number of SNMP Trap PDUs accepted and processed by the SNMP protocol entity.
		snmpOutTooBig.0	The total number of SNMP PDUs generated by the SNMP protocol entity and for which the value of the error-status field is tooBig.
		snmpOutNoSuchNames.0	The total number of SNMP PDUs generated by the SNMP protocol entity and for which the value of the error-status field is noSuchName.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		snmpOutBadValues.0	The total number of SNMP PDUs sent that were generated by the SNMP protocol entity and for which the value of the error-status field is badValue.
		snmpOutGenErrs.0	The total number of SNMP PDUs generated by the SNMP protocol entity and for which the value of the error-status field is genErr.
		snmpOutGetRequests.0	The total number of SNMP Get-Request PDUs generated by the SNMP protocol entity.
		snmpOutGetNexts.0	The total number of SNMP Get-Next PDUs generated by the SNMP protocol entity.
		snmpOutSetRequests.0	The total number of SNMP Set-Request PDUs generated by the SNMP protocol entity.
		snmpOutGetResponses.0	The total number of SNMP Get-Response PDUs generated by the SNMP protocol entity.
		snmpOutTraps.0	The total number of SNMP Trap PDUs generated by the SNMP protocol entity.
	Bridge	rcStgTimeSinceTopologyChange	The time (in hundredths of a second) since the last topology change was detected by the bridge entity.
		rcStgTopChanges	The total number of topology changes detected by this bridge since the management entity was last reset or initialized.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		rcStgMaxAge	The maximum age of Spanning Tree Protocol information learned from the network on any port before it is discarded, in hundredths of a second. This is the actual value that this bridge is currently using.
		rcStgPortForwardTransitions	The number of times this port transitioned from the Learning state to the Forwarding state.
		rcStgPortInConfigBpdus	The number of Config BPDUs received by this port.
		rcStgPortInTcnBpdus	The number of Topology Change Notification BPDUs received by this port.
		rcStgPortOutConfigBpdus	The number of Config BPDUs transmitted by this port.
		rcStgPortOutTcnBpdus	The number of Topology Change Notification BPDUs transmitted by this port.
		dot1dTpPortInFrames	The number of frames received by this port from its segment. A frame received on the interface corresponding to this port is counted by this object only if it is for a protocol being processed by the local bridging function, including bridge management frames.
		dot1dTpPortOutFrames	The number of frames transmitted by this port to its segment. A frame transmitted on the interface corresponding to this port is counted by this object if and only if it is for a protocol processed by the local bridging function, including bridge management frames.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		dot1dTpLearnedEntryDiscards.0	The total number of Forwarding Database entries learned but discarded due to a lack of space to store them in the Forwarding Database. If this counter increases, it indicates that the forwarding database is regularly becoming full (a condition that has negative performance effects on the subnetwork). If this counter has a significant value but does not increase, it indicates that the problem occurred but is not persistent.
	Utilization	rcSysBufferUtil.0	Buffer utilization as a percentage of the total amount of buffer space in the system. A high value indicates congestion.
		rcSysNVRamUsed.0	Nonvolatile RAM (NVRAM) in use in kilobytes.
		rcSysLastChange.0	Last management-initiated configuration change since sysUpTime.
		rcSysLastVlanChange.0	Last management-initiated VLAN configuration change since sysUpTime.
	MLT	rcStatMltIfExtnIfInMulticastPkts	The total number of multicast packets delivered to this MLT interface.
		rcStatMltIfExtnIfInBroadcastPkts	The total number of broadcast packets delivered to this MLT Interface.
		rcStatMltIfExtnIfOutMulticastPkts	The total number of MLT interface multicast packets delivered to this MLT interface.
		rcStatMltIfExtnIfOutBroadcastPkts	The total number of MLT interface broadcast packets delivered to this MLT interface.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		rcStatMltIfExtnIfHCInOctets	The total number of octets received on this MLT interface including framing characters detected by the high-count (64-bit) register.
		rcStatMltIfExtnIfHCInUcastPkts	The number of packets delivered by this MLT interface to a higher MLT that were not addressed to a multicast or broadcast address as detected by the high-count (64-bit) register.
		rcStatMltIfExtnIfHCInMulticastPkt	The total number of multicast packets delivered to this MLT interface detected by the high-count (64-bit) register.
		rcStatMltIfExtnIfHCInBroadcastPkt	The total number of broadcast packets delivered to this MLT interface detected by the high-count (64-bit) register.
		rcStatMltIfExtnIfHCOutOctets	The total number of octets transmitted from the MLT interface, including framing characters.
		rcStatMltIfExtnIfHCOutUcastPkts	The number of packets transmitted by this MLT interface to a higher MLT that were not addressed to a multicast or broadcast address as detected by the high-count (64-bit) register.

**Table 221: RMON alarm variables (continued)**

Category	Subcategory	Variable	Definition
		rcStatMltIfExtnIfHCOutMulticast	The total number of packets that higher-level protocols requested be transmitted, and that were addressed to a multicast address at this sublayer, including those that were discarded or not sent registered by the high-count (64-bit) register.
		rcStatMltIfExtnIfHCOutBroadcast	The total number of packets that higher-level protocols requested be transmitted, and that were addressed to a broadcast address at this sublayer, including those that were discarded or not sent registered by the high-count (64-bit) register.

**Note**

In addition to these elements that are offered in a graphical way by EDM, you can manually set any valid OID in the variable field to be monitored by an alarm. For these cases, the name of the variable cannot be translated automatically in OID, the exact OID must be set as a sequence of numbers.

	XA1400 Series	VOSS 8.0.50

## Route Filtering and IP Policies

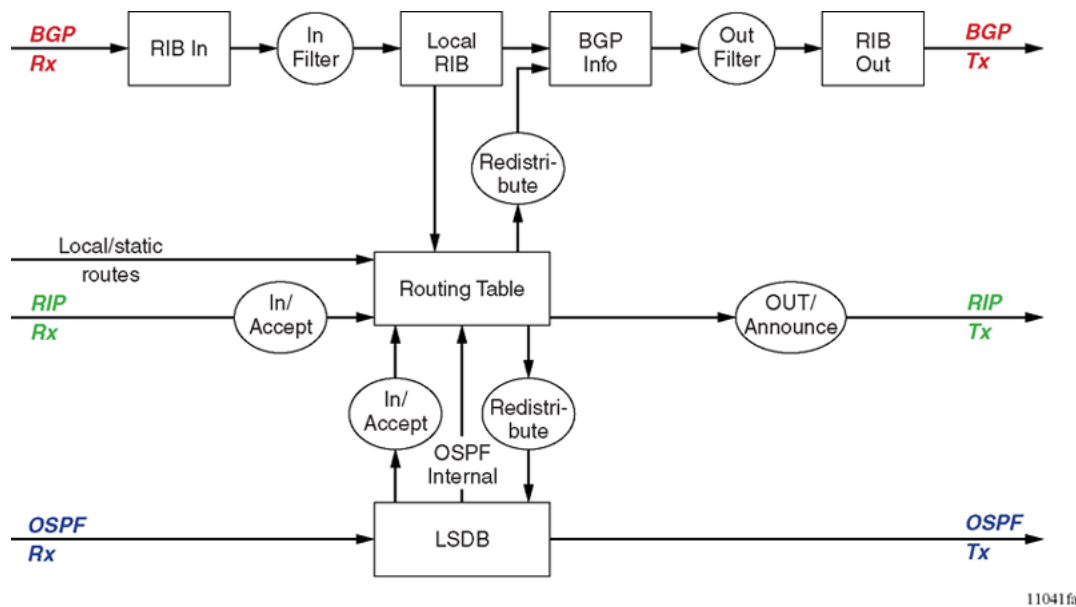

When the switch routes IP traffic, you can apply a number of filters to manage, accept, redistribute, and announce policies for unicast routing table information. Filters apply differently to different unicast routing protocols.

### Note

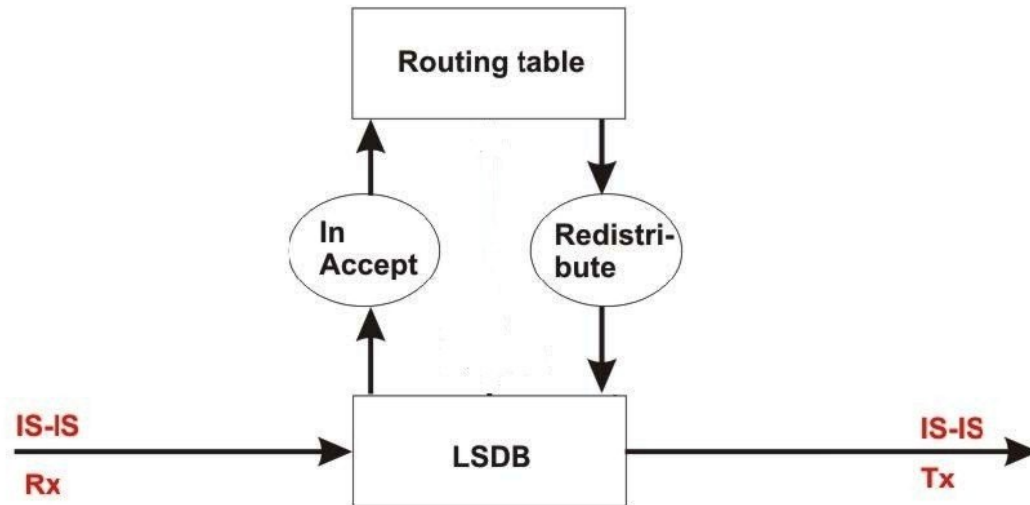

IPv6 ingress QoS ACL/Filters and IPv6 Egress Security and QoS ACL/Filters are not supported. For information on the maximum number of IPv6 ingress port/vlan security ACL/filters supported on the switch, see [VOSS Release Notes](#).

The following figure shows how filters apply to BGP, RIP, and OSPF protocols.

**Figure 230: Route filtering for BGP, RIP, and OSPF routing protocols**

The following figure shows how filters apply to the IS-IS protocol for Fabric Connect Layer 3 VSNs or IP Shortcuts.

**Figure 231: Route filtering for the IS-IS routing protocol**

## Accept Policies

Accept policies are applied to incoming traffic to determine whether to add the route to the routing table. Accept policies are applied differently to protocols, as follows:

- RIP and BGP—filters apply to all incoming route information.
- OSPF—filters apply only to external route information. Internal routing information is not filtered because otherwise, other routers in the OSPF domain can have inconsistent databases that can affect the router view of the network topology.
- IS-IS —filters apply to all incoming route information.

In a network with multiple routing protocols, you can prefer specific routes from RIP instead of from OSPF. The network prefix is a commonly used match criterion for accept policies.

## Redistribution Filters

Redistribution filters notify changes in the route table to the routing protocol (within the device). With redistribution filters, providing you do not breach the protocol rules, you can choose not to advertise everything that is in the protocol database, or you can summarize or suppress route information. By default, no external routes are leaked to protocols that are not configured.

## Announce Policies

Announce policies are applied to outgoing advertisements to neighbors or peers in the protocol domain to determine whether to announce specific route information. Out filtering applies to RIP updates and BGP NLRI updates.

In contrast, announce policies are not applied to IS-IS or OSPF information because routing information must always be consistent across the domain. To restrict the flow of external route information in the IS-IS or OSPF protocol database, apply redistribution filters instead of announce policies.

## Route Filtering Stages

The following figure shows the three distinct filter stages that are applied to IP traffic.

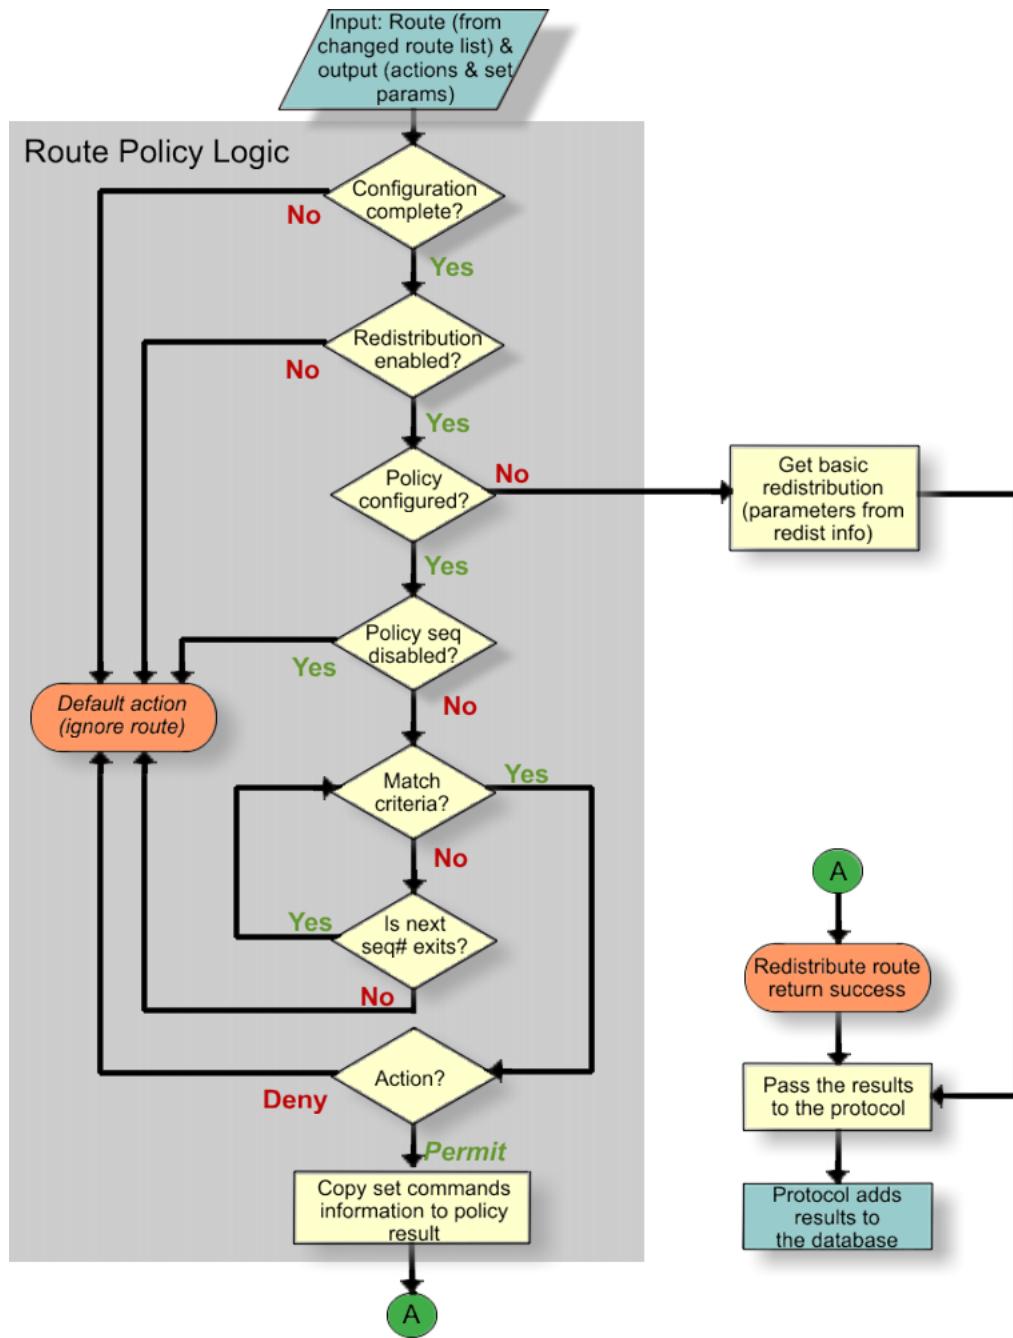

These stages are:

- Filter stage 1 is the accept policy or in filter that applies to incoming traffic to detect changes in the dynamic (protocol-learned) routing information, which are then submitted to the routing table.
- Filter stage 2 is the redistribution filter that applies to the entries in the routing table to the protocol during the leaking process.
- Filter stage 3 is the announce policy or out filter that applies to outgoing traffic within a protocol domain.

**Figure 232: Route filtering stages**

The following figure shows the logical process for route filtering on the switch.

**Figure 233: Route filtering logic**

## Prefix list

In the switch software, you can create one or more IP prefix lists and apply these lists to IP route policy.

## Route Policy Definition

---

You can define an IP route policy and its attributes globally, and then apply them individually to interfaces and protocols. You can also form a unified database of route policies that the RIP or OSPF protocol can use for type of filtering purpose. A name or ID identifies a policy.

Under a policy you can have several sequence numbers. If you do not configure a field in a policy, the system displays the field as 0 in CLI show command output. This value indicates that the device ignores the field in the match criteria. Use the clear option to remove existing configurations for the field.

Each policy sequence number contains a set of fields. Only a subset of those fields is used when the policy is applied in a certain context. For example, if a policy has a configured set-preference field, it is used only when the policy is applied for accept purposes. This field is ignored when the policy is applied for announce or redistribute purposes.

You can only apply one policy for each purpose (RIP Announce, for example) on a given RIP interface. In this case, all sequence numbers under the policy apply to that filter. A sequence number also acts as an implicit preference; a lower sequence number is preferred.

The following tables display the accept, announce, and redistribute policies for RIP, OSPF, IS-IS and BGP. The tables also display which matching criteria apply for a certain routing policy. In these tables, 1 denotes advertise router, 2 denotes RIP gateway, and 3 denotes that external type 1 and external type 2 are the only options.

### Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

**Note**

IPv4 and IPv6 route-maps cannot be configured on the same match statement.

## IP policy configuration using the CLI

Configure IP policies to form a unified database of route policies that Routing Information Protocol (RIP) or Open Shortest Path First (OSPF) can use for filtering tasks.

A policy is identified by a name or an ID. Under a given policy you can have several sequence numbers, each of which is equal to one policy in the old convention. Each policy sequence number contains a set of fields. Only a subset of those fields is used when the policy is applied in a certain context. For example, if a policy has a configured set-preference field, use only when the policy is applied for accept purposes. This field is ignored when the policy is applied for announce and redistribute purposes.

You can apply one policy for one purpose, for example, RIP announce on a RIP interface. All sequence numbers under the given policy apply to that filter. A sequence number also acts as an implicit preference; a lower sequence number is preferred.

### Configuring prefix lists

Configure a prefix list to allow or deny specific route updates. A prefix list policy specifies route prefixes to match. After a match occurs, the system uses the route.

The prefix list contains a set of contiguous or noncontiguous routes. Reference prefix lists by name from within a routing policy.

#### About This Task

##### Important

When you configure a prefix list for a route policy, add the prefix as a.b.c.d/32. You must enter the full 32-bit mask to exact a full match of a specific IP address.

You configure prefix lists on a VRF instance the same way you configure the GlobalRouter, except that you must use VRF Router Configuration mode.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure a prefix list:
 

```
ip prefix-list WORD<1-64> {A.B.C.D/X} [ge <0-32>] [id <1-2147483647>]
[le <0-32>]
```
3. (Optional) Rename an existing prefix list:
 

```
ip prefix-list WORD<1-64> name WORD<1-64>
```
4. Display the prefix list:
 

```
show ip prefix-list [prefix {A.B.C.D}] [vrf WORD<1-16>] [vrfids
WORD<0-512>] [WORD <1-64>]
```

### Example

Configure a prefix-list. Display the prefix list.

```
Switch> enable
Switch# configure terminal
Switch(config)# ip prefix-list LIST1 192.0.2.1/255.255.255.0
Switch(config)# show ip prefix-list LIST1
=====
                          Prefix List - GlobalRouter
=====

```

	PREFIX	MASKLEN	FROM	TO
List 1	LIST1:			
	192.0.1.2.1	24	24	24

```
1 Total Prefix List entries configured
=====
Name Appendix for Lists Converted from Old Config:
@A=conv addr list, @N=conv net list, @NR=conv net list modified as range
```

## Variable definitions

The following table defines parameters for the **ip prefix-list** command.

Variable	Value
<i>{A.B.C.D/X}</i>	Specifies the IP address and the mask in one of the following formats: <ul style="list-style-type: none"> <li>• a.b.c.d/x</li> <li>• a.b.c.d/x.x.x.x</li> <li>• default</li> </ul>
<i>ge &lt;0-32&gt;</i>	Specifies the minimum length to match. Lower bound and higher bound mask lengths together can define a range of networks.
<i>id &lt;1-2147483647&gt;</i>	Specifies the Prefix list ID.
<i>le &lt;0-32&gt;</i>	Specifies the maximum length to match. Lower bound and higher bound mask lengths together can define a range of networks.
<i>name WORD&lt;1-64&gt;</i>	Renames the specified prefix list. The name length is 1-64 characters.
<i>WORD&lt;1-64&gt;</i>	Specifies the name for a new prefix list.

Use the data in the following table to use the **show ip prefix-list** command.

Variable	Value
<i>{A.B.C.D}</i>	Specifies the prefix to include in the command output.
<i>vrf WORD&lt;1-16&gt;</i>	Specifies the name of the VRF.
<i>vrfids WORD&lt;0-512&gt;</i>	Specifies the ID of the VRF and is an integer in the range of 0-512.
<i>WORD&lt;1-64&gt;</i>	Specifies a prefix list, by name, to use for the command output.

The following table defines parameters for the **show ip prefix-list** command output.

Variable	Value
PREFIX	Indicates the member of a specific prefix list.
MASKLEN	Indicates the prefix mask length in bits.
FROM	Indicates the prefix mask starting point in bits.
TO	Indicates the prefix mask endpoint in bits.

## Configure IP Route Policies

Configure a route policy so that the device can control routes that certain packets can take. For example, you can use a route policy to deny certain Border Gateway Protocol (BGP) routes.

The route policy defines the matching criteria and the actions taken if the policy matches.

### About This Task

After you create and enable the policy, you can apply it to an interface. You can apply one policy for one purpose, for example, RIP Announce, on a given RIP interface. In this case, all sequence numbers under the given policy apply to that filter.

Create and enable the policy for IS-IS accept policies for Fabric Connect for Layer 3 Virtual Services Networks (VSNs) and IP Shortcuts, then apply the IS-IS accept policy filters.

#### Note

After you configure route-map in Global Configuration mode or VRF Router Configuration mode, the device enters Route-Map Configuration mode, where you configure the action the policy takes, and define other fields the policy enforces.

#### Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

#### Note

You cannot configure IPv4 and IPv6 route-maps on the same match statement.

### About This Task

## Procedure

1. Enter Route-Map Configuration mode:

```
enable
```

```
configure terminal
```

```
route-map WORD<1-64> <1-65535>
```

2. At the route-map prompt, define the match criteria for the policy:

```
match {as-path WORD<0-256> | community WORD<0-256> | community-
exact enable | extcommunity WORD<0-1027> | interface WORD<0-259> |
local-preference <0-2147483647> | metric <0-65535> | metric-type-isis
<any|internal|external> | multicast-group WORD<0-259> | multicast-
source WORD<0-259> | network WORD<0-259> | next-hop WORD<0-259> |
protocol WORD<0-60> | route-source WORD<0-259> | route-type <any|
local|internal|external|external-1|external-2> | tag WORD<0-256> | vrf
WORD<1-16> | vrfids WORD<0-512> }
```

3. Define the action the policy takes:

- Allow the route:

```
permit
```

- Ignore the route:

```
no permit
```

4. Define the set criteria for the policy:

```
set {as-path WORD<0-256> | as-path-mode <tag|prepend> | automatic-
tag enable | community WORD<0-256> | community-mode <additive|none|
unchanged> | data-isid <1-15999999> | injectlist WORD<0-1027> | ip-
preference <0-255> | local-preference <0-2147483647> | mask <A.B.C.D>
| metric <0-65535> | metric-type <type1|type2> | metric-type-internal
<0-1> | metric-type-isis <none|internal|external> | metric-type-live-
metric | next-hop WORD<0-256> | nssa-pbit enable | origin <igp|egp|
incomplete> | origin-egp-as <0-65535> | rx-only | tag WORD<0-256> | tx-
only | weight <0-65535> }
```

5. Display current information about the IP route policy:

```
show route-map [WORD<1-64>] [<1-65535>] [vrf WORD<1-16>] [vrfids
WORD<0-512>]
```

## Example

Enter Route-Map Configuration mode. At the route-map prompt, define the fields the policy enforces. Define the action the policy takes. Display current information about the IP route policy.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#route-map RedisStatic 1
Switch:1(route-map)# match metric 0
Switch:1(route-map)# permit
Switch:1(route-map)# show route-map RedisStatic
=====
Route Policy - GlobalRouter
```

NAME	SEQ	MODE	EN
RedisStatic	1	PRMT	DIS

### Variable Definitions

The following table defines the parameters for the **match** command.

Variable	Value
<code>as-path WORD&lt;0-256&gt;</code>	Configures the device to match the as-path attribute of the Border Gateway Protocol (BGP) routes against the contents of the specified AS-lists. This field is used only for BGP routes and ignored for all other route types. <i>WORD &lt;0-256&gt;</i> specifies the list IDs of up to four AS-lists, separated by a comma. Use the <b>no</b> operator to disable match as-path: <code>no match as-path WORD&lt;0-256&gt;</code>
<code>community WORD&lt;0-256&gt;</code>	Configures the device to match the community attribute of the BGP routes against the contents of the specified community lists. This field is used only for BGP routes and ignored for all other route types. <i>WORD &lt;0-256&gt;</i> specifies the list IDs of up to four defined community lists, separated by a comma. Use the <b>no</b> operator to disable match community: <code>no match community WORD&lt;0-256&gt;</code>
<code>community-exact enable</code>	When disabled, configures the device so match community-exact results in a match when the community attribute of the BGP routes match an entry of a community-list specified in match-community. When enabled, configures the device so match-community-exact results in a match when the community attribute of the BGP routes matches all of the entries of all the community lists specified in match-community. <i>enable</i> enables match community-exact. Use the <b>no</b> operator to disable match community-exact: <code>no match community-exact enable</code>
<code>extcommunity WORD &lt;0-1027&gt;</code>	Configures the device to match the extended community. <i>WORD&lt;0-1027&gt;</i> specifies an integer value from 1–1027 that represents the community list ID you want to create or modify.

Variable	Value
<code>interface WORD &lt;0-259&gt;</code>	If configured, configures the device to match the IP address of the interface by which the RIP route was learned against the contents of the specified prefix list. This field is used only for RIP routes and ignored for all other route types. <code>WORD &lt;0-259&gt;</code> specifies the name of up to four defined prefix lists, separated by a comma. Use the <b>no</b> operator to disable match-interface: <code>no match interface WORD &lt;0-259&gt;</code>
<code>local-preference &lt;0-2147483647&gt;</code>	Configures the device to match the local preference, applicable to all protocols. <code>&lt;0-2147483647&gt;</code> specifies the preference value.
<code>metric &lt;0-65535&gt;</code>	Configures the device to match the metric of the incoming advertisement or existing route against the specified value. If 0, this field is ignored. <code>&lt;0-65535&gt;</code> specifies the metric value. The default is 0.
<code>multicast-group WORD&lt;0-259&gt;</code>	Configures the device to match the multicast destination group address for the routed multicast policy. <code>WORD&lt;0-259&gt;</code> specifies the name of one or more prefix lists, separated by a comma..
<code>multicast-source WORD&lt;0-259&gt;</code>	Configures the device to match the multicast source address for the routed multicast policy. <code>WORD&lt;0-259&gt;</code> specifies the name of one or more prefix lists, separated by a comma..
<code>network WORD &lt;0-259&gt;</code>	Configures the device to match the destination network against the contents of the specified prefix lists. <code>WORD &lt;0-259&gt;</code> specifies the name of up to four defined prefix lists, separated by a comma. Use the <b>no</b> operator to disable match network: <code>no match network WORD &lt;0-259&gt;</code>
<code>next-hop WORD&lt;0-259&gt;</code>	Configures the device to match the next-hop IP address of the route against the contents of the specified prefix list. This field applies only to nonlocal routes. <code>WORD &lt;0-259&gt;</code> specifies the name of up to four defined prefix lists, separated by a comma. Use the <b>no</b> operator to disable match next hop: <code>no match next-hop WORD&lt;0-259&gt;</code>
<code>protocol WORD&lt;0-60&gt;</code>	Configures the device to match the protocol through which the route is learned. <code>WORD &lt;0-60&gt;</code> is  xxx, where xxx is local, ospf, ebgp, ibgp,isis, rip, static, or a combination separated by  . Use the <b>no</b> operator to disable match protocol: <code>no match protocol WORD&lt;0-60&gt;</code>

Variable	Value
<code>route-source WORD&lt;0-259&gt;</code>	Configures the system to match the next-hop IP address for RIP routes and advertising router IDs for OSPF routes against the contents of the specified prefix list. This option is ignored for all other route types. <code>WORD &lt;0-259&gt;</code> specifies the name of up to four defined prefix lists, separated by a comma. Use the <b>no</b> operator to disable match route source: <code>no match route-source WORD&lt;0-259&gt;</code>
<code>route-type {any local internal external external-1 external-2}</code>	Configures a specific route type to match (applies only to OSPF routes). <code>any local internal external external-1 external-2</code> specifies OSPF routes of the specified type only (External-1 or External-2). Another value is ignored.
<code>tag WORD&lt;0-256&gt;</code>	Specifies a list of tags used during the match criteria process. Contains one or more tag values. <code>WORD&lt;0-256&gt;</code> is a value from 0-256.
<code>[vrf WORD&lt;1-16&gt;] [vrfids WORD&lt;0-512&gt;]</code>	Configures a specific VRF to match (applies only to RIP routes).

Use the data in the following table to use the **set** command.

Variable	Value
<code>as-path WORD&lt;0-256&gt;</code>	Configures the device to add the AS number of the AS-list to the BGP routes that match this policy. <code>WORD&lt;0-256&gt;</code> specifies the list ID of up to four defined AS-lists separated by a comma. Use the <b>no</b> operator to delete the AS number: <code>no set as-path WORD&lt;0-256&gt;</code>
<code>as-path-mode &lt;tag prepend&gt;</code>	Configures the AS path mode. Prepend is the default configuration. The device prepends the AS number of the AS-list specified in <code>set-as-path</code> to the old <code>as-path</code> attribute of the BGP routes that match this policy. <b>Note:</b> Prepend is not applicable to an internal BGP (iBGP) peer with outbound route policy. For more information about iBGP, see <a href="#">BGP</a> on page 430.
<code>automatic-tag enable</code>	Configures the tag automatically. Used for BGP routes only. Use the <b>no</b> operator to disable the tag: <code>no set automatic-tag enable</code>

Variable	Value
<code>community WORD&lt;0-256&gt;</code>	Configures the device to add the community number of the community list to the BGP routes that match this policy. <i>WORD</i> <0-256> specifies the list ID of up to four defined community lists separated by a comma. Use the <b>no</b> operator to delete the community number: <code>no set community WORD&lt;0-256&gt;</code>
<code>community-mode &lt;additive none unchanged&gt;</code>	Configures the community mode. <i>additive</i> —the device prepends the community number of the community list specified in <code>set-community</code> to the old community path attribute of the BGP routes that match this policy. <i>none</i> —the device removes the community path attribute of the BGP routes that match this policy to the specified value.
<code>data-isid</code>	Configures the data service instance identifier (I-SID) for routed multicast policy.
<code>injectlist WORD&lt;0-1027&gt;</code>	Configures the device to replace the destination network of the route that matches this policy with the contents of the specified prefix list. <i>WORD</i> <0-1027> specifies one prefix list by name. Use the <b>no</b> operator to disable set injectlist: <code>no set injectlist</code>
<code>ip-preference &lt;0-255&gt;</code>	Configures the preference. This applies to accept policies only. <0-255> is the range you can assign to the routes.
<code>local-preference &lt;0-65535&gt;</code>	Configures the device to match the local preference, applicable to all protocols. <0-65535> specifies the preference value.
<code>mask &lt;A.B.C.D&gt;</code>	Configures the mask of the route that matches this policy. This applies only to RIP accept policies. <i>A.B.C.D</i> is a valid contiguous IP mask. Use the <b>no</b> operator to disable set mask: <code>no set mask</code>
<code>metric &lt;0-65535&gt;</code>	Configures the metric value for the route while announcing a redistribution. The default is 0. If the default is configured, the original cost of the route is advertised into OSPF for RIP, the original cost of the route or default-import-metric is used (applies to IS-IS routes also).
<code>metric-type {type1 type2}</code>	Configures the metric type for the routes to announce into the OSPF domain that matches this policy. The default is type 2. This field is applicable only for OSPF announce policies.
<code>metric-type-internal &lt;0-1&gt;</code>	Configures the MED value for routes advertised to ebgp nbrs to the IGP metric value. <0-1> specifies the metric type internal.

Variable	Value
<code>metric-type-isis &lt;none   internal   external&gt;</code>	Configures the metric type for IS-IS routes. The default is none. This field is applicable only for IS-IS policies.
<code>metric-type-live-metric</code>	Configures the metric type for BGP routes. The default is disabled. This field is applicable only for BGP policies.
<code>next-hop WORD &lt;1-256&gt;</code>	Specifies the IP address of the next-hop router. Both IPv4 and IPv6 addresses are supported. Use the <b>no</b> operator to disable set next-hop: <code>no set next-hop</code>
<code>nssa-pbit enable</code>	Configures the not so stubby area (NSSA) translation P bit. Applicable to OSPF announce policies only. Use the <b>no</b> operator to disable set nssa-pbit: <code>no set nssa-pbit enable</code>
<code>origin {igp egp incomplete}</code>	Configures the device to change the origin path attribute of the BGP routes that match this policy to the specified value.
<code>origin-egp-as &lt;0-65535&gt;</code>	Indicates the remote autonomous system number. Applicable to BGP only.
<code>rx-only</code>	Configures the rx only for routed multicast policy.
<code>tag &lt;0-65535&gt;</code>	Configures the tag of the destination routing protocol. If not specified, the device forwards the tag value in the source routing protocol. A value of 0 indicates that this parameter is not configured.  <b>Note:</b> This parameter is not supported on all hardware platforms.
<code>tx-only</code>	Configures the tx only for routed multicast policy.
<code>weight &lt;0-65535&gt;</code>	Configures the weight value for the routing table. For BGP, this value overrides the weight configured through NetworkTableEntry, FilterListWeight, or NeighborWeight. Used for BGP only. A value of 0 indicates that this parameter is not configured.

Use the data in the following table to use the **name** command.

Variable	Value
<code>WORD&lt;1-64&gt;</code>	Renames a policy and changes the name field for all sequence numbers under the given policy.

## Configure a Policy to Accept External Routes from a Router

Perform this procedure to configure a policy to accept external routes from a specified advertising router.

### Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

### Procedure

1. Enter OSPF Router Configuration mode:

```
enable  
  
configure terminal  
  
router ospf
```

2. Create a policy to accept external routes from a specified advertising route:

```
accept adv-rtr <A.B.C.D>
```

3. Exit to the Privileged EXEC mode.

```
exit
```

4. Apply the OSPF accept policy change:

```
ip ospf apply accept adv-rtr <A.B.C.D>
```

5. Confirm your configuration:

```
show ip ospf accept
```

### Example

Log on to the OSPF Router Configuration mode:

```
Switch:1>enable  
Switch:1#configure terminal  
Switch:1(config)#router ospf
```

Create a policy to accept external routes from a specified advertising route:

```
Switch:1(config-ospf)#accept adv-rtr 192.0.2.122
```

Enable an OSPF accept entry for a specified advertising route:

```
Switch:1(config-ospf)#accept adv-rtr 192.0.2.122 enable
```

Exit to the Privileged EXEC mode:

```
Switch:1(config-ospf)#exit
Switch:1(config)#exit
```

Apply the OSPF accept policy change and confirm your configuration:

```
Switch:1#ip ospf apply accept adv-rtr 192.0.2.122
Switch:1#show ip ospf accept
=====
                        Ospf Accept - GlobalRouter
=====
ADV_RTR          MET_TYPE ENABLE POLICY
-----
192.0.2.122     -          FALSE
```

### Variable definitions

Use the data in the following table to use the **accept adv-rtr** command.

Variable	Value
<A.B.C.D>	Specifies the IP address.
<i>enable</i>	Enables an OSPF accept entry for a specified advertising router. Use the <b>no</b> operator to disable an OSPF accept entry: <code>no accept adv-rtr &lt;A.B.C.D&gt; enable</code>
<i>metric-type {type1 type2 }</i>	Indicates the OSPF external type. This parameter describes which types of OSPF external routes match this entry. <i>metric-type</i> means match all external routes. <i>type1</i> means match external type 1 only. <i>type2</i> means match external type 2 only. Use the <b>no</b> operator to disable metric-type: <code>no ip ospf accept adv-rtr &lt;A.B.C.D&gt; metric-type</code>
<i>route-map WORD&lt;0-64&gt;</i>	Specifies the name of the route policy to use for filtering external routes advertised by the specified advertising router before accepting into the routing table.

## Apply OSPF Accept Policy Changes

Apply OSPF accept policy changes to enable the configuration changes in the policy to take effect in an OSPF Accept context (and to prevent the device from attempting to apply the changes one by one after each configuration change).

### About This Task

#### Important

Changing OSPF Accept contexts is a process-oriented operation that can affect system performance and network accessibility while you perform the procedures. If you want to change the default preferences for an OSPF Accept or a prefix-list configuration (as opposed to the default preference), do so before enabling the protocols.

### Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Apply an OSPF accept policy change:

```
ip ospf apply accept [vrf WORD<1-16>]
```

3. Display information about the configured OSPF entries:

```
show ip ospf accept [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

### Example

Apply the OSPF accept policy and confirm the configuration:

```
Switch:1>enable
Switch:1#ip ospf apply accept
Switch:1#show ip ospf accept
=====
                        Ospf Accept - GlobalRouter
=====
ADV_RTR      MET_TYPE  ENABLE  POLICY
-----
192.0.2.11   type1     true    test1
```

### Variable Definitions

Use the data in the following table to use the **ip ospf apply accept adv-rtr** command.

Variable	Value
<i>adv-rtr</i>	Commits entered changes. Issue this command after you modify a policy configuration that affects an OSPF accept policy.
<i>vrf WORD&lt;1-16&gt;</i>	Specifies the name of the VRF.

## Configure Inter-VRF Redistribution Policies

Configure redistribution entries to allow a protocol to announce routes of a certain source type, for example, static, RIP, or direct.

### Before You Begin

- Ensure the routing protocols are globally enabled.
- You must configure the route policy, if required.
- Ensure the VRFs exist.
- You must create the route policy and prefix list under the source VRF context.

### Note

The route policies treat permit and deny rules differently for inbound and outbound traffic.

- For an in-policy (RIP, BGP) or an accept policy (OSPF) using a route-map, if a particular route is not explicitly denied in the accept policy or in-policy with the route-map, then the route is implicitly allowed.
- For an out-policy (RIP, BGP) or a redistribute policy (RIP, OSPF, BGP) using a route-map, even if a particular route is not explicitly allowed in the redistribution policy or out-policy with the route-map, then the route is implicitly denied.
- In order to permit or deny only explicit routes, configure a policy with additional sequences, where, the last sequence permits all routes that are not explicitly permitted or denied.

### Procedure

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

```
router vrf WORD<1-16>
```

2. Create the redistribution instance:

```
ip <bgp|ospf|rip> redistribute <bgp|direct|ipv6-direct|ipv6-isis|ipv6-  
static|isis|ospf|ospfv3|rip|static|dvr>
```

3. Apply a route policy if required:

```
ip <bgp|ospf|rip> redistribute <bgp|direct|ipv6-direct|ipv6-isis|ipv6-  
static|isis|ospf|ospfv3|rip|static|dvr> route-map <WORD 0-64> [vrf-src  
<WORD 1-16>]
```

4. Use the following variable definitions table to configure other parameters as required.

5. Enable the redistribution:

```
ip <bgp|ospf|rip> redistribute <bgp|direct|ipv6-direct|ipv6-isis|ipv6-  
static|isis|ospf|ospfv3|rip|static|dvr> enable [vrf-src <WORD 1-16>]
```

## 6. Ensure that the configuration is correct:

```
show ip <bgp|ospf|rip> redistribute [vrf WORD<1-16>] [vrfids
WORD<0-512>]
```

For RIPng, use `show ipv6 rip redistribute`.

## 7. Apply the redistribution:

```
ip <bgp|ospf|rip> apply redistribute <bgp|direct|ipv6-direct|ipv6-
isis|ipv6-static|isis|ospf|ospfv3|rip|static|dvr> [vrf WORD<1-16>]
[vrf-src WORD<1-16>]
```

**Example**

```
Switch:1>enable
Switch:1#config terminal
```

## Log on to the VRF Router Configuration mode:

```
Switch:1(config)#router vrf test
```

## Create the redistribution instance:

```
Switch:1(router-vrf)#ip rip redistribute ospf
```

## Enable the redistribution

```
Switch:1(router-vrf)#ip rip redistribute ospf enable
```

## Ensure that the configuration is correct:

```
Switch:1(router-vrf)#show ip rip redistribute
```

## Exit to Global Configuration mode:

```
Switch:1(router-vrf)#exit
```

## Apply the redistribution:

```
Switch:1(config)#ip rip apply redistribute ospf
```

*Variable definitions*

Use the data in the following table to use the redistribution commands.

Variable	Value
<code>&lt;bgp direct isis ospf rip static dvr&gt;</code>	Specifies the type of routes to redistribute—the protocol source.
<code>vrf WORD&lt;1-16&gt;</code>	Specifies the VRF instance.
<code>vrfids WORD&lt;0-512&gt;</code>	Specifies a list of VRF IDs.
<code>vrf-src WORD&lt;1-16&gt;</code>	Specifies the source VRF instance. This parameter is not required for redistribution within the same VRF.

Use the data in the following table to use the `ip <bgp|ospf|rip> redistribute <bgp|direct|isis|ospf|rip|static|dvr>` command.

Variable	Value
<code>apply [vrf-src WORD&lt;1-16&gt;]</code>	Applies the redistribution configuration.
<code>enable [vrf-src WORD&lt;1-16&gt;]</code>	Enables the OSPF route redistribution instance.
<code>metric &lt;metric-value&gt; [vrf-src WORD&lt;1-16&gt;]</code>	Configures the metric to apply to redistributed routes.
<code>metric-type &lt;type1 type2&gt; [vrf-src WORD&lt;1-16&gt;]</code>	Specifies a type 1 or a type 2 metric. For metric type 1, the cost of the external routes is equal to the sum of all internal costs and the external cost. For metric type 2, the cost of the external routes is equal to the external cost alone.
<code>route-map &lt;WORD 0-64&gt; [vrf-src WORD&lt;1-16&gt;]</code>	Configures the route policy to apply to redistributed routes.
<code>subnets &lt;allow suppress&gt; [vrf-src WORD&lt;1-16&gt;]</code>	Allows or suppresses external subnet route advertisements when routes are redistributed into an OSPF domain.

## IP Policy Configuration using Enterprise Device Manager

You can form a unified database of route policies that the protocols (RIP, OSPF or Border Gateway Protocol [BGP]) can use for any type of filtering task.

For information about configuring a prefix list, see [Configure a Prefix List](#) on page 3190. For more information about community list, see [Configure a Community Access List](#) on page 549. For more information about AS path list, see [Configure an AS Path List](#) on page 549.

A name or an ID identifies a policy. Under a policy you can have several sequence numbers, each of which is equal to one policy in the old convention. If a field in a policy is not configured, the system displays it as 0 or any when the system displays it in Enterprise Device Manager (EDM). This means that the field is ignored in the match criteria. You can use the clear option to remove existing configurations for any field.

Each policy sequence number contains a set of fields. Only a subset of those fields is used when the policy is applied in a certain context. For example, if a policy has a set-preference field set, it is used only when the policy is applied for accept purposes. This field is ignored when the policy is applied for announce and redistribute purposes.

You can apply only one policy for one purpose (for example, RIP Announce on a given RIP interface). In that example, all sequence numbers under the given policy are applicable for that filter. A sequence number also acts as an implicit preference: a lower sequence number is preferred.

## Configure a Prefix List

Configure a prefix list to allow or deny specific route updates. A prefix list policy specifies route prefixes to match. After a match occurs, the system uses the route.

The prefix list contains a set of contiguous or non-contiguous routes. Reference prefix lists by name from within a routing policy.

### Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **Policy**.
3. Select the **Prefix List** tab.
4. Select **Insert**.
5. For **Id**, type an ID for the prefix list.
6. For **Prefix**, type an IP address for the route.
7. For **PrefixMaskLength**, type the length of the prefix mask.
8. Configure the remaining parameters as required.
9. Select **Insert**.

### *Prefix List* field descriptions

Use the data in the following table to use the **Prefix List** tab.

Name	Description
<b>Id</b>	Configures the list identifier.
<b>Prefix</b>	Configures the IP address of the route.
<b>PrefixMaskLen</b>	Configures the specified length of the prefix mask. You must enter the full 32-bit mask to exact a full match of a specific IP address, for example, if you create a policy to match on the next hop.
<b>Name</b>	Names a specified prefix list during the creation process or renames the specified prefix list. The name length can use from 1 to 64 characters.
<b>MaskLenFrom</b>	Configures the lower bound of the mask length. The default is the mask length. Lower bound and higher bound mask lengths together can define a range of networks.
<b>MaskLenUpto</b>	Configures the higher bound mask length. The default is the mask length. Lower bound and higher bound mask lengths together can define a range of networks.

## Configure a Route Policy

Configure a route policy so that all protocols use them for In, Out, and Redistribute purposes.

### Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

### Procedure

1. In the navigation pane, expand: **Configuration > IP**.
2. Select **Policy**.
3. Select the **Route Policy** tab.
4. Select **Insert**.
5. Enter the appropriate information for your configuration in the Insert Route Policy dialog box.
6. Select **Insert**.

### *Route Policy* Field Descriptions

Use the data in the following table to use the **Route Policy** tab.

Name	Description
<b>Id</b>	Specifies the ID of an entry in the Prefix list table.
<b>SequenceNumber</b>	Specifies a policy within a route policy group.
<b>Name</b>	Specifies the name of the policy. This command changes the name field for all sequence numbers under the given policy.
<b>Enable</b>	Indicates whether this policy sequence number is enabled or disabled. If disabled, the policy sequence number is ignored. The default is disabled.
<b>Mode</b>	Specifies the action to take when a policy is selected for a specific route. Select permit (allow the route) or deny (ignore the route). The default is permit.
<b>MatchProtocol</b>	Selects the appropriate protocol. If configured, matches the protocol through which the route is learned. This field is used only for RIP Announce purposes. The default is to enable all match protocols.
<b>MatchNetwork</b>	Specifies if the system matches the destination network against the contents of the specified prefix list.

Name	Description
<b>MatchIpRouteSource</b>	<p>Specifies if the system matches the next-hop IP address for RIP routes and advertising router IDs for OSPF routes against the contents of the specified prefix list. This option is ignored for all other route types.</p> <p>Select the ellipsis and choose from the list in the Match Route Source dialog box. You can select up to four entries. To clear an entry, use the ALT key.</p> <p>You can also change this field in the Route Policy tab of the Policy dialog box.</p>
<b>MatchIpRouteDest</b>	<p>Specifies if the system matches the next-hop IP address for RIP routes and advertising router IDs for OSPF routes against the contents of the specified prefix list. This option is ignored for all other route types.</p>
<b>MatchNextHop</b>	<p>Specifies if the system matches the next-hop IP address of the route against the contents of the specified prefix list. This field applies only to nonlocal routes.</p> <p>Select the ellipsis and choose from the list in the Match Next Hop dialog box. You can select up to four entries. To clear an entry, use the ALT key.</p>
<b>MatchInterface</b>	<p>Specifies if the system matches the IP address of the interface by which the RIP route was learned against the contents of the specified prefix list. This field is used only for RIP routes and ignored for all other type of route.</p> <p>Select the ellipsis and choose from the list in the Match Interface dialog box. You can select up to four entries. To clear an entry, use the ALT key.</p>
<b>MatchRouteType</b>	<p>Configures a specific route type to match (applies only to OSPF routes). Externaltype1 and Externaltype2 specify the OSPF routes of the specified type only. OSPF internal refers to intra- and inter-area routes. The default is any.</p>
<b>MatchMetric</b>	<p>Specifies if the system matches the metric of the incoming advertisement or existing route against the specified value (1 to 65535). If 0, this field is ignored. The default is 0.</p>
<b>MatchMetricTypeEllipsis</b>	<p>Specifies the match metric type field in the incoming ISIS routes in accept policy.</p>
<b>IpRoutePolicyMatchIpMcastGroup</b>	<p>Specifies the system matches the IP multicast destination group for the routed multicast policy.</p>

Name	Description
<b>IpRoutePolicyMatchIpMcastSource</b>	Specifies the system matches the IP multicast source address for the routed multicast policy.
<b>MatchAsPath</b>	Configures if the system matches the BGP autonomous system path. Applicable to BGP only. This overrides the BGP neighbor filter list information.
<b>MatchCommunity</b>	Filters incoming and outgoing updates based on a Community List. Applicable to BGP only. The default is disable.
<b>MatchCommunityExact</b>	Indicates if the match must be exact (that is, all of the communities specified in the path must match). Applicable to BGP only. The default is disabled.
<b>MatchTag</b>	Specifies a list of tags used during the match criteria process. Applicable to BGP only. It contains one or more tag values.
<b>MatchVrf</b>	Identifies the source VRFs that leaks routes to the local VRF (applies only to RIP routes).
<b>MatchLocalPref</b>	Specifies the local preference value to be matched.
<b>NssaPbit</b>	Configures or resets the P bit in specified type 7 link state advertisements (LSA). By default, the Pbit is always configured in case the user configures the Pbit to a disable state for a particular route policy other than all type 7. LSAs associated with that route policy have the Pbit cleared. With this intact, not so stubby area (NSSA) area border router (ABR) does not perform translation of these LSAs to type 5. The default is enable.
<b>SetRoutePreference</b>	Configures a value from 0 to 255. The default value is 0. If the default is configured, the global preference value is used. When configured to a value greater than zero, specifies the route preference value assigned to the routes that matches the policy. This feature applies to accept policies only.
<b>SetMetricTypeInternal</b>	Identifies the MED value for routes advertised to BGP numbers to the Interior Gateway Protocol (IGP) metric value. The value must be 0 or 1. The default is 0.
<b>SetMetricTypeisis</b>	Sets the metric type IS-IS.

Name	Description
<b>SetMetric</b>	Configures the system to use the metric value for the route while announcing or redistributing. The default-import-metric is 0. If the default is configured, the original cost of the route is advertised into OSPF; for RIP, the original cost of the route or the default value is used (applies to IS-IS routes also). The default is 0.
<b>SetMetricType</b>	Configures the metric type for the routes to announce into the OSPF routing protocol that matches this policy. Applicable to OSPF protocol only. The default is type 2. This field is applicable only for OSPF announce policies. The default is type2.
<b>SetNextHop</b>	Configures the IP address of the next-hop router. Applicable to BGP only. The default is 0.0.0.0.
<b>SetInjectNetList</b>	Configures the destination network of the route that matches this policy with the contents of the specified prefix list. Select the ellipsis and choose from the list in the Set Inject NetList dialog box.
<b>SetMask</b>	Configures the mask of the route that matches this policy. This applies only to RIP accept policies.
<b>SetAsPath</b>	Indicates the AS path value to use whether the SetAsPathMode field is Tag or Prepend. Applicable to BGP only.  <b>Note:</b> Prepend is not applicable to an internal BGP (iBGP) peer with outbound route policy.
<b>SetAsPathMode</b>	Configures if the system converts the tag of a route into an AS path. Applicable to BGP protocol only. The mode is either Tag or Prepend tag. The value is applicable only while redistributing routes to BGP. The default is prepend.  <b>Note:</b> Prepend is not applicable to an iBGP peer with outbound route policy.
<b>SetAutomaticTag</b>	Enables the automatic tag feature. Applicable to BGP protocol only. The default is disable.

Name	Description
<b>SetCommunityNumber</b>	Configures the community number for BGP advertisements. This value can be a number (1 to 42949672000) or no-export or no-advertise.
<b>SetCommunityMode</b>	Configures the community mode for the BGP protocol. This value can be either append, none, or unchanged. The default is unchanged. <ul style="list-style-type: none"> <li>• Unchanged—keeps the community attribute in the route path as it is.</li> <li>• None—removes the community in the route path additive.</li> <li>• Append—adds the community number specified in SetCommunityNumber to the community list attribute.</li> </ul>
<b>SetExtCommunity</b>	Configures a BGP community. The values are 0 to 256.
<b>SetExtCommunityMode</b>	Configures the extended-community mode. The value can be append, unchanged, or overwrite. The default value is unchanged. <ul style="list-style-type: none"> <li>• append — creates another community string.</li> <li>• unchanged — keeps the community attribute as it is.</li> <li>• overwrite — changes the current value.</li> </ul>
<b>SetOrigin</b>	Configures the origin for the BGP protocol to IGP, EGP, incomplete, or unchanged. If not configured, the system uses the route origin from the IP routing table (protocol). The default is unchanged.
<b>SetLocalPref</b>	Configures the local preference for the BGP protocol only. The system uses this value during the route decision process for the BGP protocol. The default is 0.
<b>SetOriginEgpAs</b>	Indicates the remote autonomous system number for the BGP protocol. The default is 0.
<b>SetWeight</b>	Configures the weight value for the routing table for the BGP protocol. This field must be used with the match as-path condition. For BGP, this value overrides the weight configured through the NetworkTableEntry, FilterListWeight, or NeighborWeight. The default is 0.
<b>SetTag</b>	Configures the list of tags used during the match criteria process for the BGP protocol. The default is 0.

Name	Description
<b>Ipv6SetNextHop</b>	Specifies the address of the IPv6 next hop router.
<b>SetDatalsid</b>	Configures the data I-SID for SPB routed multicast Policy that associates with the IP multicast groups (sender and receiver). This field should match the route-map.
<b>SetRxOnly</b>	Configures SPB routed multicast policy with permit action that allows only local receivers, not local senders. The default is disabled.
<b>SetTxOnly</b>	Configures a route-map of SPB routed multicast policy with permit action that allows only local senders, not local receivers. The default is disabled.

## Apply a Route Policy

Apply route policies to define route behavior.

### About This Task

#### Important

Changing route policies or prefix lists that affect OSPF accept or redistribute is a process-oriented operation that can affect system performance and network reachability while you perform the procedures. Therefore, if you want to change a prefix list or a routing protocol, you configure all route policies and prefix lists before enabling the protocols.

### Procedure

1. In the navigation pane, expand:**Configuration > IP**.
2. Select **Policy**
3. Select the **Applying Policy** tab.
4. Select the type of policy to apply.
5. Select **Apply**.

**Applying Policy** *Field Descriptions*

Use the data in the following table to use the **Applying Policy** tab.

Name	Description
<b>RoutePolicyApply</b>	Specifies that configuration changes in the policy take effect in an OSPF route policy context. This prevents the system from attempting to apply the changes one by one after each configuration change. The default is enabled.
<b>RedistributeApply</b>	Specifies that configuration changes in the policy take effect for an OSPF Redistribute context. This prevents the system from attempting to apply the changes one-by-one after each configuration change. The default is enabled.
<b>OspfInFilterApply</b>	<p>Specifies that configuration changes in a route policy or a prefix list take effect in an OSPF Accept context. This prevents the system from attempting to apply the changes one by one after each configuration change. The default is enabled.</p> <p><b>Note:</b> This field does not apply on all hardware platforms. If you do not see this command in EDM, the feature is not supported on your hardware.</p>

**Configure an OSPF Accept Policy**

Perform the following procedure to create or configure an OSPF accept policy.

**Before You Begin**

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

**Procedure**

1. In the navigation pane, expand: **Configuration > IP**.
2. Select **Policy**.
3. Select the **OSPF Accept** tab.
4. Select **Insert**.
5. Configure the parameters as required.
6. Select **Insert**.

**OSPF Accept** field descriptions

Use the data in the following table to use the **OSPF Accept** tab.

Name	Description
<b>AdvertisingRtr</b>	Specifies the routing ID of the advertising router.
<b>Enable</b>	Enables or disables the advertising router. You can also enable or disable advertising in the OSPF Accept tab of the Policy dialog box by clicking in the field and selecting enable or disable from the menu. The default is disable.
<b>MetricType</b>	Specifies the OSPF external type. This parameter describes which types of OSPF ASE routes match this entry. <ul style="list-style-type: none"> <li>• Any means match either ASE type 1 or 2</li> <li>• Type1 means match any external type 1</li> <li>• Type2 means match any external type 2</li> </ul> You can also select your entry in the OSPF Accept tab of the Policy dialog box by clicking in the field and selecting any, type1, or type2 from the menu. The default is any.
<b>PolicyName</b>	Specifies the name of the OSPF in filter policy. Click the ellipsis button and choose from the list in the Policy Name dialog box. To clear an entry, use the ALT key.

Configure Inbound and Outbound Filtering Policies on a RIP Interface

**Before You Begin**

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

**About This Task**

Configure inbound filtering on a RIP interface to determine whether to learn a route on a specified interface and to specify the parameters of the route when it is added to the routing table. Configure outbound filtering on a RIP interface to determine whether to advertise a route from the routing table on a specified interface and to specify the parameters of the advertisement.

The port on which the multimedia filter is enabled becomes a DIFFSERV access port.

**Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Select **Policy**.
3. Select the **RIP In/Out Policy** tab.
4. In the desired row, double-click the **InPolicy** or **OutPolicy** column.
5. Select a preconfigured In/Out policy, and then select **OK**.

**RIP In/Out Policy** field descriptions

Use the data in the following table to use the **RIP In/Out Policy** tab.

Name	Description
<b>Address</b>	Specifies the IP address of the RIP interface.
<b>Interface</b>	Specifies the internal index of the RIP interface.
<b>InPolicy</b>	Specifies the policy name used for inbound filtering on this RIP interface. This policy determines whether to learn a route on this interface and specifies the parameters of the route when it is added to the routing table.
<b>OutPolicy</b>	Specifies the policy name used for outbound filtering on this RIP interface. This policy determines whether to advertise a route from the routing table on this interface and specifies the parameters of the advertisement.

## Delete Inbound or Outbound Filtering Policies on a RIP Interface

Delete a RIP In or Out policy when you no longer want the switch to learn a route on a specified interface or advertise a route from the routing table on a specified interface.

**Before You Begin**

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

**Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Select **Policy**.
3. Select the **RIP In/Out Policy** tab.
4. In the desired row, double-click the **InPolicy** or **OutPolicy** column for the policy you want to delete.
5. In the **InPolicy** or **OutPolicy** dialog box, press **CTRL** and then, select the policy you want to delete.
6. Select **OK**.
7. Select **Apply**.

## RSMLT

---

In many cases, core network convergence time depends on the length of time a routing protocol requires to successfully converge. Depending on the specific routing protocol, this convergence time can cause network interruptions that range from seconds to minutes.

Routed Split MultiLink Trunking (RSMLT) permits rapid failover for core topologies by providing an active-active router concept to core SMLT networks.

RSMLT scenarios include SMLT triangles, squares, and SMLT full-mesh topologies, with routing enabled on the core VLANs.

Routing protocols include the following:

- IP Unicast Static Routes
- RIP1
- RIP2
- OSPF
- BGP

In the event of core router failures, RSMLT manages packet forwarding, thus eliminating dropped packets during the routing protocol convergence.

---

## IPv6 RSMLT

---

Routed Split Multi-Link Trunking (RSMLT) is an enhancement to SMLT that enables the exchange of Layer 3 information between peer nodes in a switch cluster. RSMLT provides two main advantages over SMLT:

- provides backup for the peer after the peer goes down
- routes traffic on behalf of the peer to prevent Virtual Inter-Switch Trunk (vIST) overload

IPv6 RSMLT enables the subsecond failover for IPv6 forwarding.

The overall model for IPv6 RSMLT is essentially identical to that of IPv4 RSMLT. In short, RSMLT peers exchange their IPv6 configuration and track their states by using vIST messages. An RSMLT node always performs IPv6 forwarding on the IPv6 packets destined to the MAC addresses of the peer. If an RSMLT node detects that the RSMLT peer is down, the node forwards IPv6 traffic destined to the IPv6 addresses of the peer.

With RSMLT enabled, an SMLT switch performs IP forwarding on behalf of the SMLT peer, which prevents IP traffic from being sent over the vIST.

IPv6 RSMLT supports the full set of topologies and features supported by IPv4 RSMLT, including SMLT triangles, squares, and SMLT full-mesh topologies, with routing enabled on the core VLANs.

Because you configure RSMLT on a VLAN, not at the IP layer, the configuration applies to both IPv4 and IPv6. You cannot enable or disable RSMLT on a VLAN for IPv6 but not IPv4; or for IPv4 but not IPv6.

With IPv6, you must configure the RSMLT peers to use the same set of IPv6 prefixes.

Supported routing protocols include the following:

- IPv6 static routes
- OSPFv3

#### Note

IPv6 RSMLT is not virtualized, therefore it is not possible to enable IPv6 and RSMLT together on a VLAN which is associated with a VRF.

The system will display the configuration errors if you attempt to perform the following:

- Create an IPv6 interface on a VLAN which is associated with a VRF and RSMLT is enabled on the VLAN.
- Enable RSMLT on an IPv6 enabled VLAN which is associated with a VRF.

## IPv6 differences

The following list identifies ways in which the IPv6 implementation of RSMLT differs from the IPv4 implementation of RSMLT.

- After the switch begins to forward traffic on behalf of the peer, duplicate address detection (DAD) is not executed for the IPv6 address of the peer. The implementation assumes that the peer IPv6 address is already known to be unique.
- An RSMLT switch installs a neighbor entry for the peer IPv6 address immediately after the peer disappearance is detected, possibly while a route for the peer still exists. This action can result in packets destined to the peer IPv6 address being delivered to the CP for a short period of time.
- You cannot configure a vIST with IPv6 peer address
- In a dual-stack VLAN, adding or deleting IPv4 or IPv6 does not affect the RSMLT functionality of one another. If you add IPv4 or IPv6 to an existing IPv6 or IPv4 RSMLT VLAN, the RSMLT state for the protocol you add second will be the same as the previous RSMLT state.

## SMLT and RSMLT Operation in Layer 3 Environments

[Figure 234](#) on page 3205 shows a typical redundant network example with user aggregation, core, and server access layers. To minimize the creation of many IP subnets, one VLAN (VLAN 1, IP subnet A) spans all wiring closets.

SMLT provides the loop-free topology and forwards all links for VLAN 1, IP subnet A.

The aggregation layer switches are configured with routing enabled and provide active-active default gateway functionality through RSMLT.

After you enable RSMLT on a VLAN (on both aggregation devices), the cluster devices simply inform each other (over vIST messaging) of their physical IP and MAC on that VLAN. Thereafter, the two cluster devices take mutual ownership of their IP addresses on that VLAN. This action means each cluster device routes IP traffic that is directed to

the physical MAC of the IP or the physical MAC of the peer IP on that VLAN, and when one of them is down the other cluster device:

- Replies to ARP requests for both the IP and the peer IP on that VLAN
- Replies to pings to the IP and the peer IP on that VLAN

In this case, routers R1 and R2 forward traffic for IP subnet A. RSMLT provides both router failover and link failover. For example, if the Split MultiLink Trunk link between R2 and R4 is broken, the traffic fails over to R1 as well.

For IP subnet A, VRRP with a backup master can provide the same functionality as RSMLT, as long as no additional router is connected to IP subnet A.

RSMLT provides superior router redundancy in core networks (IP subnet B), where OSPF is used for the routing protocol. Routers R1 and R2 provide router backup for each other, not only for the edge IP subnet A, but also for the core IP subnet B. Similarly routers R3 and R4 provide router redundancy for IP subnet C and also for core IP subnet B.

## Router R1 Failure

The following figure shows SMLT and RSMLT in Layer 3 environments.

**Figure 234: SMLT and RSMLT in Layer 3 environments**

R3 and R4 both use R1 as their next hop to reach IP subnet A. Even though R4 sends the packets to R2, they are routed directly at R2 into subnet A. R3 sends its packets to R1 and they are also sent directly into subnet A. After R1 fails, all packets are directed to R2, with SMLT. R2 still routes for R2 and R1. After OSPF convergence, the routing tables in R3 and R4 change their next hop to R2 to reach IP subnet A. You can configure the hold-up timer (that is, for the amount of time R2 routes for R1 in a failure) for a time period greater than the routing protocol convergence, you can configure it as indefinite (that is, the members of the pair always route for each other).

Use an indefinite hold-up timer value for applications that use RSMLT at the edge instead of VRRP.

## Router R1 Recovery

When R1 restarts after a failure, it does not route traffic for R2, nor does it provide backup for R2, until the hold-down timer expires. Similar to VRRP, the hold-down timer value must be greater than the time the routing protocol requires to converge its tables.

During the hold-down interval, R1 routes traffic if the destination MAC of the packet is its own routable VLAN MAC. R1 bridges incoming traffic to R2 if the destination MAC of the packet is the routable VLAN MAC of R2. A temporary default route (one having a route preference equal to 4) that points to R2 is installed on R1. R1 uses this temporary route to forward traffic to R2 that it cannot route itself because of the incomplete routing table; the default route is not saved in the configuration file.

After the hold-down timer expires, the temporary default route that points to R2 is deleted; from this moment on, in addition to routing packets destined to itself, R1 starts routing packets for R2, as well.

## RSMLT Network Design and Configuration

Because RSMLT is based on SMLT, all SMLT configuration rules apply. In addition, RSMLT is enabled on the SMLT aggregation switches for each VLAN. The VLAN must be a member of SMLT links and vIST's L2VSN. For more information about how to configure SMLT in a Layer 2 environment, see [MultiLink Trunking and Split MultiLink Trunking](#) on page 2571.

The VLAN also must be routable (IP address configured) and you must configure an Interior Gateway Protocol (IGP) such as OSPF on all four routers, although it is independent of RSMLT. All routing protocols, even static routes, work with RSMLT.

The RSMLT pair switches provide backup for each other. As long as one of the two routers of a vIST pair is active, traffic forwarding is available for both next hops R1/R2 and R3/R4.

## RSMLT Edge Support

The switch stores the peer MAC and IP address pair in its local configuration file and restores the configuration if the peer does not restore after a simultaneous restart of both RSMLT-peer switches.

The RSMLT edge support feature adds an enhancement whereby the peer MAC (for the IP on the VLAN) is committed to the config.cfg file after you use the **save config** command. If you power off both devices, and then power up only one of them, that single device can still take ownership of its peer IP on that VLAN even if it has not seen that peer switch since it started. This enhancement is necessary if you configure the peer (the device which is still down) IP as the default gateway in end stations.

If you enable RSMLT edge support, you must also ensure that the hold-up timer for RSMLT on those edge VLANs equals infinity (9999). This timer value ensures that if one cluster device fails, the remaining cluster device maintains ownership of the failed peer IP indefinitely.

The edge VLAN can be tagged over SMLT links, single attached links, or more SMLT links.

**Important**

If you clear the peer information the device can stop forwarding for the peer.

RSMLT implementation does not use a virtual IP address but instead uses physical IP addresses for redundancy. At the same time, you can deploy RSMLT in either routed configurations, or edge configurations, where you previously used VRRP (and back-up master). Previously, if a power outage occurred or a shutdown of both switches within a dual core vIST pair, only one device came back up. Clients using the powered-off device IP/MAC as the default gateway lost connectivity to the network. In such a scenario, even with RSMLT enabled on the device, it cannot act as a backup for the peer as it was unaware of the peer IP or MAC address.

After both the dual core vIST switches come back, the vIST is operational. If an RSMLT peer-enabled message is received from the peer, normal RSMLT operation occurs.

If the peer has either an IP or MAC change, you must save the configuration for the RSMLT edge support to operate correctly. However, if the vIST peer up message is not received (for example, if you do not enable RSMLT properly), and you enable the RSMLT edge support flag, the RSMLT hold-down timer starts and permits routing protocols to converge; during this time user operation can be affected. After the hold-down timer expires, saved peer information is picked up and the device starts to act as backup for the peer by adding the previously saved MAC and ARP records.

The hold-up timer starts and after this timer expires the previously added MAC and ARP records are deleted and the device stops acting as backup for the peer, as the peer is not running proper RSMLT for the VLAN. The RSMLT is a parameter for each VLAN, and therefore all affects are on an individual VLAN basis, not necessarily a global device. Edge support mode uses the local values of the hold-down timer (default value of 60 seconds) and hold-up timer (default value of 180 seconds).

## RSMLT Configuration using CLI

---

Use the procedures in this section to configure RSMLT using CLI.

### Configure RSMLT on a VLAN

Configure RSMLT on a VLAN to exchange Layer 3 information between peer nodes in a switch cluster. This configuration applies to both IPv4 and IPv6.

**Before You Begin**

- An IP routing protocol is enabled on VLAN Layer 3 interfaces.
- VLANs with Layer 3 interfaces participate in Split MultiLink Trunking (SMLT).

## About This Task

The VLAN can be either IPv4 or IPv6, or both. RSMLT configuration on a VLAN simultaneously affects both IPv4 and IPv6. By default, RSMLT is disabled on a VLAN.

## Procedure

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Configure the holddown timer:

```
ip rsmlt holddown-timer <0-3600>
```

3. Configure the holdup timer:

```
ip rsmlt holdup-timer <0-9999>
```

4. Enable RSMLT on the VLAN:

```
ip rsmlt
```

## Example

Configure and enable RSMLT on a VLAN:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 100
Switch:1(config-if)#ip rsmlt holddown-timer 100
Switch:1(config-if)#ip rsmlt holdup-timer 200
Switch:1(config-if)#ip rsmlt
```

## Variable Definitions

The following table defines parameters for the **ip rsmlt** command.

Variable	Value
<i>holddown-timer</i> <0-3600>	Defines how long the recovering or restarting system remains in a non-Layer 3 forwarding mode for the peer router MAC address. The default is 60. Configure this value to be longer than the anticipated routing protocol convergence. If you disable RSMLT on a VLAN, non default values for this variable do not save across restarts.
<i>holdup-timer</i> <0-3600 9999>	Defines how long the RSMLT system maintains forwarding for its peer. The value is a range from 0 to 3600 seconds or 9999. 9999 means infinity. The default is 1800. If you disable RSMLT on a VLAN, non default values for this variable do not save across restarts.

The following table defines parameters for the **interface** command.

Variable	Value
<1-4059>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.

## Enable RSMLT Edge Support

Enable RSMLT Edge support to store the RSMLT peer MAC and IP address-pair in the local configuration file and restore the configuration if the peer does not restore after a simultaneous restart of both RSMLT peer systems.

If enabled, peer MAC and IP information for all RSMLT-enabled VLANs is saved after you next use the **save config** command.

### About This Task

RSMLT Edge support configuration applies to both IPv4 and IPv6. You do not configure IPv4 and IPv6 separately.

The RSMLT Edge support default is disabled.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable RSMLT Edge support:

```
ip rsmlt edge-support
```

### Example

If you have enabled RSMLT Edge Support, disable the feature as follows:

```
Switch:1(config)#no ip rsmlt edge-support
```

## View RSMLT Information

Show RSMLT information to view data about all RSMLT interfaces. The output of the command includes IPv6 information for the local and peer nodes.

### About This Task

If you use the **show ip rsmlt** command after you delete an RSMLT, the RSMLT still shows in the command output until you restart the switch.

## Procedure

1. Enter Privileged EXEC mode:  
enable
2. Show RSMLT information about the interface:  
show ip rsmlt [local|peer] [vrf WORD<1-16>] [vrfids WORD<0-512>]
3. View the status of the switch to act as a peer forwarder:  
show ip rsmlt edge-support

## Examples

```
Switch:1>show ip rsmlt
```

```

```

### Variable definitions

Use the data in the following table to use the **show ip rsmlt** command.

Variable	Value
<i>local</i>	Shows local RSMLT information.
<i>peer</i>	Shows RSMLT information for the peer.
<i>vrf WORD&lt;1-16&gt;</i>	Shows information for a specific VRF name.
<i>vrfids WORD&lt;0-512&gt;</i>	Shows information for a specific VRF ID.

## RSMLT Configuration using EDM

Use the procedures in this section to configure RSMLT using EDM.

### Configuring RSMLT on a VLAN

Configure RSMLT on a VLAN to exchange Layer 3 information between peer nodes in a switch cluster. This configuration applies to both IPv4 and IPv6.

#### Before You Begin

- Enable an IP routing protocol on VLAN Layer 3 interfaces.
- Ensure VLANs with Layer 3 interfaces participate in Split MultiLink Trunking (SMLT).

#### About This Task

The VLAN can be either IPv4 or IPv6, or both. RSMLT configuration on a VLAN simultaneously affects both IPv4 and IPv6.

#### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN**.

2. Click **VLANs**.
3. Click the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Click the **RSMLT** tab.
7. Select **Enable**.
8. In the **HoldDownTimer** field, type a hold-down timer value.
9. In the **HoldUpTimer** field, type a holdup timer value.
10. Click **Apply**.

### *RSMLT Field Descriptions*

Use the data in the following table to use the **RSMLT** tab.

Name	Description
<b>Enable</b>	Enables RSMLT. The default is disabled.
<b>HoldDownTimer</b>	Defines how long the recovering or restarting system remains in a non-Layer 3 forwarding mode for the peer router MAC address. The range of this value is from 0 to 3600 seconds. The default is 60. If you disable RSMLT on a VLAN, non default values for this field do not save across restarts.
<b>HoldUpTimer</b>	Defines how long the RSMLT system maintains forwarding for its peer. The value is a range from 0 to 3600 seconds or 9999. 9999 means infinity. The default is 1800. If you disable RSMLT on a VLAN, non default values for this field do not save across restarts.

## Enabling RSMLT Edge support

Enable RSMLT Edge support to store the RSMLT peer MAC and IP address-pair in the local configuration file and restore the configuration if the peer does not restore after a simultaneous restart of both RSMLT peer systems.

The default is disabled.

### About This Task

RSMLT Edge support configuration applies to both IPv4 and IPv6.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > IP**.
2. Click **RSMLT**.
3. Click the **Globals** tab.
4. Select **EdgeSupportEnable**.
5. Click **Apply**.

## View and Edit IPv4 RSMLT Local Information

### About This Task

Perform the following procedure to view and edit RSMLT local VLAN information.

### Procedure

1. In the navigation pane, expand **ConfigurationIP**.
2. Select **RSMLT**.
3. Select the **Local** tab.
4. Configure the parameters as required.
5. Select **Apply**.

### *Local* field descriptions

Use the data in the following table to use the **Local** tab.

Name	Description
<b>IfIndex</b>	IP interface identification.
<b>VlanId</b>	Specifies the VLAN ID of the chosen VLAN.
<b>IpAddr</b>	Specifies the IP address on the RSMLT VLAN.
<b>MacAddr</b>	Specifies the MAC address of the selected VLAN.
<b>Enable</b>	Displays the RSMLT operating status as enabled or disabled.
<b>OperStatus</b>	Displays the RSMLT operating status as either up or down. The default is down.
<b>HoldDownTimer</b>	Defines how long the recovering/restarting system remains in a non-Layer 3 forwarding mode for the peer router MAC address. The range of this value is from 0 to 3600 seconds. The default is 60.
<b>HoldUpTimer</b>	Defines how long the RSMLT system maintains forwarding for its peer. The value is a range from 0 to 3600 seconds or 9999. 9999 means infinity. The default is 1800.
<b>SmltId</b>	Specifies the ID range for the SMLT. A valid range is 1 to 512.
<b>VrfId</b>	Identifies the VRF.
<b>VrfName</b>	Indicates the VRF name.

## Modify the IPv6 RSMLT Local Information

Edit the existing RSMLT configuration for the local node in the cluster.

### Procedure

1. In the navigation pane, expand **ConfigurationIPv6**.
2. Select **RSMLT**.

3. Select the **Local** tab.
4. Select a cell to change the value.
5. Select **Apply**.

### **Local** field descriptions

Use the data in the following table to use the **Local** tab.

Name	Description
<b>IfIndex</b>	Shows the route SMLT operation index.
<b>Ipv6Addr</b>	Configures the IPv6 address of the RSMLT interface.
<b>Ipv6PrefixLength</b>	Configures the IPv6 prefix length.
<b>Enable</b>	Enables or disables RSMLT. The default is disabled.
<b>HoldDownTimer</b>	Defines how long the recovering/rebooting switch remains in a non-Layer 3 forwarding mode for the peer router MAC address. The default is 60.
<b>HoldUpTimer</b>	Defines how long the RSMLT switch maintains forwarding for its peer. The value is a range from 0 to 3600 seconds or 9999. 9999 means infinity. The default is 1800.
<b>OperStatus</b>	Displays the RSMLT operating status as either up or down.
<b>SmltId</b>	Specifies the ID range for the SMLT.
<b>VlanId</b>	Configures the VLAN ID.
<b>MacAddr</b>	Configures the MAC address of the VLAN.
<b>VrfId</b>	Indicates the virtual router ID to which the local RSMLT instance belongs.
<b>VrfName</b>	Indicates the virtual router name to which the local RSMLT instance belongs.

## Modify IPv6 RSMLT Peer Information

Edit the existing configuration for the RSMLT peer node in the cluster.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **RSMLT**.
3. Select the **Peer** tab.
4. Select a cell to change the value.
5. Select **Apply**.

**Peer** Field Descriptions

Use the data in the following table to use the **Peer** tab.

Name	Description
<b>IfIndex</b>	Shows the route SMLT operation index.
<b>Ipv6Addr</b>	Configures the IPv6 address of the RSMLT interface.
<b>Ipv6PrefixLength</b>	Configures the IPv6 prefix length.
<b>AdminStatus</b>	Shows the administrative status of RSMLT on the peer.
<b>HoldDownTimer</b>	Defines how long the recovering/rebooting switch remains in a non-Layer 3 forwarding mode for the peer router MAC address. The default is 0.
<b>HoldDownTimeRemaining</b>	Indicates the time remaining in the HoldDownTimer.
<b>HoldUpTimer</b>	Defines how long the RSMLT switch maintains forwarding for its peer. The value is a range from 0 to 3600 seconds or 9999. 9999 means infinity. The default is 0.
<b>HoldUpTimeRemaining</b>	Indicates the time remaining in the HoldUpTimer.
<b>OperStatus</b>	Displays the RSMLT operating status as either up or down.
<b>SmltId</b>	Specifies the ID range for the SMLT.
<b>VlanId</b>	Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.
<b>MacAddr</b>	Configures the MAC address of the VLAN.
<b>VrfId</b>	Indicates the virtual router ID to which the peer belongs.
<b>VrfName</b>	Indicates the virtual router name to which the peer belongs.

## View IPv4 RSMLT Peer Information

### About This Task

Perform this procedure to view and edit RSMLT peer information.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **RSMLT**.
3. Select the **Peer** tab.

### *Peer* field descriptions

The following table defines parameters for the **Peer** tab.

Name	Description
<b>IfIndex</b>	IP interface identification.
<b>VlanId</b>	Specifies the VLAN ID of the chosen VLAN.
<b>IpAddr</b>	Specifies the IP address on the RSMLT VLAN.
<b>MacAddr</b>	Specifies the MAC address of the selected VLAN.
<b>Enable</b>	Displays the RSMLT operating status as enabled or disabled.
<b>OperStatus</b>	Displays the RSMLT operating status as either up or down. The default is down.
<b>HoldDownTimer</b>	Defines how long the recovering/restarting system remains in a non-Layer 3 forwarding mode for the peer router MAC address. The range of this value is from 0 to 3600 seconds. The default is 0.
<b>HoldUpTimer</b>	Defines how long the RSMLT system maintains forwarding for its peer. The value is a range from 0 to 3600 seconds or 9999. 9999 means infinity. The default is 0.
<b>HoldDownTimeRemaining</b>	Displays the time remaining of the HoldDownTimer. The default is 0.
<b>HoldUpTimeRemaining</b>	Displays the time remaining of the HoldUpTimer. The default is 0.
<b>SmltId</b>	Specifies the ID range for the Split MultiLink Trunk. A valid range is 1 to 32.
<b>VrfId</b>	Identifies the VRF.
<b>VrfName</b>	Indicates the VRF name.

## View IPv6 RSMLT Edge Peers

View the RSMLT peers for which the switch acts as a peer forwarder.

### Procedure

1. In the navigation pane, expand **Configuration > IPv6**.
2. Select **RSMLT**.
3. Select the **Edge Peers** tab.

#### *Edge Peers* field descriptions

Use the data in the following table to use the **Edge Peers** tab.

Name	Description
<b>PeerVlanId</b>	Specifies the ID of the VLAN associated with this entry.
<b>PeerIpv6Address</b>	Specifies the IPv6 address of the peer RSMLT interface.
<b>PeerIpv6PrefixLength</b>	Specifies the peer IPv6 address prefix.
<b>PeerMacAddress</b>	Specifies the peer MAC address.

## View IPv4 RSMLT Edge Support Information

### About This Task

View RSMLT edge support information to verify the RSMLT peer MAC/IP address-pair in its local configuration file and restore the configuration if the peer does not restore it after a simultaneous restart of both RSMLT-peer systems.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **RSMLT**.
3. Select the **Edge Peers** tab.

#### *Edge Peers* field descriptions

Use the data in the following table to use the **Edge Peers** tab fields.

Name	Description
<b>VlanId</b>	Specifies the VLAN ID of the chosen VLAN.
<b>PeerIpAddress</b>	Specifies the peer IP address.
<b>PeerMacAddress</b>	Specifies the peer MAC address.
<b>PeerVrfId</b>	Identifies the Peer VRF.
<b>PeerVrfName</b>	Specifies the Peer VRF name.

## Secure Shell Fundamentals

Methods of remote access such as Telnet or FTP generate unencrypted traffic. Anyone that can see the network traffic can see all data, including passwords and user names. Secure Shell (SSH) is a client and server protocol that specifies the way to conduct secure communications over a network. Secure Shell can replace Telnet. Secure File Transfer Protocol (SFTP) can replace FTP with an encrypted alternative.

### Note

If both SSH and SFTP are concurrently active, you have the ability to disable SFTP while allowing SSH to remain active. For more information, see [Disabling SFTP without disabling SSH](#) on page 3255.

The switch software supports Secure CoPy protocol (SCP), which is a secure file transfer protocol. Use SCP to securely transfer files between a local host and a remote host. SCP is in off state by default, but you can turn it on when you enable SSH using the **boot config flags** command in the global config mode. The switch supports SCP only as an SCP server, which means that clients can send files to the switch or can request files from the switch. Secure CoPy (SCP) can replace FTP with an encrypted alternative.

Secure Shell supports a variety of the different public and private key encryption schemes available. Using the public key of the host server, the client and server negotiate to generate a session key known only to the client and the server. This one-time key encrypts all traffic between the client and the server. The switch supports Secure Shell version 2 (SSHv2).

**Figure 235: Overview of the SSHv2 protocol**

By using a combination of host, server, and session keys, the SSHv2 protocol can provide strong authentication and secure communication over an insecure network, offering protection from the following security risks:

- IP spoofing
- IP source routing
- Domain name server (DNS) spoofing
- adversary-in-the-middle/TCP hijacking attacks
- Eavesdropping and password sniffing

Even if network security is compromised, traffic cannot be played back or decrypted, and the connection cannot be hijacked.

The SSH secure channel of communication does not provide protection against break-in attempts or denial-of-service (DoS) attacks.

With the SSHv2 server in the switch, you can use an SSHv2 client to make a secure connection to the switch and work with commercially available SSHv2 clients. For more information about supported clients, see [Third-Party SSH and SCP Client Software](#) on page 3231. The switch also supports outbound connections to remote SSHv2 servers to provide complete inbound and outbound secure access.

## Outbound Connections

The SSHv2 client supports SSHv2 DSA public key authentication and password authentication.

### Note

For certain switches in enhanced secure mode, all sensitive files are protected. You cannot access any sensitive files using Telnet, SSH, FTP, SFTP, TFTP, and SCP connections. For more information, see [Sensitive File Protection](#) on page 3623.

**Note**

You must enable SSH globally before you can generate SSH DSA user keys.

The SSHv2 client is a secure replacement for outbound Telnet. Password authentication is the easiest way to use the SSHv2 client feature.

Instead of password authentication, you can use DSA public key authentication between the SSHv2 client and an SSHv2 server. Before you can perform a public key authentication, you must generate the key pair files and distribute the key files to all the SSHv2 server systems. Because passphrase encrypts and further protects the key files, you must provide a passphrase to decrypt the key files as part of the DSA authentication.

**Note**

SSH RSA and DSA public and private keys are copied from `/intflash/shared` to `/intflash/.ssh`.

To attempt public key authentication, the SSHv2 client looks for the associated DSA key pair files in the `/intflash/.ssh` directory. If no DSA key pair files are found, the SSHv2 client automatically prompts you for password authentication. If the SSHv2 client succeeds with the authentication, then a new secured SSHv2 session is established to the remote SSHv2 server. For more information, see [.DSA Authentication Access Level and File Name](#) on page 3233.

**Important**

If you configure the DSA user key with a passphrase but you do not supply the correct passphrase when you try to make the SSHv2 connection, then the system defaults back to the password authentication. If the SSHv2 client succeeds with the authentication, then a new secured SSHv2 session is established to the remote SSHv2 server.

## SSH Version 2

SSH version 2 (SSHv2) protocol is a complete rewrite of the SSHv1 protocol. In SSHv2 the functions are divided among three layers:

- SSH Transport Layer (SSH-TRANS)

The SSH Transport Layer manages the server authentication and provides the initial connection between the client and the server. After the connection is established, the Transport Layer provides a secure, full-duplex connection between the client and server.

- SSH Authentication Protocol (SSH-AUTH)

The SSH Authentication Protocol runs on top of the SSH Transport Layer and authenticates the client-side user to the server. SSH-AUTH defines three authentication methods: public key, host-based, and password. SSH-AUTH provides a single authenticated tunnel for the SSH connection protocol.

- SSH Connection Protocol (SSH-CONN)

The SSH Connection Protocol runs on top of the SSH Transport Layer and user authentication protocols. SSH-CONN provides interactive logon sessions, remote execution of commands, forwarded TCP/IP connections, and forwarded X11 connections. These services are multiplexed into the single encrypted tunnel provided by the SSH transport layer.

The following figure shows the three layers of the SSHv2 protocol.

**Figure 236: Separate SSH version 2 protocols**

The modular approach of SSHv2 improves on the security, performance, and portability of the SSHv1 protocol.

**Important**

The SSHv1 and SSHv2 protocols are not compatible. The switch does not support SSHv1.

*Security Features*

The SSHv2 protocol supports the following security features:

- **Authentication.** This feature determines, in a reliable way, the SSHv2 client. During the log on process, the SSHv2 client is queried for a digital proof of identity.

Supported authentications with the switch as a server for SSHv2, are: RSA, DSA, and passwords. Supported authentications with the switch as a client for SSHv2, are: DSA and passwords. The switch does not support RSA when the switch acts as a client.

When the switch acts as an SSH server, by default the switch allows a maximum of only four sessions, although it can accommodate up to eight sessions at a time. However, only one SSH public key encryption per access level is allowed at a time. For instance, if multiple SSH public key encryption clients need to connect to the server with the same access level, such as *rwa*, then the clients must connect to the server one-by-one as the switch only supports one public key per access level.

- **Encryption.** The SSHv2 server uses encryption algorithms to scramble data and render it unintelligible except to the receiver.

Supported encryption and ciphers are: 3DES, AES128-cbc, AES192-cbc, AES256-cbc, AES128-ctr, AES192-ctr, AES256-ctr, MD5, secure hash algorithm 1 (SHA-1) and SHA-2.

- **Integrity.** This feature guarantees that the data transmits from the sender to the receiver without alterations. If a third party captures and modifies the traffic, the SSHv2 server detects this alteration.

**Note**

SCP is supported for RWA users only. RW or R level will not work and the switch logs a message on the device.

*SSHv2 Considerations using EDM*

You must use CLI to initially configure SSHv2. You can use Enterprise Device Manager (EDM) to change the SSHv2 configuration parameters. CLI is the user interface for

SSHv2 configuration and use the console port to configure the SSHv2 parameters. Depending on the hardware platform, the console port displays as console or 10101.

### Important

Do not enable SSHv2 secure mode using Configuration and Orchestration Manager (COM). If you enable SSHv2 secure mode, then the system disables Simple Network Management Protocol (SNMP). This locks you out of a COM session. Enable SSH secure mode using CLI or EDM.

SSHv2 secure mode is different from enhanced secure mode and hsecure. SSHv2 secure mode disables unsecure management protocols on the device such as FTP, SNMP, Telnet, and TFTP. SSHv2 secure mode is enabled through the **ssh secure** command.

When you enable SSHv2 secure mode, the system disables FTP, SNMPv1, SNMPv2, SNMPv3, Telnet and TFTP. After SSHv2 secure mode is enabled, you can choose to enable individual non-secure protocols. However, after you save the configuration and restart the system, the non-secure protocol is again disabled, even though it is shown as enabled in the configuration file. After you enable SSHv2 secure mode, you cannot enable non-secure protocols by disabling SSHv2 secure mode.

You can disable block-snmp after you enable SSHv2 secure mode, and you can connect again using COM.

## User ID Logs

### *User ID log of an SSH session established by SCP client*

The switch logs the user ID of an SSH session initiated by the SCP client. If an SCP client establishes an SSH session, the system displays the message in the following format:

```
CP1 [08/06/15 09:43:42.230:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SSH user
authentication succeeded for user rwa on host 10.68.231.194
CP1 [08/06/15 09:43:42.232:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SSH SCP session
start by user rwa on host 10.68.231.194
CP1 [08/06/15 09:43:44.020:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SCP session
closed by user rwa on host 10.68.231.194
CP1 [08/06/15 09:43:44.021:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SSH session
closed by user rwa on host 10.68.231.194
```

In the preceding example log output, rwa is the user name.

### *User ID log of an SSH session established by SFTP*

The switch logs the user ID of an SSH session initiated by SFTP. If SFTP establishes an SSH session, the system displays the message in the following format:

```
CP1 [08/06/15 09:45:32.903:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SSH user
authentication succeeded for user rwa on host 10.68.231.194
CP1 [08/06/15 09:45:32.905:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SFTP session
start: user rwa on host 10.68.231.194
CP1 [08/06/15 09:45:46.775:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SFTP session
closed by user rwa on host 10.68.231.194
CP1 [08/06/15 09:45:46.776:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SSH SFTP
session end: user rwa on host 10.68.231.194
```

```
CP1 [08/06/15 09:45:46.776:UTC] 0x000d8602 00000000 GlobalRouter SSH INFO SSH session
closed by server for user rwa on host 10.68.231.194
```

In the preceding example log output, rwa is the user name.

## User Key Files

Generating keys requires that you have free space on the flash. A typical configuration requires less than 2 kbyte of free space. Before you generate a key, verify that you have sufficient space on the flash, using the **dir** command. If the flash is full when you attempt to generate a key, the system displays an error message and the key is not generated. You must delete some unused files and regenerate the key.

If you remove only the public keys, enabling the SSH does not create new public keys.

SSHv2 password authentication uses the same login and password authentication mechanism as Telnet. The SSHv2 client also supports DSA public key authentication compatible with the switch SSHv2 server and Linux SSHv2 server for SSHv2.

If the switch is the client, use the following table to locate the DSA user key files for DSA authentication for user access level `rwa`.

### Note

For certain switches in enhanced secure mode, all sensitive files are protected. The home directory for enhanced secure mode is `/intflash/shared`. You cannot access any sensitive files using Telnet, SSH, FTP, SFTP, TFTP, and SCP connections. For more information, see [Sensitive File Protection](#) on page 3623.

**Table 230: DSA user key files**

SSH server	SSH client side	SSH server side
switch with enhanced secure mode disabled	Private and public keys by access level: <ul style="list-style-type: none"> <li>• <code>rwa—/intflash/ssh/id_dsa_rwa</code> (private key), <code>/intflash/ssh/id_dsa_rwa.pub</code> (public key)</li> <li>• <code>rw—/intflash/ssh/id_dsa_rw</code> (private key), <code>/intflash/ssh/id_dsa_rw.pub</code> (public key)</li> <li>• <code>ro—/intflash/ssh/id_dsa_ro</code> (private key), <code>/intflash/ssh/id_dsa_ro.pub</code> (public key)</li> <li>• <code>rw1—/intflash/ssh/id_dsa_rw1</code> (private key), <code>/intflash/ssh/id_dsa_rw1.pub</code> (public key)</li> <li>• <code>rw2—/intflash/ssh/id_dsa_rw2</code> (private key), <code>/intflash/ssh/id_dsa_rw2.pub</code> (public key)</li> <li>• <code>rw3—/intflash/ssh/id_dsa_rw3</code> (private key), <code>/intflash/ssh/id_dsa_rw3.pub</code> (public key)</li> </ul>	Public keys on the server side based on access level: <ul style="list-style-type: none"> <li>• <code>rwa—/intflash/ssh/dsa_key_rwa</code> (public key)</li> <li>• <code>rw—/intflash/ssh/dsa_key_rw</code> (public key)</li> <li>• <code>ro—/intflash/ssh/dsa_key_ro</code> (public key)</li> <li>• <code>rw1—/intflash/ssh/dsa_key_rw1</code> (public key)</li> <li>• <code>rw2—/intflash/ssh/dsa_key_rw2</code> (public key)</li> <li>• <code>rw3—/intflash/ssh/dsa_key_rw3</code> (public key)</li> </ul>
switch with enhanced secure mode enabled	Private and public keys by access role level: <ul style="list-style-type: none"> <li>• <code>administrator—/intflash/shared/id_dsa_admin</code> (private key), <code>/intflash/shared/id_dsa_admin.pub</code> (public key)</li> <li>• <code>operator —/intflash/shared/id_dsa_operator</code> (private key), <code>/intflash/shared/id_dsa_operator.pub</code> (public key)</li> <li>• <code>security —/intflash/shared/id_dsa_security</code> (private key), <code>/intflash/shared/</code></li> </ul>	Public keys on the server side based on access level: <ul style="list-style-type: none"> <li>• <code>administrator—/intflash/shared/dsa_key_admin</code> (public key)</li> <li>• <code>operator—/intflash/shared/dsa_key_operator</code> (public key)</li> <li>• <code>security—/intflash/shared/dsa_key_security</code> (public key)</li> <li>• <code>privilege—/intflash/shared/dsa_key_priv</code> (public key)</li> <li>• <code>auditor—/intflash/shared/dsa_key_auditor</code> (public key)</li> </ul>

**Table 230: DSA user key files (continued)**

SSH server	SSH client side	SSH server side
	id_dsa_security.pub (public key) • auditor —/intflash/shared/id_dsa_auditor (private key), /intflash/shared/id_dsa_auditor.pub (public key) • privilege —/intflash/shared/id_dsa_priv (private key), /intflash/shared/id_dsa_priv.pub (public key)	
Linux with Open SSH	~/.ssh/id_dsa (private key) file permission 400 ~/.ssh/id_dsa.pub (public key) file permission 644	~/.ssh/authorized_keys (public key) file

When you attempt to make an SSH connection from the switch, the SSHv2 client looks in its own internal flash for the public key pair files. If the key files exist, the SSHv2 client prompts you for the passphrase to decrypt the key files. If the passphrase is correct, the SSHv2 client initiates the DSA key authentication to the remote SSHv2 server. The SSHv2 client looks for the login user access level public key file on the SSHv2 server to process and validate the public key authentication. If the DSA authentication is successful, then the SSHv2 session is established.

If no matching user key pair files exist on the client side when initiating the SSHv2 session, or if the DSA authentication fails, you are automatically prompted for a password to attempt password authentication.

If the remote SSHv2 server is a Linux system, the server looks for the login user public key file `~/.ssh/authorized_keys` by default for DSA authentication. For a Linux SSHv2 client, the user DSA key pair files are located in the user home directory as `~/.ssa/id_dsa` and `~/.ssa/id_dsa.pub`.

## Block SNMP

The boot flag setting for block-snmpp (**boot config flags block-snmpp**) and the runtime configuration of SSH secure (**ssh secure**) each modify the block-snmpp boot flag. If you enable SSH secure mode, the system automatically sets the block-snmpp boot flag to true; the change takes effect immediately. After enabling SSH in secure mode, you can manually change the block-snmpp flag to false to allow both SSH and SNMP access.

### Important

The block flag setting for block-snmpp blocks Simple Network Management Protocol (SNMP)v1, SNMPv2, and SNMPv3.

## SCP command

Use short file names with the Secure CoPy (SCP) command. The entire SCP command, including all options, user names, and file names must not exceed 80 characters. The switch supports incoming SCP connections but does not support outgoing connections using an SCP client.

## Third-Party SSH and SCP Client Software

### *Tested Software*

The following table describes the third-party SSH and SCP client software that has been tested but is not included with the switch software.

**Table 231: Tested software**

SSH Client	Secure Shell (SSH)	Secure Copy (SCP)
Tera Term Pro with TTSSH extension MS Windows	<ul style="list-style-type: none"> <li>• Supports SSHv2.</li> <li>• Authentication:               <ul style="list-style-type: none"> <li>- RSA is supported when the switch acts as a server. The switch does not support RSA as a client.</li> <li>- DSA</li> <li>- Password</li> </ul> </li> <li>• Provides a keygen tool.</li> <li>• It creates both RSA and DSA keys.</li> </ul>	<ul style="list-style-type: none"> <li>• Client distribution does not include SCP client.</li> </ul>
Secure Shell Client Windows 2000	<ul style="list-style-type: none"> <li>• Supports SSHv2 client.</li> <li>• Authentication               <ul style="list-style-type: none"> <li>◦ DSA</li> <li>◦ Password</li> </ul> </li> <li>• Provides a keygen tool.</li> <li>• It creates a DSA key in SSHv2 format.</li> <li>• The switch generates a log message stating that a DSA key has been generated.</li> </ul>	<ul style="list-style-type: none"> <li>• Client distribution includes an SCP client that is not compatible with switch.</li> </ul>

**Table 231: Tested software (continued)**

SSH Client	Secure Shell (SSH)	Secure Copy (SCP)
OpenSSH Unix Solaris 2.5 / 2.6	<ul style="list-style-type: none"> <li>• Supports SSHv2 clients.</li> <li>• Authentication: <ul style="list-style-type: none"> <li>- RSA is supported when the switch acts as a server. The switch does not support RSA as a client.</li> <li>- DSA</li> <li>- Password</li> </ul> </li> <li>• Provides a keygen tool.</li> <li>• It creates both RSA and DSA keys.</li> </ul>	<ul style="list-style-type: none"> <li>• Client distribution includes an SCP client that is supported on switch.</li> </ul>
WinSCP		This SCP client is unsupported on the switch.

*Switch As Client*

The switch acting as the SSHv2 client generates a DSA public and private server key pair. The public part of the key for DSA is stored in the following location:

```
/intflash/.ssh/dsa_key_rwa
```

**Note**

For certain switches in enhanced secure mode, all sensitive files are protected. The home directory for protected files is `/intflash/shared`. You cannot access any sensitive files using Telnet, SSH, FTP, SFTP, TFTP, and SCP connections. For more information, see [Sensitive File Protection](#) on page 3623.

The public part of the key must be copied to the SSH server and be named according to the naming requirement of the server.

Consult [DSA Authentication Access Level and File Name](#) on page 3233 for proper naming convention.

If a DSA key pair does not exist, you can generate the DSA key pair using the **ssh dsa-user-key [WORD<1-15>] [size <1024-1024>]** command.

You need to copy the DSA public key to the SSHv2 server that you connect to using the switch as a client. RSA is not supported when using the switch as a client, but you can use RSA when the switch is acting as the server.

**Note**

SSH RSA and DSA public and private keys are copied from `/intflash/shared` to `/intflash/.ssh`.

*Switch As Server*

After you install one of the SSHv2 clients you must generate a client and server key using the RSA or DSA algorithms.

To authenticate an SSHv2 client using DSA, the administrator must copy the public part of the client DSA key to `/intflash/.ssh` directory on the switch that acts as the SSHv2 server. The file that is copied over to the SSHv2 server must be named according to [DSA Authentication Access Level and File Name](#) on page 3233.

## DSA Authentication Access Level and File Name

The following table lists the access levels and file names that you must use to store the SSHv2 client authentication information using DSA onto the switch that acts as the SSHv2 server.

For certain switches in enhanced secure mode, all sensitive files are protected. The home directory for enhanced secure mode is `/intflash/shared`. You cannot access any sensitive files using Telnet, SSH, FTP, SFTP, TFTP, and SCP connections. For more information, see [Sensitive File Protection](#) on page 3623.

**Table 232: DSA authentication access levels and file names**

Client key format or WSM	Access level	File name
Client key in non IETF and IETF format with enhanced secure mode disabled  <b>Note:</b> The switch supports IETF and non-IETF for DSA.	RWA	<code>/intflash/.ssh/dsa_key_rwa</code>
	RW	<code>/intflash/.ssh/dsa_key_rw</code>
	RO	<code>/intflash/.ssh/dsa_key_ro</code>
	L3	<code>/intflash/.ssh/dsa_key_rwl3</code>
	L2	<code>/intflash/.ssh/dsa_key_rwl2</code>
	L1	<code>/intflash/.ssh/dsa_key_rwl1</code>
Client key in enhanced secure mode  <b>Note:</b> Exception: does not apply to VSP 8600 Series.	administrator	<code>/intflash/shared/dsa_key_admin</code>
	operator	<code>/intflash/shared/dsa_key_operator</code>
	security	<code>/intflash/shared/dsa_key_security</code>
	privilege	<code>/intflash/shared/dsa_key_priv</code>
	auditor	<code>/intflash/shared/dsa_key_auditor</code>
Client key in enhanced secure mode  <b>Note:</b> Exception: only applies to VSP 8600 Series.	administrator	<code>/intflash/.ssh/dsa_key_admin</code>
	operator	<code>/intflash/.ssh/dsa_key_operator</code>
	security	<code>/intflash/.ssh/dsa_key_security</code>
	privilege	<code>/intflash/.ssh/dsa_key_priv</code>
	auditor	<code>/intflash/.ssh/dsa_key_auditor</code>

The switch generates an RSA public and private server key pair. The public part of the key for RSA is stored in `/intflash/.ssh/ssh_key_rsa_pub.key`. If an RSA key pair does not exist, then the switch automatically generates one when you enable the SSH server.

To authenticate a client using RSA, the administrator must copy the public part of the client RSA key to the switch.

For a certain switches in enhanced secure mode, sensitive files are protected. You cannot copy public or private keys directly to `/intflash/.ssh`. You must import the DSA/RSA private and public key from `/intflash/shared`. For more information, see [Import DSA and RSA Private or Public Keys](#) on page 3240.

#### Note

Sensitive file protection does not apply to VSP 8600 Series.

## RSA Authentication Access Level and File Name

For certain switches in enhanced secure mode, all sensitive files are protected. The home directory for enhanced secure mode is `/intflash/shared`. You cannot access any sensitive files using Telnet, SSH, FTP, SFTP, TFTP, and SCP connections. For more information, see [Sensitive File Protection](#) on page 3623.

The following table lists the access levels and file names you can use for storing the SSH client authentication information using RSA.

**Table 233: RSA authentication access levels and file names**

Client key format or WSM	Access level	File name
Client key in IETF format with enhanced secure mode disabled.	RWA	/flash/ssh/rsa_key_rwa
	RW	/flash/ssh/rsa_key_rw
	RO	/flash/ssh/rsa_key_ro
	L3	/flash/ssh/rsa_key_rwl3
	L2	/flash/ssh/rsa_key_rwl2
	L1	/flash/ssh/rsa_key_rwl1
Client key with enhanced secure mode enabled <b>Note:</b> Exception: does not apply to VSP 8600 Series.	administrator	/intflash/shared/rsa_key_admin
	operator	/intflash/shared/rsa_key_operator
	security	/intflash/shared/rsa_key_security
	privilege	/intflash/shared/rsa_key_priv
	auditor	/intflash/shared/rsa_key_auditor
Client key with enhanced secure mode enabled <b>Note:</b> Exception: only applies to VSP 8600 Series.	administrator	/intflash/ssh/rsa_key_admin
	operator	/intflash/ssh/rsa_key_operator
	security	/intflash/ssh/rsa_key_security
	privilege	/intflash/ssh/rsa_key_priv
	auditor	/intflash/ssh/rsa_key_auditor
	administrator	/intflash/ssh/rsa_key_admin

## SSH Rekeying

An SSHv2 server or client can use the SSH rekeying feature to force a key exchange between server and client, while changing the encryption and integrity keys. After you enable SSH rekeying, key exchanges occur after a pre-determined time interval or after the data transmitted in the session reaches the data-limit threshold. You can configure these values using the **ssh rekey** command.

SSH rekeying is optional. You can enable SSH rekey only if SSH is enabled globally. Most SSH clients and servers do not provide a rekey mechanism; do not enable SSH rekey in such cases. Active sessions shut down if the rekey fails.

### Note

You cannot enable SSH rekey selectively for the SSH client, SSH server, Secure Copy (SCP), or Secure File Transfer Protocol (SFTP); SSH rekey is enabled for all of these functions simultaneously.

## Configure Secure Shell using CLI

Use Secure Shell version 2 (SSHv2) to enable secure communications support over a network for authentication, encryption, and network Integrity.

### Before You Begin

- Disable the sshd daemon. All SSHv2 commands, except enable, require that you disable the sshd daemon.
- Set the user access level to read/write/all community strings.
- Disable all nonsecure access services. As a best practice, disable the following services: Trivial File Transfer Protocol (TFTP), File Transfer Protocol (FTP), and Telnet. For more information about disabling access services, see [Enable Remote Access Services](#) on page 194.
- Use the console port to configure the SSHv2 parameters. Depending on your hardware platform, the console port displays as console or 10101.

## Enabling the SSHv2 server

Enable the SSHv2 server to provide secure communications for accessing the switch. The switch does not support SSHv1.

### Before You Begin

To enable SSH, ensure to enable RSA or DSA authentication, or both using command **ssh rsa-auth** or **ssh dsa-auth**.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable the SSH server:  
`boot config flags sshd`
3. Save the configuration file:  
`save config`

### Example

Enable the SSHv2 server:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags sshd
Switch:1(config)#save config
```

## Changing the SSH server authentication mode

Use this procedure to change the SSH server authentication mode from the default of password-authentication to keyboard-interactive.

### About This Task

If you enable keyboard-interactive authentication mode, the server uses that mode over other authentication methods, except for public-key authentication, if the SSH client supports it.

If you enable keyboard-interactive authentication mode, the server generates the password prompts to display to the client rather than the client generating the prompts automatically like with password-authentication.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable keyboard-interactive authentication:  
`ssh keyboard-interactive-auth`

## Configure SSH Authentication Type

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Configure the authentication type to use:  
`ssh authentication-type {[aead-aes-128-gcm-ssh] [aead-aes-256-gcm-ssh]  
[hmac-sha1] [hmac-sha2-256]}`

### Variable Definitions

The following table defines parameters for the **ssh authentication-type** command.

Variable	Value
<code>[aead-aes-128-gcm-ssh] [aead-aes-256-gcm-ssh] [hmac-sha1] [hmac-sha2-256]</code>	Specifies the authentication type. Select from one of the following: <ul style="list-style-type: none"> <li>• aead-aes-128-gcm-ssh</li> <li>• aead-aes-256-gcm-ssh</li> <li>• hmac-sha1</li> <li>• hmac-sha2-256</li> </ul>

## Enable DSA Authentication

### Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Enable DSA authentication:

```
ssh dsa-auth
```

## Generate the DSA Host Key

### Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Generate a new DSA host key:

```
ssh dsa-host-key [<1024-1024>]
```

### Variable Definitions

The following table defines parameters for the **ssh dsa-host-key** command.

Variable	Value
<code>&lt;1024-1024&gt;</code>	The DSA host key size is 1024.

## Generate a DSA User Key

### Before You Begin

You must enable SSH globally before you can generate DSA user keys.

**Procedure**

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create the DSA user key:

```
ssh dsa-user-key WORD<1-15> [size <1024-1024>]
```

## Variable Definitions

The following table defines parameters for the **ssh dsa-user-key** command.

Variable	Value
<i>WORD</i> <1-15>	<p>Specifies the user access level. You must enable SSH globally before you can generate SSH DSA user keys. If enhanced secure mode is disabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> <li>• rwa — Specifies read-write-all.</li> <li>• rw — Specifies read-write.</li> <li>• ro — Specifies read-only.</li> <li>• rw1 — Specifies read-write for Layer 1.</li> <li>• rw2 — Specifies read-write for Layer 2.</li> <li>• rw3 — Specifies read-write for Layer 3.</li> </ul> <p>If you enable enhanced secure mode, the switch uses role-based authentication. You associate each username with a specific role and the appropriate authorization rights to commands based on that role. If enhanced secure mode is enabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> <li>• admin—Specifies a user role with access to all of the configurations, show commands, and the ability to view the log file and security commands. The administrator role is the highest level of user roles.</li> <li>• operator—Specifies a user role with access to all of the configurations for packet forwarding on Layer 2 and Layer 3, and has access to show commands to view the configuration, but cannot view the audit logs and cannot access security and password commands.</li> <li>• auditor—Specifies a user role that can view log files and view all configurations, except password configuration.</li> <li>• security—Specifies a user role with access only to security settings and the ability to view the configurations.</li> <li>• priv—Specifies a user role with access to all of the commands that the administrator has access to, and is referred to as an emergency-admin. However, the user with the privilege role must be authenticated within the switch locally. RADIUS and TACACS+ authentication is not accessible. A user role at the privilege level must login to the switch through the console port only.</li> </ul>
<i>size</i> <1024-1024>	Specifies the size of the DSA user key.

## Import DSA and RSA Private or Public Keys

### Note

This procedure does not apply to VSP 8600 Series.

### About This Task

Use this task to import SSH RSA and DSA public and private keys.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enter the following command to install the DSA or RSA public or private key:

```
ssh install-user-key WORD<1-15> {rwa | rw | ro | rwl1 | rwl2 | rwl3  
| admin | operator | auditor | security | priv} WORD<1-15 {public |  
private} WORD<1-15 {dsa | rsa}
```

### Examples

```
Switch:1(config)#ssh install-user-key admin public dsa  
Switch(config)#1 2021-07-22T14:09:43.278+03:00 VSP-4900-24S CP1 - 0x0041460b - 00000000  
GlobalRouter CLOUD_AGENT INFO  
Successfully installed SSH public key to path </intflash/.ssh/dsa_key_admin>.  
Switch:1(config)#ssh install-user-key admin private dsa  
Info: Successfully installed the private key to path /intflash/.ssh/id_dsa_admin  
Switch:1(config)#1 2021-07-22T14:08:00.354+03:00 VSP-4900-24S CP1 - 0x0041460b - 00000000  
GlobalRouter CLOUD_AGENT INFO Successfully installed SSH private key to path </  
intflash/.ssh/id_dsa_admin>.
```

## Variable Definitions

the following table defines parameters for the **ssh install-user-key** command.

Variable	Value
<pre>WORD&lt;1-15&gt;{ rwa   rw   ro   rwl1   rwl2   rwl3, enhanced-secured mode : admin   operator   auditor   security   priv }</pre>	<p>Specifies the user access level. You must enable SSH globally before you can generate SSH DSA user keys. If enhanced secure mode is disabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> <li>• rwa — Specifies read-write-all.</li> <li>• rw — Specifies read-write.</li> <li>• ro — Specifies read-only.</li> <li>• rwl1 — Specifies read-write for Layer 1.</li> <li>• rwl2 — Specifies read-write for Layer 2.</li> <li>• rwl3 — Specifies read-write for Layer 3.</li> </ul> <p>If you enable enhanced secure mode, the switch uses role-based authentication. You associate each username with a specific role and the appropriate authorization rights to commands based on that role. If enhanced secure mode is enabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> <li>• admin—Specifies a user role with access to all of the configurations, show commands, and the ability to view the log file and security commands. The administrator role is the highest level of user roles.</li> <li>• operator—Specifies a user role with access to all of the configurations for packet forwarding on Layer 2 and Layer 3, and has access to show commands to view the configuration, but cannot view the audit logs and cannot access security and password commands.</li> <li>• auditor—Specifies a user role that can view log files and view all configurations, except password configuration.</li> <li>• security—Specifies a user role with access only to security settings and the ability to view the configurations.</li> <li>• priv—Specifies a user role with access to all of the commands that the administrator has access to, and is referred to as an emergency-admin. However, the user with the privilege role must be authenticated within the switch locally. RADIUS and TACACS+ authentication is not accessible. A user role at the privilege level must login</li> </ul>

Variable	Value
	to the switch through the console port only.
<i>WORD</i> <1-15>{ <i>public</i>   <i>private</i> }	Specifies the public key or the private key type to copy from /intflash/shared to /intflash/.ssh.
<i>WORD</i> <1-15>{ <i>dsa</i>   <i>rsa</i> }	Specifies the DSA or RSA signature algorithm for the public key or the private key to copy.

## Configure Encryption Type

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the type of encryption to use:

```
ssh encryption-type {[3des-cbc][aead-aes-128-gcm-ssh ][aead-aes-256-gcm-ssh] [aes128-cbc][aes128-ctr][aes192-cbc][aes192-ctr][aes256-cbc][aes256-ctr][blowfish-cbc] [rijndael128-cbc][rijndael192-cbc]}
```

### Variable Definitions

The following table defines parameters for the **ssh encryption-type** command.

Variable	Value
<i>[3des-cbc][aead-aes-128-gcm-ssh ][aead-aes-256-gcm-ssh] [aes128-cbc][aes128-ctr][aes192-cbc][aes192-ctr][aes256-cbc][aes256-ctr][blowfish-cbc] [rijndael128-cbc][rijndael192-cbc]</i>	<p>Configures the encryption-type. Select an encryption-type from one of the following:</p> <ul style="list-style-type: none"> <li>• 3des-cbc</li> <li>• aead-aes-128-gcm-ssh</li> <li>• aead-aes-256-gcm-ssh</li> <li>• aes128-cbc</li> <li>• aes128-ctr</li> <li>• aes192-cbc</li> <li>• aes192-ctr</li> <li>• aes256-cbc</li> <li>• aes256-ctr</li> <li>• blowfish-cbc</li> <li>• rijndael128-cbc</li> <li>• rijndael192-cbc</li> </ul> <p>By default, all encryption types are enabled. If you configure the switch in Enhanced Secure Mode, <i>3des-cbc</i> and <i>blowfish-cbc</i> are disabled by default.</p>

## Configure the Key-Exchange Method

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the key-exchange to use:
 

```
ssh key-exchange-method {[diffie-hellman-group14-sha1] [diffie-
hellman-group-exchange-sha256]}
```

### Variable Definitions

The following table defines parameters for the **ssh key-exchange-method** command.

Variable	Value
<code>[diffie-hellman-group14-sha1] [diffie-hellman-group-exchange-sha256]</code>  <b>Note:</b> Exception: diffie-hellman-group-exchange-sha256 is not supported on VSP 8600 Series.	Configures the key-exchange method. Select a key-exchange method from one of the following: <ul style="list-style-type: none"> <li>• diffie-hellman-group14-sha1</li> <li>• diffie-hellman-group-exchange-sha256</li> </ul>

## Configure the Maximum Number of SSH Sessions

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the maximum number of SSH sessions:
 

```
ssh max-sessions <0-8>
```

### Variable Definitions

The following table defines parameters for the **ssh max-sessions** command.

Variable	Value
<code>&lt;0-8&gt;</code>	Specifies the maximum number of SSH sessions allowed. A value from 0 to 8. Default is 4.

## Enable SSH Password Authentication

Enable password authentication. The default is enabled.

**Procedure**

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Enable password authentication:  
`ssh pass-auth`

## Configure the SSH Connection Port

**Procedure**

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Configure the SSH connection port:  
`ssh port <22,1024..49151>`

*Variable Definitions*

The following table defines parameters for the **ssh port** command.

Variable	Value
<code>&lt;22,1024-49151&gt;</code>	<p>Specifies the TCP port number. The default is 22.</p> <p><b>Important:</b> You cannot configure TCP port 6000 as the SSH connection port.</p>

## Enable RSA Authentication

**Procedure**

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Enable the RSA authentication:  
`ssh rsa-auth`

## Generate an RSA Host Key

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Generate a new RSA host key:  
`ssh rsa-host-key [<1024-2048>]`

### Variable Definitions

The following table defines parameters for the **ssh rsa-host-key** command.

Variable	Value
<1024-2048>	Specify an optional key size from 1024 to 2048. The default is 2048.

## Generate an RSA User Key

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Generate a new RSA user key.  
`ssh rsa-user-key WORD<1-15> [size <1024-2048> ]`

## Variable Definitions

The following table defines parameters for the `ssh rsa-user-key` command.

Variable	Value
<i>WORD</i> <1-15>	<p>Specifies the user access level.</p> <p>If enhanced secure mode is disabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> <li>• rwa — Specifies read-write-all</li> <li>• rw — Specifies read-write</li> <li>• ro — Specifies read-only</li> <li>• rw1 — Specifies read-write for Layer 1</li> <li>• rw2 — Specifies read-write for Layer 2</li> <li>• rw3 — Specifies read-write for Layer 3</li> </ul> <p>If you enable enhanced secure mode, the switch uses role-based authentication. You associate each username with a specific role and the appropriate authorization rights to commands based on that role.</p> <p>If enhanced secure mode is enabled, the value user access levels for the switch are:</p> <ul style="list-style-type: none"> <li>• admin—Specifies a user role with access to all of the configurations, show commands, and the ability to view the log file and security commands. The administrator role is the highest level of user roles.</li> <li>• operator—Specifies a user role with access to all of the configurations for packet forwarding on Layer 2 and Layer 3, and has access to show commands to view the configuration, but cannot view the audit logs and cannot access security and password commands.</li> <li>• auditor—Specifies a user role that can view log files and view all configurations, except password configuration.</li> <li>• security—Specifies a user role with access only to security settings and the ability to view the configurations</li> <li>• priv—Specifies a user role with access to all of the commands that the administrator has access to, and is referred to as an emergency-admin. However, the user with the privilege role must be authenticated within the switch locally. RADIUS and TACACS+ authentication is not accessible. A user role at the privilege level must login to the switch through the console port only.</li> </ul>
<i>size</i> <1024-1024>	Specifies the size of the RSA user key.

## Enable SSH Secure Mode

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable SSH secure mode:  

```
ssh secure
```

## Configure the SSH version

Configure Secure Shell version 2 (SSHv2). The switch does not support SSHv1.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the SSH version:  

```
ssh version <v2only>
```

## Configure the SSH Authentication Timeout

Configure the timeout for SSH connection authentication.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the authentication timeout:  

```
ssh timeout <1-120>
```

### Variable Definitions

The following table defines parameters for the **ssh timeout** command.

Variable	Value
<1-120>	Specifies the SSH connection authentication timeout in seconds. Default is 60 seconds.

## Resetting the SSH

## About This Task

Perform this task to terminate all SSH sessions and restart SSH server.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Reset the SSH.

```
ssh reset
```

## Configure X.509 V3 Authentication

### Note

DEMO FEATURE - Two-Factor Authentication–X.509v3 Certificates for SSH is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [Fabric Engine and VOSS Feature Support Matrix](#).

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable X.509 V3 authentication:

```
ssh x509v3-auth enable
```

3. Configure X.509 V3 revocation:

```
ssh x509v3-auth revocation-check-method {none | ocsf}
```

4. Configure X.509 V3 username:

```
ssh x509v3-auth username {overwrite | strip-domain | use-domain  
WORD<1-254>}
```

5. Configure X.509 V3 CA trustpoint name:

```
ssh x509v3-auth ca-name WORD<1-45>
```

6. Configure the X.509 V3 digital certificate subject name to use as the identity certificate:

```
ssh x509v3-auth cert-subject-name WORD<1-45>
```

## Example

Display the certificate authority details:

```
Switch:1(config)#show certificate ca

CA table entry
Name                : 823-pki[auto-installed]
```

```
CommonName      : CaA2-1
KeyName         : pki
SubjectName     : 823

## Variable Definitions

The following table defines parameters for the `ssh x509v3-auth` command.

Variable	Value
<code>&lt;none ocsp&gt;</code>	<p>Specifies the X.509 V3 authentication revocation check method. The default is OCSP.</p> <ul style="list-style-type: none"> <li><code>none</code> - Specifies no revocation check method.</li> <li><code>ocsp</code> - Specifies Online Certificate Status Protocol (OCSP) as revocation check method.</li> </ul> <p><b>x509v3-auth</b> is available for demonstration purposes on some products. For more information, see <a href="#">Fabric Engine and VOSS Feature Support Matrix</a>.</p>
<code>overwrite strip-domain use-domain WORD&lt;1-254&gt;</code>	<p>Specifies the X.509 V3 username configuration. The default is disabled.</p> <ul style="list-style-type: none"> <li><code>overwrite</code> - Specifies the switch to send the principal name and domain name from the certificate to the RADIUS server for authorization.</li> <li><code>strip-domain</code> - Specifies the switch to send the principal name from the certificate without the domain name to the RADIUS server for authorization.</li> <li><code>use-domain WORD&lt;1-254&gt;</code> - Specifies the switch to send the principal name from the certificate, with the domain name you entered to the RADIUS server for authorization.</li> </ul> <p><b>x509v3-auth</b> is available for demonstration purposes on some products. For more information, see <a href="#">Fabric Engine and VOSS Feature Support Matrix</a>.</p>
<code>ca-name WORD&lt;1-45&gt;</code> <b>Note:</b> Exception: Not supported on VSP 8600 Series	Specifies the X.509 V3 CA trustpoint name.
<code>cert-subject-nameWORD&lt;1-45&gt;</code> <b>Note:</b> Exception: Not supported on VSP 8600 Series	Specifies the digital certificate subject name to be used as the identity certificate.

## Verify and Display SSH Configuration Information

Verify that SSH services are enabled on the switch and display SSH configuration information to ensure that the SSH parameters are properly configured.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Verify that SSH services are enabled and view the SSH configuration:

```
show ssh <global|session>
```

### Example

Display global system SSH information:

```
Switch:1(config)#show ssh global

Total Active Sessions           : 0
version                         : v2only
port                            : 22

### Variable Definitions

The following table defines parameters for the **show ssh** command.

Variable	Value
<i>global</i>	Display global system SSH information.
<i>session</i>	Display the current session SSH information.

## Connect to a Remote Host using the SSH Client

Make an SSH connection to a remote host.

### Before You Begin

Enable the SSH server on the remote host.

### About This Task

The command format, for the CLI SSH client command, is similar to Telnet with two additional parameters: `-l login` and an optional `-p port` parameter.

On IPv6 networks, the switch supports SSH server only. The switch does not support outbound SSH client over IPv6. On IPv4 networks, the switch supports both SSH server and SSH client.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. Connect to a remote host:  
`ssh WORD<1-256> -l WORD<1-32> [-p <1-32768>]`

### Example

Connect to the remote host:

```
Switch:1>enable
Switch:1#ssh 192.0.2.1 -l rwa
```

### Variable Definitions

The following table defines parameters for the **ssh** command.

Variable	Value
<code>WORD&lt;1-32&gt;</code>	Specifies the user login name of the remote SSH server.
<code>-p &lt;1-32768&gt;</code>	Specifies the port number to connect to the remote SSH server. The default is 22.

## Generate User Key Files

Configure the SSH parameters to generate DSA user key files.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable SSH server.
3. Create the DSA user key file:  
`ssh dsa-user-key [WORD<1-15>][size <1024-1024>]`

4. Enter the encryption password to protect the key file.
5. Copy the user public key file to the remote SSH servers.

**Note**

For certain switches in enhanced secure mode, the public key is copied from `/intflash/.ssh` to `/intflash/shared` after key pair generation to be available in enhanced secure mode.

6. If you are generating the compatible keys on a Linux system, use the following steps:
  - a. Create the DSA user key file:

```
ssh-keygen -t dsa
```
  - b. Copy the user public key to the remote SSH servers.

**Note**

The DSA pair key files can be generated on the Linux system and used by the SSH client on the switch.

**Example**

Create the DSA user key file with the user access level set to read-write-all and size of the DSA user key set to 1024 bits:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ssh dsa-user-key rwa size 1024
```

### Variable Definitions

The following table defines parameters for the `ssh dsa-user-key` command.

Variable	Value
<code>WORD &lt;1-15&gt;</code>	<p>Specifies the user access level. If enhanced secure mode is disabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> <li>• <code>rwa</code>—Specifies read-write-all.</li> <li>• <code>rw</code>—Specifies read-write.</li> <li>• <code>ro</code>—Specifies read-only</li> <li>• <code>rw13</code>—Specifies read-write for Layer 3.</li> <li>• <code>rw12</code>—Specifies read-write for Layer 2.</li> <li>• <code>rw11</code>—Specifies read-write for Layer 1.</li> </ul> <p>If you enable enhanced secure mode, the switch uses role-based authentication. You associate each username with a specific role and the appropriate authorization rights to commands based on that role.</p> <p>If enhanced secure mode is enabled, the valid user access levels for the switch are:</p> <ul style="list-style-type: none"> <li>• <code>admin</code>—Specifies a user role with access to all of the configurations, show commands, and the ability to view the log file and security commands. The administrator role is the highest level of user roles.</li> <li>• <code>operator</code>—Specifies a user role with access to all of the configurations for packet forwarding on Layer 2 and Layer 3, and has access to show commands to view the configuration, but cannot view the audit logs and cannot access security and password commands.</li> <li>• <code>auditor</code>—Specifies a user role that can view log files and view all configurations, except password configuration.</li> <li>• <code>security</code>—Specifies a user role with access only to security settings and the ability to view the configurations.</li> <li>• <code>priv</code>—Specifies a user role with access to all of the commands that the administrator has access to, and is referred to as an emergency-admin. However, the user with the privilege role must be authenticated within the switch locally. RADIUS and TACACS+ authentication is not accessible. A user role at the privilege level must login to the switch through the console port only.</li> </ul>
<code>size &lt;1024-1024&gt;</code>	Specifies the size of the DSA user key. The default is 1024 bits.

## Manage an SSL Certificate

### Note

For certain switches in enhanced secure mode, all sensitive files are protected. You cannot access any sensitive files using Telnet, SSH, FTP, SFTP, TFTP, and SCP connections. For more information, see [Sensitive File Protection](#) on page 3623.

The TLS server selects a certificate authority (CA)-signed certificate if the certificate is already installed in the Digital Certificate module.

If the server certificates are not available, the TLS server generates a new self-signed certificate at startup and uses that by default. You can choose to use an online or an offline CA-signed certificate, which takes precedence over the self-signed certificate.

For more information about SSL certificate manipulation, see [Certificate Order Priority](#) on page 3287.

### About This Task

If a certificate is already present, you must confirm that it can be deleted before a new one is created.

After you create a certificate, the system logs one of the following INFO alarms:

- New default Server Certificate and Key are generated and installed
- Current Server Certificate and Key are installed

The default certificate key length for a certificate generated on the switch is 2,048 bits.

#### Note

The **ssl certificate [validity-period-in-days <30-3650>]** command in this procedure does not require a system reboot.

### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Create and install a new self-signed certificate:  
ssl certificate [validity-period-in-days <30-3650>]
3. Delete a certificate:  
no ssl certificate

#### Note

The certificate loaded in memory remains valid until you use the **ssl reset** command or reboot the system.

### Variable Definitions

The following table defines parameters for the **ssl certificate** command.

Variable	Value
<i>validity-period-in-days</i> <30-3650>	Specifies an expiration time for the certificate. The default is 365 days.

## Disabling SFTP without disabling SSH

Disable SFTP while allowing SSH to remain active.

### Before You Begin

Enhanced secure mode must be enabled. For information about enabling enhanced secure mode, see [Enabling enhanced secure mode](#) on page 3639.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable the SSHv2 server:  

```
no ssh sftp enable
```
3. Save the configuration file:  

```
save config
```

## Enable SSH Rekey

You cannot enable SSH rekey selectively for the SSH client, SSH server, Secure Copy (SCP), or Secure File Transfer Protocol (SFTP); SSH rekey is enabled for all of these functions simultaneously.

**Before You Begin**

Enable SSH globally.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enter the following command:  

```
ssh rekey enable
```

*Variable Definitions*

The following table defines parameters for the **ssh rekey** command.

Variable	Value
<i>enable</i>	Enables SSH rekey globally. The default is disabled.

## Configure the SSH Rekey Data Limit Threshold

Use the following procedure to limit data transmission during the session.

**Procedure**

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enter the following command:  

```
ssh rekey data-limit <1-6>
```

## Example

Configure the data limit to 2 GB:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ssh rekey data-limit 2
```

### Variable Definitions

The following table defines parameters for the **ssh rekey data-limit** command.

Variable	Value
<1-6>	Specifies the SSH rekey data limit in GB. The default is 1 GB.

## Configure the SSH Rekey Time Interval

Use the following procedure to configure a time interval, after which the key exchange takes place.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enter the following command:
 

```
ssh rekey time-interval <1-6>
```

### Example

Configure the SSH rekey time-interval to 3 hours:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#ssh rekey time-interval 3
```

### Variable Definitions

The following table defines parameters for the **ssh rekey time-interval** command.

Variable	Value
<1-6>	Specifies the time-interval for SSH rekeying in hours. The default is 1 hour.

## Display SSH Rekey Information

Use the following procedure to display the SSH rekey information.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Enter the following command:  
show ssh rekey

### Example

```
Switch:1> enable
Switch:1#show ssh rekey
    Rekey Status      : TRUE
    Rekey data limit  : 1 GB
    Rekey time interval : 1 hours
```

## Enabling or Disabling the SSH Client

### About This Task

You can disable the SSH client functionality on the switch. By default, the SSH client functionality is enabled.

#### Note

In order to enable the SSH client functionality, SSH must be enabled globally.

### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Disable the SSH client functionality:  
no ssh client <enable>
3. Use one of the following commands to enable the SSH client functionality:
  - ssh client <enable>
  - default ssh client <enable>

#### Note

You must enable SSH globally before the SSH client functionality can be re-enabled.

### Example

Display the general SSH settings::

```
Switch:1(config)# show ssh global
```

```
Total Active Sessions : 0
    version              : v2only
    port                 : 22
    max-sessions         : 4
    timeout              : 60
```

```

action rsa-host key      : rsa-hostkeysize 2048
action dsa-host key      : dsa-hostkeysize 1024
rsa-auth                  : true
dsa-auth                  : true
pass-auth                 : true
keyboard-interactive-auth : false
sftp enable               : true
enable                    : true
client enable             : true

```

Disable SSH client functionality:

```
Switch:1(config)# no ssh client
```

```
Switch:1(config)# show ssh global
```

```

Total Active Sessions   : 0
  version                : v2only
  port                   : 22
  max-sessions           : 4
  timeout                : 60
  action rsa-host key    : rsa-hostkeysize 2048
  action dsa-host key    : dsa-hostkeysize 1024
  rsa-auth               : true
  dsa-auth               : true
  pass-auth              : true
  keyboard-interactive-auth : false
  sftp enable            : true
  enable                 : true
  client enable          : false

```

## Downgrading or Upgrading from Releases that Support Different Key Sizes

Use this procedure if you need to downgrade or upgrade from a release that supports different key sizes.

Different releases can support different DSA host key, RSA host key, and DSA user key sizes. If you need to upgrade or downgrade to an earlier release that does not support the same key size, you must delete all of the keys from the `.ssh` directory and generate new keys for SSH. If you do not do this, key sizes that are no longer supported will no longer function.

You only need to perform this procedure if you have previously generated DSA host, RSA host, or DSA user keys with a release that supports different key sizes.

### Procedure

1. Use the following command to disable SSH:  
`no ssh`
2. From the config terminal go to the `.ssh` directory using the command:  
`cd /intflash/.ssh`
3. After you upgrade or downgrade, delete the following keys from the `.ssh` directory.

```

ssh_dss.key
ssh_rsa.key
moc_sshc_dsa_file
moc_sshc_rsa_file
id_dsa_rwa

```

```
id_dsa_rwa.pub
id_rsa_rwa
id_rsa_rwa.pub
moc_sshc_dsa_file_fed
moc_sshc_rsa_file_fed
known_hosts
ssh_ecdsa.key
dsa_key_<access level like rwa/rw/ro/admin/security/privilege/operator/auditor>,
example: dsa_key_rwa
rsa_key_<access level like rwa/rw/ro/admin/security/privilege/operator/auditor>,
example: rsa_key_rwa
```

4. Generate a new DSA host key:

```
ssh dsa-host-key [<1024-1024>]
```

5. Generate a new SSH DSA user key:

```
ssh dsa-user-key WORD<1-15> [size <1024-1024>]
```

6. Generate a new RSA host key:

```
ssh rsa-host-key [<1024-2048>]
```

## Secure Shell configuration using Enterprise Device Manager

Use Secure Shell version 2 (SSHv2) to enable secure communications support over a network for authentication, encryption, and network Integrity.

On IPv6 networks, the switch supports SSHv2 server only. The switch does not support outbound SSHv2 client over IPv6. On IPv4, the switch supports both SSHv2 server and SSHv2 client.

For more information, see [Change Secure Shell Parameters](#) on page 3260.

### Change Secure Shell Parameters

You can use Enterprise Device Manager to change the SSHv2 configuration parameters. However, as a best practice, use the CLI to perform the initial configuration of SSHv2. The switch does not support SSHv1.

#### Before You Begin

- The user access level is read/write/all community strings.
- You must disable the SSH service before you configure the SSH service parameters. If the SSHv2 service is enabled, the system displays all fields dimmed until the SSH service is disabled.

#### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **SSH**.
3. Select the **SSH** tab.
4. In the **Enable** field, select the type of SSH service you want to enable.
5. In the **Version** field, select a version.
6. In the **Port** field, type a port number.
7. In the **MaxSession** field, type the maximum number of sessions allowed.

8. In the **Timeout** field, type the timeout value in seconds.
9. From the **KeyAction** field, choose a key action.
10. In the **RsaKeySize** field, type the RSA key size in bytes.
11. In the **DSAKeySize** field, type the DSA key size in bytes.
12. Select the **RsaAuth** check box for RSA authentication.
13. Select the **DsaAuth** check box for DSA authentication.
14. Select the **PassAuth** check box for password authentication.
15. In the **AuthType** section, select the authentication types you want.
16. In the **Encryption Type** section, select the encryption types you want.
17. In the **KeyExchangeMethod** section, select the key exchange method you want.
18. Select **Apply**.

### SSH Field Descriptions

Use the data in the following table to use the **SSH** tab.

Name	Description
<b>Enable</b>	<p>Enables, disables, or securely enables SSHv2. The options are:</p> <ul style="list-style-type: none"> <li>• false</li> <li>• true</li> <li>• secure</li> </ul> <p>Select false to disable SSHV2 services. Select true to enable SSHV2 services. Select secure to enable SSH and disable access services (SNMP, FTP, TFTP, and Telnet). The default is false.</p> <p><b>Important:</b> Do not enable SSHV2 secure mode using EDM. Enabling secure mode disables SNMP, which locks you out of the EDM session. Enable SSHV2 secure mode using CLI.</p>
<b>Version</b>	<p>Configures the SSH version. The options are:</p> <ul style="list-style-type: none"> <li>• v2only</li> </ul> <p>The default is v2only.</p>
<b>Port</b>	<p>Configures the SSHV2 connection port number. &lt;22 or 1024–49151&gt; is the port range of SSHV2.</p> <p><b>Important:</b> You cannot configure the TCP port 6000 as SSHv2 connection port.</p>
<b>MaxSession</b>	<p>Configures the maximum number of SSHv2 sessions allowed. The value can be from 0 to 8. The default is 4.</p>
<b>Timeout</b>	<p>Configures the SSHV2 authentication connection timeout in seconds. The default is 60 seconds.</p>

Name	Description
<b>KeyAction</b>	Configures the SSHv2 key action. The options are: <ul style="list-style-type: none"> <li>• none</li> <li>• generateDsa</li> <li>• generateRsa</li> <li>• deleteDsa</li> <li>• deleteRsa</li> </ul>
<b>RsaKeySize</b>	Configures SSHv2 RSA key size. The value can be from 1024 to 2048. The default is 2048.
<b>DsaKeySize</b>	Configures the SSHv2 DSA key size. The value can be from 512 to 1024. The default is 1024.
<b>RsaAuth</b>	Enables or disables SSHv2 RSA authentication. The default is enabled.
<b>DsaAuth</b>	Enables or disables SSHv2 DSA authentication. The default is enabled.
<b>PassAuth</b>	Enables or disables SSHv2 RSA password authentication. The default is enabled.
<b>RekeyEnable</b> <b>Note:</b> Exception: Not supported on XA1400 Series or VSP 8600 Series	<b>Note:</b> You cannot enable SSH rekey selectively for the SSH client, SSH server, Secure Copy (SCP), or Secure File Transfer Protocol (SFTP); SSH rekey is enabled for all of these functions simultaneously.
<b>RekeyTimeInterval</b> <b>Note:</b> Exception: Not supported on XA1400 Series or VSP 8600 Series	Configures a time interval, after which the key exchange takes place. The default is 1 hour.
<b>RekeyDataLimit</b> <b>Note:</b> Exception: Not supported on XA1400 Series or VSP 8600 Series	Configures the limit for data transmission during the session. The default is 1 GB.
<b>SftpEnable</b>	Enables or disables SFTP. You can use this check box to disable SFTP without affecting the SSH status. The default is enabled.
<b>KeyboardInteractiveAuth</b>	Changes the SSH server authentication mode from the default of password authentication to keyboard interactive.
<b>ClientEnable</b>	Enables SSH client functionality on the switch. By default, the SSH client functionality is enabled. To enable the SSH client functionality, SSH must be enabled globally.

Name	Description
<b>X509AuthEnable</b>	Enables SSH x509 authentication. The default is enabled.
<b>X509AuthRevocationCheckMethod</b>	<p>Specifies the X.509 V3 authentication revocation check method. The default is OCSP.</p> <ul style="list-style-type: none"> <li>• none - Specifies no revocation check method.</li> <li>• oscp - Specifies Online Certificate Status Protocol (OCSP) as revocation check method.</li> </ul>
<b>X509AuthUserNameOverwrite</b>	Enables the switch to send the principal name and domain name from the certificate to the RADIUS server for authorization. The default is disabled.
<b>X509AuthUserNameStripDomain</b>	Enables the switch to send the principal name from the certificate without the domain name to the RADIUS server for authorization. The default is disabled.
<b>X509AuthUserNameUseDomain</b>	Enables the switch to send the principal name from the certificate, with the domain name you entered to the RADIUS server for authorization.
<b>X509AuthCertificateSubjectName</b>	Specifies the digital certificate subject name used as identity certificate.
<b>X509AuthCertificateCAName</b>	Specifies the digital certificate CA trustpoint name to use.
<b>AuthType</b>	<p>Specifies the authentication type. Select from one of the following:</p> <ul style="list-style-type: none"> <li>• hmacSha1</li> <li>• hmacSha2256</li> <li>• aeadAes128GcmSsh</li> <li>• aeadAes256GcmSsh</li> </ul> <p>By default, all authentication types are selected.</p>

Name	Description
<b>EncryptionType</b>	<p>Configures the encryption-type. Select an encryption-type from one of the following:</p> <ul style="list-style-type: none"> <li>• aes128Cbc</li> <li>• aes256Cbc</li> <li>• threeDesCbc</li> <li>• aeadAes128GcmSsh</li> <li>• aeadAes256GcmSsh</li> <li>• aes128Ctr</li> <li>• rijndael128Cbc</li> <li>• aes256Ctr</li> <li>• aes192Ctr</li> <li>• aes192Cbc</li> <li>• rijndael192Cbc</li> <li>• blowfishCbc</li> </ul> <p>By default, all encryption types are enabled. If you configure the switch in enhanced secure mode, <b>threeDesCbc</b> and <b>blowfishCbc</b> are disabled by default.</p>

	7720 Series	Planned for Fabric Engine 8.10.1
	VSP 4450 Series	Planned for VOSS 8.10.1
	VSP 4900 Series	Planned for VOSS 8.10.1
	VSP 7200 Series	Planned for VOSS 8.10.1
	VSP 7400 Series	Planned for VOSS 8.10.1
	VSP 8200 Series	Planned for VOSS 8.10.1
	VSP 8400	Planned for VOSS 8.10.1
	XA1400 Series	Not Supported

### Important

Fabric Extend Integration with ExtremeCloud SD-WAN is added to the document in advance of feature support. Feature support is planned for 8.10.1.

If you have remote branch sites with only Internet connectivity and you want to extend the capabilities of fabric to that site, or if you have a branch office with a private WAN connection and you want to have a backup link using the public Internet, you can extend the Fabric network over the Internet towards a remote branch by connecting Fabric switches through ExtremeCloud SD-WAN.

Fabric Extend Integration with ExtremeCloud SD-WAN integrates the following features for SD-WAN deployments:

- Automation of Fabric Extend Tunnels over IP WAN infrastructure
- MTU configuration per IS-IS logical interface for Layer 3 interfaces
- SD-WAN infrastructure adjusts packet size to accommodate restricted MTU paths, such as Internet by fragmenting the end user IP packets.

This deployment provides the following benefits:

- Encrypted transport
- Automated provisioning of Fabric switches - Fabric Extend tunnels, MTU, and tunnel state exchange between the SD-WAN Appliance and Fabric switches through LLDP. Only one port on the switch supports this capability. For more information, see [Auto-sense Port States](#) on page 21.
- Enhanced branch resiliency - one or more Fabric switches must be connected to the LAN port or ports of the SD-WAN Appliance to achieve automated redundancy.
- Visibility of branch application traffic and optimized performance

# Security

---

[Security Fundamentals](#) on page 3267

[Security Configuration using CLI](#) on page 3290

[Security Configuration using EDM](#) on page 3336

This section provides conceptual and procedural information about security services on the switch.

## Security Fundamentals

---

This section provides conceptual content to help you configure and customize the security services on the switch.

### Security overview

Security is a critical attribute of networking devices. Security features are split into two main areas:

- Control path—protects the access to the device from a management perspective.
- Data path—protects the network from malicious users by controlling access authorization to the network resources (such as servers and stations). This protection is primarily accomplished by using filters or access lists.

You can protect the control path using the following mechanism:

- logon and passwords
- access policies to specify the network and address that can use a service or daemon
- secure protocols, such as Secure Shell (SSH), Secure Copy (SCP), and the Simple Network Management Protocol version 3 (SNMPv3)
- the Message Digest 5 Algorithm (MD5) to protect routing updates, Open Shortest Path First (OSPF), and Border Gateway Protocol (BGP)

You can protect the data path using the following mechanism

- Media Access Control (MAC) address filtering
- Layer 3 filtering, such as Internet Protocol (IP) and User Datagram Protocol (UDP)/Transmission Control Protocol (TCP) filtering
- routing policies to prevent users from accessing restricted areas of the network
- mechanisms to prevent denial-of-service (DOS) attacks

## Security Modes

The switch support three security modes:

- Enhanced secure
- Hsecure
- SSH secure

Enable SSH secure mode to permit only SSH and disable all other protocols, which include Telnet, FTP, SNMP, TFTP, HTTP, and HTTPS. Enabling this mode disables Telnet, FTP, SNMP, TFTP, HTTP, and HTTPS by setting the boot flags for these protocols to off. You can over-ride the configuration and enable required protocols individually for run-time use. The administrator must enable required protocols individually for run-time use again following a reboot even if you save the configuration. This is because the SSH secure mode enable takes precedence at the time of reboot and the other protocols will be disabled even though the configuration file has them set to enabled.

### Note

Disabling SSH secure mode will not automatically enable the OAM protocols that were disabled. The boot flags for the required protocols will have to be individually set to enabled.

The following table lists the differences between enhanced secure mode and hsecure mode.

**Table 235: Enhanced secure mode versus hsecure mode**

Feature	Enhanced secure	Hsecure
Authentication	Role-based: <ul style="list-style-type: none"> <li>• admin</li> <li>• privilege</li> <li>• operator</li> <li>• security</li> <li>• auditor</li> </ul>	Access-level based: <ul style="list-style-type: none"> <li>• rwa</li> <li>• rw</li> <li>• ro</li> <li>• l3</li> <li>• l2</li> <li>• l1</li> </ul>
Password length	Minimum of 8 characters with the exception of the Admin, which requires a minimum of 15 characters	10 characters, minimum
Password rules	1 or 2 upper case, lower case, numeric and special characters	Minimum of 2 upper case, 2 lower case, 2 numeric and 2 special characters
Password expiration	Per-user minimum change interval is enforced, which is programmed by the Administrator	Global expiration, configured by the Admin
Password-unique	Previous passwords and common passwords between users are prevented	The same
Password renewal	Automatic password renewal is enforced	The same

**Table 235: Enhanced secure mode versus hsecure mode (continued)**

Feature	Enhanced secure	Hsecure
Audit logs	Audit logs are encrypted, and authorized users are able to view, modify, and delete.	Standard operation
SNMPv3	Password rules apply to SNMPv3 Auth&Priv. SNMPv3 is required (V1/V2 disabled)	SNMPv1 and SNMPv2 can be enabled.
EDM	Site Admin to enable or disable	Disabled
Telnet and FTP	Site Admin to enable or disable	The same
DOS attack Prevention		Prevents DOS attacks by filtering IP addresses and IP address ranges.

For information on Enhanced secure mode and SSH, see [Enhanced Secure Mode](#) on page 3618.

## hsecure Mode

The switch supports a flag called high secure (hsecure). hsecure introduces the following behaviors for passwords:

- 10-character enforcement
- aging time
- limitation of failed logon attempts
- protection mechanism to filter certain IP addresses

After you enable the hsecure flag, the software enforces the 10-character rule for all passwords. This password must contain a minimum of two uppercase characters, two lowercase characters, two numbers, and two special characters.

After you enable hsecure, the system requires you to save the configuration file and reboot the system for hsecure to take effect. If the existing password does not meet the minimum requirements for hsecure, the system prompts you to change the password during the first login.

The default username is rwa and the default password is rwa. In hsecure, the system prompts you to change these during first login because they do not meet the minimum requirements for hsecure.

When you enable hsecure, the system disables Simple Network Management Protocol (SNMP) v1, SNMPv2 and SNMPv3. If you want to use SNMP, you must re-enable SNMP, using the command **no boot config flag block-snmp**.

### *Aging Enforcement*

After you enable the hsecure flag, you can configure a duration after which you must change your password. You configure the duration by using the aging parameter.

For SNMP and File Transfer Protocol (FTP), after a password expires, access is denied. Before you access the system, you must change a community string to a new string consisting of more than eight characters.

### Important

Consider the following after you enable the hsecure flag:

- You cannot enable the web server for Enterprise Device Manager (EDM) access.
- You cannot enable the Secure Shell (SSH) password authentication.

### Filtering Mechanism

Incorrect IP source addresses as network or broadcast addresses are filtered at the virtual router interface. Source addresses 192.168.168.0 and 192.168.168.255 are discarded.

This change is valid for all IP subnets, not only for /24.

You can filter addresses only if you enable the hsecure mode.

## CLI Passwords

**Table 236: Password Hash**

Feature	Product	Release introduced
<b>SHA512 Password Hashing</b>  <b>Note:</b> When upgrading, SHA1 password hashes and custom users are retained, until a factory default reset or until the password hash level is changed. During a factory default reset, SHA2 512-bit becomes the default password hash, all custom users are deleted, and SHA1 passwords are removed.	5320 Series	Fabric Engine 8.8
	5420 Series	Fabric Engine 8.8
	5520 Series	Fabric Engine 8.8
	5720 Series	Fabric Engine 8.8
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	VSP 4450 Series	VOSS 8.8
	VSP 4900 Series	VOSS 8.8
	VSP 7200 Series	VOSS 8.8
	VSP 7400 Series	VOSS 8.8
	VSP 8200 Series	VOSS 8.8
	VSP 8400 Series	VOSS 8.8
	VSP 8600 Series	VSP 8600 8.1
	XA1400 Series	VOSS 8.8

### Important

The default passwords are documented and well known. Change the default passwords and community strings immediately after you first log on.

The switch ships with default passwords assigned for access to Command Line Interface (CLI) through a console or management session. If you have read/write/all access authority, and you are using SNMPv3, you can change passwords that are in an encrypted format. If you use EDM, you can also specify the number of available Telnet sessions.

After a factory default or if your switch has no primary or backup configuration files, a password change is required to access the CLI. The system provides three attempts to change the password, if unsuccessful you are taken back to the login prompt but are not locked out. You cannot reuse a password and your password cannot be empty. A password change is required irrespective of security mode, console, SSH, or Telnet access.

You can select SHA1 for 160-bit or SHA2 for 512-bit password hash security. You can switch the password hashing with the **password hash** command. After a hashing change, all custom users and passwords are deleted, and on first login each default user must change their default password.

#### Note

If you upgrade to a release that supports password hash configuration, custom users are retained until a factory default reset or until a password hash level change. During a factory default reset, all customer users are deleted, all SHA1 passwords are removed, and SHA2 becomes the new default password hash.

If you enable enhanced secure mode with the **boot config flags enhancedsecure-mode** command, you enable different access levels, along with stronger password complexity, length, and minimum change intervals. For more information on system access fundamentals and configuration, see [System Access](#) on page 3611.

## Port Lock feature

You can use the Port Lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until the ports are first unlocked.

## Access Policies for Services

You can control access to the switch by creating an access policy. An access policy specifies the hosts or networks that can access the device through various services, such as Telnet, SNMP, Trivial File Transfer Protocol (TFTP), File Transfer Protocol (FTP), and Hypertext Transfer Protocol (HTTP). You can enable or disable access services by setting flags from CLI.

You can define network stations that can explicitly access the switch or stations that cannot access it. For each service you can also specify the level of access, such as read-only or read-write-all.

**Important**

A third-party security scan shows the switch service ports open and in the listen state. No connections are accepted on these ports unless you enable the particular daemon. The switch does not dynamically start and stop the daemons at runtime and needs to keep them running from system startup.

For more information about configuring access policies, see [Access Policies for Services](#) on page 3615.

## User-based policy support

You can set up a user-based policy (UBP) system by using Enterprise Policy Manager (EPM), a RADIUS server.

EPM is an application designed to manage the traffic prioritization and network access security for business applications. It provides centralized control of advanced packet classification and the ability to priority mark, police, meter, or block traffic.

EPM 5.0 supports UBPs, which allow security administrators to establish and enforce roles and conditions for each user for all access ports in the network. The UBP feature in EPM works in conjunction with Extensible Access Protocol (EAP) technology to enhance the security of the network. Users log on to the networks and are authenticated as the network connection is established.

The UBP feature works as an extension to the Roles feature in EPM. In a UBP environment, role objects are linked directly to specific users (as RADIUS attributes), as opposed to being linked simply to device interfaces. The role object then links the users to specific policies that control the user's access to the network.

When the RADIUS server successfully authenticates a user, the device sends an EAP session start event to the EPM policy server. The policy server then sends user-based policy configuration information for the new user roles to the interface, based on the role attribute that was assigned to that user on the RADIUS server.

## Denial-of-Service Attack Prevention

**Table 237: Denial-of-service attack prevention product support**

	VSP 8600 Series	VSP 8600 4.5
XA1400 Series	VOSS 8.0.50	

*Hsecure*

The switch supports a configurable flag, called high secure (hsecure). High secure mode introduces a protection mechanism to filter certain IP addresses, and two restrictions on passwords: 10-character enforcement and aging time.

If the device starts in hsecure mode with default factory settings, and no previously configured password, the system will prompt you to change the password. The new password must follow the rules mandated by high secure mode. After you enable hsecure and restart the system, if you have an invalid-length password you must change the password.

If you enable hsecure for the first time and the password file does not exist, then the device creates a normal default username (rwa) and password (rwa). In this case, the password does not meet the minimum requirements for hsecure and as a result the system prompts you to change the password.

The following information describes hsecure mode operations:

- When you enable the hsecure flag, after a certain duration you are asked to change your password. If not configured, the aging parameter defaults to 90 days.
- For SNMP and FTP, access is denied when a password expires. You must change the community strings to a new string made up of more than eight characters before accessing the system.
- You cannot enable the web server at any time.
- You cannot enable the SSH password-authentication feature at any time.

Hsecure is disabled by default. When you enable hsecure, the desired behavior applies to all ports.

For more information, see [Preventing certain types of DOS attacks](#) on page 3297.

#### *Prioritization of Control Traffic*

The switch uses a sophisticated prioritization scheme to schedule control packets on physical ports. This scheme involves two levels with both hardware and software queues to guarantee proper handling of control packets regardless of the switch load. In turn, this scheme guarantees the stability of the network. Prioritization also guarantees that applications that use many broadcasts are handled with lower priority.

You cannot view, configure, or modify control-traffic queues.

#### *Directed Broadcast Suppression*

You can enable or disable forwarding for directed broadcast traffic on an IP-interface basis. A directed broadcast is a frame sent to the subnet broadcast address on a remote IP subnet. By disabling or suppressing directed broadcasts on an interface, you cause all frames sent to the subnet broadcast address for a local router interface to be dropped. Directed broadcast suppression protects hosts from possible DoS attacks.

To prevent the flooding of other networks with DoS attacks, such as the Smurf attack, the switch is protected by directed broadcast suppression. This feature is enabled by default. As a best practice, do not disable it.

For more information, see [Configuring directed broadcast](#) on page 3296.

### *ARP Request Threshold*

The Address Resolution Protocol (ARP) request threshold defines the maximum number of outstanding unresolved ARP requests. The default value for this function is 500 ARP requests. To avoid excessive amounts of subnet scanning that a virus can cause, as a best practice, change the ARP request threshold to a value between 100 and 50. This configuration protects the CPU from causing excessive ARP requests, protects the network, and lessens the spread of the virus to other PCs. The following list provides further ARP threshold values:

- Default: 500
- Severe conditions: 50
- Continuous scanning conditions: 100
- Moderate: 200
- Relaxed: 500

For more information about how to configure the ARP threshold, see [Address Resolution Protocol](#) on page 325.

### *Multicast Learning Limitation*

The Multicast Learning Limitation feature protects the CPU from multicast data packet bursts generated by malicious applications. If more than a certain number of multicast streams enter the CPU through a port during a sampling interval, the port is shut down until the user or administrator takes the appropriate action.

For more information, see [IP Multicast](#) on page 1586.

## Authentication for Privileged EXEC Command Mode

**Table 238: Authentication for Privileged EXEC Mode product support**

Feature	Product	Release introduced
Authentication for Privileged EXEC CLI Command Mode	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.4
	5720 Series	Fabric Engine 8.7
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	VSP 4450 Series	VOSS 8.2
	VSP 4900 Series	VOSS 8.2
	VSP 7200 Series	VOSS 8.2
	VSP 7400 Series	VOSS 8.2
	VSP 8200 Series	VOSS 8.2
	VSP 8400 Series	VOSS 8.2
	VSP 8600 Series	VSP 8600 8.0
	XA1400 Series	VOSS 8.2

For enhanced security, you can enable user authentication to enter Privileged EXEC command mode. Use the **sys priv-exec-password** command to enable password authentication.

After you enable password authentication for Privileged EXEC command mode, the system prompts you to enter a password to access Privileged EXEC command mode from User EXEC command mode. You must enter the same password that you used to log on to the switch.

### Considerations

- The same username and password used to Telnet or SSH to the switch is used to access Privileged EXEC command mode when authentication is enabled.
- RADIUS and TACACS+ protocols are supported. If RADIUS and TACACS+ servers are not reachable, access to Privileged EXEC command mode is denied. You must open a new session and type the same username and password used to Telnet or SSH to the switch.
- No timeout exists for the password used to log on to the Privileged EXEC command mode.
- No limit to the number of retries if you enter an incorrect password.

## Configuration Considerations

Use the information in this section to understand the limitations of some security functions, such as BSAC RADIUS servers and Layer 2 protocols before you attempt to configure security.

### *Attribute Format for a Third-party RADIUS Server*

If you use a third-party RADIUS server and need to modify the dictionary files, you must add a vendor-specific attribute (attribute #26) and use 1584 as vendor code for all the devices and then send back access-priority vendor-assigned attribute number 192 with a decimal value of 1 to 6, depending upon whether you want read only to read-write-all.

### *Authentication for Privileged EXEC Command Mode*

Authentication for Privileged EXEC command mode supports RADIUS and TACACS+ protocols. If RADIUS and TACACS+ servers are not reachable, access to Privileged EXEC command mode is denied. You must open a new session and type the same username and password used to Telnet or SSH to the switch

### *RADIUS on Management Ports*

The management port supports the RADIUS protocol. When RADIUS packets are sent out of the management port, the SRC-IP address is properly entered in the RADIUS header.

For more information about the supported RADIUS servers, see the documentation of the RADIUS server.

### *RADIUS Server SNMP Accounting*

An SNMP query sent by an unreachable RADIUS server configured as used-by snmp and with accounting enabled, can cause a timeout. A timeout can occur if the device that receives the SNMP query attempts to send accounting packets to the unreachable server. You can mitigate the timeout issue by configuring lower retry and timeout values on the RADIUS server. Alternatively, you can configure a higher timeout value for SNMP.

### *Single Profile Enhancement for BSAC RADIUS Servers*

Before enabling Remote Access Dial-In User Services (RADIUS) accounting on the device, you must configure at least one RADIUS server.

The switch software supports Microsoft Radius Servers (NPS Windows 2008, Windows 2003 IAS Server), BaySecure Access Control (BSAC), Merit Network servers and Linux based servers. To use these servers, you must first obtain the software for the server. You must also make changes to one or more configuration files for these servers.

Single Profile is a feature that is specific to BSAC RADIUS servers. In a BSAC RADIUS server, when you create a client profile, you can specify all the returnable attributes. When you use the same profile for different products, you specify all the returnable attributes in the single profile.

### *SNMP Cloned User Considerations*

If the user from which you are cloning has authentication, you can choose for the new user to either have the same authentication protocol as the user from which it was cloned, or no authentication. If you choose authentication for the new user, you must provide a password for that user. If you want a new user to have authentication, you must indicate that at the time you create the new user. You can assign a privacy protocol only to a user that has authentication.

If the user from which you are cloning has no authentication, then the new user has no authentication.

### *Source IP Configuration*

#### **Note**

The following Source IP configuration considerations are only applicable on hardware platforms running VOSS Release 8.2 and later.

The Source IP is the Internet Protocol address of the device sending the IP data packet. For devices running VOSS Release 8.2 and later, the system limits the Source IP to a maximum of three interfaces; the management Out-of-Band (OOB) management interface, the VLAN management interface, or the Circuitless IP (CLIP) management interface. The system uses separate routing tables for each Segmented Management Instance interface, plus a default main table. Since multiple routing tables are in use, each management interface can have overlapping or identical static routes without interfering with each other. The main table has a super-set of all routes where the weight of the static route can tie-break routes to the same destination going through different segmented management interfaces. By default, the following weights are used and the default route priority is management CLIP, then management VLAN, then management OOB:

- mgmt CLIP - 100
- mgmt VLAN - 200
- mgmt OOB - 300

You can route packets through a different management interface than the default configuration, but you must add a specific static route or change the default weight of the management interface.

For example, if the default route uses mgmt CLIP and you want to use the mgmt OOB interface as the source IP to reach a RADIUS server, you must perform one of the following options:

- Configure a specific source IP static route for the mgmt OOB interface:

```
mgmt oob
ip route 192.0.2.0/24 next-hop 198.51.100.1
```

OR

- Configure the default mgmt OOB route weight lower than the default mgmt CLIP route weight:

```
mgmt oob
no ip route 0.0.0.0/24 next-hop 198.51.100.1
ip route 0.0.0.0/24 next-hop 198.51.100.1 weight 50
```

**Note**

If you change the default route weight, the management interface with the lowest weight value becomes the default route for all segmented management interface traffic.

For VOSS Release 8.1.5 and earlier, there was a potential for thousands of different Source IP management interfaces for applications initiating an outbound connection without a Source IP specified. To avoid Source IP fluctuations for many management interfaces with frequent route updates, you could specify the Source IP for applications where the source IP identifies the client. Configuring a Source IP for specific management applications is deprecated in VOSS Release 8.2 and later.

**Note**

This applies only to client mgmt applications initiating an outgoing connection, where the source IP address is not specified. If an application is running in server mode, the source IP address of the reply packet is configured to the destination IP address of the original request for TCP connections.

## Interoperability configuration

The switch is compatible with RADIUS servers.

## Unicast Reverse Path Forwarding (uRPF)

**Table 239: Unicast Reverse Path Forwarding product support**

Feature	Product	Release introduced
Unicast Reverse Path Forwarding (URPF) checking (IPv4)	5320 Series	Fabric Engine 8.6 5320-48P-8XE and 5320-48T-8XE only

Unicast Reverse Path Forwarding (URPF) checking (IPv6)	5320 Series	Fabric Engine 8.6 5320-48P-8XE and 5320-48T-8XE only
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	VSP 4450 Series	VOSS 5.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 5.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 5.0
	VSP 8400 Series	VOSS 5.0
	VSP 8600 Series	VSP 8600 4.5
XA1400 Series	Not Supported	

The Unicast Reverse Path Forwarding (uRPF) feature prevents packet forwarding for incoming unicast IP packets that have incorrect or forged (spoofed) IP addresses. The uRPF feature checks that the traffic received on an interface comes from a valid IP

address, thereby preventing address spoofing. On a reverse path check, if the source IP address of the received packet at the interface is not reachable using the FIB, the system drops the packet as the packet may have originated from a misconfigured or a malicious source.

You can configure uRPF for each IP interface or VLAN. When uRPF is enabled on an interface, the switch checks all routing packets that come through that interface. It ensures that the system displays the source address and source interface in the routing table, and that it matches the interface, on which the packet was received.

You can use one of two modes for uRPF:

- **Strict mode:** In strict mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. If the incoming interface is not the best reverse path, the packet check fails and uRPF drops the packet. If the routing engine finds the source IP entry, uRPF further checks if the source IP interface matches the incoming interface of the packet. If they match, the system forwards the packet as usual, otherwise, the system discards the packet.

**Note**

The number of packets dropped due to uRPF check on the ingress interface gets incremented along with other general dropped statistics under the `IN-DISCARD` column in the output of the command `show interfaces gigabitEthernet error <collision|verbose> {slot/port[-slot/port]} [, ...]`.

- **Loose mode:** In loose mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. The packet is dropped only if the source address is not reachable via any interface on that router.

uRPF can be enabled independently for IPv4 and IPv6. However, on a given interface, if uRPF is enabled for both IPv4 and IPv6, the `urpf-mode` can be either `strict-mode` or `loose-mode` for both IPv4 and IPv6. That means we cannot have IPv4 `urpf-mode` configured differently than that of IPv6.

**Note**

When you enable uRPF mode the MTU values for both IPv4 and IPv6 packets on the same VLAN are matched. Different Layer 3 MTU sizes on the same VLAN are not allowed in uRPF mode.

**Note**

uRPF check cannot detect spoofed source IP address if the source IP address belongs to a known subnet.

## Digital Certificate/PKI

**Table 240: Digital Certificate/PKI product support**

Feature	Product	Release introduced
Digital Certificate/PKI  <b>Note:</b> VOSS Releases 6.0 and 6.0.1 do not support this feature.	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

This section provides information on the digital certificate framework and offline certificate management.

A digital certificate is an electronic document that identifies the subject, proves the ownership of a public key, and is digitally signed by a certificate authority (CA) that certifies the validity of the information in the certificate. A digital certificate is valid for a specific time period.

The switch uses Public Key Infrastructure (PKI) support to obtain and use digital certificates for secure communication in the network.

To be certified, a switch performs the following tasks:

- Generate a certificate signing request.
- Verify that a present certificate has not been revoked.
- Validate the certificate.
- Renew the certificate before it expires.
- Remove the certificate, if required.

#### *Subject*

An administrator configures the subject parameters, such as common name, organization name, organization unit, locality, state, country, and subject name for requesting the identity certificate.

#### *Subject Name*

You can configure up to 10 distinguished subject names.

#### *Subject Alternative Name*

A subject alternative name associates host name values, such as an e-mail address, an IP address, or a Fully qualified domain name (FQDN) with a security certificate. You can protect these additional host names with a single certificate.

#### *Challenge Password*

A password is required for Simple Certificate Enrollment Protocol (SCEP) operations, such as the enrollment and renewal of identity certificates. This password is given offline by the CA during end entity registration. The administrator provides this password during enroll and renew operations.

#### *UsePost*

There are different types of CAs such as EJBCA, Win2012, and others. The *usePost* parameter enables you to choose the style of HTTP request. The value for the *usePost* parameter can be **True** or **False**.

For example, if Win2012 SCEP does not support the POST mode of HTTP request, configure the *usePost* as False for Win2012 and configure *usePost* as True for EJBCA.

#### *Root CA Certificate*

The Root CA certificate obtained offline from a CA must be installed for SCEP operations. This Root CA certificate is transferred to the device during the certificate installation. SCEP operations cannot be performed if the offline Root CA certificate is not installed and if error messages are logged.

#### *Key Generation*

The supported key type is RSA with RSA key of size 2048. There can be only one active key-pair associated with the trustpoint CA and digital certificate. A new key-pair cannot

be generated if there is a key-pair already associated with the active digital certificate. The system logs the error message if such new key generation is attempted. In such a case, the certificate must be revoked before a new key-pair is generated.

### *Trustpoint CA*

Use trustpoints to manage and track CAs and certificates. A trustpoint is a representation of a CA or of an identity pair. A trustpoint contains the identity of the CA, CA-specific configuration parameters, and an association with one generated key. The switch can enroll with a trustpoint to obtain an identity certificate. Trustpoint is configured after the RSA key pair is generated and the CA identity and other configuration parameters are available. You can configure up to eight CA trustpoints by providing the CA name.

#### **Note**

For VSP 8600 Series, you can configure only a single CA trustpoint.

You can configure a SHA-256 fingerprint to authenticate a received CA certificate that matches the configured common name. The switch first checks for an installed, offline root certificate and validates against it. If no root certificate is present, the switch checks the SHA-256 fingerprint in the received CA certificate. The SHA-256 fingerprint does not authenticate the root certificate.

### *Certificate Enrollment*

Certificate enrollment involves generating a certificate signing request (CSR). Before certificate enrollment, the trustpoint CA must be configured and the user configuration parameters should be available. The key usage extension parameter is required as an input; it indicates the purpose of the key contained in the certificate, that the key can be used for encipherment, digital signature, certificate signing and so on.

The certificate enrollment is not allowed if there is an active certificate already available. If new certificate enrollment is required, the existing active certificate must be revoked first. The system logs the enrollment success or failure responses.

### *Certificate Renewal*

The administrator must renew the certificate before it expires. A trap is configured for a pre-defined period before the expiry date of the certificate, and the system logs the certificate renewal due warning message. A certificate renewal request is not performed if an active certificate is not available. The system replaces the existing certificate with the newly obtained certificate on successful renewal. The system logs the renewal success or failure responses.

### *Certificate Revocation or Removal*

The certificate can be revoked or withdrawn from the specific device for a specific reason at any time. A certificate revocation request is not performed if an active certificate is not available. The system releases the existing certificate on successful revocation. The system logs the revocation success or failure responses.

During boot up, the system checks whether an active installed certificate is available. If a valid certificate is not available, the system logs the warning message.

#### *Offline Certificate Management*

Offline certificate management supports switches that cannot communicate with the Certificate Authority to obtain the identity certificate or certificates online by certificate enrollment operation.

The certificate signing request (CSR) is used to obtain the offline identity certificate. Configure the subject and RSA key-pair to obtain the offline identity certificate. You can generate and store up to 10 RSA keys identified by the key name label. To obtain multiple offline certificates, you must specify a distinguished subject-name and key-name.

You must install the Root CA certificate and all the intermediate CA certificates of the certificate chain in the device before installing the offline identity or device certificate. All the intermediate and Root CA certificates are stored in the certificate store and are used for CA certificate chain validation. The CA certificate chain validation is performed starting from the issuing CA certificate to the Root CA certificate during the installation of offline identity certificate. The offline identity certificate is installed only if the CA certificate chain validation, subject, and key match.

#### *Storage*

No digital certificate configuration is visible if you use the **show running-config** command. Instead, use the commands appropriate for displaying digital certificate information. For more information, see [View the Certificate Details](#) on page 3316.

## Certificate Order Priority

**Table 241: Certificate order priority product support**

Feature	Product	Release introduced
Certificate order priority	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	VSP 4450 Series	VOSS 5.1.2
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 5.1.2
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 5.1.2
	VSP 8400 Series	VOSS 5.1.2
	VSP 8600 Series	Not Supported
	XA1400 Series	VOSS 8.0.50

Use the following information to understand the certificate order priority when the Transport Layer Security (TLS) server and switch connect.

**Note**

For certain switches in enhanced secure mode, all sensitive files are protected. You cannot access any sensitive files using Telnet, SSH, FTP, SFTP, TFTP, and SCP connections. For more information, see [Sensitive File Protection](#) on page 3623.

The TLS server selects a certificate authority (CA)-signed certificate if the certificate is already installed in the Digital Certificate module.

If the server certificates are not available, the TLS server generates a new self-signed certificate at startup and uses that by default. You can choose to use an online or an offline CA-signed certificate, which takes precedence over the self-signed certificate.

**SSL-Based Self-Signed Certificate**

Some early releases use the default certificate available in the `/intflash/.ssh` folder, which is the open SSL-based self-signed certificate that is named `host.cert`.

To use the Mocana stack-based self-signed certificate, delete the open SSL self-signed certificate prior to upgrading your software release. The Mocana certificate offers better and stronger encryption than open SSL-based certificates.

If you do not delete the `host.cert` file in the `/intflash/.ssh` folder used in earlier releases, you must generate a self-signed certificate automatically during upgrade or post upgrade using the command **`config ssl certificate`**.

If you have a subscribed CA-signed certificate renamed as `host.cert` in folder `/intflash/.ssh` in a previous release, it cannot be reused.

To use your subscribed CA-signed certificate, upgrade with the Mocana-based self-signed certificate, and then use the digital certificates feature to install a CA-signed certificate through the online or offline method.

You cannot obtain a CA-signed certificate and rename the certificate as `host.cert`. You must use the online or offline method to obtain a certificate.

### SAN Entries in Default TLS Certificates

The default TLS certificates add `hostname.domainname` and management IP address as subject alternative name (SAN) entries:

- If you configure both `hostname` and `domain-name`, the self-signed certificate uses `hostname.domain-name` for both common name (CN) and SAN DNS.
- If you configure `domain-name` but not `hostname`, the self-signed certificate uses `*.domain-name` for both CN and SAN DNS.
- If you configure `hostname` but not `domain-name`, the self-signed certificate uses `hostname.extremenetworks.com` for both CN and SAN DNS.
- If you do not configure either `hostname` or `domain-name`, the self-signed certificate uses `*.extremenetworks.com` for both CN and SAN DNS.
- All management IP addresses are added as SAN IP entries.

If you use default self-signed certificates generated in a release that did not include SAN entries in the certificate, generate the certificate again to avoid certificate errors in Web browsers that require these entries.

#### Note

As a best practice, use custom Public Key Infrastructure (PKI) certificates rather than the default self-signed certificates.

*Two-Factor Authentication for SSH***Table 242: Two-Factor Authentication for SSH product support**

Feature	Product	Release introduced
Two-Factor Authentication for SSH	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	VSP 4450 Series	VOSS 8.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 8.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 8.0
	VSP 8400 Series	VOSS 8.0
	VSP 8600 Series	VSP 8600 8.0 demo feature
	XA1400 Series	VOSS 8.0.50

**Note**

DEMO FEATURE - Two-Factor Authentication–X.509v3 Certificates for SSH is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [Fabric Engine and VOSS Feature Support Matrix](#).

Use the following information to understand the Two-Factor Authentication feature.

Two-Factor Authentication uses smart card technology for remote device management. Two-Factor Authentication requires enhanced secure mode with Secure Shell (SSH) and X.509 V3 authorization enabled on the switch. You must provide the digital certificates to enable the identity management for the SSH client and SSH server. Two-Factor Authentication requires the following items:

- a VSP Operating System Software (VOSS) switch
- a switch
- a computer with Secure CRT 8.3.2 or 8.3.3 as the SSH client
- a smart card reader
- a Common Access Card (CAC) or Personal Identity Verification (PIV) card for each configured user

You can also use a Windows Server 2008, or newer, configured with a Remote Access Dial-In User Services (RADIUS) server and Active Directory.

Digital certificates in the X.509 V3 format provide identity management. A chain of signatures by a trusted certificate authority (CA) and its intermediate certificate CAs binds a given public signing key to a given digital identity. For user authentication, the SSH client sends the user certificate stored on the CAC or PIV card to the SSH server for verification. The SSH server validates the incoming user certificate using Public Key Infrastructure (PKI) trust-store.

After the switch validates the SSH certificate, the system parses for a username to forward to the RADIUS server for authorization. The switch prompts you to enter a password for the username. If the RADIUS server is unreachable or not configured, the authorization occurs locally on the switch for the username and password.

Two-Factor Authentication on the switch uses SSH and the X.509 V3 certificates stored on the smart card. X.509 V3 digital certificates are documented in RFC5280.

#### Smart Card Authentication Process

The process for PIV or CAC card authentication is as follows:

1. The PIV Authentication or the Card Authentication certificate is read from the PIV Card Application.
2. The relying system validates the PIV Authentication certificate from the PIV Card Application using standards-compliant PKI path validation to ensure that the certificate is valid and from a trusted source.
3. The cardholder is prompted to submit a PIN to activate the card.
4. The relying system issues a challenge string to the card and requests an asymmetric operation in response.
5. The card responds to the previously issued challenge by signing using the PIV Authentication private key.
6. The relying system verifies that the response from the card is expected for the issued challenge.
7. A unique identifier from the PIV Authentication certificate is extracted and passed as input to the access control decision.

## Security Configuration using CLI

---

Configure security information used on the control and data paths to protect the network from uncontrolled access to network resources.

For more information about how to configure passwords and access policies, see [System access configuration using CLI](#) on page 3625.

### Enable hsecure

Enables High Secure mode. This mode provides the following password behavior:

- 10 character enforcement
- The password must contain a minimum of 2 uppercase characters, 2 lowercase characters, 2 numbers, and 2 special characters.

- Aging time
- Failed login attempt limitation

### About This Task

If you enable the hsecure flag, you cannot enable the flags for the web server or SSH password-authentication.

When you upgrade from a previous release, if the password does not have at least 10 characters, you receive a prompt to change your password to the mandatory 10-character length.

If you enable hsecure for the first time and the password file does not exist, then the device creates a normal default username (rwa) and password (rwa). In this case, the password does not meet the minimum requirements for hsecure and as a result the system prompts you to change the password.

The default value is disabled. If you enable High Secure mode, you must restart the switch to enforce secure passwords. If you operate the switch in High Secure mode, the switch prompts a password change if you enter invalid-length passwords.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable or disable hsecure mode:

```
boot config flags hsecure
```

The system displays the following warning messages:

```
Warning: For security purposes, all unsecure services - TFTP, FTP, Rlogin, Telnet,
SNMP are disabled. Individually enable the required services.
Warning: Please save boot configuration and reboot the switch for this to take effect.
```

3. Save the configuration and restart the device for the change to take effect.

### Example

Enable hsecure mode. Save the configuration. Restart the switch.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags hsecure
Warning: For security purposes, all unsecure services - TFTP, FTP, Rlogin, Telnet,
SNMP are disabled. Individually enable the required services. Warning: Please save boot
configuration and reboot the switch for this to take effect.
Switch:1(config)#save config
Switch:1(config)#reset
Are you sure you want to reset the switch (y/n)?y
```

## Change an Invalid-Length Password

### Before You Begin

#### Important

When you enable hsecure, passwords must contain a minimum of 10 characters or numbers. The password must contain a minimum of: two uppercase characters, two lowercase characters, two numbers, and two special characters.

### About This Task

After you enable hsecure mode and restart the system, change your password if you have an invalid-length password.

### Procedure

1. At the CLI prompt, log on to the system.
2. Enter the password.

If you have an invalid-length password, the system displays the following message:

```
Your password is valid but less than mandatory 10 characters.  
Please change the password to continue.
```

3. When prompted, enter the new password.
4. When prompted, re-enter the new password.

### Example

Log on to the switch:

```
Login: rwa
```

Enter the password:

```
Password: ***  
Your password is valid but less than mandatory 10 characters. Please change the password  
to continue.
```

Enter the new password:

```
Enter the new password: *****
```

Re-enter the new password:

```
Re-enter the new password: *****  
Password successfully changed.
```

## Configure New Passwords

Configure new passwords for each access level, or change the logon or password for the different access levels of the switch. After you receive the switch, use default passwords to initially access CLI. If you use Simple Network Management Protocol version 3 (SNMPv3), you can change encrypted passwords.

## Before You Begin

- You must use an account with read-write-all privileges to change passwords. For security, the switch saves passwords to a hidden file.

## About This Task

If you enable the hsecure flag, after the aging time expires, the system prompts you to change your password. If you do not configure the aging time, the default is 90 days.

## Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Change a password:  
cli password WORD<1-20> {layer1|layer2|layer3|read-only|read-write|read-write-all}
3. Enter the old password.
4. Enter the new password.
5. Enter the new password a second time.
6. Configure password options:  
password access-level WORD<2-8>  
  
password aging-time day <1-365>  
  
password default-lockout-retries <1-255>  
  
password default-lockout-time <60-65000>  
  
password lockout WORD<0-46> [time <60-65000>]  
  
password min-passwd-len <10-20>  
  
password password-history <3-32>

## Example

```
Switch:1>enable  
Switch:1#configure terminal
```

Change a password:

```
Switch:1(config)# password smith read-write-all
```

Enter the old password:

```
Switch:1(config)#*****
```

Enter the new password:

```
Switch:1(config)#*****
```

Enter the new password a second time:

```
Switch:1(config)#*****
```

Set password to an access level of read-write-all and the expiration period for the password to 60 days:

```
Switch:1(config)#access-level rwa aging-time 60
```

### Variable Definitions

The following table defines parameters for the `cli password` command.

Variable	Value
<code>layer1 layer2 layer3 read-only read-write read-write-all</code>	Changes the password for the specific access level.
<code>WORD&lt;1-20&gt;</code>	Specifies the user logon name.

The following table defines parameters for the `password` command.

Variable	Value
<code>access level WORD&lt;2-8&gt;</code>	Permits or blocks this access level. The available access level values are as follows: <ul style="list-style-type: none"> <li>• l1</li> <li>• l2</li> <li>• l3</li> <li>• ro</li> <li>• rw</li> <li>• rwa</li> </ul>
<code>aging-time day &lt;1-365&gt;</code>	Configures the expiration period for passwords in days, from 1–365. The default is 90 days.
<code>default-lockout-retries &lt;1-255&gt;</code>	Configures the default number of login attempts. The default is 3.
<code>default-lockout-time &lt;60-65000&gt;</code>	Changes the default lockout time after three invalid attempts. Configures the lockout time, in seconds, and is in the 60–65000 range. The default is 60 seconds. To configure this option to the default value, use the <b>default</b> operator with the command.
<code>lockout WORD&lt;0-46&gt; time &lt;60-65000&gt;</code>	Configures the host lockout time. <ul style="list-style-type: none"> <li>• <code>WORD&lt;0-46&gt;</code> is the host IP address in the format a.b.c.d.</li> <li>• <code>&lt;60-65000&gt;</code> is the lockout-out time, in seconds, in the 60–65000 range. The default is 60 seconds.</li> </ul>

Variable	Value
<code>min-passwd-len &lt;10-20&gt;</code>	Configures the minimum length for passwords in high-secure mode. The default is 10 characters. To configure this option to the default value, use the <b>default</b> operator with the command.
<code>password-history &lt;3-32&gt;</code>	Specifies the number of previous passwords the switch stores. You cannot reuse a password that is stored in the password history. The default is 3. To configure this option to the default value, use the <b>default</b> operator with the command.

## Configure Password Hash

You can configure the Secure Hash Algorithm (SHA) level for password hash security. After a password hash level change, all custom users and passwords are deleted, and on first login each default user must change their default password.

### Before You Begin

- You must use an account with read-write-all privileges to change password hash.

### About This Task

Configure the password hash level as SHA1 or SHA2.

### Procedure

- Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
- Change the password hash level:  

```
password hash sha1|sha2
```
- Read the warning prompt, then confirm the password hash change:  

```
y
```

### Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

Change password hash to SHA2 512-bit hash value:

```
Switch:1(config)#password hash sha2
```

Warning: Changing the password hash will reset all existing passwords and users to Factory defaults. All custom Users will be deleted. Are you sure you want to proceed (y/n) ? y

### Variable Definitions

The following table defines parameters for the **password hash** command.

Variable	Value
<i>sha1 sha2</i>	Specifies the password hash SHA value: <ul style="list-style-type: none"> <li>• SHA1 - 160-bit password hash</li> <li>• SHA2 - 512-bit password hash</li> </ul>

## Configuring directed broadcast

A directed broadcast is a frame sent to the subnet broadcast address on a remote IP subnet. When you disable (or suppress) directed broadcasts on an interface, all frames sent to the subnet broadcast address for a local router interface are dropped. Disabling directed broadcasts protects hosts from possible denial-of-service (DOS) attacks. By default, this feature is enabled on the device.

### Procedure

1. Enter VLAN Interface Configuration mode:
 

```
enable
configure terminal
interface vlan <1-4059>
```
2. Configure the switch to forward directed broadcasts for a VLAN:
 

```
ip directed-broadcast enable
```

### Example

Enable directed broadcast on a VLAN:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#interface vlan 2
Switch:1(config-if)#ip directed-broadcast enable
```

Display VLAN IDs with directed broadcast enabled:

```
Switch:1>show ip directed-broadcast vlan

Vlan Directed-Broadcast
-----
VLAN ID  DIRECTED-BROADCAST
-----
2         true
```

### Variable Definitions

The following table defines parameters for the **ip directed-broadcast** command.

Variable	Value
<i>enable</i>	Enables the device to forward directed broadcast frames to the specified VLAN. The default setting for this feature is enabled.

## Preventing certain types of DOS attacks

Protect the switch against IP packets with illegal IP addresses such as loopback addresses or a source IP address of ones, or Class D or Class E addresses from being routed. The switch supports high-secure configurable flag.

### About This Task

#### Important

After you enable this flag, the desired behavior (not routing source packets with an IP address of 255.255.255.255) applies to all ports that belong to the same port.

#### Important

The setting to enable hsecure only takes effect for packets going to the CP; not to datapath traffic.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable high-secure mode:

```
high-secure [port {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]] enable
```

### Example

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface GigabitEthernet 1/16
Switch:1(config-if)# high-secure enable
```

### Variable Definitions

The following table defines parameters for the **high-secure** command.

Variable	Value
<code>port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the port on which you want to enable high-secure mode. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>enable</code>	Enables the high-secure feature that blocks packets with illegal IP addresses. This flag is disabled by default. Use the <b>no</b> operator to remove this configuration. To configure this option to the default value, use the <b>default</b> operator with the command.

## Configuring port lock

Configure port lock to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify a locked port until you unlock the port.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable port lock globally:

```
portlock enable
```

3. Enter GigabitEthernet Interface Configuration mode:

```
interface gigabitethernet {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

4. Lock a port:

```
lock [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]]
enable
```

### Example

```
Switch:1> enable
Switch:1# configure terminal
```

Log on to GigabitEthernet Interface Configuration mode:

```
Switch:1(config)# interface GigabitEthernet 1/1
```

Lock port 1/1:

```
Switch:1(config-if)# lock port 1/1 enable
```

Unlock port 1/1:

```
Switch:1(config-if)# no lock port 1/1 enable
```

### Variable Definitions

The following table defines parameters for the **interface gigabitethernet** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

The following table defines parameters for the **lock port** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Specifies the port you want to lock. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. The default is disabled.

## Unicast Reverse Path Forwarding configuration using CLI

This section provides CLI procedures for Unicast Reverse Path Forwarding configuration.

### Enable urpf-mode Boot Flag

#### Note

Exception: not supported on VSP 8600 Series and XA1400 Series.

To configure Unicast Reverse Path Forwarding on a port or VLAN, you are required to enable the urpf-mode boot flag. If you try to configure uRPF on an interface, that is, enable or change the urpf operating mode with the urpf-mode boot flag disabled, a consistency check error message is displayed: Unicast Reverse Path Forwarding configuration is not supported when urpf-mode boot flag is disabled.

## About This Task

Use the following procedure to enable the urpf-mode boot flag. By default, urpf-mode is disabled.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable the urpf-mode boot flag:  

```
boot config flags urpf-mode
```
3. When you get the following prompt to reboot the switch, enter `y` to reboot.  
The new setting requires a reboot to take effect!  
The configuration will be saved and rebooted.  
Are you sure you want to re-boot the switch (y/n)?

#### Note

If you enter `n`, the following message is displayed: `Warning: Please save the configuration and reboot the switch for this configuration to take effect.`

4. Check the status of the urpf-mode boot flag:  

```
show boot config flags
```

### Example

Enable the urpf-mode boot flag:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# boot config flags urpf-mode
The new setting requires a reboot to take effect!
The configuration will be saved and rebooted.
Are you sure you want to re-boot the switch (y/n)? y
```

View the status of the urpf-boot flag:

#### Note

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
flags block-snmp false
flags debug-config false
flags debugmode false
flags dvr-leaf-mode false
flags enhancedsecure-mode false
flags factorydefaults false
flags flow-control-mode true
flags ftpd true
flags hsecure false
```

```
flags ipv6-egress-filter true
flags ipv6-mode false
flags linerate-directed-broadcast false
flags logging true
flags nni-mstp false
flags reboot true
flags spanning-tree-mode mstp
flags spbm-config-mode true
flags sshd true
flags syslog-rfc5424-format true
flags telnetd true
flags tftpd true
flags trace-logging false
flags urpf-mode true
flags verify-config true
flags vrf-scaling true
flags vxlan-gw-full-interworking-mode false
```

### Configure Unicast Reverse Path Forwarding on a Port

#### Before You Begin

- You must enable the urpf-mode boot flag. See [Enable urpf-mode Boot Flag](#) on page 3299.

#### Note

When you try to configure uRPF on an interface, that is, enable or change the urpf operating mode with the urpf-mode boot flag disabled, a consistency check error message is displayed: Unicast Reverse Path Forwarding configuration is not supported when urpf-mode boot flag is disabled.

- You must log on to the GigabitEthernet Interface Configuration mode in CLI.

#### About This Task

You can use the Unicast Reverse Path Forwarding (uRPF) feature to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. When you enable uRPF, the switch performs a check to determine if the source IP address of the packet is verifiable. If the address is not verifiable, the system drops the packet.

uRPF runs in two modes:

- strict mode
- loose mode (exist-only mode)

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Set or change the urpf operating mode on a port:

For IPv4, enter: `ip rvs-path-chk mode {strict|exist-only}`

For IPv6, enter: `ipv6 rvs-path-chk mode {strict|exist-only}`

3. To verify the configuration on the port, see [View the IPv4 and IPv6 Interface Configuration on a Port](#) on page 2035.

## Example

### Example for IPv4:

```
Switch:1> enable  
Switch:1# configure terminal  
Switch:1(config)# interface GigabitEthernet 1/10
```

Check whether the source IP address of the incoming packet exists in the FIB table:

```
Switch:1(config-if)# ip rvs-path-chk mode strict
```

### Example for IPv6:

```
Switch:1> enable  
Switch:1# configure terminal  
Switch:1(config)# interface GigabitEthernet 4/16
```

Check whether the source IP address of the incoming packet exists in the FIB table:

```
Switch:1(config-if)# ipv6 rvs-path-chk mode strict
```

## Variable Definitions

The following table defines parameters for the `ip rvs-path-chk mode` and `ipv6 rvs-path-chk mode` commands.

Variable	Value
mode{strict exist-only}	Specifies the mode for Unicast Reverse Path Forwarding (uRPF). In strict mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. If the incoming interface is not the best reverse path, the packet check fails and uRPF drops the packet. In exist-only mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. The packet is dropped only if the source address is not reachable via any interface on that router.

### Configure Unicast Reverse Path Forwarding on a VLAN

#### Before You Begin

- You must enable the `urpf-mode boot` flag.

#### Note

When you try to configure uRPF on an interface, that is, enable or change the `urpf` operating mode with the `urpf-mode boot` flag disabled, a consistency check error message is displayed: `Unicast Reverse Path Forwarding configuration is not supported when urpf-mode boot flag is disabled.`

- You must log on to the VLAN Interface Configuration mode in CLI.

#### Important

You must assign a valid IP address to the selected port.

#### About This Task

Use the Unicast Reverse Path Forwarding (uRPF) feature to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. When you enable uRPF, the switch performs a check to determine if the source IP address of the packet is verifiable. If the address is not verifiable, the system drops the packet.

uRPF runs in two modes:

- strict mode
- loose mode (exist-only mode)

## Procedure

1. Enter VLAN Interface Configuration mode:  

```
enable

configure terminal

interface vlan <1-4059>
```
2. Set or change the urpf operating mode on a VLAN:  
 For IPv4, enter: `ip rvs-path-chk mode {strict|exist-only}`  
 For IPv6, enter: `ipv6 rvs-path-chk mode {strict|exist-only}`
3. To verify the configuration on the VLAN, see [View the IPv4 and IPv6 Interface Configuration on a VLAN](#) on page 4118.

## Example

### Example for IPv4:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface vlan 2
```

Check whether the source IP address of the incoming packet exists in the FIB table:

```
Switch:1(config-if)#ip rvs-path-chk mode exist-only
```

### Example for IPv6:

```
Switch:1> enable
Switch:1# configure terminal
Switch:1(config)# interface vlan 2
```

Check whether the source IP address of the incoming packet exists in the FIB table:

```
Switch:1(config-if)# ipv6 rvs-path-chk mode exist-only
```

## Variable Definitions

The following table defines parameters for the `ip rvs-path-chk mode` and `ipv6 rvs-path-chk mode` commands.

Variable	Value
mode{strict exist-only}	Specifies the mode for Unicast Reverse Path Forwarding (uRPF). In strict mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. If the incoming interface is not the best reverse path, the packet check fails and uRPF drops the packet. In exist-only mode, uRPF checks whether the source IP address of the incoming packet exists in the FIB. The packet is dropped only if the source address is not reachable via an interface on that router.

## Configuring Digital Certificates using CLI

The following section provides procedures to configure digital certificates using CLI.

*Configure Device Subject Parameters***About This Task**

Use this procedure to configure the device subject parameters to identify the device, such as the name, Email ID, company, department, location, and subject name.

**Procedure**

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the subject parameters of the device:

```
certificate subject {[common-name WORD<0-64>] [country WORD<2-2>] [e-mail WORD<0-254>] [locality WORD<0-128>] [organization WORD<0-64>] [province WORD<0-128>] [subject-name WORD<1-45>] [unit WORD<0-64>]}
```

3. Verify the subject names configured on the switch:

```
show certificate subject
```

**Example**

Configuring subject parameters:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)# certificate subject common-name 822-pki e-mail
client1@extemenetworks.com unit Engineering
organization ExtremeNetworks locality Salem province Massachusetts country US subject-
name 822
```

View the configuration.

```
Switch:1>show certificate subject
Subject Name      : 822
Common Name      : 822-pki
Email Address     : client1@extemenetworks.com
Organizational Unit : Engineering
Organization      : ExtremeNetworks
Locality          : Salem
Province         : Massachusetts
Country          : US

Subject Name      : 823
Common Name      : 823-pki
Email Address     : client1@extemenetworks.com
Organizational Unit : Engineering
Organization      : ExtremeNetworks
Locality          : Salem
Province         : Massachusetts
Country          : US

Subject Name      : Global
Common Name      : 821
Email Address     : client1@extemenetworks.com
Organizational Unit : Engineering
Organization      : ExtremeNetworks
Locality          : Salem
```

```
Province      : Massachusetts
Country      : US
```

## Variable Definitions

The following table defines parameters for the **certificate subject** command.

Variable	Value
<i>common-name</i> <i>WORD&lt;0-64&gt;</i>	Specifies the name of the subject sending the Certificate Signing Request to the Certificate Authority.
<i>country</i> <i>WORD&lt;2-2&gt;</i>	Specifies the country of the subject sending the Certificate Signing Request to the Certificate Authority.
<i>e-mail</i> <i>WORD&lt;0-254&gt;</i>	Specifies the Email address of the subject sending the Certificate Signing Request to the Certificate Authority.
<i>locality</i> <i>WORD&lt;0-128&gt;</i>	Specifies the locality of the subject sending the Certificate Signing Request to the Certificate Authority.
<i>organization</i> <i>WORD&lt;0-64&gt;</i>	Specifies the organization of the subject sending the Certificate Signing Request to the Certificate Authority.
<i>province</i> <i>WORD&lt;0-128&gt;</i>	Specifies the state or province of the subject sending the Certificate Signing Request to the Certificate Authority.
<i>subject-name</i> <i>WORD&lt;1-45&gt;</i>	Specifies the Subject Identity Label to be used in local digital certificate request. You can configure up to 10 subject DN identities. If a subject name is not specified, the default subject name is Global.
<b>Note:</b> Exception: Not supported on VSP 8600 Series.	
<i>unit</i> <i>WORD&lt;0-64&gt;</i>	Specifies the organizational unit of the subject sending the Certificate Signing Request to the Certificate Authority.

## Configure Subject Alternative Names

### About This Task

Use this procedure to protect additional host names with a single certificate.

#### Note

The switch supports 100 subject alternative names.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

## 2. Configure a subject alternative name for the entity:

```
certificate subject-alternative-name {[dns WORD<1-255>] [e-mail
WORD<1-255>] [ip> WORD<1-255>] [subject-name WORD<1-45>]}
```

### Note

### Note

You can configure up to 10 distinct subject names. The default subject name is Global.

## 3. View the subject alternative names configured on the switch:

```
show certificate subject-alternative-name
```

### Examples

#### Configure a subject alternative name subject name 822:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#certificate subject-alternative-name subject-name 822 dns
822.extremenetworks.com
Switch:1(config)#certificate subject-alternative-name subject-name 822 e-mail
name@company.com
Switch:1(config)#certificate subject-alternative-name subject-name 822 ip 192.0.2.22
```

#### View the configuration:

```
Switch:1>show certificate subject-alternative-name
=====
SAN Table
=====
TYPE      NAME                SUBJECT
-----
E-MAIL    name@company.com    822
DNS       822.extremenetworks.com 822
IP        192.0.2.22         822
```

#### Configure a subject alternative name with the default subject name:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#certificate subject-alternative-name dns name@extrnetwk.com
Switch:1(config)#certificate subject-alternative-name e-mail j.smith@extremenetworks.com
Switch:1(config)#certificate subject-alternative-name ip 192.0.2.23
```

#### View the configuration:

```
Switch:1>show certificate subject-alternative-name
=====
SAN Table
=====
TYPE      NAME                SUBJECT
```

```
-----
E-MAIL    j.smith@extremenetworks.com      Global
DNS       name@extrnetwk.com              Global
IP        192.0.2.23                 Global
```

## Variable Definitions

The following table defines parameters for the **certificate subject-alternative-name** command.

Variable	Value
<i>dns</i> WORD<1-255>	Specifies the DNS subject alternative name.
<i>e-mail</i> WORD<1-255>	Specifies the e-mail subject alternative name.
<i>ip</i> WORD<1-255>	Specifies the IP subject alternative name.
<i>subject-name</i> WORD<1-45> <b>Note:</b> Exception: Not supported on VSP 8600 Series.	Specifies the Subject Identity Label to be used in local digital certificate request. You can configure up to 10 subject DN identities. If the subject-name is not specified, the default subject name is Global.

## Generate the Key Pair

### About This Task

Use the following procedure to generate the private and public key pair for the specific cryptography type. By default, the switch generates a 2,048 RSA key when the system starts. You can use this procedure to generate a new RSA key or to generate multiple RSA keys identified by a key-name. You can generate up to 10 RSA keys.

### Procedure

- Enter Global Configuration mode:  
enable  
  
configure terminal
- Generate the key pair:  
certificate generate-keypair {[type rsa size 2048] | [key-name WORD<1-45>]}

### Example

Generating the key pair identified by a key-name:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#certificate generate-keypair key-name pki_key
Switch:1(config)#1 2021-06-22T11:33:53.036Z VSP-4900-24XE CP1 - 0x003a864c - 00000000
GlobalRouter DIGITALCERT INFO Digicert Key-pair generation is in progress
Switch:1(config):#1 2021-06-22T11:33:53.052Z VSP-4900-24XE CP1 - 0x003a8604 - 00000000
GlobalRouter
DIGITALCERT INFO Generation of RSA key-pair for digital certificate is successful
```

```
1 2021-06-22T11:33:58.711Z Switch CP1 - 0x003a864d - 00000000 GlobalRouter DIGITALCERT
INFO Digicert Key-pair generation completed successfully for key-name: pki_key
```

Display the configured key pairs:

```
Switch:1>show certificate key-name
Key Name: pki_key
Public Key Value:
0000000000000001000000010200000000301000100000100bdb1cf8382d66a2d2d0d24b4477908641c16423c

```

## Variable Definition

The following table defines parameters for the **generate-keypair** command.

Variable	Value
<i>type</i> <i>rsa</i>	Specifies type of cryptography algorithm used to generate the key-pair. The switch uses only <i>rsa</i> as the cryptography algorithm type.
<i>size</i> <i>2048</i>	Specifies the size or modulus of key-pair to be generated. The switch only supports 2048.
<i>key-name</i> <i>WORD&lt;1-45&gt;</i>  <b>Note:</b> Exception: Not supported on VSP 8600 Series.	Specifies the key label for RSA 2048 key to be generated. You can configure up to 10 RSA keys by specifying the key-name label. The default key-name label is <i>rsa_2048</i> .

## Configure a Trustpoint CA

### About This Task

Use this procedure to configure the certificate authority and perform related actions. You can configure up to eight CA trustpoints.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the trustpoint and associate it with the generated key pair:

```
certificate ca WORD<1-45> {[subject-name WORD<1-45>] [common-name WORD<0-64>] [key-name WORD<0-45>] [ca-url WORD<0-1000>] [use-post <true|false>]}
```

3. Configure an SHA-256 fingerprint to authenticate the received CA certificate:

```
certificate ca WORD<1-45> sha256-fingerprint WORD<64-64>
```

4. Configure the appropriate action:

- Configure trustpoint, authenticate the trustpoint CA by getting the certificate of the CA, and store the CA certificate locally:

```
certificate ca WORD<1-45> action caauth
```

- Generate certificate signing request to obtain identity certificate from configured trustpoint CA, get the digital certificate, and store it locally, associating with the trustpoint CA:

```
certificate ca WORD<1-45> action enroll [validity-days <7-1185>]
```

- Get the Certificate Revocation List from the CDP and store into a file:

```
certificate ca WORD<1-45> action get-crl
```

- Install the subject certificate obtained from the given trustpoint CA:

```
certificate ca WORD<1-45> action install
```

- Configure trustpoint and perform no other operation:

```
certificate ca WORD<1-45> action noop
```

- Release the locally stored certificate associated with the trustpoint CA post revocation:

```
certificate ca WORD<1-45> action remove
```

- Generate certificate renew request for given trustpoint CA, get the new digital certificate, and store it locally by replacing the old certificate with the new one:

```
certificate ca WORD<1-45> action renew [validity-days <7-1185>]
```

5. Install the Root Certificate Authority certificate obtained offline:

```
certificate ca WORD<1-45> install-file {root-ca-filename WORD<1-80>}
```

6. Set the HTTP request type to support the type of CA:

```
certificate ca WORD<1-45> use-post <false | true>
```

## Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#certificate ca ej common-name CaA2 key-name pki_key subject-name 822
Switch:1(config)#certificate ca ej action enroll
```

```

### Variable Definitions

The following table defines parameters for the **certificate ca** command.

Variable	Value
<code>action caauth</code>	Authenticates the trustpoint CA by getting the certificate of the CA and stores the CA certificate locally.
<code>action enroll</code> <code>[validity-days &lt;7-1185&gt;]</code>	Generates certificate signing request to obtain identity certificate from configured trustpoint CA, gets the digital certificate, and stores it locally, associating with the trustpoint CA. The validity-days specifies the number of days for which the certificate will remain valid. The default value is 365 days.
<code>action get-crl</code>	Gets the Certificate Revocation List from the CDP and stores into a file.
<code>action install</code>	Installs the subject certificate obtained from the given trustpoint CA.
<code>action noop</code>	Specifies that no operation should be performed after configuring trustpoint.
<code>action remove</code>	Releases the locally stored certificate associated with the trustpoint CA post revocation.
<code>action renew</code> <code>[challenge-password</code> <code>WORD&lt;0-128&gt;]</code>	Specifies the password. This password is provided offline by the CA during the end entity registration.
<code>action renew</code> <code>[validity-days &lt;7-1185&gt;]</code>	Generates certificate renewal request for given trustpoint CA, gets the digital certificate, and stores it locally by replacing the old certificate with the new one. The validity-days specifies the number of days for which the certificate will remain valid. The default value is 365 days.
<code>ca WORD&lt;1-45&gt;</code>	Specifies the name of the CA. You can configure up to 8 CA trustpoints by specifying the CA name. It should be alphanumeric and case-sensitive. The maximum length should be 45 characters.
<code>ca-url WORD&lt;0-1000&gt;</code>	Specifies the trusted CA url.
<code>common-name</code> <code>WORD&lt;0-64&gt;</code>	Specifies the name of the owner of the device or user.
<code>key-name WORD&lt;0-45&gt;</code>	Specifies the key pair generated by the command that was first associated with the CA trustpoint.
<code>install-file</code> <code>root-ca-filename</code> <code>WORD&lt;1-80&gt;</code>	Installs the Root CA file obtained offline from the CA.
<code>sha256-fingerprint</code> <code>WORD&lt;64-64&gt;</code>	Specifies an encrypted fingerprint of the expected certificate to match.

Variable	Value
<code>subject-name</code> <code>WORD&lt;1-45&gt;</code>  <b>Note:</b> Exception: Not supported on VSP 8600 Series.	Specifies the configured Subject Identity label. The default is Global.
<code>use-post &lt;false   true&gt;</code>	Specify the HTTP request style. The default value is True. For example, True for EJBCA and False for Win2012 CA.

### Install the Certificate

#### About This Task

Use this procedure to install the following:

- certificate authority (CA) certificate
- root CA certificates
- subject certificates
- Certificate Revocation List (CRL) file obtained offline from the CA

#### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Install the offline CA certificate:

```
certificate install-file offline-ca-filename WORD<1-80>
```

3. Install the CRL offline file:

```
certificate install-file offline-crl-filename WORD<1-80>
```

4. Install the root CA offline certificate:

```
certificate install-file offline-root-ca-filename WORD<1-80>
```

5. Install the subject offline certificate:

```
certificate install-file offline-subject-filename WORD<1-80> [relaxed]
[key-name WORD<1-45>] [subject-name WORD<1-45>]
```

#### Note

To obtain the offline subject certificate, you must first generate a certificate signing request (CSR).

6. (Optional) Install the subject offline certificate with PKCS12-format:

```
certificate install-file offline-subject-filename WORD<1-80> relaxed
pkcs12-password WORD<1-128>
```

## Example

View the installed offline subject certificate:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1#certificate install-file offline-subject-filename 823pki.crt subject-name 823 key-
name pki
1 2021-02-02T14:19:01.587Z Switch CP1 - 0x003a864f - 00000000 GlobalRouter DIGITALCERT

## Variable Definitions

The following table defines parameters for the **certificate install-file** command.

Variable	Definition
<i>offline-ca-filename</i> WORD<1-80>	Specifies the certificate authority (CA) file name obtained from the CA.
<i>offline-crl-filename</i> WORD<1-80>	Specifies the CRL file obtained from the CA.
<i>offline-root-ca-filename</i> WORD<1-80>	Specifies the root CA file name obtained from the CA.
<i>offline-subject-filename</i> WORD<1-80>	Specifies the subject certificate file name obtained from the CA.

Variable	Definition
<code>relaxed [pkcs12-password WORD&lt;1-128&gt;]</code>  <b>Note:</b> Exception: not supported on VSP 8600 Series.	Uses the relaxed mode for offline subject certificate installation for less restrictive consistency checks. You can also install a PKCS12 format certificate and secret key in relaxed mode. <code>WORD&lt;1-128&gt;</code> is the password to extract the PKCS12 container. If you do not include this parameter, the supported format is Distinguished Encoding Rules (DER).
<code>key-name WORD&lt;1-45&gt;</code>  <b>Note:</b> Exception: Not supported on VSP 8600 Series.	Refers to the key name of the generated key-pair.
<code>subject-name WORD&lt;1-45&gt;</code>  <b>Note:</b> Exception: Not supported on VSP 8600 Series.	Refers to the subject identity name.

### Generate the Certificate Signing Request

#### About This Task

Use this procedure to generate a certificate signing request (CSR) and store it into a file. This CSR is required to obtain the offline subject certificate. The generated file is located in the `/intflash/shared/certs` folder.

#### Procedure

- Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
- Generate certificate signing request:  

```
certificate generate-csr [relaxed]
```
- (Optional) Configure the subject-name and the key name:  

```
certificate generate-csr subject-name WORD<1-45> key-name WORD<1-45>
```

#### Example

Display the generated CSR.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#certificate generate-crs subject-name 823 key-name pki
```

```
Switch:1(config)#1 2021-02-02T13:57:39.716z Switch CP1 - 0x003a8635 - 0000000
GlobalRouter DIGITALCERTIFICATE INFO Generate CSR for Digital Certificate successful!
```

## Display Configured Key Pairs

### About This Task

#### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Display the names and public keys of all the key-pairs:
 

```
show certificate key-name [WORD<1-64>]
```

### Example

The following output example displays the names and public keys of all the key-pairs.

```
Switch:1(config)#show certificate key-name

Key Name: pki_key
Public Key Value:
000000000000001020000000003010001000001009a8d66a1efaeac7bd2a4918ffdda59d8bebfd682

## View the Certificate Details

### About This Task

Use this procedure for the following tasks:

- Displaying the digital certificate for given certificate type or list all the certificate details from the local store for given certificate type.
- Displaying the CA details for a given trustpoint CA name or listing all the CA details from the local store if the CA name is not specified.

- Displaying the configured key details for given key name.
- Displaying the configured subject details.

### Procedure

1. To enter User EXEC mode, log on to the switch.

2. Display the digital certificate for given certificate type:

```
show certificate cert-type [default-tls-certificate] | [intermediate-
ca-cert WORD<1-80>] | [offline-ca-cert] | [offline-subject-cert] |
[online-ca-cert] | [online-subject-cert] | [root-ca-cert WORD<1-80>]
```

3. Display the certificate authority details:

```
show certificate ca WORD<1-45>
```

4. Display the name and public key of all the key-pairs:

```
show certificate key-name
```

5. Display the details of the configured subject:

```
show certificate subject
```

### Example

Display the Root CA certificate:

```
Switch:1>show certificate cert-type root-ca-cert

## Variable Definitions

The following table defines parameters for the **show certificate** command.

Variable	Value
cert-type default-tls-certificate	Displays the default TLS certificate (self-signed).
cert-type online-ca-cert	Specifies Certificate Authority's Certificate obtained online from Certificate Authority.
cert-type online-subject-cert	Specifies subject certificate obtained online from Certificate Authority.
cert-type offline-ca-cert	Specifies Certificate Authority's certificate obtained offline from Certificate Authority.
cert-type offline-subject-cert	Specifies subject certificate obtained offline from Certificate Authority.
cert-type intermediate-ca-cert [WORD<1-80>]	Specifies the intermediate certificate obtained offline from Certificate Authority.
cert-type root-ca-cert [WORD<1-80>]	Specifies root certificate obtained offline from Root Certificate Authority.
ca [WORD<1-45>]	Specifies name of the Certificate Authority. If the name is not specified, the command displays the CA details of all configured CA.

## Configure a Web Server Certificate

### Note

This procedure does not apply to VSP 8600 Series.

## About This Task

Use this task to configure a web server certificate.

## Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the Certificate Authority for the installed digital certificate:
 

```
web-server certificate ca-name <1-45>
```
3. Configure the subject identity label to be used
 

```
web-server certificate cert-subject-name <1-45>
```

## Example

Display the web server certificate information:

```
Switch:1(config)#web-server certificate cert-subject-name 823
Switch:1(config)#1 2021--2--2T14:35:38.865z Switch CP1 - 0x003z8604 - 0000000
GlobalRouter DIGITALCERT INFO Digital Certificate Module: Configuration Saved
1 2021--2--2T14:35:38.865z Switch CP1 Switch CP1 - 0x00040601 - 0000000 Global Router
WEB INFO HTTPS: Using the CA Signed Server Cert
```

## Variable Definitions

Use the data in the following table to use the **web-server certificate** command

Variable	Value
<code>ca-name WORD&lt;1-45&gt;</code>	Specifies the name of the Certificate Authority.
<code>ca-subject-label WORD&lt;1-45&gt;</code>	Specifies the name of the local certificate used.

Configure Certificate Authority Trustpoint for Syslog

### Note

This procedure does not apply to VSP 8600 Series.

## Before You Begin

Configure and install the digital certificate.

## About This Task

Use this procedure to configure the certificate authority for the syslog.

## Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure the Certificate Authority trustpoint:
 

```
syslog certificate ca-common-name WORD<1-45>
```

## Variable Definitions

The following table defines parameters for the **syslog certificate** command.

Variable	Value
<code>ca-common-name WORD&lt;1-45&gt;</code>	Specifies the Certificate Authority common name.

Digital certificate configuration examples

This section shows how to obtain an online CA signed certificate, remove the expired certificate, renew the certificate, and install an offline subject certificate.

## Obtain an Online CA-signed Subject Certificate

Use the following procedure as an example to obtain an online CA signed subject certificate that the application can use.

### About This Task

In the following commands, the variable `WORD<1-45>` refers to the name of the certificate authority and the variable `WORD<1-80>` refers to the certificate filename.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the subject:

```
certificate subject common-name 822-pki
certificate subject e-mail 822@extremenetworks.com
certificate subject unit Engineering
certificate subject organization ExtremeNetworks
certificate subject locality Salem
certificate subject country US
certificate subject province Massachusetts
certificate subject subject-name 822

certificate subject common-name 823-pki
certificate subject e-mail 823@extremenetworks.com
certificate subject unit Engineering
certificate subject organization ExtremeNetworks
certificate subject locality Salem
certificate subject country US
certificate subject province Massachusetts
certificate subject subject-name 823
```

#### Note

The values mentioned are for example only.

3. Generate the key pair:

```
certificate generate-keypair {[type rsa size 2048] | [key-name WORD<1-45>]}
```

4. Configure the certificate authority (CA):

```
certificate ca ej common-name subca5
certificate ca ej key-name rsa_2048
certificate ca ej ca-url http://192.51.100.9:8080/ejbca/publicweb/apply/scep/test/
pkiclient.exe
certificate ca ej use-post true
```

#### Note

The values mentioned are for example.

5. Use SCP to upload the Root CA certificate to: `/intflash/shared/certs`.
6. Install the Root CA certificate:

```
certificate ca WORD<1-45> install-file root-ca-filename WORD<1-80>
```

## 7. Authenticate the CA:

```
certificate ca WORD<1-45> action caauth
```

## 8. Enroll the subject certificate by the CA:

```
certificate ca WORD<1-45> action enroll
```

## 9. Install the certificate:

```
certificate ca WORD<1-45> action install
```

## 10. (Optional) If the certificate expires, remove the enrolled subject certificate:

```
certificate ca WORD<1-45> action remove
```

## 11. (Optional) To obtain the new certificate before the old certificate expires, enter the following command to renew the certificate:

```
certificate ca WORD<1-45> action renew
```

The Certificate Authority generates a new certificate for the subject.

### Install an Offline CA Certificate

Use the following procedure as an example to install an offline CA certificate.

#### About This Task

In the following commands, the variable *WORD<1-80>* refers to the certificate filename.

#### Procedure

## 1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

## 2. Configure the subject:

```
certificate subject common-name 822-pki
certificate subject e-mail client1@extemenetworks.com
certificate subject unit Engineering
certificate subject organization ExtremeNetworks
certificate subject locality Salem
certificate subject province Massachusetts
certificate subject country US
certificate subject subject-name 822
```

#### Note

The values mentioned are for example only.

## 3. Generate the certificate signing request to support multiple subject identities on the switch:

```
certificate generate-csr subject-name WORD< 1-45> key-name WORD<1-64>
```

```
#certificate generate-csr subject-name 823 key-name mimi
Switch:1(config)#1 2021-02-02T13:57:39.716Z VSP-8284XSQ CP1 - 0x003a8635 - 00000000
GlobalRouter DIGITALCERT
INFO Generate CSR For Digital Certificate successful!
```

## 4. Use the generated CSR file to enroll the certificate on the server.

- Use SCP to upload the enrolled certificate along with Root certificate and all intermediary certificates to:

```
/intflash/shared/certs/
```

- Install the Root CA certificate:

```
certificate install-file offline-root-ca-filename WORD<1-80>
```

#### Note

If the subject certificate issuer is directly the Root, then Step 7 and 8 are optional. If the subject is issued by Intermediate CA, then Step 7 and 8 are mandatory, also in the certificate chain between Root and Subject, all the Intermediates must be installed using these steps.

- Copy and paste the Intermediate CA certificate to:

```
/intflash/shared/certs/
```

- Install the intermediate CA:

```
certificate install-file offline-ca-filename WORD<1-80>
```

- Install the offline subject filename:

```
certificate install-file offline-subject-filename WORD<1-80>
```

```
#certificate install-file offline-subject-filename sd
```

```
Error: File Name Not Found in /intflash/shared/certs/ or /intflash/.cert/.offlineCert/
#certificate install-file offline-subject-filename 823mimi.crt subject-name 823 key-
name mimi

## Configuring X.509 V3 certificates for SSH Two Factor Authentication

#### Note

DEMO FEATURE - Two-Factor Authentication–X.509v3 Certificates for SSH is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [Fabric Engine and VOSS Feature Support Matrix](#).

Use the following procedure as an example to configure the SSH server on the switch, and the SSH client Secure CRT for two factor authentication using X.509 V3 certificates.

## Before You Begin

The following certificates must be loaded on the SSH server and SSH client:

- For the Secure CRT (SSH client):
  - subject certificate from the PIV card.
- For the switch (SSH server):
  - CAC-server.pem - the subject certificate
  - ca.cert.pem - the root CA certificate
  - Self-signedTrustAnchorCertificate.cer - the root CA certificate that signed the intermediate certificate
  - RSA2048IssuingCACertificate.cer - the intermediate certificate signed by the previous root CA that signed the subject certificate.

## About This Task

Use the following steps as an example to configure the SSH server on the switch, the RADIUS Windows server, and the SSH client Secure CRT.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Ensure the switch is running in Enhanced Secure Mode:

```
Switch:1(config)#show boot config flags
flags enhancedsecure-mode true
```

### Note

This shows a partial output of only the relevant entry.

3. Ensure the switch clock is synchronized:

```
Switch:1#show clock
System Clock time : Fri Oct 12 19:36:36 2018 UTC
```

4. Provision PKI with certificates.

For information about provisioning PKI with certificates, see the following sections:

- [Obtain an Online CA-signed Subject Certificate](#) on page 3326
- [Install an Offline CA Certificate](#) on page 3327

## X.509 Authentication Username Option Example

Use the following procedure as an example to configure username authentication options using X.509 V3 certificates.

## Procedure

1. Enable X.509 V3 authentication username override:

```
Switch:1(config)# ssh x509v3-auth username overwrite
```

The switch disregards the username sent by the SSH client and uses the principal name from the client's certificate for authentication. If RADIUS authentication is configured, the username is sent after you type the RADIUS password. For example, if you configure the SSH client with the username "John" and enable x509v3-auth username overwrite on the device, the switch sends the principal name 1403824387@mil to the RADIUS server for authorization.

```
Test CAC John Smith
Issuer: CN=DOD JITC ID CA-49, OU=PKI, OU=DoD, O=U.S. Government, C=US

64 5c 85 78 10 93 ee
Cert: 8066aec3484d3740d7d99ec2f5ed1983365bb1
```

## 2. Enable X.509 V3 authentication username strip:

```
Switch:1(config)#ssh x509v3-auth username strip-domain
```

If x509v3-auth username strip-domain is configured, the switch sends the principal name without the domain to the RADIUS for authorization. The username is sent after you type the RADIUS password. For example: If you select principal name 1403824387@mil, the switch sends the principal name 1403824387 without the domain to the RADIUS server for authorization.

```
Test CAC John Smith
Issuer: CN=DOD JITC ID CA-49, OU=PKI, OU=DoD, O=U.S. Government, C=US

64 5c 85 78 10 93 ee
Cert: 8066aec3484d3740d7d99ec2f5ed1983365bb129
```

## 3. Enable X.509 V3 authentication username use-domain:

```
Switch:1(config)ssh x509v3-auth username use-domain extreme.com
```

If you select the username as the principal name, the switch sends the principal name from the certificate with the domain configured on the switch to the RADIUS for authorization. The username is sent after typing the RADIUS password. For example: If you configure use-domain "extreme.com" on the switch and you configure the username to be the principal name 1403824387@mil, the switch sends the username 1403824387@extreme.com to the RADIUS server for authorization.

```
Test CAC John Smith
Issuer: CN=DOD JITC ID CA-49, OU=PKI, OU=DoD, O=U.S. Government, C=US
NotBefore: 12/19/2017 7:00 PM

64 5c 85 78 10 93 ee
Cert: 8066aec3484d3740d7d99ec2f5ed1983365bb129
```

#### 4. RADIUS server is not configured:

If the Radius server is not configured, the authorization fallbacks locally on the switch, for the username. You must configure the usernames on the switch. You are prompted for the password. For example: If you select the principal name 1403824387@mil, the switch authorizes locally the username as 1403824387@mil or 1403824387 if strip domain is enabled. You are prompted for the password.

```

### Install Online Certificates for Fabric Extend with IPsec

Use the following procedure as an example to install subject certificates for switches that use Fabric Extend with IPsec. After you complete the certificate configuration, you must configure the IPsec authentication method for the Fabric Extend tunnel. For more information about IPsec configuration, see [IPsec configuration using CLI](#) on page 1954. For more information about Fabric Extend, see [Fabric Extend configuration using the CLI](#) on page 1164.

#### Note

The values mentioned are for example only.

### Before You Begin

Configure the Fabric Extend tunnels between the branch and hub switches.

### Procedure

#### 1. Configure the CA instance:

```
Switch:1(config)#certificate ca aaa common-name CaAaa
Switch:1(config)#certificate ca aaa key-name rsa_2048
Switch:1(config)#certificate ca aaa ca-url http://192.0.2.9:8080/ejbca/publicweb/apply/
scep/test/pkiclient.exe
Switch:1(config)#certificate ca aaa use-post true
Switch:1(config)#certificate ca aaa sha256-fingerprint
EEA68F35CC6195CBB038073F520AA385A5A78F42
```

#### 2. Authenticate the CA TrustPoint:

```
Switch:1(config)# certificate ca aaa action caauth

### 4. Configure the IPsec authentication-method:

```

Switch:1(config-isis-1-192.0.2.74)#ipsec auth-method rsa-sig

```

## Configure TCP Keepalive and TCP Timestamp

### About This Task

TCP Keepalive configures the system TCP keepalive interval, probes, and time.

TCP Timestamp option (RFC 1323) allows TCP to determine the order in which the packets are sent. The TCP Timestamp provides protection against Wrapped Sequence numbers. However, it is possible to calculate the system uptime when the Timestamp option is enabled. The analysis of timestamp behaviour can provide information on the system identity, which poses security threats and can cause a potential attack.

The TCP Timestamp option is enabled by default. You can disable the timestamp to avoid any security risks.

#### Note

The configuration will be applied only to the new TCP connections and the existing connections are not affected. You must perform a **config save** and **reboot** to apply the new configuration to all TCP connections.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Configure the TCP keepalive interval:  
`sys control tcp-keepalive-interval <1-3600>`
3. Configure the TCP keepalive probes:  
`sys control tcp-keepalive-probes <1-50>`
4. Configure the TCP keepalive time:  
`sys control tcp-keepalive-time <5-65535>`
5. Enable the TCP Timestamp:  
`sys control tcp-timestamp`
6. Disable the TCP Timestamp:  
`no sys control tcp-timestamp`
7. View the status of TCP Timestamp:  
`show sys control`

### Examples

Configure the TCP keepalive to interval 60 seconds, with 15 probes, and 120 seconds time:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys control tcp-keepalive-interval 60
Switch:1(config)#sys control tcp-keepalive-probes 15
Switch:1(config)#sys control tcp-keepalive-time 120
```

Disable TCP Timestamp:

```
Switch:1>enable
Switch:1#configure terminal
```

```
Switch:1(config)#no sys control tcp-timestamp
```

Warning: Existing TCP connections won't be affected.

A config save and reboot is required to apply this configuration for all TCP connections

Display the status of the TCP Timestamp:

```
Switch:1>show sys control
```

```
=====
                        System Control Settings
=====
      tcp-timestamp : enable
      tcp-keepalive-time : 60
tcp-keepalive-interval : 10
      tcp-keepalive-probes : 5
      tcp-mtu-probing : disabled
      tcp-base-mss : 1024
      mac-move-protection : on
```

### Variable Definitions

The following table defines parameters for the **sys control** command.

Variable	Value
<i>tcp-keepalive-interval</i> <1-3600>	Configure the TCP keepalive interval in seconds. The default is 10.
<b>Note:</b> Exception: Not supported on VSP 8600 Series	
<i>tcp-keepalive-probes</i> <1-50>	Configure the TCP keepalive probes. The default is 5.
<b>Note:</b> Exception: Not supported on VSP 8600 Series	
<i>tcp-keepalive-time</i> <5-65535>	Configure the TCP keepalive time in seconds. The default is 60.
<b>Note:</b> Exception: Not supported on VSP 8600 Series	
<i>tcp-timestamp</i>	Enable or disable tcp-timestamp.
	<b>Note:</b> The timestamp is enabled by default. The system displays the following warning message when a new configuration is applied: Warning: Existing TCP connections won't be affected. A config save and reboot is required to apply this configuration for all TCP connections.

## Enable Authentication for Privileged EXEC Command Mode using CLI

With authentication enabled, you must enter a username and password to access Privileged EXEC command mode from User-EXEC command mode. The username and password is the same username and password you used to Telnet or SSH to the switch.

### Note

When you enable authentication for the Privileged EXEC CLI command mode, the changes do not affect any existing CLI sessions. For the changes to take effect, you must first log out from your current CLI session and log back in on a new session.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable authentication for Privileged EXEC CLI command mode:  
`sys priv-exec-password`
3. Verify the configuration:  
`show sys priv-exec-password`

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Switch:1(config)#sys priv-exec-password
```

## Enable MAC Move Protection on vIST

### About This Task

Perform this procedure to enable MAC move protection on virtual interswitch trunk (vIST).

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable MAC move protection:  
`sys control virtual-ist mac-move-protection`
3. Confirm the configuration:  
`show sys control`

### Examples

Enable MAC move protection on vIST:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#sys control virtual-ist mac-move-protection
Switch:1>show sys control
=====
                        System Control Settings
=====
      tcp-timestamp : enable
      tcp-keepalive-time : 60
tcp-keepalive-interval : 10
      tcp-keepalive-probes : 5
          tcp-mtu-probing : disabled
          tcp-base-mss : 1024
      mac-move-protection : on
```

### Variable Definitions

The following table defines parameters for the **sys control virtual-ist** command.

Variable	Value
<i>mac-move-protection</i>	Enable MAC move protection on vIST. The default value is disabled.

## Security Configuration using EDM

Configure security information used on the control and data paths to protect the network from uncontrolled access to network resources.

For more information about how to configure passwords and access policies, see [System access configuration using EDM](#) on page 3652.

### Enable Port Lock

#### About This Task

Use the port lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until you first unlock the port.

#### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Port Lock** tab.
4. To enable port lock, select the **Enable** check box.
5. Click **Apply**.

**Port Lock** field descriptions

Use the data in the following table to use the **Port Lock** tab.

Name	Description
<b>Enable</b>	Activates the port lock feature. Clear this check box to unlock ports. The default is disabled.
<b>LockedPorts</b>	Lists the locked ports. Click the ellipsis (...) button to select the ports you want to lock or unlock.

## Lock a Port

**Before You Begin**

- You must enable port lock before you lock or unlock a port.

**About This Task**

Use the port lock feature to administratively lock a port or ports to prevent other users from changing port parameters or modifying port action. You cannot modify locked ports until you first unlock the port.

**Procedure**

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Port Lock** tab.
4. In the **LockedPorts** box, click the ellipsis (...) button.
5. Click the desired port or ports.
6. Click **Ok**.
7. In the **Port Lock** tab, click **Apply**.

**Port Lock** field descriptions

Use the data in the following table to use the **Port Lock** tab.

Name	Description
<b>Enable</b>	Activates the port lock feature. Clear this check box to unlock ports. The default is disabled.
<b>LockedPorts</b>	Lists the locked ports. Click the ellipsis (...) button to select the ports you want to lock or unlock.

## Change Passwords

**About This Task**

Configure new passwords for each access level, or change the logon or password for the different access levels of the system to prevent unauthorized access. After you receive the switch, use default passwords to initially access CLI. If you use Simple

Network Management Protocol version 3 (SNMPv3), you can change passwords in encrypted format.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **CLI** tab.
4. Specify the username and password for the appropriate access level.
5. Click **Apply**.

### CLI Field Descriptions

The following table defines parameters for the **CLI** tab.

Name	Description
<b>RWAUserName</b>	Specifies the user name for the read-write-all CLI account.
<b>RWAPassword</b>	Specifies the password for the read-write-all CLI account.
<b>RWEnable</b>	Activates the read-write access. The default is enabled.
<b>RWUserName</b>	Specifies the user name for the read-write CLI account.
<b>RWPassword</b>	Specifies the password for the read-write CLI account.
<b>RWL3Enable</b>	Activates the read-write Layer 3 access. The default is enabled.
<b>RWL3UserName</b>	Specifies the user name for the Layer 3 read-write CLI account.
<b>RWL3Password</b>	Specifies the password for the Layer 3 read-write CLI account.
<b>RWL2Enable</b>	Activates the read-write Layer 2 access. The default is enabled.
<b>RWL2UserName</b>	Specifies the user name for the Layer 2 read-write CLI account.
<b>RWL2Password</b>	Specifies the password for the Layer 2 read-write CLI account.
<b>RWL1Enable</b>	Activates the read-write Layer 1 access. The default is enabled.
<b>RWL1UserName</b>	Specifies the user name for the Layer 1 read-write CLI account.
<b>RWL1Password</b>	Specifies the password for the Layer 1 read-write CLI account.
<b>ROEnable</b>	Activates the read-only CLI account. The default is enabled.

Name	Description
<b>ROUserName</b>	Specifies the user name for the read-only CLI account.
<b>ROPassword</b>	Specifies the password for the read-only CLI account.
<b>MaxTelnetSessions</b>	Specifies the maximum number of concurrent Telnet sessions in a range from 0–8. The default is 8.
<b>Timeout</b>	Specifies the number of seconds of inactivity for a Telnet before the system initiates automatic timeout and disconnect, expressed in a range from 30–65535. The default is 900 seconds.
<b>NumAccessViolations</b>	Indicates the number of CLI access violations detected by the system. This variable is a read-only field.
<b>CustomBannerText</b> <b>Note:</b> Exception: not supported on VSP 8600 Series.	Specifies the text message that is displayed to users on the CLI before authentication. The message can be company information, such as company name and contact, or a warning message for the users of CLI. With character limitation from 1-1800, the text box displays 79 characters per line.
<b>CustomBannerEnable</b> <b>Note:</b> Exception: not supported on VSP 8600 Series.	Specifies whether custom logon banner is enabled or disabled. The default is enabled.

## Configure Directed Broadcast on a VLAN

Configure directed broadcast on a VLAN to enable or disable directed broadcast traffic forwarding for an IP interface.

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANS**.
3. Select the **Basic** tab.
4. Select a VLAN.
5. Click **IP**.
6. Click the **Direct Broadcast** tab.
7. Select **DirectBroadcastEnable**.

#### Important

Configure multiple VLANs or IPs in the same subnet but in different systems simultaneously.

8. Click **Apply**.

**Direct Broadcast** field descriptions

Use the data in the following table to use the **Direct Broadcast** tab.

Name	Description
<b>DirectBroadcastEnable</b>	<p>Specifies that an Isolated Routing Port (IRP) can forward directed broadcast traffic. A directed broadcast is a frame sent to the subnet broadcast address on a remote IP subnet. By disabling or suppressing directed broadcast on an interface, all frames sent to the subnet broadcast address for a local router interface are dropped. Disabling this function protects a host from possible denial of service (DoS) attacks. With the feature enabled, the Control Processor (CP) does not receive a copy of the directed broadcast. As a result, the system does not respond to a subnet broadcast ping sent from a remote subnet. The default is disabled.</p>

Unicast Reverse Path Forwarding configuration using EDM

This section provides EDM procedures for Unicast Reverse Path Forwarding configuration.

*Configure Reverse Path Checking on a Port*

**Before You Begin**

- The system supports reverse path checking only on ports that have a valid IP address.

**About This Task**

Configure reverse path checking on a port to determine if a packet IP address is verifiable. Use reverse path checking to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. After you enable reverse path checking, the switch performs a reverse path check to determine if the packet IP address is verifiable. If the address is not verifiable, the system discards the packet.

Reverse path checking operates in one of two modes:

- exist-only mode
- strict mode

**Procedure**

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.

3. Click **IP**.
4. Click the **Reverse Path Checking** tab.
5. Select the **Enable** check box to enable reverse path checking.
6. Select **exist-only** or **strict**.
7. Click **Apply**.

### Reverse Path Checking field descriptions

Use the data in the following table to use the **Reverse Path Checking** tab.

Name	Description
<b>Enable</b>	Enables reverse path checking on the selected port. The default is disabled.
<b>Mode</b>	Specifies the mode for reverse path checking. The modes are <ul style="list-style-type: none"> <li>• exist-only—reverse path checking checks whether the incoming packet source IP address exists in the routing table. If reverse path checking finds the source IP entry, the packet is forwarded; otherwise the packet is discarded.</li> <li>• strict—reverse path checking checks whether the incoming packet source IP address exists in routing table. If reverse path checking does not find the source IP entry, the packet is dropped; otherwise, reverse path checking further checks if the source IP interface matches the incoming interface of the packet. If they match, the packet is forwarded; otherwise the packet is discarded.</li> </ul> The default is exist-only.

### Configure Reverse Path Checking on an IPv6 Port

#### Before You Begin

- The system supports reverse path checking only on ports that have a valid IP address.

#### About This Task

Configure reverse path checking on a port to determine if a packet IP address is verifiable. Use reverse path checking to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. After you enable reverse path checking, the switch performs a reverse path check to determine if the packet IP address is verifiable. If the address is not verifiable, the system discards the packet.

Reverse path checking operates in one of two modes:

- exist-only mode
- strict mode

**Procedure**

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **IPv6**.
4. Click the **Reverse Path Checking** tab.
5. Select the **ReversePathCheckEnable** check box to enable reverse path checking.
6. Select **exist-only** or **strict**.
7. Click **Apply**.

**Reverse Path Checking field descriptions**

Use the data in the following table to use the **Reverse Path Checking** tab.

Name	Description
<b>ReversePathCheckEnable</b>	Enables reverse path checking on the selected port. The default is disabled.
<b>ReversePathCheckMode</b>	Specifies the mode for reverse path checking. The modes are <ul style="list-style-type: none"> <li>• exist-only—reverse path checking checks whether the incoming packet source IP address exists in the routing table. If reverse path checking finds the source IP entry, the packet is forwarded; otherwise the packet is discarded.</li> <li>• strict—reverse path checking checks whether the incoming packet source IP address exists in routing table. If reverse path checking does not find the source IP entry, the packet is dropped; otherwise, reverse path checking further checks if the source IP interface matches the incoming interface of the packet. If they match, the packet is forwarded; otherwise the packet is discarded.</li> </ul> The default is exist-only.

*Configure Reverse Path Checking on a VLAN*

**Before You Begin**

- Before you can configure reverse path checking on a VLAN, you must assign a valid IP address to the selected VLAN.

**About This Task**

Configure reverse path checking on a VLAN to determine if a packet IP address is verifiable. Use reverse path checking to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. After you enable reverse path checking, the switch performs a reverse path check to determine if the packet IP address is verifiable. If the address is not verifiable, the system discards the packet.

Reverse path checking operates in one of two modes:

- exist-only mode

- strict mode

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANS**.
3. Click the VLAN on which you want to configure reverse path checking.
4. In the toolbar, click **IP**.
5. Click the **Reverse Path Checking** tab.
6. Select the **Enable** box to enable reverse path checking.
7. Select **exist-only** or **strict**.
8. Click **Apply**.

### Reverse Path Checking field descriptions

Use the data in the following table to use the **Reverse Path Checking** tab.

Name	Description
<b>Enable</b>	Enables reverse path checking on the selected VLAN.
<b>Mode</b>	<p>Specifies the mode for reverse path checking. The modes are</p> <ul style="list-style-type: none"> <li>• <b>exist-only</b>—reverse path checking checks whether the incoming packet source IP address exists in the routing table. If reverse path checking finds the source IP entry, the packet is forwarded; otherwise, the packet is discarded.</li> <li>• <b>strict</b>—reverse path checking checks whether the incoming packet source IP address exists in routing table. If reverse path checking does not find the source IP entry, then the packet is dropped. Otherwise, reverse path checking further checks if the source IP interface matches the incoming interface of the packet. If they match, then the packet is forwarded. Otherwise, the packet is discarded.</li> </ul> <p>The default is exist-only.</p>

### Configure Reverse Path Checking on an IPv6 VLAN

#### Before You Begin

- Before you can configure reverse path checking on a VLAN, you must assign a valid IP address to the selected VLAN.

#### About This Task

Configure reverse path checking on a VLAN to determine if a packet IP address is verifiable. Use reverse path checking to reduce the problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network. After you enable reverse path checking, the switch performs a reverse path check to

determine if the packet IP address is verifiable. If the address is not verifiable, the system discards the packet.

Reverse path checking operates in one of two modes:

- exist-only mode
- strict mode

### Procedure

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Basic** tab.
4. Click the VLAN on which you want to configure reverse path checking.
5. Click **IPv6**.
6. Click the **Reverse Path Checking** tab.
7. Select the **ReversePathCheckEnable** box to enable reverse path checking.
8. Select **exist-only** or **strict**.
9. Click **Apply**.

### Reverse Path Checking field descriptions

Use the data in the following table to use the **Reverse Path Checking** tab.

Name	Description
<b>ReversePathCheckEnable</b>	Enables reverse path checking on the selected VLAN.
<b>ReversePathCheckMode</b>	<p>Specifies the mode for reverse path checking. The modes are</p> <ul style="list-style-type: none"> <li>• exist-only—reverse path checking checks whether the incoming packet source IP address exists in the routing table. If reverse path checking finds the source IP entry, the packet is forwarded; otherwise, the packet is discarded.</li> <li>• strict—reverse path checking checks whether the incoming packet source IP address exists in routing table. If reverse path checking does not find the source IP entry, then the packet is dropped. Otherwise, reverse path checking further checks if the source IP interface matches the incoming interface of the packet. If they match, then the packet is forwarded. Otherwise, the packet is discarded.</li> </ul> <p>The default is exist-only.</p>

## Digital certificate configuration using EDM

The following section provides procedures to configure digital certificates using EDM.

*Configure Device Subject Parameters*

Use this procedure to configure the device subject parameters to identify the device. The parameters include name, Email ID, company, department, and location of the subject.

**Procedure**

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Certificate**.
3. Select the **Subject** or **Global Subject** tab.
4. In the **CommonName** field, type the name of the subject.
5. Complete the remaining optional configuration to customize the policy.
6. Select **Apply**.

**Subject field descriptions**

Use the data in the following table to use the **Subject** tab.

Name	Description
<b>CommonName</b>	Specifies the name of the subject sending the Certificate Signing Request to the Certificate Authority.
<b>EmailAddress</b>	Specifies the Email address of the subject sending the Certificate Signing Request to the Certificate Authority.
<b>OrganizationalUnit</b>	Specifies the organizational unit of the subject sending the Certificate Signing Request to the Certificate Authority.
<b>Organization</b>	Specifies the organization of the subject sending the Certificate Signing Request to the Certificate Authority.
<b>Locality</b>	Specifies the locality of the subject sending the Certificate Signing Request to the Certificate Authority.
<b>Province</b>	Specifies the province of the subject sending the Certificate Signing Request to the Certificate Authority.
<b>Country</b>	Specifies the country of the subject sending the Certificate Signing Request to the Certificate Authority.
<b>InstallFile</b>	Installs the specific certificate file type obtained offline from the Certificate Authority.
<b>InstallFileName</b>	Specifies the certificate file name to install.
<b>UninstallFile</b>	Uninstalls the specific certificate file type obtained offline from the Certificate Authority.

Name	Description
<b>UninstallFileName</b>	Specifies the certificate file name to uninstall.
<b>GenerateCsr</b>	Generates the certificate signing request to obtain the offline subject certificate.

### Configure Device Subject Entries Parameters

Use this procedure to configure the device subject parameters to identify the device. The parameters include name, Email ID, company, department, and location of the subject.

#### Note

This procedure does not apply to VSP 8600 Series.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Certificate**.
3. Select the **Subject Entries** tab.
4. Select **Insert**.
5. In the **Name** field, type the name of the subject.
6. Complete the remaining optional configuration to customize the policy.
7. Select **Insert**.

### Subject Entries Field Descriptions

Use the data in the following table to use the **Subject Entries** tab.

Name	Description
<b>Name</b>	Specifies the user defined name referring to the subject.
<b>CommonName</b>	Specifies the name of the subject sending the Certificate Signing Request to the Certificate Authority.
<b>EmailAddress</b>	Specifies the Email address of the subject sending the Certificate Signing Request to the Certificate Authority.
<b>OrganizationalUnit</b>	Specifies the organizational unit of the subject sending the Certificate Signing Request to the Certificate Authority.
<b>Organization</b>	Specifies the organization of the subject sending the Certificate Signing Request to the Certificate Authority.
<b>Locality</b>	Specifies the locality of the subject sending the Certificate Signing Request to the Certificate Authority.

Name	Description
<b>Province</b>	Specifies the province of the subject sending the Certificate Signing Request to the Certificate Authority.
<b>Country</b>	Specifies the country of the subject sending the Certificate Signing Request to the Certificate Authority.
<b>InstallFile</b>	Installs the specific certificate file type obtained offline from the Certificate Authority.
<b>InstallFileName</b>	Specifies the certificate file name to install.
<b>UninstallFile</b>	Uninstalls the specific certificate file type obtained offline from the Certificate Authority.
<b>UninstallFileName</b>	Specifies the certificate file name to uninstall.
<b>GenerateCsr</b>	Generates the certificate signing request to obtain the offline subject certificate.
<b>RelaxedMode</b> <b>Note:</b> Exception: Not supported on VSP 8600 Series.	Specifies relaxed mode for offline subject certificate installation for less restrictive consistency checks.
<b>Pkcs1Password</b> <b>Note:</b> Exception: Not supported on VSP 8600 Series.	Specifies the password to extract the PKCS12 container when in relaxed mode.
<b>KeyName</b> <b>Note:</b> Exception: Not supported on VSP 8600 Series.	Specifies the key name of the generated key-pair.

### Generate the Key Pair

Use the following procedure to generate the private and public key pair for the specific cryptography type.

#### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Certificate**.
3. Select the **Key-Pair** tab.
4. Select **Insert**.
5. In the **Type** field, select the cryptography type.
6. In the **Size** field, type the size of the key.
7. Select **Insert**.

### Certificate key-pair field description

Use the data in the following table to use the **Certificate > Key-Pair** tab.

Name	Description
<b>Type</b>	Specifies the cryptography algorithm used to generate the key-pair. Only RSA is supported.
<b>Size</b>	Specifies the size of the key-pair to be generated. Only 2048 is supported.
<b>Name</b>	Specifies the name of the key-pair generated for the subject. This name is auto-generated as the combination of key-type and key-size.

### Configure the Certificate Authority

Use this procedure to configure the certificate authority (CA) and perform related actions. You can configure only one CA in a device at a time.

#### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Certificate**.
3. Select the **CA** tab.
4. Select **Insert**.
5. In the **Name** field, type a user-defined name of the CA.
6. In the **CommonName** field, type the common name of the CA.
7. In the **KeyName** field, type the name of the associated key pair.
8. Complete the remaining optional configuration to customize the policy.
9. Select **Insert**.
10. (Optional) Select **Retry Action** if the trustpoint CA certificate authentication fails or takes time for authentication. This can be done only when the selected Action is **caauth**.

### CA field descriptions

Use the data in the following table to use the **CA** tab.

Name	Description
<b>Name</b>	Specifies the user-defined name referring to the Certificate Authority issuing the Digital Certificate.
<b>CommonName</b>	Specifies the Common Name of the Certificate Authority issuing the Digital Certificate.
<b>KeyName</b>	Specifies the name of the associated key pair.

Name	Description
<b>CaUrl</b>	Specifies the URL of the Certificate Authority issuing the Digital Certificate.
<b>Action</b>	Specifies the action the Certificate Authority can take: <ul style="list-style-type: none"> <li>• noop — no operation</li> <li>• caauth — CA authentication</li> <li>• enroll — certificate enrolment request</li> <li>• renew — certificate renew request</li> <li>• remove — remove the subject certificate obtained online from the CA</li> <li>• install — install the subject certificate obtained online from the CA</li> <li>• getCrl — retrieve the Certificate Revocation List (CRL) from the CRL Distribution Point (CDP).</li> </ul>
<b>ActionChallengePassword</b>	Specifies the challenge password required to perform the SCEP operation.
<b>LastActionStatus</b>	Specifies the status of the last action: <ul style="list-style-type: none"> <li>• none - No action is performed yet</li> <li>• success - Execution of the action triggered is completed successfully</li> <li>• failed - Execution of the action triggered has failed</li> <li>• inProgress - Execution of the action triggered is in progress</li> </ul>
<b>LastActionFailureReason</b>	Specifies the reason of failure for the last action performed by the Certificate Authority.
<b>InstallRootCaFileName</b>	Specifies the certificate file obtained offline from the Root Certificate Authority.
<b>SubjectCertificateValidityDays</b>	Specifies the number of days for which subject certificate will remain valid. The default value is 365 days.
<b>UsePost</b>	Specifies the HTTP request type: URL or POST. TRUE for EJBCA and FALSE for Win2012 CA
<b>Sha256Fingerprint</b>  <b>Note:</b> Exception: not supported on VSP 8600 Series.	Specifies an encrypted fingerprint of the expected certificate to match.

Name	Description
<b>SubjectName</b> <b>Note:</b> Exception: not supported on VSP 8600 Series.	Specifies the Subject Name of the subject sending the Certificate Signing Request to the Certificate Authority.
<b>UsedFor</b> <b>Note:</b> Exception: not supported on VSP 8600 Series.	Specifies the name of the application the certificate uses. The default is enabled if there is only 1 CA trustpoint configured.

### View the Certificate Details

Use this procedure to:

- display the configured key details for given key name.
- display the digital certificate for the given certificate index or list all the certificate details from the local store if the certificate index is not specified.
- display the CA details for given trustpoint CA name or list all the CA details from the local store if the CA name is not specified.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Certificate**.
3. Select the **Certificate** tab.

### Certificate Field Descriptions

Use the data in the following table to use the **Certificate** tab.

Name	Description
<b>Type</b>	Specifies the certificate type.
<b>VersionNumber</b>	Specifies the version number of the certificate for the subject as issued by the Certificate Authority.
<b>SerialNumber</b>	Specifies the serial number of the certificate for the subject as issued by the Certificate Authority.
<b>IssuerName</b>	Specifies the name of the issuer of the certificate for the subject as issued by the Certificate Authority.
<b>ValidStartPeriod</b>	Specifies the start date of the validation period of the certificate for the subject as issued by the Certificate Authority.
<b>ValidEndPeriod</b>	Specifies the last date of the validation period of the certificate for the subject as issued by the Certificate Authority.

Name	Description
<b>CertificateSignatureAlgorithm</b>	Specifies the algorithm used for the signature of the issuer on the certificate for the subject as issued by the Certificate Authority.
<b>CertificateSignature</b>	Specifies the signature of the issuer on the certificate for the subject as issued by the Certificate Authority.
<b>Subject</b>	Specifies the details of the subject on its certificate as issued by Certificate Authority.
<b>SubjectPublicKeyAlgorithm</b>	Specifies the algorithm used to generate the public key of the subject for the certificate issued by the Certificate Authority.
<b>SubjectPublicKey</b>	Specifies the public key of the subject used for the Certificate Signing Request.
<b>HasBasicConstraint</b>	Specifies whether the certificate contains any basic certificate constraint or not.
<b>HasKeyUsage</b>	Specifies whether the certificate contains basic key usage constraint or not.
<b>IsCa</b>	Specifies whether the certificate is a ca certificate or not.
<b>KeyUsage</b>	<p>Specifies the purpose of the key used in the certificate. It is represented in the form of bits as follows:</p> <ul style="list-style-type: none"> <li>• bit 0 - digitalSignature</li> <li>• bit 1 - nonRepudiation</li> <li>• bit 2 - keyEncipherment</li> <li>• bit 3 - dataEncipherment</li> <li>• bit 4 - keyAgreement</li> <li>• bit 5 - keyCertSign</li> <li>• bit 6 - cRLSign</li> <li>• bit 7 - encipherOnly</li> <li>• bit 8 - decipherOnly</li> </ul>
<b>Status</b>	Specifies the status of the certificate.
<b>Installed</b>	Specifies whether the certificate is installed or not.
<b>CdpUrl</b>	Specifies the CDP URL present in the Digital Certificate Extensions field.
<b>OcspUrl</b>	Specifies the OCSP URL present in the Digital Certificate AIA field.

Name	Description
<b>ExtendedKeyUsage</b>	Indicates the purpose for which the key is used in addition to or in place of the basic purposes indicated in the key-usage field of the certificate.
<b>RevocationStatus</b> <b>Note:</b> Exception: not supported on VSP 8600 Series.	Specifies the revocation status of the certificate.

### Install the Root CA Certificate

Use the following procedure to install the Root CA certificate obtained offline.

#### Note

This procedure applies to VSP 8600 Series only.

### Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **System Log**.
3. Select **Root Certificate Table** tab.
4. Select **Insert**.
5. In the **Filename** field, enter the filename obtained offline from the CA.
6. In the **Action** field, select the action.
7. Select **Insert**.

### Root Certificate Table field description

Use the data in the following table to use the **System Log > Root Certificate Table** tab.

Name	Description
<b>Filename</b>	Specifies the certificate filename obtained offline from the Root Certificate Authority.
<b>Action</b>	<p>Specifies the action to be performed on Root CA.</p> <ul style="list-style-type: none"> <li>• noaction: No action is performed.</li> <li>• install: Installs the Root CA certificate obtained offline.</li> <li>• uninstall: Uninstalls the Root CA certificate.</li> </ul> <p>The system displays the Conversion Fail if the execution of the action fails.</p>

### View the Certificate Store

Use the following procedure to view the online, offline and root certificates in the local store.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **Certificate**.
3. Click the **Certificate Store** tab.

### Certificate Store field descriptions

Use the data in the following table to use the **Certificate Store** tab.

Name	Description
<b>CommonName</b>	Specifies the Common Name of the Certificate Authority issuing the Digital Certificate.
<b>Type</b>	Specifies the certificate type.
<b>VersionNumber</b>	Specifies the version number of the certificate for the subject as issued by the Certificate Authority.
<b>SerialNumber</b>	Specifies the serial number of the certificate for the subject as issued by the Certificate Authority.
<b>IssuerName</b>	Specifies the name of the issuer of the certificate for the subject as issued by the Certificate Authority.
<b>ValidStartPeriod</b>	Specifies the start date of the validation period of the certificate for the subject as issued by the Certificate Authority.
<b>ValidEndPeriod</b>	Specifies the last date of the validation period of the certificate for the subject as issued by the Certificate Authority.
<b>CertificateSignatureAlgorithm</b>	Specifies the algorithm used for the signature of the issuer on the certificate for the subject as issued by the Certificate Authority.
<b>CertificateSignature</b>	Specifies the signature of the issuer on the certificate for the subject as issued by the Certificate Authority.
<b>Subject</b>	Specifies the details of the subject on its certificate as issued by Certificate Authority.
<b>SubjectPublicKeyAlgorithm</b>	Specifies the algorithm used to generate the subject's public key for the certificate issued by the Certificate Authority.
<b>SubjectPublicKey</b>	Specifies the public key of the subject used for Certificate Signing Request.
<b>HasBasicConstraint</b>	Specifies whether certificate contains basic certificate constraint.
<b>HasKeyUsage</b>	Specifies whether certificate contains basic key usage constraint.

Name	Description
<b>IsCa</b>	Specifies if the certificate is a CA certificate or not.
<b>KeyUsage</b>	Specifies the purpose of the key used in the certificate. It is represented in the form of bits as follows: <ul style="list-style-type: none"> <li>• bit 0 - digitalSignature</li> <li>• bit 1 - nonRepudiation</li> <li>• bit 2 - keyEncipherment</li> <li>• bit 3 - dataEncipherment</li> <li>• bit 4 - keyAgreement</li> <li>• bit 5 - keyCertSign</li> <li>• bit 6 - cRLSign</li> <li>• bit 7 - encipherOnly</li> <li>• bit 8 - decipherOnly</li> </ul>
<b>Status</b>	Specifies the status of the certificate.
<b>Installed</b>	Specifies whether the certificate is installed or not.
<b>CdpUrl</b>	Specifies the CDP URL present in the Digital Certificate Extensions field.
<b>OscpUrl</b>	Specifies the OCSP URL present in the Digital Certificate AIA field.
<b>ExtendedKeyUsage</b>	Indicates the purpose for which the key is used in addition to or in place of the basic purposes indicated in the key-usage field of the certificate.
<b>CaFileName</b>	Specifies the certificate file obtained offline from the Root Certificate Authority.

## Configure TCP Keepalive and TCP Timestamp

### About This Task

TCP Keepalive configures the system TCP keepalive interval, probes, and time.

TCP Timestamp option (RFC 1323) allows TCP to determine the order in which the packets are sent. The TCP Timestamp provides protection against Wrapped Sequence numbers. However, it is possible to calculate the system uptime when the Timestamp option is enabled. The analysis of timestamp behaviour can provide information on the system identity, which poses security threats and can cause a potential attack.

The TCP Timestamp option is enabled by default. You can disable the timestamp to avoid any security risks.

#### Note

The configuration will be applied only to the new TCP connections and the existing connections are not affected. You must save the configuration and reboot the switch to apply the new configuration to all TCP connections.

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **System Control** tab.
4. Configure the TCP timestamp by performing one of the following actions:
  - a. Select **TcpTimestamp** to enable the TCP timestamp.
  - b. Clear **TcpTimestamp** to disable the TCP timestamp.
5. In **KeepaliveTime**, enter a number in seconds.
6. In **KeepaliveInterval**, enter a number in seconds.
7. In **KeepaliveProbes**, enter a number of probes.
8. Select **Apply**.

### *System Control Field Descriptions*

Use the data in the following table to use the **System Control** tab.

Name	Description
<b>TcpTimestampEnable</b>	Enables or disables the TCP timestamp. The timestamp is enabled by default. The system displays the following warning message after you apply a new configuration: Warning: Existing TCP connections won't be affected. A config save and reboot is required to apply this configuration for all TCP connections.
<b>KeepaliveTime</b> <b>Note:</b> Exception: Not supported on VSP 8600 Series.	Specify the TCP keepalive time in seconds. The default is 60.
<b>KeepaliveInterval</b> <b>Note:</b> Exception: Not supported on VSP 8600 Series.	Specify the TCP keepalive interval in seconds. The default is 10.

Name	Description
<p><b>KeepaliveProbes</b></p> <p><b>Note:</b> Exception: Not supported on VSP 8600 Series.</p>	<p>Specify the TCP keepalive probes. The default is 5.</p>
<p><b>PrivExecPasswordEnable</b></p>	<p>Enables authentication to access Privileged EXEC CLI command mode. Authentication is disabled by default.</p>

## Enable Authentication for Privileged EXEC Command Mode

### Procedure

1. In the navigation pane, expand **Configuration > Edit**.
2. Select **Chassis**.
3. Select the **System Control** tab.
4. Select **PrivExecPasswordEnable**.

The switch supports the Service Level Agreement Monitor (SLA Mon) agent as part of the SLA Mon solution.

SLA Mon uses a server and agent relationship to perform end-to-end network Quality of Service (QoS) validation and to distribute monitoring devices. You can use the test results to target under-performing areas of the network for deeper analysis.

## SLA Mon Server and Agent

The switch supports the SLA Mon agent. You must have an Avaya Diagnostic Server with SLA Mon technology in your network to use the SLA Mon feature. Most of the SLA Mon configuration occurs on the server; configuration on the SLA Mon agent is minimal.

The SLA Mon server initiates the SLA Mon functions on one or more agents, and the agents run specific QoS tests at the request of the server. Agents can exchange packets between one another to conduct the QoS tests.

SLA Mon can monitor a number of key items, including the following:

- network paths
- Differentiated Services Code Point (DSCP) markings
- loss
- jitter
- delay

The following figure shows an SLA Mon implementation.

**Figure 237: SLA Monitor network**

An SLA Mon agent remains dormant until it receives a User Datagram Protocol (UDP) discovery packet from a server. The agent accepts the discovery packet to register with an SLA Mon server. If the registration process fails, the agent remains dormant until it receives another discovery packet.

An agent can attempt to register with an SLA Mon server once every 60 seconds. After a successful registration, the agent reregisters with the server every 6 hours to exchange a new encryption key.

An agent only accepts commands from the SLA Mon server to which it is registered. An agent can use alternate SLA Mon servers to provide backup for time-out and communication issues with the primary SLA Mon server.

**Note**

If you configure the SLA Mon agent address under an IP address for a VLAN or router, you must remove the SLA Mon address before you can remove the IP address for the VLAN or router.

## QoS tests

---

SLA Mon uses two types of tests to determine QoS benchmarks:

- Real Time Protocol (RTP)

This test measures network performance — for example, jitter, delay, and loss — by injecting a short stream of UDP packets from source to destination (an SLA Mon agent).

- New Trace Route (NTR)

This test is similar to traceroute but also includes DSCP values at each hop in the path from the source to the destination. The destination does not need to be an SLA Mon agent.

## Limitations

---

SLA Mon agent communications are IPv4-based. Agent communications do not currently support IPv6.

## SLA Mon configuration using CLI

---

This section provides procedures to configure Service Level Agreement Monitor (SLA Mon) using the command line interface (CLI).

### Configure the SLA Mon Agent

Configure the SLA Mon agent to communicate with an SLA Mon with SLA Mon technology to perform Quality of Service (QoS) tests of the network.

**Before You Begin**

- To use the SLA Mon agent, you must have an Avaya Diagnostic Server with SLA Mon technology in your network.

## About This Task

To configure the SLA Mon agent, you must assign an IP address and enable it. Remaining agent parameters are optional and you can operate the agent using the default values.

### Note

- If you want to change SLA Mon parameters, you must first disable SLA Mon.

If you are configuring SLA Mon at the switch side for the first time, make sure you configure the SLA Mon agent address under an IP address for a VLAN or brouter, and you must remove the SLA Mon address before you can remove the IP address for the VLAN or brouter. To remove the SLA Mon address, first use the command **no slamon oper-mode enable**, followed by **slamon agent ip address 0.0.0.0**.

## Procedure

1. Enter Application Configuration mode:

```
enable

configure terminal

application
```

2. Configure the SLA Mon agent IP address:

### Note

The SLA Mon Agent uses its own reserved Host IP address, reachable via the Switch VLAN IP interface of the same IP subnet.

```
slamon agent ip address {A.B.C.D} [vrf WORD<1-16>]
```

3. (Optional) Configure the UDP port for agent-server communication:

```
slamon agent port <0-65535>
```

4. (Optional) Restrict which servers an agent can use:

```
slamon server ip address {A.B.C.D} [{A.B.C.D}]
```

```
slamon server port <0-65535>
```

5. (Optional) Control the port used for Real Time Protocol (RTP) and New Trace Route (NTR) testing:

```
slamon agent-comm-port <0-65535>
```

6. (Optional) Install a Secure Socket Layer (SSL) certificate for the agent:

```
slamon install-cert-file WORD<0-128>
```

7. Enable the agent:

```
slamon oper-mode enable
```

8. Verify the agent configuration:

```
show application slamon agent
```

## Example

Configure the SLA Mon agent IP address. Configure the agent so that it only accepts registration packets from a specific server communicating on a specific port. Finally, enable the SLA Mon agent, and then verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#application
Switch:1(config-app)#slamon agent ip address 192.0.2.1
Switch:1(config-app)#slamon server ip address 192.0.2.24
Switch:1(config-app)#slamon server port 50011
Switch:1(config-app)#slamon oper-mode enable
Switch:1(config-app)#show application slamon agent

Vlan130   198.51.100.7 255.255.255.0  ones     1500  130 false
All 5 out of 5 Total Num of IP interfaces displayed
```

## What to Do Next

If you have configured SLA Mon, but the agent does not function as expected, use the **show khi performance pthread [{slot[-slot] [, ...]}** command to verify that the slamon task is running.

If the SLA Mon agent is not running, use the commands **no slamon oper-mode enable** and **slamon oper-mode enable** to start the agent.

If the agent task is running, perform typical troubleshooting steps to verify agent accessibility:

- Verify IP address assignment and port use.
- Ping the server IP address.
- Verify the server configuration.
- Use the **trace level 192 <0-4>** command to observe the status of the SLA Mon software module.

#### Variable definitions

Use the data in the following table to use the **slamon** command.

Variable	Value
<i>agent-comm-port</i> <0-65535>	Configures the port used for RTP and NTR testing in agent-to-agent communication. The default port is 50012. If you configure this value to zero (0), the default port is used.
<i>agent ip address</i> {A.B.C.D}	Configures the SLA Mon agent IP address. You must configure the IP address before the agent can process received discovery packets from the server. The agent ip address is a mandatory parameter. The default value is 0.0.0.0.
<i>agent port</i> <0-65535>	Configures the UDP port for agent-server communication. The SLA Mon agent receives discovery packets on this port. The default is port 50011. The server must use the same port.
<i>install-cert-file</i>	Installs an SSL certificate. <i>WORD</i> <0-128> specifies the file name and path of the certificate to install. If you install a certificate on the SLA Mon agent, you must ensure a matching configuration on the server.
<i>oper-mode enable</i>	Enables the SLA Mon agent. The default is disabled. If you disable the agent, it does not respond to discovery packets from a server. If you disable the agent because of resource concerns, consider changing the server configuration instead, to alter the test frequency or duration, or the number of targets.
<i>server ip address</i> {A.B.C.D} [ {A.B.C.D} ]	Restricts the SLA Mon agent to use the server at this IP address only. The default is 0.0.0.0, which means the agent can register with any server. You can specify a secondary server as well.
<i>server port</i> <0-65535>	Restricts the SLA Mon agent to use this registration port only. The default is 0, which means the agent disregards the source port information in server traffic. The server must use the same port.
<i>vrf</i> <i>WORD</i> <1-16>	Specifies the name of a VRF.

## SLA Mon Configuration using EDM

---

This section provides procedures to configure Service Level Agreement Monitor (SLA Mon) using Enterprise Device Manager (EDM).

### Configure the SLA Mon Agent

Configure the SLA Mon agent to communicate with an Avaya Diagnostic Server with SLA Mon technology to perform Quality of Service (QoS) tests of the network.

#### Before You Begin

- To use the SLA Mon agent, you must have an Avaya Diagnostic Server with SLA Mon technology in your network.

#### About This Task

To configure the SLA Mon agent, you must assign an IP address and enable it. Remaining agent parameters are optional and you can operate the agent using the default values.

#### Note

If you want to change SLA Mon parameters, you must first disable SLA Mon.

If you configure the SLA Mon agent address under an IP address for a VLAN or brouter, you must remove the SLA Mon address, before you can remove the IP address for the VLAN or brouter. To remove the SLA Mon address, first select **disabled** from the **Status** field, then configure the IP address in the **ConfiguredAgentAddr** field to 0.0.0.0.

#### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Select **SLA Monitor**.
3. Select the **SLA Monitor** tab.
4. For the status, select **enabled**.
5. In the **ConfiguredAgentAddr** field, enter the SLA Mon agent IP address
6. Configure optional parameters as required.
7. Select **Apply**.

**SLA Monitor** field descriptions

Use the data in the following table to use the **SLA Monitor** tab.

Name	Description
<b>Status</b>	Enables or disables the SLA Mon agent. The default is disabled. If you disable the agent, it does not respond to discovery packets from a server. If you disable the agent because of resource concerns, consider changing the server configuration instead, to alter the test frequency or duration, or the number of targets.
<b>CertFileInstallAction</b>	Installs or uninstalls a Secure Sockets Layer (SSL) certificate file. The default is noAction.
<b>CertFile</b>	Specifies the file name and path of the SSL certificate. If you install a certificate on the SLA Mon agent, you must ensure a matching configuration on the server.
<b>ConfiguredAgentAddrType</b>	Specifies the address type of the agent: IPv4.
<b>ConfiguredAgentAddr</b>	Configures the agent IP address. You must configure the IP address before the agent can process received discovery packets from the server. The agent IP address is a mandatory parameter. The default value is 0.0.0.0.
<b>ConfiguredAgentPort</b>	Configures the UDP port for agent-server communication. The SLA Mon agent receives discovery packets on this port. The default is port 50011. The server must use the same port.
<b>ConfiguredAgentVrfName</b>	Specifies the name of a VRF.
<b>ConfiguredServerAddrType</b>	Specifies the address type of the server: IPv4.
<b>ConfiguredServerAddr</b>	Restricts the SLA Mon agent to use the server at this IP address only. If the default of 0.0.0.0 is used, then the SLA Mon agent can register with any server.
<b>ConfiguredServerPort</b>	Restricts the SLA Mon agent to use this registration port only. The default is 0, which means the agent disregards the source port information in server traffic. The server must use the same port.
<b>ConfiguredAltServerAddrType</b>	Specifies the address type of the secondary server: IPv4.
<b>ConfiguredAltServerAddr</b>	Configures a secondary server in the event that the primary server is unreachable.
<b>ConfiguredAltServerPort</b>	Restricts the SLA Mon agent to use this registration port on the secondary server only. The default is 0, which means the agent disregards the source port information in server traffic. The server must use the same port.
<b>SupportedApps</b>	Shows the type of testing supported: Real Time Protocol (RTP) and New Trace Route (NTR).
<b>AgentAddressType</b>	Shows the SLA Mon agent address type.

Name	Description
<b>AgentAddress</b>	Shows the configured SLA Mon agent IP address.
<b>AgentPort</b>	Shows the configured SLA Mon agent port.
<b>RegisteredWithServer</b>	Indicates if the SLA Mon agent has registered with a server.
<b>RegisteredServerAddrType</b>	Shows the address type for the registered server.
<b>RegisteredServerAddr</b>	Shows the IP address for the registered server.
<b>RegisteredServerPort</b>	Shows the port number for the registered server.
<b>RegistrationTime</b>	Shows the amount of time, in seconds, since the SLA Mon agent registered with the server.
<b>AgentToAgentPort</b>	Shows the port for SLA Mon agent-to-agent communication.
<b>ConfiguredAgentToAgentPort</b>	Configures the port used for RTP and NTR testing in SLA Mon agent-to-agent communication. The default port is 50012. If you configure this value as zero (0), the default port is used.

## sFlow Fundamentals

sFlow monitors traffic in a data network. Use sFlow to monitor routers and switches in the network, and capture traffic statistics about those devices. sFlow uses sampling to provide scalability for network-wide monitoring, and therefore applies to high speed

networks. The switch sends the sampled data as a User Datagram Protocol (UDP) packet to the specified host and port.

**Note**

sFlow and Application Telemetry send mirrored packets from a common source to a common destination. sFlow sends samples directly to the destination, while Application Telemetry sends mirrored packets through a GRE tunnel, to the same destination. For more information, see [Common Elements Between sFlow and Application Telemetry](#) on page 365.

sFlow consists of the following:

- sFlow agent—Performs two types of sampling:
  - Flow samples: Flow sampling randomly samples an average of 1 out of n packets for each operation.
  - Counter samples: Counter sampling periodically polls and exports counters for a configured interface. This type of sampling uses a counter to determine if the packet is sampled. Each packet that an interface receives, and that a filter does not drop, reduces the counter by one. After the counter reaches zero, the sFlow agent takes a sample.

**Note**

Only generic interface counters and Ethernet interface counters are supported.

- sFlow datagrams—Supports both flow samples and counter samples. Datagrams can be sent from the front panel port or an out-of-band (OOB) port. Each datagram provides information about the sFlow version, the originating IP address of the device, a sequence number, the number of samples it contains, and one or more flow and/or counter samples.
- sFlow collector—Located on a central server and runs software that analyzes and reports on network traffic. Two sFlow collectors can be configured to be reachable over a management network or Shortest Path Bridging (SPB).

## Operational Considerations

The following section describes operational considerations for deploying sFlow.

- Application-specific integrated circuit (ASIC) or Software Development Kit (SDK) limitation—To avoid wobbling, the counter interval for sFlow is 20 seconds. Minor wobbling can still occur even after configuring the counter interval due to the interaction between the sFlow agent counter export schedule and the frequency with which the switch ASIC SDK copies and caches counters from the ASIC.
- sFlow supports a maximum of two collectors.
- UDP datagram size and the collector buffer are restricted to 1400 bytes. sFlow sends datagrams to the collector when the buffer reaches the 1400-byte capacity or after a timeout of one second is triggered. The collector buffer size cannot be modified.
- The switch supports IPv4 collector IP addresses.
- VLAN counters/statistics are not supported.

- sFlow can be enabled only on the front panel ports.
- You cannot configure the sampling limit. The sampling limit applies system-wide rather than on a per port basis. Sampling rates differ depending on the hardware platform so any sampled packets beyond the limit are dropped. For more information about feature support, see [VOSS Release Notes](#).
- The switch supports only ingress sampling. The switch does not support egress sampling.
- The switch does not support enabling sFlow on a link aggregation group (LAG) interface. However, you can enable sFlow on the member interfaces of a LAG.
- When you specify the sFlow source IP as the Segmented Management Instance OOB instance, the Management Instance OOB routing table determines reachability to the collector.
- When you specify the sFlow source IP as the Segmented Management Instance VLAN instance, the Management Instance VLAN routing table determines reachability to the collector.
- When you specify the sFlow source IP as the Segmented Management Instance CLIP instance, the VRF associated with the Management Instance CLIP checks reachability to the collector, including GRT, VRFs or Layer 3 VSNS.
- When you specify the sFlow source IP as a routing VLAN or loopback IP, only the GRT checks reachability to the collector. User-defined VRFs or Layer 3 VSNS are not supported for this option.
- For Segmented Management Instance interfaces, both collectors must be reachable through the Management Instance interface bound to the sFlow source IP. Configurations where one sFlow collector is a Management Instance OOB interface and the other sFlow collector is on an in-band interface are not supported.
- You must use Segmented Management Instance CLIP to access VRFs and Layer 3 VSNS.
- sFlow supports user created VRFs when Segmented Management Instance CLIP interface IP address is used as the sFlow source IP.
- You can use the onboarding VLAN to manage the switch and enable sFlow without any additional management or routing interface configuration.
- A packet can have only one mirror destination. You cannot configure sFlow and Port Mirroring on the same port.

**Note**

This restriction applies to the VSP 8600 Series only. Other platforms mirror copies to both destinations.

## Configuration Considerations

The following section describes configuration considerations for sFlow.

- If the sFlow collector has two network interface controller (NIC) cards, add a route to the agent IP address for the NIC card on which the sFlow datagrams are received to avoid dropped sFlow datagrams due to reverse path checks.

After you configure the sFlow agent on the network device that you want to monitor, the system collects flow samples or counter samples, and exports these traffic statistics as sFlow datagrams to the sFlow collector on a server or appliance.

For example, after the buffers reach capacity or a timeout is triggered, an sFlow datagram, which is a UDP packet, sends the measurement information to the sFlow collector buffers. The UDP payload contains the sFlow datagram.

The following figure shows the sFlow agent on various routers and switches with sFlow datagrams being sent to the sFlow collector.

**Table 245: sFlow legend**

Number	Description
1	sFlow collector
2	sFlow datagrams
3	sFlow agents

As a general rule, drop action occurs after sampling completes. However, in situations related to Layer 1 errors such as, MTU exceeded packets, the drop action occurs before

sampling begins. For errors such as, frame too long, packets are dropped due to the size of the frame being greater than the interface MTU. In this situation, the packets are dropped before sampling begins so only counter polling occurs. To enable trace, use **line-card 1 trace level 232 <0-4>**.

**Important**

The defined sampling rate, an average of 1 out of n packets/operations does not provide a 100% accurate result, but it does provide a result with quantifiable accuracy.

## sFlow Configuration Using CLI

---

Use sFlow to capture traffic statistics to monitor traffic in a data network. This section provides procedures to view and configure sFlow using CLI.

### Configure the Agent IP Address and Enable sFlow Globally

Configure the sFlow agent IPv4 address, and then enable sFlow before the system can monitor and capture traffic statistics to send to an sFlow collector. By default, sFlow is globally disabled.

You can configure sFlow on Segmented Management Instance interfaces OOB, VLAN, and CLIP. You can also use routing VLANs or loopback IPs as the source IP address. Configure the agent IP address to match the Management Instance interface, routing VLAN or loopback IP address.

**Procedure**

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Configure the sFlow source IP address:  
`sflow agent-ip {A.B.C.D}`
3. Configure the sFlow collector:  
`sflow collector <1-2> address {A.B.C.D}`
4. Configure the sFlow destination port number:  
`sflow collector <1-2> port <1-65535>`
5. Configure the sFlow collector timeout:  
`sflow collector <1-2> timeout <1-65535>`

6. Enter GigabitEthernet Interface Configuration mode to bind the port the collector:  

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

7. (Optional) Configure the interface sampling rate:  

```
sflow sampling-rate <1024-100000>
```
8. (Optional) Configure the interface counter intervals:  

```
sflow counter-interval <1-3600>
```
9. (Optional) Configure the interface max header size:  

```
sflow max-header-size <64-256>
```
10. Enable sFlow:  

```
sflow enable
```

**Example**

Displays sFlow configuration:

```
Switch:1(config)#show sflow

=====
=====
                               sFlow Global Configuration

Variable Definitions

The following table defines parameters for the **sflow** commands related to configuring sFlow as the source IP.

Variable	Value
<i>agent-ip</i>	Specifies the agent-ip address (IPv4).
<i>collector &lt;1-2&gt;</i>	Specifies the id to export sFlow datagrams to the collector id. Use the no operator to remove an sflow collector id and a collector name. <code>no sflow collector &lt;1-2&gt; owner WORD&lt;1-20&gt;</code> To configure the default value, enter <code>default sflow collector &lt;1-2&gt;</code>
<i>address {A.B.C.D.}</i>	Specifies the collector IP address. Use the no operator to remove an sflow collector address. <code>no sflow collector &lt;1-2&gt; address {A.B.C.D}</code>
<i>owner WORD&lt;1-20&gt;</i>	Specifies the sFlow collector name.
<i>port &lt;1-65535&gt;</i>	Specifies the destination UDP port. The default port is 6343. To configure the default value, enter <code>default sflow collector &lt;1-2&gt; port</code>
<i>timeout &lt;1-65535&gt;</i>	Specifies the time remaining (in seconds) before the collector is released. The default timeout is 0, which means the timeout is not used and the collector sends data forever. To configure the default value, enter <code>default sflow collector &lt;1-2&gt; timeout</code>
<i>sampling-rate &lt;1024-1000000&gt;</i>	Configures the packet sampling rate on a port. The default value is 0 (disabled). To configure the default value, enter <b>default sflow sampling-rate</b> .

Variable	Value
<i>counter-interval</i> <1-3600>	Specifies the polling interval on a port to determine how often the sFlow agent polls and exports counters for a configured interface. The default value is 0 (disabled).
<i>max-header-size</i> <64-256>	Specifies the maximum number of bytes to be copied from the sampled packet. The default is 128 bytes.

## Configuring an sFlow Collector

Configure an sFlow collector to determine the device to which the sFlow agent sends sFlow datagrams. You can configure up to two collectors for each interface slot in the chassis.

### Before You Begin

- You must globally enable sFlow.

### About This Task

The sFlow datagrams that the agent sends to the collector are not encrypted. Use a VLAN to create a secure measurement network to route sFlow datagrams.

To further protect the sFlow collector, configure it to accept only sFlow datagrams, or to check sequence numbers and verify source addresses.

### Procedure

- Enter Global Configuration mode:
 

```
enable

configure terminal
```
- Configure the collector information:
 

```
sflow collector <1-2> address {A.B.C.D} [Owner WORD <1-20>] [port <1-65535>] [timeout <1-65535>]
```
- Verify the collector configuration:
 

```
show sflow collector <1-2>
```

### Example

Configure collector ID, and then verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#sflow collector 1 address 192.0.2.26 owner sflow1 port 6343 timeout 497
Switch:1(config)#sflow collector 2 address 192.0.2.27 owner sflow2 port 6343 timeout 531
Switch:1(config)#show sflow collector
```

```
=====

```

Id	Owner	Collector-IP	Port	Timeout (secs)	Reachable via
1	sflow1	192.0.2.26	6343	497	192.0.2.15
2	sflow2	192.0.2.27	6343	531	192.0.2.16

All 2 out of 2 Total Num of sflow collector entries displayed

### What to Do Next

After you configure the sFlow collector, configure the packet sampling rate to enable sFlow on a port or ports.

### Variable Definitions

Use the data in the following table to use the **sflow collector** command.

Variable	Value
<code>collector &lt;1-2&gt;</code>	Specifies the id to export sFlow datagrams to the collector id. Use the no operator to remove an sflow collector id and a collector name. <code>no sflow collector &lt;1-2&gt; owner WORD&lt;1-20&gt;</code> To configure the default value, enter <code>default sflow collector &lt;1-2&gt;</code>
<code>address {A.B.C.D.}</code>	Specifies the collector IP address. Use the no operator to remove an sflow collector address. <code>no sflow collector &lt;1-2&gt; address {A.B.C.D}</code>
<code>owner WORD&lt;1-20&gt;</code>	Specifies the sFlow collector name.
<code>port &lt;1-65535&gt;</code>	Specifies the destination UDP port. The default port is 6343. To configure the default value, enter <code>default sflow collector &lt;1-2&gt; port</code>
<code>timeout &lt;1-65535&gt;</code>	Specifies the time remaining (in seconds) before the collector is released. The default timeout is 0, which means the timeout is not used and the collector sends data forever. To configure the default value, enter <code>default sflow collector &lt;1-2&gt; timeout</code>
<code>vrf WORD&lt;1-16&gt;</code>	Specifies the name of the VRF used to reach the collector. <b>Note:</b> This parameter is not supported on all hardware platforms.

## Configuring the Packet Sampling Rate

Configure the packet sampling rate at port level to determine how many packets the system counts before it takes a sample. Configuring the sampling rate enables sFlow on the port.

### Before You Begin

- You must globally enable sFlow.

## About This Task

If you configure a conservative sampling rate to prevent overloading the sFlow agent, the result will reflect high values that do not reflect typical traffic levels.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure the collector id:

```
sflow collector <1-2>
```

3. Configure the sampling rate:

```
sflow sampling-rate <1024-1000000>
```

4. Verify the configuration:

```
show sflow interface {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

## Example

Configure sampling rates for ports 2/1, 2/2, 2/3, and 2/4.

```
Switch:1(config-if)#interface gigabitethernet 2/1,2/2
Switch:1(config-if)#sflow collector 1
Switch:1(config-if)#sflow sampling-rate 10000
Switch:1(config-if)#interface gigabitethernet 2/3
Switch:1(config-if)#sflow collector 2
Switch:1(config-if)#sflow sampling-rate 8192
Switch:1(config-if)#interface gigabitethernet 2/4
Switch:1(config-if)#sflow collector 2
Switch:1(config-if)#sflow sampling-rate 12001
Switch:1(config-if)#show sflow interface enabled
=====

2/2     10000                128                0                    1
2/3     8192                 128                0                    2
2/4     12001                128                0                    2
-----
All 4 out of 4 Total Num of sflow port entries displayed
```

### Variable Definitions

Use the data in the following table to use the **sflow sampling-rate** and **show sflow interface** commands.

Variable	Value
<1024-1000000>	Configures the packet sampling rate on a port. The default value is 0 (disabled). To configure the default value, enter <code>default sflow sampling-rate</code> .
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Configuring sFlow Maximum Header Size

Configure the maximum header size on a single port or multiple ports.

### Before You Begin

- You must globally enable sFlow.

### Procedure

- Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Configure the maximum-header size:

```
sflow max-header-size <64-256>
```

- Verify the configuration:

```
show sflow interface {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Example

For ports 1/1 to 1/10, configure the maximum header size, and then verify the configuration.

```
Switch:1(config-if)#interface gigabitethernet 1/1-1/10
Switch:1(config-if)#sflow max-header-size 255
Switch:1(config-if)#show sflow interface 1/1-1/10
```

```

=====

1/2      0                   255              525              1,2
1/3      0                   255              525              1,2
1/4      0                   255              525              1,2
1/5      0                   255              525              1,2
1/6      0                   255              525              1,2
1/7      0                   255              525              1,2
1/8      0                   255              525              1,2
1/9      0                   255              525              1,2
1/10     0                   255              525              1,2

```

### Variable Definitions

Use the data in the following table to use the **max-header-size** command.

Variable	Value
<64-256>	Identifies the maximum number of bytes to be copied from the sampled packet. Default 128 bytes.

## Configuring the Counter Sampling Interval

Configure the counter sampling interval values at port level to determine how often the sFlow agent polls and exports counters for a configured interface.

### Before You Begin

- You must globally enable sFlow.

### Procedure

- Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

- Configure the counter sampling interval:

```
sflow counter-interval <1-3600>
```

- Verify the configuration:

```
show sflow interface {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

## Example

Verify all slots use the default polling-interval configuration.

```
Switch:1(config-if)#sflow counter-interval 525
Switch:1(config-if)#show sflow interface 1/1-1/10
```

```

1/5      0                   128              525              1,2
1/6      0                   128              525              1,2
1/7      0                   128              525              1,2
1/8      0                   128              525              1,2
1/9      0                   128              525              1,2
1/10     0                   128              525              1,2
-----
All 10 out of 10 Total Num of sflow port entries displayed
```

### Variable Definitions

Use the data in the following table to use the **sflow counter-interval** and **show sflow interface** commands.

Variable	Value
<1-3600>	Specifies the polling interval for a slot. Default value is 0 (disabled).
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Viewing sFlow Statistics

Display statistics for sFlow datagrams.

### Before You Begin

- You must globally enable sFlow.

### Procedure

- To enter User EXEC mode, log on to the switch.
- View sFlow statistics:

```
show sflow statistics [collector <1-2>]
```

**Example**

```
Switch:1>show sflow statistics

=====
sFlow Statistics Info
=====
Collector-id      sFlow-Datagrams
-----
1                 1001
2                 0
-----

All 2 out of 2 Total Num of sflow statistics entries displayed
```

## Clearing sFlow Statistics

Use this procedure to clear the statistics for each collector.

**Before You Begin**

- You must globally enable sFlow.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Clear sFlow statistics:  
clear sflow statistics [collector <1-2>]
3. Verify the collector information:  
show sflow statistics [collector <1-2>]

**Example**

Clear the statistics for collector ID 1.

```
Switch:1>enable
Switch:1#clear sflow statistics collector 1
Switch:1#show sflow statistics collector 1

=====
sFlow Statistics Info
=====
Collector-id      sFlow-Datagrams
-----
1                 0
-----

All 1 out of 1 Total Num of sflow statistics entries displayed
```

## sFlow Configuration Using EDM

Use sFlow to capture traffic statistics to monitor traffic in a data network. This section provides procedures to view and configure sFlow using EDM.

## Enable sFlow and Configure the Agent IP Address

Use this procedure to enable sFlow and configure the sFlow agent IP address so the system can send packets to an sFlow collector.

### About This Task

Application Telemetry and sFlow both use the **sFlow Globals** tab.

You can configure sFlow on Segmented Management Instance interfaces OOB, VLAN, and CLIP. You can also use routing VLANs or loopback IPs as the source IP address. Configure the agent IP address to match the Management Instance interface, routing VLAN or loopback IP address.

### Before You Begin

You must enable sFlow before you enable Application Telemetry.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Select **Sflow**.
3. Select the **Globals** tab.
4. Select **AdminEnable** to enable sFlow.
5. In the **AgentAddress** field, enter the agent IPv4 address.
6. Select **Apply**.

### What to Do Next

After you configure the agent IP address and globally enable sFlow, proceed to configuring the sFlow collector.

#### *Globals Field Descriptions*

Use the data in the following table to use the **Globals** tab.

Name	Description
<b>AdminEnable</b>	Shows whether sFlow is enabled. By default, the check box is not enabled.
<b>AgentAddressType</b>	Specifies the collector IP address type. Only IPv4 collector addresses are supported.
<b>AgentAddress</b>	Specifies the agent IP address of an interface that exists in the local management VRF or GRT.  <b>Note:</b> For Segmented Management Instance interfaces, you must configure AgentAddress to the IP address of the Segmented Management Instance interface on which datagrams egress.

## Configuring an sFlow Collector

Use this procedure to configure the device used as either an sFlow Collector or an Application Telemetry Analytics Engine. This device is where the agent sends sFlow datagrams and Application Telemetry packets for analysis.

sFlow supports up to two collectors for each interface slot in the chassis. However, Application Telemetry supports Collector 1 only.

### Note

- You can configure two Collectors, but Application Telemetry uses Collector 1 only. You must configure Collector 1 before you enable Application Telemetry.
- Before you change or remove Collector 1, you must disable Application Telemetry.
- By default, Application Telemetry is globally disabled.

### About This Task

### Tip

You can configure the **Collector** tab to select only the columns you are interested in seeing. By default, the system does not display **AddressType** option. To make the **AddressType** column visible, click the down arrow on one of the menu headings, navigate to **Columns**, and select the **AddressType** check box.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **Sflow**.
3. Click the **Collector** tab.
4. Configure the fields for Collector 1.
5. Click **Apply**.

### What to Do Next

After you configure the sFlow collector, configure the packet sampling rate to enable sFlow on a port or ports.

#### *Collector Field Descriptions*

Use the data in the following table to use the **Collector** tab.

Name	Description
<b>Index</b>	Shows collector 1 and collector 2. The switch exports sFlow and Application Telemetry traffic to the collector.
<b>Owner</b>	Specifies the sFlow collector name. The string length is 1 to 20 characters.

Name	Description
<b>Timeout</b>	Specifies the time remaining (in seconds) before the collector is released and stops sampling. The default timeout is 0, which means the timeout is not used and the switch sends data forever.
<b>Address</b>	Specifies the collector IP address. If the default address is set to 0.0.0.0, no traffic is sent.
<b>Port</b>	Specifies the destination port. The default port is 6343.
<b>IsReachable</b>	Shows whether the sFlow collector is reachable.
<b>NextHop</b>	If the collector is reachable, shows the name or address of the next hop through which the collector is reachable.

## Configure the Packet Samples and Counter Samples

Configure the packet sampling rate to determine how many packets the system counts before it takes a sample and configure the counter sampling interval to determine how often the sFlow agent polls and exports counters for a configured interface. You can also configure the maximum header size on a single port or multiple ports.

Configuring the sampling rate enables sFlow on the port.

### Before You Begin

- You must globally enable sFlow.

### About This Task

#### Tip

You can configure the **Interfaces** tab to select only the columns you are interested in seeing. By default, the system does not display **Instances** option. To make the **Instances** column visible, click the down arrow on one of the menu headings, navigate to **Columns**, and select the **Instances** check box.

### Procedure

- In the navigation pane, expand **Configuration > Serviceability**.
- Select **Sflow**.
- Select the **Interfaces** tab.
- In the **DataSource** column, navigate to the slot and port where you want to configure sFlow, and configure the following:
  - PacketSamplingRate—Double-click the field, and enter a sampling rate value.
  - MaximumHeaderSize—Double-click the field, and enter a maximum header size value.

- c. Interval—Double-click the field, and enter the counter sampling interval value in seconds.
5. Select **Apply**.

### Interfaces Field Descriptions

Use the data in the following table to use the **Interfaces** tab.

Name	Description
<b>DataSource</b>	Shows the slot and port for which traffic statistics are collected. The field name is different on different hardware platforms.
<b>Instance</b>	Shows the number of sFlow samplers associated with a specific datasource.  <b>Note:</b> You must select this field for it to display on the Interfaces tab.
<b>Collectors</b>	Shows the collectors that have been configured for the sFlow agent to send sFlow datagrams. Two collectors are supported. The field name is different on different hardware platforms.
<b>PacketSamplingRate</b>	Specifies the packet sampling rate to determine how many packets the system counts before it take a sample. The default is 0.
<b>MaximumHeaderSize</b>	Specifies the maximum header size on a single port or multiple ports. The default is 128 bytes.
<b>Interval</b>	Specifies the counter sampling interval to determine how often the sFlow agent polls and exports counters for a configured interface. The default is 0.

## Displaying sFlow Statistics

Use the following procedure to display (true) sFlow statistics. Statistics for sFlow are cleared (false), by default.

### About This Task

#### Tip

You can configure the **Stats** tab to select only the columns you are interested in seeing. The system displays all the options, by default. To hide a column, click the down arrow on one of the menu headings, navigate to **Columns**, and select the check box for the column you want to hide.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **sFlow**.
3. Click the **Stats** tab.
4. In the **ClearStats** column, double-click the field, and select true or false from the list.
5. Click **Apply**.

#### Stats Field Descriptions

Use the data in the following table to use the **Statistics** tab.

Name	Description
<b>Index</b>	Shows sFlow collector ID 1 and 2
<b>DatagramCount</b>	Shows the number of datagrams that have been sent to the collector.
<b>ClearStats</b>	Shows whether the sFlow statistics are displayed (true) or cleared (false). The default is false.

## Configuring counter polling

### About This Task

Use this procedure to configure counter polling using the EDM.

#### Note

This procedure only applies to VSP 8600 Series.

### Procedure

1. In the navigation pane, expand the **Configuration > Serviceability** folders.
2. Click **sFlow**.
3. Click the **Counter Polling** tab.
4. In the **Index** column, navigate to the slot and port where you want to configure sFlow.
5. Double-click the **Interval** field and enter a value in seconds.
6. Click **Apply**.

#### Counter Polling Field Descriptions

Use the data in the following table to use the **Counter Polling** tab.

Name	Description
<b>Index</b>	Identifies the source of the data for counter polling.
<b>Receiver</b>	The sFlow receiver associated with the counter polling.
<b>Interval</b>	The maximum number of seconds between successive samples of the counters associated with this data source. A sampling interval of 0 disables counter sampling.

	XA1400 Series	Not Supported

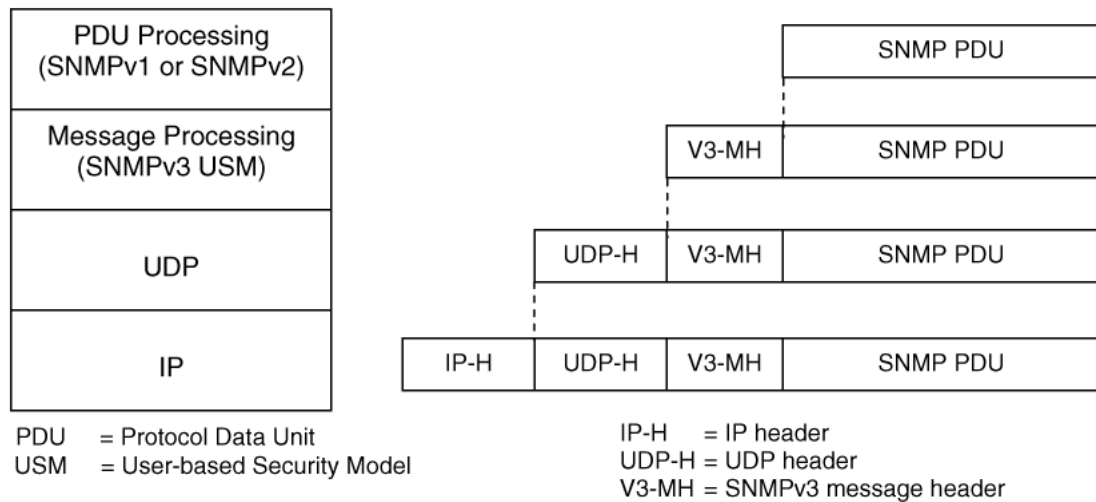

You can use the Simple Network Management Protocol (SNMP) to remotely collect management data and configure devices.

An SNMP agent is a software process that monitors the UDP port 161 for SNMP messages. Each SNMP message sent to the agent contains a list of management objects to retrieve or modify.

## SNMPv3

The SNMP version 3 (v3) is the third version of the Internet Standard Management Framework and is derived from and builds upon both the original Internet Standard Management Framework SNMP version 1 (v1) and the second Internet Standard Management Framework SNMP version 2 (v2).

The SNMPv3 is not a stand-alone replacement for SNMPv1 or SNMPv2. The SNMPv3 defines security capabilities you must use in conjunction with SNMPv2 (preferred) or SNMPv1. The following figure shows how SNMPv3 specifies a user-based security model (USM) that uses a payload of either an SNMPv1 or an SNMPv2 Protocol Data Unit (PDU).

**Figure 238: SNMPv3 USM**

SNMPv3 is an SNMP framework that supplements SNMPv2 by supporting the following:

- New SNMP message formats
- Security for messages
- Access control
- Remote configuration of SNMP parameters

The recipient of a message can use authentication within the USM to verify the message sender and to detect if the message is altered. According to RFC2574, if you use authentication, the USM checks the entire message for integrity.

An SNMP entity is an implementation of this architecture. Each SNMP entity consists of an SNMP engine and one or more associated applications.

## SNMP Engine

An SNMP engine provides services for sending and receiving messages, authenticating and encrypting messages, and controlling access to managed objects. A one-to-one association exists between an SNMP engine and the SNMP entity, which contains the SNMP engine.

## EngineID

Within an administrative domain, an EngineID is the unique identifier of an SNMP engine. Because there is a one-to-one association between SNMP engines and SNMP entities, the ID also uniquely and unambiguously identifies the SNMP entity within that

administrative domain. The system generates an EngineID during the startup process. The SNMP engine contains a:

- [Dispatcher](#) on page 3391.
- [Message Processing Subsystem](#) on page 3391.
- [Security Subsystem](#) on page 3391.
- [Access Control Subsystem](#) on page 3392.

Automatic discovery of a Remote EngineID is performed so that Inform messages are populated properly and not rejected by the SNMP Manager. This automatic discovery is performed by the switch using a request to the Manager for a response that contains the EngineID. The switch then uses this Remote EngineID value to populate all subsequent Inform messages.

## Dispatcher

The dispatcher is part of an SNMP engine. You can use the dispatcher for concurrent support of multiple versions of SNMP messages in the SNMP engine through the following ways:

- To send and receive SNMP messages to and from the network.
- To determine the SNMP message version and interact with the corresponding message processing model.
- To provide an abstract interface to SNMP applications for delivery of a PDU to an application.
- To provide an abstract interface for SNMP applications to send a PDU to a remote SNMP entity.

## Message Processing Subsystem

The message processing subsystem prepares messages for sending and extracts data from received messages. The subsystem can contain multiple message processing models.

## Security Subsystem

The security subsystem provides the following features:

- Authentication
- Privacy
- Security

## Authentication

You can use authentication within the SNMPv3 to verify the message sender and whether the message is altered. If you use authentication, the integrity of the message is verified. The supported SNMPv3 authentication protocols are HMAC-MD5 and HMAC-SHA-96. By default, the switch uses HMAC-SHA1-96 with 160-bit key length.

## Privacy

SNMPv3 is an encryption protocol for privacy. Only the data portion of a message is encrypted; the header and the security parameters are not. The privacy protocol that SNMPv3 supports is CBC-DES Symmetric Encryption Protocol and Advanced Encryption Standard (AES).

## Security

The SNMPv3 security protects against:

- Modification of information—protects against altering information in transit.
- Masquerade—protects against an unauthorized entity assuming the identity of an authorized entity.
- Message stream modification—protects against delaying or replaying messages.
- Disclosure—protects against eavesdropping.

The SNMPv3 security also offers:

- Discovery procedure—finds the EngineID of an SNMP entity for a given transport address or transport endpoint address.
- Time synchronization procedure—facilitates authenticated communication between entities

The SNMPv3 does not protect against the following:

- Denial-of-service—prevention of exchanges between manager and agent.
- Traffic analysis—general pattern of traffic between managers and agents.

## Access Control Subsystem

SNMPv3 provides a group option for access policies.

The access policy feature in the switch determines the access level for the users connecting to the device with different services like File Transfer Protocol (FTP), Trivial FTP (TFTP), and Telnet. The system access policy feature is based on the user access levels and network address. This feature covers services, such as TFTP, HTTP, SSH, and SNMP. However, with the SNMPv3 engine, the community names do not map to an access level. The View-based Access Control Model (VACM) determines the access privileges.

Use the configuration feature to specify groups for the SNMP access policy. You can use the access policy services to cover SNMP. Because the access restriction is based on groups defined through the VACM, the synchronization is made using the SNMPv3 VACM configuration. The administrator uses this feature to create SNMP users (USM community) and associate them to groups. You can configure the access policy for each group and network.

The following are feature specifications for the group options:

- After you enable SNMP service, this policy covers all users associated with the groups configured under the access policy. The access privileges are based on access allow

or deny. If you select allow, the VACM configuration determines the management information base (MIB)-views for access.

- The SNMP service is disabled by default for all access policies.
- The access level configured under **access-policy policy <id>** does not affect SNMP service. The VACM configuration determines the SNMP access rights.

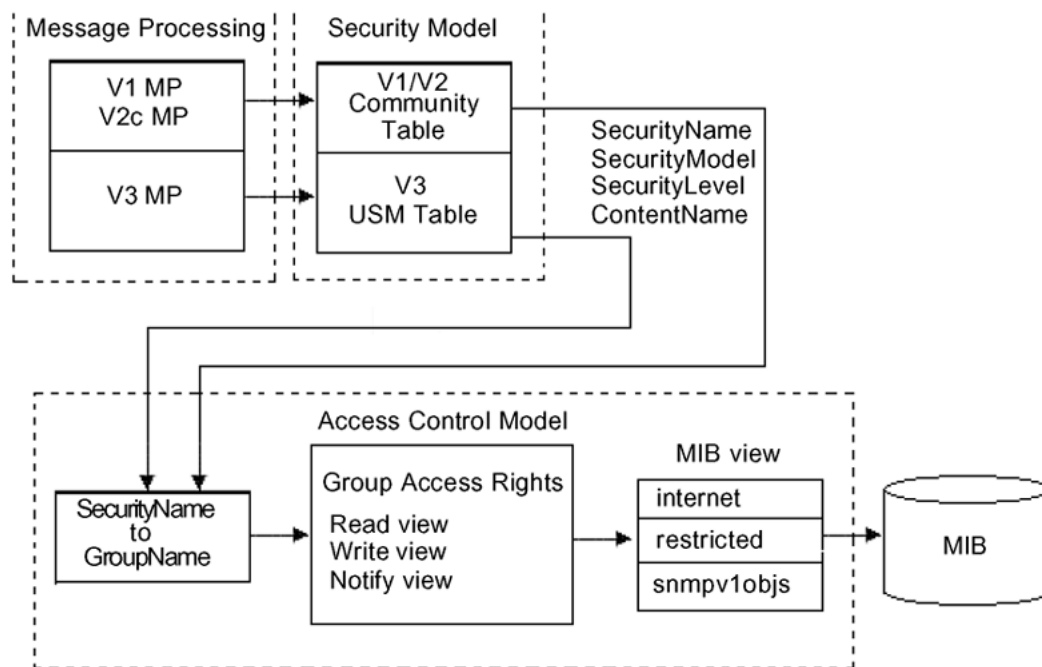

## User-Based Security Model

In a USM system, the security model uses a defined set of user identities for any authorized user on a particular SNMP engine. A user with authority on one SNMP engine must also have authorization on all SNMP engines with which the original SNMP engine communicates.

The USM provides the following levels of communication:

- NoAuthNoPriv—communication without authentication and privacy.
- AuthNoPriv—communication with authentication and without privacy.
- AuthPriv—communication with authentication and privacy.

The following figure shows the relationship between USM and VACM.

**Figure 239: USM association with VACM**

## View-Based Access Control

View-based Access Control Model (VACM) provides group access, group security levels, and context based on a predefined subset of MIB objects. These MIB objects define a set of managed objects and instances.

VACM is the standard access control mechanism for SNMPv3, and it provides:

- Authorization service to control access to MIB objects at the PDU level.
- Alternative access control subsystems.

The access is based on principal, security level, MIB context, object instance, and type of access requested (read or write). You can use the VACM MIB to define the policy and control remote management.

## SNMPv3 Encryption

A user-based security port for SNMPv3 is defined as a security subsystem within an SNMP engine. The switch USM uses HMAC-MD5-96 and HMAC-SHA-96 as the authentication protocols, and CBC-DES as the privacy protocol. Use USM to use other protocols instead of, or concurrently with, these protocols. CFB128-AES-128, an AES-based Symmetric Encryption Protocol, is an alternative privacy protocol for the USM.

The AES standard is the current encryption standard, Federal Information Processing Standard 140-2 (FIPS 140-2), intended to be used by the U.S. Government organizations to protect sensitive information. The AES standard is also becoming a global standard for commercial software and hardware that uses encryption or other security features.

## The AES-Based Symmetric Encryption Protocol

This symmetric encryption protocol provides support for data confidentiality. The system encrypts the designated portion of the SNMP message and includes it as part of the transmitted message.

The USM specifies that the scoped PDU is the portion of the message that requires encryption. An SNMP engine that can legitimately originate messages on behalf of the appropriate user shares a secret value, in combination with a timeliness value and a 64-bit integer, used to create the (localized) encryption/decryption key and the initialization vector.

## The AES Encryption Key and Initialization Vector

The AES encryption key uses the first 128 bits of the localized key. The 128-bit Initialization Vector (IV) is the combination of the authoritative SNMP engine 32-bit snmpEngineBoot, the SNMP engine 32-bit snmpEngineTime, and a local 64-bit integer. The system initializes the 64-bit integer to a pseudo-random value at startup time.

## Data Encryption

The switch handles data encryption in the following manner:

1. The system treats data as a sequence of octets.
2. The system divides the plaintext into 128-bit blocks.

The first input block is the IV, and the forward cipher operation is applied to the IV to produce the first output block.

3. The system produces the first cipher text block by executing an exclusive-OR function on the first plaintext block with the first output block.
4. The system uses the cipher text block as the input block for the subsequent forward cipher operation.
5. The system repeats the forward cipher operation with the successive input blocks until it produces a cipher text segment from every plaintext segment.
6. The system produces the last cipher text block by executing an exclusive-OR function on the last plaintext segment of  $r$  bits ( $r$  is less than or equal to 128) with the segment of the  $r$  most significant bits of the last output block.

## Data Decryption

The switch handles data decryption in the following manner:

1. In CFB decryption, the IV is the first input block, the system uses the first cipher text for the second input block, the second cipher text for the third input block, and this continues until the system runs out of blocks to decrypt.
2. The system applies the forward cipher function to each input block to produce the output blocks.
3. The system passes the output blocks through an exclusive-OR function with the corresponding cipher text blocks to recover the plaintext blocks.
4. The system sends the last cipher text block (whose size  $r$  is less than or equal to 128) through an exclusive-OR function with the segment of the  $r$  most significant bits of the last output block to recover the last plaintext block of  $r$  bits.

## Trap Notifications

You configure traps by creating SNMP trap notifications, creating a target address to which you want to send the notifications, and specifying target parameters. For more information about how to configure trap notifications, see [Logs and Traps](#) on page 2463.

## SNMP Community Strings

For security reasons for SNMPv1 and SNMPv2, the SNMP agent validates each request from an SNMP manager before responding to the request by verifying that the manager belongs to a valid SNMP community. An SNMP community is a logical relationship between an SNMP agent and one or more SNMP managers (the manager software implements the protocols used to exchange data with SNMP agents). You define communities locally at the agent level.

The agent establishes one community for each combination of authentication and access control characteristics that you choose. You assign each community a unique name (community string), and all members of a community have the same access privileges, either read-only or read-write:

- Read-only: members can view configuration and performance information.
- Read-write: members can view configuration and performance information, and change the configuration.

By defining a community, an agent limits access to its MIB to a selected set of management stations. By using more than one community, the agent can provide different levels of MIB access to different management stations.

SNMP community strings are used when a user logs on to the device over SNMP, for example, using an SNMP-based management software. You set the SNMP community strings using CLI . If you have read/write/all access authority, you can modify the SNMP community strings for access to the device through Enterprise Device Manager (EDM).

You are provided with community strings for SNMPv1 and SNMPv2. If you want to use SNMPv3 only, you must disable SNMPv1 and SNMPv2 access by deleting the default community string entries and create the SNMPv3 user and group.[SNMPv3](#).

#### Note

If you enable enhanced secure mode, the switch does not support the default SNMPv1 and default SNMPv2 community strings, and default SNMPv3 user name. The individual in the administrator access level role can configure a non-default value for the community strings, and the switch can continue to support SNMPv1 and SNMPv2. The individual in the administrator access level role can also configure a non-default value for the SNMPv3 user name and the switch can continue to support SNMPv3.

If you disable enhanced secure mode, the SNMPv1 and SNMPv2 support for community strings remains the same, and the default SNMPv3 user name remains the same. Enhanced secure mode is disabled by default.

For more information on enhanced secure mode, see [Enhanced Secure Mode](#) on page 3618.

The following table lists the default community strings for SNMPv1 and SNMPv2.

VRF	Default community string	Access
GlobalRouter VRF	public	Read access
	private	Write access
ManagementRouter VRF	public:512	Read access
	private:512	Write access

Community strings are encrypted using the AES encryption algorithm. The system does not display community strings on the device and are not stored in the configuration file.

#### Caution Security risk

For security reasons, as a best practice, set the community strings to values other than the factory defaults.

The switch handles community string encryption in the following manner:

- When the device starts up, community strings are restored from the hidden file.

- When the SNMP community strings are modified, the modifications are updated to the hidden file.
- Stale snmp-server community entries for different VRFs that the system displays it after reboot with no VRFs . On an node with any valid config file saved with more than the default vrf0 , snmp\_community entries for that VRF are created and maintained in a separate txt file, snmp\_comm.txt, on every boot. The node reads this file and updates the snmp communities available on the node. As a result for a boot with config having no VRFs, you may still see snmp\_community entries for VRFs other than the globalRouter vrf0.

## Hsecure with SNMP

If you enable hsecure, the system disables SNMPv1, SNMPv2 and SNMPv3. If you want to use SNMP, you must use the command **no boot config flag block-snmp** to re-enable SNMP.

## SNMPv3 support for VRF

Use Virtual Router Forwarding (VRF) to offer networking capabilities and traffic isolation to customers that operate over the same node (switch). Each virtual router emulates the behavior of a dedicated hardware router and is treated by the network as a separate physical router. You can use VRF Lite to perform the functions of many routers using a single router running VRF Lite. This substantially reduces the cost associated with providing routing and traffic isolation for multiple clients.

## SNMPv3 Remote Engine ID Discovery

The following sections contain information about SNMPv3 remote engine ID discovery.

### Traps and Informs

SNMPv3 supports two types of notifications, traps and informs.

Traps are unacknowledged notifications sent by agents to managers. Traps are generated by the agent, and the authoritative SNMP engine for a trap packet is the sending SNMP agent. Because the generator of the message and the authoritative engine are the same, there is no need for the SNMPv3 discovery process.

Informs are acknowledged notifications. An agent sends an inform notification and waits for acknowledgement. If the agent does not receive the acknowledgement within the configured timeout period, it resends the inform notification. The agent continues to resend the inform notification until a reply is received or until the maximum retry value is reached. For information about configuring an inform timeout period or configuring a maximum retry value, see [Configure SNMP settings](#) on page 3398.

## Remote Engine ID Discovery

Inform packets must contain the management (remote) SNMP engine ID. The agent generates informs, but the authoritative SNMP engine is the manager. To generate valid inform packets and avoid manual configuration of the manager SNMP engine ID, the agent must discover the SNMP engine ID of the manager.

The agent discovers the management SNMP Engine ID by sending a probe message to the manager. The manager response to the probe message is a report message that contains the SNMP engine ID of the authoritative SNMP engine. The agent stores the SNMP engine ID received from the manager in the engine table, and sends inform packets using the manager SNMP engine ID. If the manager SNMP engine ID changes, the discovery process updates the manager SNMP engine ID value in the engine table.

### Note

Remote engine ID discovery cannot use SNMP config files created in releases prior to VOSS 8.1. Config files must be saved in Release VOSS 8.1 or higher in order to be compatible with remote engine ID discovery.

## SNMP Configuration Using CLI

Configure the SNMP engine to provide services to send and receive messages, authenticate and encrypt messages, and control access to managed objects. A one-to-one association exists between an SNMP engine and the SNMP entity.

### Configure SNMP settings

Configure Simple Network Management Protocol (SNMP) to define or modify the SNMP settings, and specify the security level for SNMP communications.

#### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable the generation of authentication traps:  
`snmp-server authentication-trap enable`
3. Configure the contact information for the system:  
`snmp-server contact WORD<0-255>`
4. Configure the SNMP and IP sender flag to the same value:

### Note

This step only applies to VSP 8600 Series.

```
snmp-server force-iphdr-sender enable
```

- Send the configured source address (sender IP) as the sender network in the notification message:

**Note**

This step only applies to VSP 8600 Series.

```
snmp-server force-trap-sender enable
```

- Create an SNMPv1 server host:

```
snmp-server host WORD<1-256> [port <1-65535>] v1 WORD<1-32> [filter WORD<1-32>]
```

- Create an SNMPv2 server host:

```
snmp-server host WORD<1-256> [port <1-65535>] v2c WORD<1-32> [inform] [timeout <1-2147483647>] [retries <0-255>] [mms <0-2147483647>] [filter WORD<1-32>]
```

- Create an SNMPv3 server host:

```
snmp-server host WORD<1-256> [port <1-65535>] v3 {noAuthNoPriv|authNoPriv|authPriv WORD<1-32> [inform] [timeout <1-2147483647>] [retries <0-255>]} [filter WORD<1-32>]
```

- Configure the system location:

```
snmp-server location WORD<0-255>
```

- Enable login-success traps:

```
snmp-server login-success-trap enable
```

- Configure the SNMP system name:

```
snmp-server name WORD<0-255>
```

- Create a new entry in the notify filter table:

```
snmp-server notify-filter WORD<1-32> WORD<1-32>
```

- Configure the SNMP trap receiver and source IP addresses:

**Note**

This step only applies to VSP 8600 Series.

```
snmp-server sender-ip {A.B.C.D} {A.B.C.D}
```

**Example**

Enable the generation of SNMP traps. Configure the contact information for the system. Configure hosts to receive SNMP notifications:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmp-server authentication-trap enable
Switch:1(config)#snmp-server contact xxxx@company.com
Switch:1(config)#snmp-server host 192.0.2.16 port 1 v1 SNMPv1 filter SNMPfilterv1
```

Configure the SNMP and IP sender flag to the same value.

### Note

Exception: configuring the SNMP and IP sender flag to the same value only applies to VSP 8600 Series.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmp-server force-iphdr-sender enable
```

### Variable Definitions

The following table defines parameters for the `snmp-server` command.

Variable	Value
<code>authentication-trap</code> {enable}	Enables generation of SNMP server authentication traps.
<code>contact</code> WORD<0-255>	Changes the sysContact information for the switch. WORD<0-255> is an ASCII string from 0-255 characters (for example, a phone extension or email address).
<code>host</code> WORD<1-256> [port <1-65535>] {v1 WORD<1-32> v2c WORD<1-32> [inform] [timeout <1-2147483647>] [retries <0-255>] [mms <0-2147483647>]}  v3 {noAuthPriv  authNoPriv authPriv} WORD<1-32> [inform [timeout <1-2147483647>] [retries <0-255>]}  [filter WORD<1-32>]	Configures hosts to receive SNMP notifications. <ul style="list-style-type: none"> <li>• <code>host</code> WORD&lt;1-256&gt; specifies the IPv4 or IPv6 host address</li> <li>• <code>port</code> &lt;1-65535&gt; specifies the port number</li> <li>• <code>v1</code> WORD&lt;1-32&gt; specifies the SNMPv1 security name</li> <li>• <code>v2c</code> WORD&lt;1-32&gt; specifies the SNMPv2 security name</li> <li>• <code>inform</code> specifies the notify type</li> <li>• <code>timeout</code> &lt;1-2147483647&gt; specifies the timeout value</li> <li>• <code>retries</code> &lt;0-255&gt; specifies the number of retries</li> <li>• <code>mms</code> &lt; 1-2147483647&gt; specifies the maximum message size</li> <li>• <code>v3</code> specifies SNMPv3</li> <li>• <code>noAuthPriv</code> <code>authNoPriv</code> <code>authPriv</code> specifies the security level</li> <li>• WORD&lt;1-32&gt; specifies the user name</li> <li>• <code>filter</code> specifies a filter profile name</li> </ul>
<code>location</code> WORD<0-255>	Configures the sysLocation information for the system. <WORD 0-255> is an ASCII string from 0-255 characters.
<code>login-success-trap</code> {enable}	Enables generation of SNMP server login-success traps.
<code>name</code> WORD<0-255>	Configures the sysName information for the system. <WORD 0-255> is an ASCII string from 0-255 characters. SNMP system name is derived from the global system name that is synchronized with SNMP system name, until the SNMP system name is manually configured.

Variable	Value
<code>notify-filter WORD&lt;1-32&gt; WORD&lt;1-32&gt;</code>	Creates a new entry in the notify filter table. The first WORD<1-32> specifies the filter profile name, and the second WORD<1-32> specifies the subtree object identifier (OID).
<code>sender-ip {A.B.C.D} {A.B.C.D}</code> <b>Note:</b> Exception: only supported on VSP 8600 Series.	The first {A.B.C.D} configures the SNMP trap receiver and source IP addresses. Specify the IP address of the destination SNMP server that receives the SNMP trap notification in the first IP address. The second {A.B.C.D} specifies the source IP address of the SNMP trap notification packet that is transmitted in the second IP address. If you set this to 0.0.0.0, the system uses the IP address of the local interface that is closest (from an IP routing table perspective) to the destination SNMP server.

## Creating a user

Create a new user in the USM table to authorize a user on a particular SNMP engine.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a user on a remote system:

```
snmp-server user engine-id WORD<16-97> WORD<1-32> {md5 | sha } [aes |  
des ]
```

3. Enter and confirm your password.

4. Create a user on the local system:

```
snmp-server user WORD<1-32> [notify-view WORD<0-32>] [read-view  
WORD<0-32>] [write-view WORD<0-32>] {md5 | sha} [aes | des ]
```

5. Enter and confirm your password.

6. Add the user to a group:

```
snmp-server user WORD<1-32> group WORD<1-32> {md5 | sha} [aes | des ]
```

7. Enter and confirm your password.

8. Verify the configuration:

```
show snmp-server user
```

### Example

Create a user named test1 on a remote system with MD5:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmp-server user engine-id 0x80:00:08:E0:03:10:CD:AE:6B:D0:00 test1 md5
aes
Enter the authentication protocol password : *****
Re-enter the authentication protocol password : *****
```

```

Enter the privacy protocol password : *****
Re-enter the privacy protocol password : *****

WARNING: For best security practices avoid the use
         of repeated patterns in passwords.

Switch:1(config)#show snmp-server user
*****
Engine ID = 0x80:00:08:E0:03:10:CD:AE:6B:D0:00

=====
                               USM Configuration
=====
User/Security Name      Engine Id                Protocol
-----
User2                   0x80:00:08:E0:03:10:CD:AE:6B:D0:00 HMAC_MD5, AES PRIVACY,
test1                   0x80:00:08:E0:03:10:CD:AE:6B:D0:00 HMAC_MD5, AES PRIVACY,

2 out of 2 Total entries displayed
=====
    
```

Variable Definitions

The following table defines parameters for the `snmp-server user` command.

Variable	Value
<code>{aes des}</code>	Specifies a privacy protocol. If no value is entered, no authentication capability exists. The choices are aes or des.  <b>Important:</b> You must set authentication before you can set the privacy option.
<code>engine-id WORD&lt;16-97&gt;</code>	Assigns an SNMPv3 engine ID. Use the <b>no</b> operator to remove this configuration.
<code>group WORD&lt;1-32&gt;</code>	Specifies the group access name.
<code>{md5 sha}</code>	Specifies an authentication protocol. If no value is entered, no authentication capability exists. The protocol choices are: MD5 and SHA.
<code>notify-view WORD&lt;0-32&gt;</code>	Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.
<code>read-view WORD&lt;0-32&gt;</code>	Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.

Variable	Value
<code>write-view WORD&lt;0-32&gt;</code>	Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.
<code>user WORD&lt;1-32&gt;</code>	Creates the new entry with this security name. The name is used as an index to the table. The range is 1–32 characters. Use the <b>no</b> operator to remove this configuration.

## Create a New User Group

Create a new user group to logically group users who require the same level of access. Create new access for a group in the View-based Access Control Model (VACM) table to provide access to managed objects.

### Note

There are several default groups (public and private) created that you can use. To see the list of default groups and their associated security names (secnames), enter **show snmp-server group**. If you use one of these groups, there is no need to create a new group.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a new user group:

```
snmp-server group WORD <1-32> WORD<1-32> {auth-no-priv|auth-priv|no-
auth-no-priv} [notify-view WORD<1-32>] [read-view WORD<1-32>] [write-
view WORD<1-32>]
```

### Examples

The following example uses the following variable names:

- The new group name is `lan6grp`.
- The context of the group is `"`, which represents the Global Router (VRF 0).
- The security level is `no-auth-no-priv`.
- The access view name is `v1v2only` for all three views: **notify-view**, **read-view**, and **write-view**.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmp-server group lan6grp "" no-auth-no-priv notify-view v1v2only read-
view v1v2only write-view v1v2only
```

## Variable Definitions

The following table defines parameters for the `snmp-server group` command.

Variable	Value
<code>auth-no-priv</code>	Assigns the minimum level of security required to gain the access rights allowed by this conceptual row. If the <code>auth-no-priv</code> parameter is included, it creates one entry for SNMPv3 access.
<code>auth-priv</code>	Assigns the minimum level of security required to gain the access rights allowed by this conceptual row. If the <code>auth-priv</code> parameter is included, it creates one entry for SNMPv3 access.
<code>group WORD&lt;1-32&gt; WORD&lt;1-32&gt;</code>	The first <code>WORD&lt;1-32&gt;</code> specifies the group name for data access. The range is 1–32 characters. Use the <b>no</b> operator to remove this configuration. The second <code>WORD&lt;1-32&gt;</code> specifies the context name. The range is 1–32 characters. If you use a particular group name value but with different context names, you create multiple entries for different contexts for the same group. You can omit the context name and use the default. If the context name value ends in the wildcard character (*), the resulting entries match a context name that begins with that context. For example, a context name value of <code>foo*</code> matches contexts starting with <code>foo</code> , such as <code>foo6</code> and <code>fooforum</code> . Use the <b>no</b> operator to remove this configuration.
<code>no-auth-no-priv</code>	Assigns the minimum level of security required to gain the access rights allowed by this conceptual row. If the <code>no-auth-no-priv</code> parameter is included, it creates 3 entries, one for SNMPv1 access, one for SNMPv2c access, and one for SNMPv3 access.
<code>notify-view WORD&lt;1-32&gt;</code>	Specifies the view name in the range of 0–32 characters.
<code>read-view WORD&lt;1-32&gt;</code>	Specifies the view name in the range of 0–32 characters.
<code>write-view WORD&lt;1-32&gt;</code>	Specifies the view name in the range of 0–32 characters.

## Creating a new entry for the MIB in the view table

Create a new entry in the MIB view table. The default Layer 2 MIB view cannot modify SNMP settings. However, a new MIB view created with Layer 2 permission can modify SNMP settings.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Create a new entry:
 

```
snmp-server view WORD<1-32> WORD<1-32>
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
```

Create MIB views:

```
Switch:1(config)#snmp-server view 2 1.3.8.7.1.4
```

*Variable Definitions*

The following table defines parameters for the `snmp-server view` command.

Variable	Value
The first <i>WORD</i> <1-32>	Specifies the prefix that defines the set of MIB objects accessible by this SNMP entity. The range is 1-32 characters.
The second <i>WORD</i> <1-32>	Specifies a new entry with this group name. The range is 1-32 characters.

**Creating a community**

Create a community to use in forming a relationship between an SNMP agent and one or more SNMP managers. You require SNMP community strings to access the system using an SNMP-based management software.

**Procedure**

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create a community:

```
snmp-server community WORD<1-32> [group WORD<1-32>] [index WORD<1-32>]
[secname WORD<1-32>]
```

**Important**

- The **group** parameter is only required if you created a new user group using the procedure in [Creating a new user group](#). If you use any of the default groups, the **secname** automatically links the community to its associated group so there is no need specify the group in this command.
- If you do create a new group, use the **snmp-server community** command to create an SNMP community with a new security name and link it to the new group you created. There is no separate command to create a security name (secname). You use the **snmp-server community** command. The security name is the key to link the community name to a group.
- You cannot use the @ character or the string :: when you create community strings.

## Example

In the following example, the community name is *anewcommunity*, the index is *third*, and the secname is *readview*. There is no group specified because this is a default public/read only group.

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#snmp-server community anewcommunity index third secname
readview
```

## Variable Definitions

The following table defines parameters for the `snmp-server community` command.

Variable	Value
<i>community</i> <i>WORD&lt;1-32&gt;</i>	Specifies a community string. The range is 1–32 characters.
<i>group</i> <i>WORD&lt;1-32&gt;</i>	Specifies the group name. The range is 1–32 characters.
<i>index</i> <i>WORD&lt;1-32&gt;</i>	Specifies the unique index value of a row in this table. The range is 1–32 characters.
<i>secname</i> <i>WORD&lt;1-32&gt;</i>	Maps the community string to the security name in the VACM Group Member Table. The range is 1–32 characters.

## Add a User to a Group

Add a user to a group to logically group users who require the same level of access.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Create a new user group:
 

```
snmp-server user WORD<1-32> group WORD<1-32> {md5 | sha} [aes | des]
```
3. Enter and confirm your password.
4. Verify the configuration:
 

```
show snmp-server group
```

### Example

Add a user to a group to logically group users who require the same level of access:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#snmp-server user test4 group grouptest4 md5 aes
Enter the authentication protocol password : *****
```

```

Re-enter the authentication protocol password : *****
Enter the privacy protocol password : *****
Re-enter the privacy protocol password : *****

```

```

WARNING: For best security practices avoid the use
of repeated patterns in passwords.

```

```

Switch:1(config)#show snmp-server group

```

```

*****

```

```

### Variable Definitions

The following table defines parameters for the `snmp-server` user command.

Variable	Value
<code>{aes des}</code>	Specifies a privacy protocol. If no value is entered, no authentication capability exists. The choices are aes or des.  <b>Important:</b> You must set authentication before you can set the privacy option.
<code>engine-id WORD&lt;16-97&gt;</code>	Assigns an SNMPv3 engine ID. Use the <b>no</b> operator to remove this configuration.
<code>group WORD&lt;1-32&gt;</code>	Specifies the group access name.
<code>{md5 sha}</code>	Specifies an authentication protocol. If no value is entered, no authentication capability exists. The protocol choices are: MD5 and SHA.
<code>notify-view WORD&lt;0-32&gt;</code>	Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.
<code>read-view WORD&lt;0-32&gt;</code>	Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.
<code>write-view WORD&lt;0-32&gt;</code>	Specifies the view name in the range of 0 to 32 characters. The first instance is a noAuth view. The second instance is an auth view and the last instance is an authPriv view.
<code>user WORD&lt;1-32&gt;</code>	Creates the new entry with this security name. The name is used as an index to the table. The range is 1-32 characters. Use the <b>no</b> operator to remove this configuration.

## Block SNMP Access

Disable SNMP by using the SNMP block flag. By default, SNMP access is enabled.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Disable SNMP access:
 

```
boot config flags block-snmp
```

### Variable Definitions

The following table defines parameters for the `boot config flags` command.

Variable	Value
<code>block-snmp</code>	Configures the block SNMP flag as active. Use the <b>no</b> operator to remove this configuration. The default is off. To set this option to the default value, use the <b>default</b> operator with the command.

## View SNMP System Information

View SNMP system information to view trap and authentication profiles.

For a comprehensive set of SNMP-related `show` commands, see [VOSS CLI Commands Reference](#).

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View SNMP system information:

```
show snmp-server
```

### Example

```
Switch:1>show snmp-server

      trap-sender :
force-trap-sender : FALSE
force-iphdr-sender : FALSE
      contact: none
      location : none
      name : Switch:1
AuthenticationTrap : false
LoginSuccessTrap  : false
```

#### Note

The `trap-sender`, `force-trap-sender`, and `force-iphdr-sender` only applies to VSP 8600 Series.

## SNMP Configuration Using EDM

Configure SNMP to provide services to send and receive messages, authenticate and encrypt messages, and control access to managed objects with EDM.

## Create a User

### About This Task

Create a new user in the USM table to authorize a user on a particular SNMP engine.

#### Note

In EDM, to create new SNMPv3 users you must use the **CloneFromUser** option. However, you cannot clone the default user, named **initial**. As a result, you must first use CLI to configure at least one user, and then you can use EDM to create subsequent users with the **CloneFromUser** option.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **USM Table**.
3. Click **Insert**.
4. In the **EngineID** box, use the default Engine ID provided or type an administratively-unique identifier to an SNMP engine.
5. In the **User Name** box, type a name.
6. From the **CloneFromUser** list, select a security name from which the new entry copies authentication data and private data, if required.
7. From the **Auth Protocol** list, select an authentication protocol.
8. In the **Cloned User's Auth Password** box, type the authentication password of the cloned user.
9. In the **New User's Auth Password** box, type an authentication password for the new user.
10. From the **Priv Protocol** list, select a privacy protocol.
11. In the **Cloned User's Priv Password** box, type the privacy password of the cloned user.
12. In the **New User's Priv Password** box, type a privacy password for the new user.
13. Click **Insert**.

#### Caution

##### Security risk

To ensure security, change the GroupAccess table default view after you set up a new user in the USM table. This prevents unauthorized people from accessing the system using the default user logon. Also, change the Community table defaults, because the community name is used as a community string in SNMPv1/v2 PDU.

**USM Table** field descriptions

Use the data in the following table to use the **USM Table** tab and the **Insert USM Table** dialog box. The system displays some fields only on the Insert USM Table dialog box.

Name	Description
<b>EngineID</b>	Specifies an administratively-unique identifier to an SNMP engine.
<b>UserName</b>	Creates the new entry with this security name. The name is used as an index to the table. The range is 1–32 characters.
<b>SecurityName</b>	Identifies the name on whose behalf SNMP messages are generated.
<b>Clone From User</b>	Specifies the security name from which the new entry must copy privacy and authentication parameters. The range is 1–32 characters. The system displays this option only in the <b>Insert USM Table</b> dialog box.
<b>Auth Protocol</b> (Optional)	Assigns an authentication protocol (or no authentication) from a list. If you select an authentication protocol, you must enter an old AuthPass and a new AuthPass.
<b>Cloned User's Auth Password</b>	Specifies the current authentication password of the cloned user. The system displays this option only in the <b>Insert USM Table</b> dialog box.
<b>New User's Auth Password</b>	Specifies the authentication password of the new user. The system displays this option only in the <b>Insert USM Table</b> dialog box.
<b>Priv Protocol</b> (Optional)	Assigns a privacy protocol (or no privacy) from a list. If you select a privacy protocol, you must enter an old PrivPass and a new PrivPass.
<b>Cloned User's Priv Password</b>	Specifies the current privacy password of the cloned user. The system displays this option only in the <b>Insert USM Table</b> dialog box.
<b>New User's Priv Password</b>	Specifies the privacy password of the new user. The system displays this option only in the <b>Insert USM Table</b> dialog box.

## Create a New Group Membership

### About This Task

Create a new group membership to logically group users who require the same level of access.

#### Note

There are several default groups (public and private) created that you can use. To see the list of default groups and their associated security names (secnames), enter **show snmp-server group**. If you use one of these groups, there is no need to create a new group.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **VACM Table**.
3. Click the **Group Membership** tab.
4. Click **Insert**.
5. From the **SecurityModel** options, select a security model.
6. In the **SecurityName** box, type a security name.
7. In the **GroupName** box, type a group name.
8. Click **Insert**.

### **Group Membership** field descriptions

Use the data in the following table to use the **Group Membership** tab.

Name	Description
<b>SecurityModel</b>	Specifies the security model to use with this group membership.
<b>SecurityName</b>	Specifies the security name assigned to this entry in the View-based Access Control Model (VACM) table. The range is 1–32 characters.
<b>GroupName</b>	Specifies the name assigned to this group in the VACM table. The range is 1–32 characters.

## Create Access for a Group

### About This Task

Create access for a group in the View-based Access Control Model (VACM) table to provide access to managed objects.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **VACM Table**.
3. Click the **Group Access Right** tab.
4. Click **Insert**.
5. In the **GroupName** box, type a VACM group name.
6. In the **ContextPrefix** box, select a VRF instance. This is an optional step.
7. From the **SecurityModel** options, select a model.
8. From the **SecurityLevel** options, select a security level.
9. In the **ContextMatch** option, select a value to match the context name. This value is **exact** by default.
10. (Optional) In the **ReadViewName** box, type the name of the MIB view that forms the basis of authorization when reading objects. This is an optional step.
11. (Optional) In the **WriteViewName** box, type the name of the MIB view that forms the basis of authorization when writing objects. This is an optional step.

12. (Optional) In the **NotifyViewName** box, type MIB view that forms the basis of authorization for notifications. This is an optional step.
13. Click **Insert**.

### **Group Access Right** field descriptions

Use the data in the following table to use the **Group Access Right** tab.

Name	Description
<b>GroupName</b>	Specifies the name of the new group in the VACM table. The range is 1–32 characters.
<b>ContextPrefix</b>	Specifies if the contextName must match the value of the instance of this object exactly or partially. The range is an SnmpAdminString, 1–32 characters.
<b>SecurityModel</b>	Specifies the authentication checking to communicate to the switch. The security models are: <ul style="list-style-type: none"> <li>• SNMPv1</li> <li>• SNMPv2</li> <li>• USM</li> </ul>
<b>SecurityLevel</b>	Specifies the minimum level of security required to gain the access rights allowed. The security levels are: <ul style="list-style-type: none"> <li>• noAuthNoPriv</li> <li>• authNoPriv</li> <li>• authpriv</li> </ul>
<b>ContextMatch</b>	Specifies if the prefix and the context name must match. If the value is exact, all rows where the contextName exactly matches vacmAccessContextPrefix are selected. If you do not select exact, all rows where the contextName with starting octets that exactly match vacmAccessContextPrefix are selected.
<b>ReadViewName</b>	Identifies the MIB view of the SNMP context to which this conceptual row authorizes read access. The default is the empty string.
<b>WriteViewName</b>	Identifies the MIB view of the SNMP context to which this conceptual row authorizes write access. The default is the empty string.
<b>NotifyViewName</b>	Identifies the MIB view of the SNMP context to which this conceptual row authorizes access for notifications. The default is the empty string.

## Create Access Policies for SNMP Groups

Create an access policy to determine the access level for the users who connect to the switch with different services like File Transfer Protocol (FTP), Trivial FTP (TFTP), and Telnet.

### About This Task

You only need to create access policies for SNMP groups if you have the access policy feature enabled.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Access Policies**.
3. Select the **Access Policies-SNMP Groups** tab.
4. Select **Insert**.
5. Enter an **ID**.
6. In the **Name** box, type a name.
7. From the **Model** options, select a security model.
8. Select **Insert**.

### *Access Policies — SNMP Groups field descriptions*

The following table defines parameters for the **Access Polices-SNMP Groups** tab.

Name	Description
<b>Id</b>	Specifies the ID of the group policy.
<b>Name</b>	Specifies the name assigned to the group policy. The range is 1–32 characters.
<b>Model</b>	Specifies the security model {SNMPv1 SNMPv2c USM}.

## Assign MIB View Access for an Object

### About This Task

Create a new entry in the MIB View table.

You cannot modify SNMP settings with the default Layer 2 MIB view. However, you can modify SNMP settings with a new MIB view created with Layer 2 permissions.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **VACM Table**.
3. In the **VACM Table** tab, click the **MIB View** tab.
4. Click **Insert**.
5. In the **ViewName** box, type a view name.
6. In the **Subtree** box, type a subtree.
7. In the **Mask** box, type a mask.
8. From the **Type** options, select whether access to the MIB object is granted.
9. Click **Insert**.

**MIB View** field descriptions

Use the data in the following table to use the **MIB View** tab.

Name	Description
<b>ViewName</b>	Creates a new entry with this group name. The range is 1–32 characters.
<b>Subtree</b>	Specifies a valid object identifier that defines the set of MIB objects accessible by this SNMP entity, for example, 1.3.6.1.1.5.
<b>Mask</b> (optional)	Specifies a bit mask with vacmViewTreeFamilySubtree to determine whether an OID falls under a view subtree.
<b>Type</b>	Determines whether access to a MIB object is granted (included) or denied (excluded). The default is included.

## Create a Community

**About This Task**

Create a community to use in forming a relationship between an SNMP agent and one or more SNMP managers. You require SNMP community strings for access to the switch using an SNMP-based management software.

**Procedure**

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **Community Table**.
3. Click **Insert**.
4. In the **Index** box, type an index.
5. In the **Name** box, type a name that is a community string.
6. In the **SecurityName** box, type a security name.
7. In the **ContextName** box, type the context name.
8. Click **Insert**.

**Community Table** field descriptions

Use the data in the following table to use the **Community Table** tab.

Name	Description
<b>Index</b>	Specifies the unique index value of a row in this table. The range is 1–32 characters.
<b>Name</b>	Specifies the community string for which a row in this table represents a configuration.
<b>SecurityName</b>	Specifies the security name in the VACM group member table to which the community string is mapped. The range is 1–32 characters.

Name	Description
<b>ContextEngineID</b>	Indicates the location of the context in which management information is accessed when using the community string specified in <b>Name</b> .
<b>ContextName</b>	Specifies the context in which management information is accessed when you use the specified community string.

## View All Contexts for an SNMP Entity

### About This Task

View contexts to see the contents of the context table in the View-based Access Control Model (VACM). This table provides information to SNMP command generator applications so that they can properly configure the VACM access table to control access to all contexts at the SNMP entity.

### Procedure

1. In the navigation pane, expand **Configuration > Edit > SnmpV3**.
2. Click **VACM Table**.
3. In the **VACM Table** tab, click the **Contexts** tab.

### **Contexts** field descriptions

Use the data in the following table to use the **Contexts** tab.

Variable	Value
<b>ContextName</b>	Shows the name identifying a particular context at a particular SNMP entity. The empty contextName (zero length) represents the default context.

## Showing SNMP Statistics

### About This Task

Display SNMP statistics to monitor the number of specific error messages, such as the number of messages that were delivered to SNMP but were not allowed.

### Procedure

1. In the navigation pane, expand the **Configuration > Security > Control Path** folders.
2. Click **General**.
3. Click the **SNMP** tab.

**SNMP** Field Descriptions

Use the data in the following table to display SNMP statistics.

Name	Description
<b>OutTooBigs</b>	Shows the number of SNMP PDUs that the SNMP protocol entity generated and for which the value of the error-status field is tooBig.
<b>OutNoSuchNames</b>	Shows the number of SNMP PDUs that the SNMP protocol entity generated and for which the value of the error-status is noSuchName.
<b>OutBadValues</b>	Shows the number of SNMP PDUs that SNMP protocol entity generated and for which the value of the error-status field is badValue.
<b>OutGenErrors</b>	Shows the number of SNMP PDUs that the SNMP protocol entity generated and for which the value of the error-status field is genErr.
<b>InBadVersions</b>	Shows the number of SNMP messages that were delivered to the SNMP protocol entity and were for an unsupported SNMP version.
<b>InBadCommunityNames</b>	Shows the number of SNMP messages delivered to the SNMP protocol entity that used an SNMP community name not known to the entity.
<b>InBadCommunityUsers</b>	Shows the number of SNMP messages delivered to the SNMP protocol entity that represented an SNMP operation not allowed by the SNMP community named in the message.
<b>InASNParseErrs</b>	Shows the number of ASN.1 or BER errors encountered by the SNMP protocol entity when decoding received SNMP messages.
<b>InTooBigs</b>	Shows the number of SNMP PDUs that were delivered to the SNMP protocol entity and for which the value of the error-status field is tooBig.
<b>InNoSuchNames</b>	Shows the number of SNMP PDUs that were delivered to the SNMP protocol entity and for which the value of the error-status field is noSuchName.
<b>InBadValues</b>	Shows the number of SNMP PDUs that were delivered to the SNMP protocol entity and for which the value of the error-status field is badValue.
<b>InReadOnlys</b>	Shows the number of valid SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is "read-only". It is a protocol error to generate an SNMP PDU that contains the value "read-only" in the error-status field; this object is provided as a means of detecting incorrect implementations of the SNMP.
<b>InGenErrors</b>	Shows the number of SNMP PDUs delivered to the SNMP protocol entity and for which the value of the error-status field is "genErr."

# Spanning Tree Configuration

---

[Spanning Tree Fundamentals](#) on page 3418

[Spanning Tree Configuration Using CLI](#) on page 3426

[Spanning Tree Configuration Using EDM](#) on page 3448

This section provides conceptual and procedural information about Spanning Tree.

## Spanning Tree Fundamentals

---

**Table 247: Spanning Tree Protocol product support**

Feature	Product	Release introduced
Spanning Tree Protocol (STP): <ul style="list-style-type: none"> <li>• Multiple STP (MSTP)</li> <li>• Rapid STP (RSTP)</li> </ul>	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	VSP 4450 Series	VSP 4000 4.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 4.2.1
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VSP 8200 4.0
	VSP 8400 Series	VOSS 4.2
	VSP 8600 Series	VSP 8600 4.5
	XA1400 Series	VOSS 8.0.50

The switch supports Rapid Spanning Tree Protocol (RSTP) and Multiple Spanning Tree Protocol (MSTP).

## Spanning Tree

Spanning Tree protocols detect and eliminate logical loops in a bridged or switched network. If multiple paths exist, the spanning Tree algorithm configures the network so that a bridge or device uses the root bridge path based on hop counts. Although link

speed is taken into account, the path is based on the root bridge rather than on an optimized path. If that path fails, the protocol automatically reconfigures the network and makes another path active, thereby sustaining network operations. The switch supports RSTP and MSTP but can downgrade a port automatically if it receives an STP Bridge Protocol Data Unit (BPDU) from a switch that runs STP.

**Note**

Spanning Tree is disabled on all Switched UNI (S-UNI) ports. The ports will move into forwarding state as soon as the physical port or VLACP or LACP comes up on the port. If the platform VLAN is associated to the S-UNI Service Instance Identifier (I-SID), then the S-UNI ports added to the platform VLAN will become the member of MSTP instances associated with the platform VLAN. To enable SLPP on the S-UNI ports, the platform VLAN must be associated with the S-UNI I-SID.

## Spanning Tree Groups

Spanning Tree Groups (STGs) represent logical topologies. A topology is created based on bridge configuration values such as root bridge priority. In the case of multiple STGs, you can map a VLAN to the most appropriate logical topology in the physical network.

The switch supports Spanning Tree modes RSTP and MSTP. The default Spanning Tree mode is MSTP. The default STG is 0. In RSTP mode, all VLANs run in the default STG. In MSTP mode, you can create additional STGs by using the VLAN create command. The switch supports up to 64 STGs.

Although STP and MSTP are variations of the same Spanning Tree protocol, they communicate information differently. A switch in MSTP mode cannot recognize the Spanning Tree groups running on a chassis configured with STP. MSTP Spanning Tree groups are not the same as STP Spanning Tree groups. Using a switch in MSTP mode with a chassis in STP mode can create a loop in the network.

The root bridge for Rapid Spanning Tree Protocol (RSTP) and Multiple Spanning Tree Protocol (MSTP) is determined by comparing attributes of each bridge in the network.

The protocol considers bridge priority first. If more than one bridge has the same priority, then the protocol must consider the bridge ID. The bridge with the lowest ID becomes the root bridge. For MSTP, this bridge is called the Common and Internal Spanning Tree (CIST) Root because it is the root of the entire physical network.

In MSTP mode, you can create additional Spanning Tree instances, by using the VLAN command. These instances, known as Multiple Spanning Tree Instances (MSTIs), can assign different priorities to switches. The MSTIs have different link costs or port priorities and as a result create separate logical topologies.

MSTP also allows the creation of MSTP regions. A region is a collection of switches sharing the same view of physical and logical topologies. For switches to belong to the same region, the following attributes must match:

- MSTP configuration ID selector
- MSTP configuration name
- MSTP configuration revision number
- VLAN instance mapping

Links connecting sections are called boundary ports. In a region, the boundary switch that contains the boundary port providing the shortest external path cost to the CIST Root is the CIST Regional Root.

## STGs and VLANs

When you map VLANs to STGs, be aware that all links on the bridge belong to all STGs. Because each Spanning Tree group can differ in its decision to make a link forwarding or blocking, you must ensure that the ports you add to a VLAN are in the expected state.

Untagged ports can only belong to one VLAN and therefore can only belong to one STG. Tagged ports can belong to multiple VLANs and therefore to multiple STGs.

## BPDUs handling on S-UNI port/MLT

The switch handles Bridge Protocol Data Units (BPDUs) according to whether or not you configure a platform VLAN.

- When you configure a platform VLAN:
  - BPDUs are forwarded to the CPU by default.
  - For both the ingress and egress ports, BPDUs are not flooded in the S-UNI I-SID associated with the platform VLAN.

### Note

If the platform VLAN is configured for the S-UNI port, you cannot enable BPDU forwarding.

- When you DO NOT configure a platform VLAN:
  - BPDUs received on untagged-traffic ports are dropped by default.
  - To flood BPDUs in its I-SID, enable BPDU forwarding under S-UNI I-SID using the command **untagged-traffic port <port no> bpdu enable**.

## BPDU Guard

**Table 248: Bridge Protocol Data Unit (BPDU) Guard product support**

Feature	Product	Release introduced
Bridge Protocol Data Unit (BPDU) Guard	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	VSP 4450 Series	VOSS 6.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 6.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 6.0
	VSP 8400 Series	VOSS 6.0
	VSP 8600 Series	VSP 8600 6.2
	XA1400 Series	Not Supported

The switch supports Bridge Protocol Data Unit (BPDU) Guard for STGs, RSTP, and MSTP.

### Overview

Spanning Tree eliminates loops in a network. A bridge that participates in spanning tree uses BPDUs to exchange information with other bridges. The bridges select a single bridge as the root bridge based on the BPDU information exchange. The bridge with the lowest priority becomes the root bridge. If all bridges share the same priority, the bridge with the lowest bridge ID becomes the root bridge. This process is the root selection process.

After you add a new bridge to the network, or remove an existing bridge, the bridges repeat the root selection process, and then select a new root bridge.

To ensure the correct operation of Spanning Tree in the network, BPDU Guard protects the stability of the Root Bridge by dropping stray, unexpected, or unwanted BPDU packets entering a port, and immediately shutting down those ports for a specified time period. BPDU Guard is normally enabled on access ports connecting to end user devices such as servers that are not expected to operate Spanning Tree.

Use BPDU Guard to achieve the following results:

- Block the root selection process after an edge device, such as a laptop that uses Linux with STP enabled, is added to the network. Blocking the root selection process prevents unknown devices from influencing the spanning tree topology.
- Block BPDU flooding of the switch from an unknown device.

### *Operation*

You can enable or disable BPDU Guard on an individual port basis, regardless of the spanning tree state. Each port uses a timer to determine port-state recovery.

After you enable BPDU Guard on a port and the port receives a BPDU, the following actions occur:

1. The guard disables the port.
2. The switch generates an SNMP trap and alarm, and the following log message:

```
BPDU Guard - Port <slot/port> is being shutdown by BPDU Guard, timeout  
<time_seconds>
```

3. The port timer begins.
4. The port remains in the disabled state until the timer expires.

If you disable BPDU Guard before the timer expires, the timer stops and the port remains in the disabled state. You must manually enable the port.

BPDU Guard is enabled at the interface level. You can configure the BPDU Guard timer for each port, for 10 to 65535 seconds. If you set the port timer to zero, it will not expire.

## Rapid Spanning Tree Protocol and Multiple Spanning Tree Protocol

The Rapid Spanning Tree Protocol (RSTP or IEEE 802.1w) reduces the recovery time after a network breakdown. It also maintains backward compatibility with IEEE 802.1d (the spanning tree implementation prior to RSTP). In certain configurations, the recovery time of RSTP can be reduced to less than 1 second. RSTP also reduces the amount of flooding in the network by enhancing the way Topology Change Notification (TCN) packets are generated.

With Multiple Spanning Tree Protocol (MSTP or IEEE 802.1s), you can configure multiple instances or Spanning Tree groups on the same device. Each instance or Spanning Tree group can include one or more VLANs.

By using RSTP and MSTP, the switch achieves the following:

- reduces convergence time after a topology change (from 30 seconds to less than 1 or 2 seconds)
- eliminates unnecessary flushing of the MAC database and the flooding of traffic to the network
- creates backward compatibility with classic 802.1d switches
- creates support for 64 instances of spanning tree in MSTP mode

The following sections relate to RSTP and MSTP:

- [RSTP interoperability with STP](#) on page 3423
- [Differences in port roles for STP and RSTP](#) on page 3423
- [Port roles: root forwarding role](#) on page 3424
- [Port roles: designated forwarding role](#) on page 3424
- [Port roles: alternate blocking role](#) on page 3424

- [Edge port](#) on page 3425
- [Path cost values](#) on page 3425
- [RSTP negotiation process](#) on page 3425

#### *RSTP interoperability with STP*

RSTP provides a parameter called ForceVersion to provide backward compatibility with standard STP. A user can configure a port in either STP-compatible mode or RSTP mode:

- An STP-compatible port transmits and receives only STP Bridge Protocol Data Units (BPDUs). An RSTP BPDU that the port receives in this mode is discarded.
- An RSTP-compatible port transmits and receives only RSTP BPDUs. If an RSTP port receives an STP BPDU, it becomes an STP port. User intervention is required to change this port back to RSTP mode. This process is called Port Protocol Migration.

#### **Note**

You must configure protocol migration to true on all spanning-tree enabled interfaces when you change the spanning tree version from STP-compatible to MSTP for those interfaces to work in the proper mode.

Before implement MSTP or RSTP you must be aware of the following:

- The default mode is MSTP. A special boot configuration flag identifies the mode.
- You can lose your configuration if you change the spanning tree mode from MSTP to RSTP and the configuration file contains VLANs configured with MSTI greater than 0. RSTP only supports VLANs configured with the default instance 0.
- For best interoperability results, contact your vendor representative.

#### *Differences in port roles for STP and RSTP*

RSTP is an enhanced version of STP. These two protocols have almost the same parameters.

The following table lists the differences in port roles for STP and RSTP. STP supports two port roles, while RSTP supports four port roles.

**Table 249: Differences in port roles for STP and RSTP**

Port Role	STP	RSTP	Description
Root	Yes	Yes	This port receives a better BPDU than its own and has the best path to reach the Root. The root port is in Forwarding state. The root port and designated ports can be in the Discarding state before they go to root forwarding.
Designated	Yes	Yes	This port has the best BPDU on the segment. The designated port is in the Forwarding state.

**Table 249: Differences in port roles for STP and RSTP (continued)**

Port Role	STP	RSTP	Description
Alternate	No	Yes	This port receives a better BPDU than its own BPDU, and a root port exists within the same device. The alternate port is in the Discarding state.
Backup	No	Yes	This port receives a better BPDU than its own BPDU, and this BPDU is from another port within the same device. The backup port is in the Discarding state.

*Port roles: root forwarding role*

MSTP and RSTP root forwarding roles are as follows:

- The port that receives the best path BPDU on a device is the root port, and is referred to as a Root Forwarding (RF) port. This is the port that is the closest to the root bridge in terms of path cost.
- The spanning tree algorithm elects a single root bridge in a bridged network. With MSTP, a root bridge is selected for the Common and Internal Spanning Tree (CIST). A root bridge is selected for the region, and a root bridge is selected for each spanning tree instance.
- The root bridge is the only bridge in a network that does not have root ports; all ports on a root bridge are Designated Forwarding (DF).
- Only one path towards a root bridge can exist on a given segment; otherwise, loops can occur.

*Port roles: designated forwarding role*

MSTP and RSTP designated forwarding roles are as follows:

- All bridges connected on a segment monitor the BPDUs of all other bridges. The bridge that sends the best BPDU is the root bridge for the segment.
- The corresponding port on the bridge is referred to as a Designated Forwarding Port.

*Port roles: alternate blocking role*

MSTP and RSTP alternate blocking roles are as follows:

- A blocked port is defined as not being the designated or root port. An alternate port provides an alternate path to the root and can replace the root port if it fails.
- An alternate blocked port is a port that is blocked because it received better path cost BPDUs from another bridge.

*Port roles: backup blocking role*

MSTP and RSTP backup blocking roles are as follows:

- A backup port receives the more useful BPDUs from the bridge on which the port exists.

*Edge port*

RSTP uses a parameter called the edge port. After a port connects to a nonswitch device, such as a PC or a workstation, it must be configured as an edge port. An active edge port enters the forwarding state without delay. An edge port becomes a nonedge port if it receives a BPDU.

*Path cost values*

RSTP and MSTP path cost values support a wide range of link speeds. The following table lists the path cost values.

**Table 250: Path cost values**

Link speed	Value
Less than or equal to 100 Kbps	200 000 000
1 Mbps	20 000 000
10 Mbps	2 000 000
100 Mbps	200 000
1 Gbps	20 000
10 Gbps	2000
100 Gbps	200
1 Tbps	20
10 Tbps	2

*RSTP negotiation process*

The following section describes the negotiation process between switches that takes place before PCs can exchange data (see the following figure).

**Figure 240: RSTP negotiation process**

After turning on, all ports assume the role of designated ports. All ports are in the discarding state except edge ports. Edge ports go directly into the forwarding state without delay.

Unit A port 1 and Unit B port 1 exchange BPDUs. Unit A knows that it is the root and that Unit A port 1 is the designated port. Unit B learns that Unit A has higher priority. Unit B port 1 becomes the root port. Both Unit A port 1 and Unit B port 1 are still in the discarding state.

Unit A starts the negotiation process by sending a BPDU with the proposal bit set.

Unit B receives the proposal BPDU and configures its nonedge ports to discarding state. This operation occurs during the synchronization process.

Unit B sends a BPDU to Unit A with the agreement bit set.

Unit A configures port 1 to the forwarding state, and Unit B configures port 1 to the forwarding state. PC 1 and PC 2 can now communicate. The negotiation process now moves on to Unit B port 3 and its partner port. PC 3 cannot exchange data with either PC 1 or PC 2 until the negotiation process between Unit B and Unit C finishes.

The RSTP convergence time depends on how quickly the switches can exchange BPDUs during the negotiation process, and on the number of switches in the network.

## Spanning Tree Configuration Using CLI

---

### Important

The switch supports up to 64 STGs on a device, however, SPBM uses STG 63 and MSTI 62 for internal use. STG 63 or MSTI 62 cannot be used by other VLANs or MSTIs.

## Configure the Spanning Tree Mode

Specifies the Multiple Spanning Tree Protocol (MSTP) or Rapid Spanning Tree Protocol (RSTP) mode. If you do not specify a protocol, the switch uses the default mode, which is mstp. If you change the spanning tree mode, you must save the current configuration and restart the switch.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the STP mode:

```
boot config flags spanning-tree-mode {mstp | rstp}
```

### Example

Configure the STP mode:

```
Switch:1(config)#boot config flags spanning-tree-mode mstp
```

```
Warning: Please save the configuration and reboot the switch
         for this to take effect.
```

```
Warning: Please carefully save your configuration files before
         starting configuring the switch in RSTP or MSTP mode.
```

## Configure BPDU Guard

Configure BPDU Guard to block the root selection process or to prevent BPDU flooding from unknown devices.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable BPDU Guard for the port:

```
spanning-tree bpduguard enable
```

3. (Optional) Configure the timer for port-state recovery:

```
spanning-tree bpduguard timeout <0, 10-65535>
```

4. (Optional) Enable BPDU Guard on an additional port or group of ports:

```
spanning-tree bpduguard port {slot/port[/sub-port] [-slot/port[/
subport]][,...]} enable
```

5. (Optional) Configure the timer for port-state recovery for an additional port or group of ports:

```
spanning-tree bpduguard port {slot/port[/sub-port] [-slot/port[/
subport]][,...]} timeout <0-65535>
```

6. Verify the configuration:

```
show spanning-tree bpduguard [GigabitEthernet {slot/port[/
sub-port] [-slot/port[/subport]][,...]}] [{slot/port[/sub-port] [-slot/
port[/subport]][,...]}]
```

### Example

Enable BPDU Guard on port 1/8, and specify a timer value of 200 seconds. Verify the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#interface gigabitEthernet 1/8
Switch:1(config-if)#spanning-tree bpduguard enable
```

```
Switch:1(config-if)#spanning-tree bpduguard timeout 200
Switch:1(config-if)#show spanning-tree bpduguard 1/8
```

```
=====
                                Bpdu Guard
=====
Port      PORT      PORT      TIMER  BPDUGUARD  BPDUGUARD
NUM MLTID  ADMIN_STATE  OPER_STATE  TIMEOUT  COUNT  ADMIN_STATE  ORIGIN
-----
1/8      Up        Up        200     0         Enabled  CONFIG
```

Variable Definitions

Use the data in the following table to use the **spanning-tree bpduguard** commands.

Variable	Value
<i>enable</i>	Enables BPDU Guard on the port. The default is disabled.
<i>port</i> {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<i>timeout</i> <0, 10-65535>	Specifies the value to use for port-state recovery. After a BPDU guard disables a port, the port remains in the disabled state until this timer expires. You can configure a value from 10 to 65535. The default is 120 seconds. If you configure the value to 0, the expiry is infinity.

Use the data in the following table to use the **show spanning-tree bpduguard** command.

Variable	Value
{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Configuring Rapid Spanning Tree Protocol

Configure Rapid Spanning Tree Protocol (RSTP) to reduce the recovery time after a network breakdown.

Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```

## 2. Configure RSTP:

```
spanning-tree rstp [forward-time <400-3000>] [group-stp enable]
[hello-time <100-1000>] [max-age <600-4000>] [pathcost-type <bits16|
bits32>] [priority <0-61440>] [tx-holdcount <1-10>] [version <rstp|
stp-compatible>]
```

### Example

#### Configure RSTP:

```
Switch:1(config)# spanning-tree rstp forward-time 1000 hello-time 200 max-age 4000
pathcost-type bits16 priority 4096 tx-holdcount 10 version rstp group-stp enable
```

### Variable Definitions

Use the data in the following table to use the **spanning-tree rstp** command.

Variable	Value
<i>forward-time &lt;400-3000&gt;</i>	Configures the RSTP forward delay for the bridge in hundredths of a second.
<i>group-stp enable</i>	Enables or disables RSTP for a specific STG. Enter the <b>no</b> form of the command to disable RSTP for the STG ( <code>no spanning-tree rstp group-stp enable</code> ).
<i>hello-time &lt;100-1000&gt;</i>	Assigns the RSTP hello time delay for the bridge in hundredths of a second.
<i>max-age &lt;600-4000&gt;</i>	Assigns the RSTP maximum age time for the bridge in hundredths of a second.
<i>pathcost-type {bits16 bits32}</i>	Assigns the RSTP default pathcost version. The default is 32 bits.
<i>priority &lt;0-61440&gt;</i>	Assigns the RSTP bridge priority.
<i>tx-holdcount &lt;1-10&gt;</i>	Assigns the RSTP transmit hold count from 1 to 10. The default value is 6.
<i>version {rstp/stp-compatible}</i>	Sets the version to RSTP or STP compatible.

## Configuring Rapid Spanning Tree Protocol for a port

Configure RSTP to reduce the recovery time after a network breakdown.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure RSTP:

```
spanning-tree rstp cost <1-200000000> edge-port <false|true> p2p
<auto|force-false|force-true> priority <0-240> protocol-migration
<false|true> stp enable
```

## Example

Configure RSTP:

```
Switch:1(config-if)# spanning-tree rstp cost 100 edge-port true p2p auto
priority 32 protocol-migration true stp enable
```

### Variable Definitions

Use the data in the following table to use the **spanning-tree rstp** command.

Variable	Value
<code>cost &lt;1-200000000&gt;</code>	Specifies the contribution of this port to the path cost.
<code>edge-port &lt;false true&gt;</code>	Configures the edge-port value for the port. A value of true indicates that this port is an edge-port, and a value of false indicates that this port is a nonedge-port.
<code>p2p &lt;auto force-false force-true&gt;</code>	Specifies the point-to-point status of the LAN segment attached to this port. A value of force-true indicates that this port is treated as if it connects to a point-to-point link. A value of force-false indicates that this port is treated as having a shared media connection. A value of auto indicates that this port is considered to have a point-to-point link if it is an aggregator and all of its members are aggregatable, or if the MAC entity is configured for full-duplex operation, either through autonegotiation or by management means.

Variable	Value
<code>priority &lt;0-240&gt;</code>	Assigns the RSTP bridge priority in a range of 0–240. The value has to increment in steps of 16.
<code>protocol-migration &lt;false true&gt;</code>	If you chose true, the option initiates protocol migration for a port. If you chose false, the option terminates protocol migration for a port. An RSTP-compatible port transmits and receives only RSTP BPDUs. If an RSTP port receives an STP BPDU, it becomes an STP port. User intervention is required to change this port back to RSTP mode. This process is called Port Protocol Migration.
<code>stp enable</code>	Configures STP for the port.

## Configuring the Rapid Spanning Tree Protocol version

Perform this procedure to specify the RSTP mode.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure Rapid Spanning Tree Protocol version:  

```
spanning-tree rstp version {rstp|stp-compatible}
```

### Example

Configure Rapid Spanning Tree Protocol version:

```
Switch:1(config)# spanning-tree rstp version rstp
```

### Variable Definitions

Use the data in the following table to use the **spanning-tree rstp version** command.

Variable	Value
<code>rstp version {rstp stp-compatible}</code>	Sets the version to RSTP or to STP compatible. The default is RSTP.

## Viewing the global RSTP configuration information

View the global RSTP configuration information to display the Rapid Spanning Tree Protocol (RSTP) configuration details.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. View global RSTP configuration information:

```
show spanning-tree rstp config
```

**Example**

View global RSTP configuration information:

```
Switch:1> show spanning-tree rstp config
```

```

=====
                        RSTP Configuration
=====
Rstp Module Status      : Enabled
Priority                 : 32768 (0x8000)
Stp Version             : rstp Mode
Bridge Max Age          : 20 seconds
Bridge Hello Time       : 2 seconds
Bridge Forward Delay Time : 15 seconds
Tx Hold Count           : 6
PathCost Default Type   : 32-bit
=====

```

## Viewing RSTP statistics

Perform this procedure to view RSTP statistics.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. View RSTP statistics:

```
show spanning-tree rstp statistics
```

**Example**

View RSTP statistics:

```
Switch:1> show spanning-tree rstp statistics
```

```

=====
                        RSTP Statistics
=====
Rstp UP Count           : 1
Rstp Down Count         : 0
Count of Root Bridge Changes : 0
Stp Time since Topology change: 0 day(s), 00H:00M:00S
Total No. of topology changes : 0
=====

```

## Viewing the RSTP status

View the RSTP status to display the RSTP related status information for the selected bridge.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the RSTP status:

```
show spanning-tree rstp status
```

## Example

View the RSTP status:

```
Switch:1> show spanning-tree rstp status
```

```

=====
                        RSTP Status Information
=====
Designated Root          : 80:00:00:24:7f:9f:60:00
Stp Root Cost            : 0
Stp Root Port           : cpp
Stp Max Age              : 20 seconds
Stp Hello Time           : 2 seconds
Stp Forward Delay Time  : 15 seconds
=====

```

## Viewing the RSTP Configuration Information

View the RSTP configuration information to display the RSTP-related port level configuration details.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. View RSTP configuration information:

```
show spanning-tree rstp port config {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

### Note

If your platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Example

View RSTP configuration information:

```
Switch:1> show spanning-tree rstp port config 1/1
```

```

=====
                        RSTP Port Configurations
=====
Port Number              : 1/1
Port Priority             : 128 (0x80)

=====

```

### Variable Definitions

Use the data in the following table to use optional parameters with the **show spanning-tree rstp port config** command.

Variable	Value
<code>{slot/port[/sub-port][-slot/port[/sub-port]][,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Viewing the RSTP Status for a Port

View the RSTP status for a port to display the RSTP-related status information for a selected port.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the RSTP status for a port:

```
show spanning-tree rstp port status {slot/port[/sub-port][-slot/port[/sub-port]][,...]}
```

### Note

If your platform supports channelization for 40 Gbps ports and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

### Example

View the RSTP status for a port:

```
Switch:1> show spanning-tree rstp port status 1/2
```

```

=====
                        RSTP Port Status
                        (Port Priority Vector)
=====
Port Number              : 1/2
Port Designated Root    : 80:00:00:24:7f:9f:60:00
Port Designated Cost    : 0
Port Designated Bridge  : 80:00:00:24:7f:9f:60:00
Port Designated Port    : 80:c1

```

### Variable Definitions

Use the data in the following table to use optional parameters with the **show spanning-tree rstp port status** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

### Viewing RSTP information for a selected port

View the RSTP information for a selected port to display the RSTP-related configuration information for the selected port.

#### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. View the RSTP information for a selected port:

```
show spanning-tree rstp port statistics [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

#### Example

View the RSTP information for a selected port:

```
Switch:1# show spanning-tree rstp port statistics 1/4
```

```

=====
                        RSTP Port Statistics
=====
Port Number                : 1/4
Number of Fwd Transitions  : 0
Rx RST BPDUs Count        : 0
Rx Config BPDU Count      : 0
Rx TCN BPDU Count         : 0
Tx RST BPDUs Count        : 9
Tx Config BPDU Count      : 0
Tx TCN BPDU Count         : 0
Invalid RST BPDUs Rx Count : 0
Invalid Config BPDU Rx Count : 0
Invalid TCN BPDU Rx Count  : 0
Protocol Migration Count   : 0

```

*Variable definitions*

Use the data in the following table to use optional parameters with the `show spanning-tree rstp port statistics` command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Viewing the RSTP role

View the RSTP role to display the RSTP information.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. View the RSTP role:

```
show spanning-tree rstp port role [{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]]
```

**Example**

View the RSTP role:

```
Switch:1>show spanning-tree rstp port role 1/3
```

```

=====
                        RSTP Port Roles and States
=====
Port-Index  Port-Role   Port-State   PortSTPStatus  PortOperStatus
-----
1/3         Designated Forwarding   Enabled        Enabled

```

*Variable definitions*

Use the data in the following table to use optional parameters with the **show spanning-tree rstp port role** command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

## Viewing spanning tree configuration

Perform this procedure to view configuration and status information for spanning tree in your network.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. View spanning tree configuration information:  
`show spanning-tree config`
3. View spanning tree status information:  
`show spanning-tree status`

**Example**

View spanning tree configuration information:

```
Switch:1> show spanning-tree config
```

```

=====
                        Spanning Tree Config
=====

1   80:00:00:24:7f:a1:70:00 0     cpp  20  0     1    15

Total number of Spanning Tree IDs : 2

```

## Configuring Multiple Spanning Tree Protocol

Use the following procedure to configure the Multiple Spanning Tree Protocol.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure MSTP:

```
spanning-tree mstp
```

### Example

Configure Multiple Spanning Tree Protocol to configure the MSTP configuration version.

```
Switch:1(config)# spanning-tree mstp forward-time 500 max-age 3000 max-hop 200 pathcost-type bits32 priority 8192 tx-holdcount 10 version mstp
```

### Variable Definitions

Use the data in the following table to use the **spanning-tree mstp** command.

Variable	Value
<i>forward-time</i> <400-3000>	Configures the MSTP forward delay for the bridge from 400 to 3000 hundredths of a second.
<i>max-age</i> <600-4000>	Assigns the MSTP maximum age time for the bridge from 600 to 4000 one hundredths of a second.

Variable	Value
<i>max-hop</i> <100-4000>	Assigns the MSTP bridge maximum hop count. The range is 100 to 4000 one hundredths of a second. The original MIB erroneously designated the value in hundredths of a second, when it should have been in hops. The replacement MIB kept the range at 100-4000 to remain backwards compatible. To convert this value to hops, divide by 100 so 100-4000 equals 1-40 hops.
<i>msti</i> <1-63> <i>priority</i> <0-65535>	Assigns the MSTP MSTI instance parameter.
<i>pathcost-type</i> { <i>bits16</i>   <i>bits32</i> }	Assigns the MSTP default pathcost type to either 16 bits or 32 bits. The default is 32 bits.
<i>priority</i> <0-61440>	Assigns the MSTP bridge priority in a range of 0 to 61440 in steps of 4096.
<i>region</i> [ <i>config-id-sel</i> <0-255>] [ <i>region-name</i> <WORD 1-32>] [ <i>region-version</i> <0-65535>]	Assigns the MSTP region commands: <ul style="list-style-type: none"> <li>• <i>config-id-sel</i>—Assigns the MSTP region configuration ID number. The range is 0 to 255.</li> <li>• <i>region-name</i>—Assigns the MSTP region name. The character string can be a range of 1 to 32 characters</li> <li>• <i>region-version</i>—Assigns the MSTP region version. The range is 0 to 65535.</li> </ul>
<i>tx-holdcount</i> <1-10>	Assigns the MSTP transmit hold count. The range is 1 to 10. The default value is 3.
<i>version</i> { <i>mstp</i>   <i>rstp</i>   <i>stp-compatible</i> }	Assigns the bridge version. Although STP and MSTP are variations of the same spanning tree protocol, they communicate information differently. A switch in MSTI mode cannot recognize the spanning tree groups running on a chassis configured with STP. MSTP spanning tree groups are not the same as STP spanning tree groups. Using a switch in MSTP mode with another chassis in STP mode can create a loop in the network. You must configure protocol migration to true on all spanning-tree enabled interfaces when you change the spanning tree version from STP-compatible to MSTP for those interfaces to work in the proper mode.  <b>Note:</b> You cannot configure the MSTP version when MSTP-Fabric Connect Multi Homing is enabled on the switch.

## Configuring MSTP MSTI options

Use the following procedure to configure MSTP multiple spanning tree instance (MSTI) options.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure MSTP MSTI:
 

```
spanning-tree mstp msti <1-63> priority <0-65535>
```

### Example

Configure MSTP MSTI:

```
Switch:1(config)# spanning-tree mstp msti 62 priority 4096
```

### Variable Definitions

Use the data in the following table to use the **spanning-tree mstp msti <1-63> priority <0-65535>** command.

Variable	Value
<1-63>	Specifies the instance ID.
<0-65535>	Specifies the priority value. Enter values in increments of 4096: <ul style="list-style-type: none"> <li>• 4096</li> <li>• 8192</li> <li>• 12288</li> <li>• 16384</li> <li>• 20480</li> <li>• 24576</li> <li>• 28672</li> <li>• 32768</li> <li>• 36864</li> <li>• 40960</li> <li>• 45056</li> <li>• 49152</li> <li>• 53248</li> <li>• 57344</li> <li>• 61440</li> </ul>

## Configuring Ethernet MSTP

Configure Ethernet MSTP on a port to enable this feature.

## Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Ethernet MSTP:

```
spanning-tree mstp [cost <1-200000000>] [edge-port <false|true>]
[force-port-state enable] [hello-time <100-1000>] [msti <1-63>] [p2p
{auto|force-false|force-true}] [port {slot/port[/sub-port]}] [priority
<0-240>] [protocol-migration <false|true>]
```

## Example

Configure Ethernet MSTP:

```
Switch:1(config)# spanning-tree mstp cost 1 edge-port true force-port-
state enable hello-time 100 p2p auto priority 2 protocol-migration true
```

### Variable Definitions

Use the data in the following table to use the **spanning-tree mstp** command.

Variable	Value
<i>cost &lt;1-200000000&gt;</i>	Configures the path cost for a port. Valid values are 1 to 200000000
<i>edge-port &lt;false true&gt;</i>	Enables or disables the port as an edge port.
<i>force-port-state enable</i>	Enables STP.
<i>hello-time &lt;100-1000&gt;</i>	Configures the hello-time for a port.
<i>msti &lt;1-63&gt;</i>	Configures the port MSTP MSTI.
<i>p2p {auto force-false force-true}</i>	Enables or disables point-to-point for a port.
<i>{slot/port[/sub-port]}</i>	Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

Variable	Value
<code>priority &lt;0-240&gt;</code>	Configures priority for the port.
<code>protocol-migration {false true}</code>	If you chose true, the option initiates protocol migration for a port. If you chose false, the option terminates protocol migration for a port. An MSTP-compatible port transmits and receives only RSTP BPDUs. If an MSTP port receives an STP BPDU, it becomes an STP port. User intervention is required to change this port back to MSTP mode. This process is called Port Protocol Migration. You must configure protocol migration to true on all spanning-tree enabled interfaces when you change the spanning tree version from STP-compatible to MSTP for those interfaces to work in the proper mode.

## Configuring Ethernet MSTP MSTI

Use the following procedure to configure the Ethernet MSTP MSTI parameters on a port.

### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Configure Ethernet MSTP MSTI:

```
spanning-tree mstp msti <1-63> [cost <1-200000000>] [force-port-state  
enable] [port {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}]  
[priority <0-240>]
```

### Example

Configure Ethernet MSTP MSTI:

```
Switch(config-if)# spanning-tree mstp msti 62 priority 32
```

### Variable Definitions

Use the data in the following table to use the **spanning-tree mstp msti <1-63>** command.

Variable	Value
<1-63>	Specifies the instance ID.
<i>cost</i> <1-200000000>	Configures the path cost for the port
<i>force-port-state enable</i>	Enables MSTI learning for the port.
{ <i>slot/port</i> [/ <i>sub-port</i> ][ <i>-slot/port</i> [/ <i>sub-port</i> ]][,...]}	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<i>priority</i> <0-240>	Configures the priority for the port. Enter the priority value (0-240) as increments of 16.

### Viewing MSTP configurations

View the MSTP configurations to display the MSTP-related bridge-level VLAN and region information.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the MSTP configurations:  

```
show spanning-tree mstp config
```

#### Example

View the MSTP configurations:

```
Switch:1> show spanning-tree mstp config
```

```

=====
                        MSTP Configurations
=====
Mstp Module Status      : Enabled
Number of Msti Supported : 64
Cist Bridge Priority    : 32768 (0x8000)
Stp Version            : Mstp Mode
Cist Bridge Max Age    : 20 seconds
Cist Bridge Forward Delay : 15 seconds

Msti Region Version   : 0
Msti Config Digest    : b2:96:8d:23:9d:73:39:e4:4f:bd:94:c2:14:d4:8d:09

```

## Viewing MSTP status

View the MSTP status to display the MSTP-related status information known by the selected bridge.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the MSTP status:

```
show spanning-tree mstp status
```

### Example

View the MSTP status:

```
Switch:1> show spanning-tree mstp status
```

```

=====
                        MSTP Status
=====
-----

=====

```

## Viewing MSTP Port Information

View the MSTP port information to display the MSTP, CIST port, and MSTI port information maintained by every port of the common spanning tree.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. View the MSTP port information:

```
show spanning-tree mstp port role [slot/port[/sub-port]] [-slot/port[/sub-port]] [, ...]
```

### Note

If your platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

### Example

View the MSTP port information:

```
Switch:1> show spanning-tree mstp port role 1/3
```

```
=====
                        CIST Port Roles and States
=====
```

Port-Index	Port-Role	Port-State	PortSTPStatus	PortOperStatus
1/3	Disabled	Discarding	Enabled	Disabled

```
-----
```

## Viewing MSTP MSTI Information

View MSTP MSTI information to ensure the feature is configured correctly for your network.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show MSTI information:

```
show spanning-tree mstp msti [config <1-63>] [port
<config {slot/port[/sub-port]}[-slot/port[/sub-port]][,...]]|role
{slot/port[/sub-port]}[-slot/port[/sub-port]][,...]]|statistics {slot/
port[/sub-port]}[-slot/port[/sub-port]][,...]]
```

### Note

If your platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

### Example

Show MSTI information:

```
Switch:1> show spanning-tree mstp msti config 62
```

```
=====
                        MSTP Instance Status
=====
```

Instance Id	: 62
Msti Bridge Regional Root	: 80:00:00:15:e8:9e:10:01
Msti Bridge Priority	: 32768 (0x8000)
Msti Root Cost	: 0
Msti Root Port	: cpp
Msti Instance Vlan Mapped	:
Msti Instance Vlan Mapped2k	:
Msti Instance Vlan Mapped3k	:
Msti Instance Vlan Mapped4k	: 4000

```
Switch(config)# show spanning-tree mstp msti port statistics 1/1
```

```
=====
                        MSTP Instance-specific Per-Port Statistics
=====
```

Msti Port Invalid BPDUs Rcvd : 0
```

### Variable Definitions

Use the data in the following table to use the **show spanning-tree mstp msti** command.

Variable	Value
<code>config [&lt;1-63&gt;]</code>	Shows the configuration for one or all MSTP instance IDs.
<code>port</code>	Shows the configuration, role, or statistics information of a MSTP port. <ul style="list-style-type: none"> <li><code>config {slot/port[/sub-port] [-slot/port[/sub-port]] [...]}</code></li> <li><code>role {slot/port[/sub-port] [-slot/port[/sub-port]] [...]}</code></li> <li><code>statistics {slot/port[/sub-port] [-slot/port[/sub-port]] [...]}</code></li> </ul>

## Viewing MSTP statistics

View MSTP MSTI information to ensure the feature is configured correctly for your network.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Show MSTP statistics:

```
show spanning-tree mstp statistics
```

### Example

Show MSTP statistics:

```
Switch:1> show spanning-tree mstp statistics
```

```
=====
                        MSTP Bridge Statistics

Topology Change Count   : 0
New Root Bridge Count   : 1
```

## Configuring tc-receive-alarm-threshold

### About This Task

You can establish a threshold rate for receiving TC/TCN packets by configuring values for count and interval. If the threshold rate is exceeded, you receive a warning message.

Use the following procedure to configure values for **tc-receive-alarm-threshold count** and **tc-receive-alarm-threshold interval**.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Configure a value for count:
 

```
spanning-tree tc-receive-alarm-threshold count <1-1000>
```
3. Configure a value for interval:
 

```
spanning-tree tc-receive-alarm-threshold interval <1-15>
```

### Example

Configure count and interval values:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#spanning-tree tc-receive-alarm-threshold count 3
Switch:1(config)#spanning-tree tc-receive-alarm-threshold interval 2
```

Display the alarm threshold configuration:

```
Switch:1#show spanning-tree tc-receive-alarm-threshold
```

```
=====
Spanning Tree TC/TCN Rx Alarm Threshold Configuration
=====
Interval                : 2 minutes
Count                   : 3
```

### Variable definitions

Use the data in the following table to use the **tc-receive-alarm-threshold** command.

Variable	Value
count <1-1000>	Specifies the number of packets used to establish the threshold rate. The default is 2.
interval <1-15>	Specifies the time interval (in minutes) used to establish the threshold rate. The default is 1.

## Displaying the tc-receive-alarm-threshold configuration

### About This Task

You can configure a threshold rate for receiving TC/TCN packets. If the threshold is exceeded, you receive a warning message. Use the following procedure to display the tc-receive-alarm-threshold configuration.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the tc-receive-alarm-threshold configuration:  

```
show spanning-tree tc-receive-alarm-threshold
```

**Example**

```
Switch:1(config)#show spanning-tree tc-receive-alarm-threshold
```

```
=====
Spanning Tree TC/TCN Rx Alarm Threshold Configuration
=====
Interval          : 1 minutes
Count             : 2
```

## Spanning Tree Configuration Using EDM

This section describes how to create, manage, and monitor spanning tree groups (STG). It also describes how to configure the Rapid Spanning Tree Protocol (RSTP) and the Multiple Spanning Tree Protocol (MSTP) using Enterprise Device Manager (EDM).

**Important**

The switch supports up to 64 STGs in a device, however, SPBM uses STG 63 and MSTI 62 for internal use. STG 63 or MSTI 62 cannot be used by other VLANs or MSTIs.

### Configuring the Spanning Tree mode

Configure the Spanning Tree mode to change the mode to MSTP or RSTP mode.

**Important**

After you change the mode, restart the system for the changes to take effect.

**Procedure**

1. In the navigation pane, expand the **Configuration > VLAN > Spanning Tree** folders.
2. Click **Globals**.
3. Select the required spanning tree mode.
4. Click **Apply**.

The system notifies you that the setting takes effect after you save the configuration and restart the server.

**Globals** field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
<b>SpanningTreeAdminMode</b>	Configures the spanning tree mode as either RSTP or MSTP. The default is MSTP.
<b>SpanningTreeOperMode</b>	Specifies the current mode of the spanning tree.

## Configure BPDU Guard

Configure BPDU Guard to block the root selection process or to prevent BPDU flooding from unknown devices.

**About This Task**

To configure multiple ports simultaneously, select more than one port in the Device Physical View tab. The system displays **BPDU Guard** tab as a table-based tab.

**Procedure**

1. In the Device Physical View tab, select a port.
2. In the navigation pane, expand the following folders: **Configuration > Edit > Port**.
3. Click **General**.
4. Click the **Interface** tab.
5. Select **BpduGuardAdminEnabled** to enable BPDU Guard for the port.
6. (Optional) Type a value in **BpduGuardTimeout** to configure the timer for port-state recovery.
7. Click **Apply**.

**Interface** Field Descriptions

Use the data in the following table to use the **Interface** tab.

Name	Description
<b>Index</b>	Displays the index of the port, written in the slot/port[/sub-port] format.
<b>Name</b>	Configures the name of the port.
<b>Descr</b>	Displays the description of the port. A textual string containing information about the interface.
<b>Type</b>	Displays the type of connector plugged in the port.

Name	Description
<b>Mtu</b>	Displays the Maximum Transmission Unit (MTU) for the port. The size of the largest datagram which can be sent or received on the interface, specified in octets. For interfaces that are used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface.
<b>PhysAddress</b>	Displays the physical address of the port. The address of the interface at the protocol layer immediately `below' the network layer in the protocol stack. For interfaces which do not have such an address, for example, a serial line, this object should contain an octet string of zero length.
<b>VendorDescr</b>	Displays the vendor of the connector plugged in the port.
<b>DisplayFormat</b>	Identifies the slot and port numbers (slot/port). If the port is channelized, the format also includes the sub-port in the format slot/port/sub-port
<b>AdminStatus</b>	Configures the port as enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.
<b>OperStatus</b>	Displays the current status of the port. The status includes enabled (up) or disabled (down) or testing. The testing state indicates that no operational packets can be passed.
<b>LicenseControlStatus</b>  <b>Note:</b> Exception: only supported on VSP 7200 Series.	Shows the port license status.
<b>ShutdownReason</b>	Indicates the reason for a port state change.
<b>LastChange</b>	Displays the timestamp of the last change.
<b>LinkTrap</b>	Enable or disable link trapping.
<b>AutoNegotiate</b>	Enables or disables Auto-Negotiation for this port. The default Auto-Negotiation behavior depends on the switch model and transceiver type.

Name	Description
<b>AutoNegAd</b>	<p>Specifies the port speed and duplex abilities to advertise during link negotiation.</p> <p>Supported speeds and duplex modes vary, depending on your hardware.</p> <p>The abilities specified in this object are only used when auto-negotiation is enabled on the port. If all bits in this object are disabled, and auto-negotiation is enabled on the port, then the physical link process on the port will be disabled (if hardware supports this ability).</p> <p>Any change to this configuration restarts the auto-negotiation process, which has the same effect as physically unplugging and reattaching the cable attached to the port.</p> <p>If you select <b>default</b>, all capabilities supported by the hardware are advertised.</p>
<b>AdminDuplex</b>	Configures the administrative duplex setting for the port.
<b>OperDuplex</b>	Indicates the operational duplex setting for the port.
<b>AdminSpeed</b>	<p>Configures the administrative speed for the port.</p> <p><b>Important:</b> If Auto-Negotiation is disabled and you change the administrative speed on a port that results in a configuration mismatch in speed between two ports, VSP 4450 Series and VSP 4900 Series switches can show an incorrect operational status of "up" for the mismatched ports.</p>
<b>OperSpeed</b>	Indicates the operational speed for the port.
<b>QoSLevel</b>	Selects the Quality of Service (QoS) level for this port. The default is level1.
<b>DiffServ</b>	Enables the Differentiated Service feature for this port. The default is disabled.
<b>Layer3Trust</b>	Configures if the system should trust Layer 3 packets coming from access links or core links only. The default is core.
<b>Layer2Override8021p</b>	Specifies whether Layer 2 802.1p override is enabled (selected) or disabled (cleared) on the port. The default is disabled (clear).
<b>MLtid</b>	Shows the MLT ID associated with this port. The default is 0.

Name	Description
<b>Locked</b>	Shows if the port is locked. The default is unlocked.
<b>UnknownMacDiscard</b>	Discards packets that have an unknown source MAC address, and prevents other ports from sending packets with that same MAC address as the destination MAC address. The default is disabled.
<b>DirectBroadcastEnable</b>	Specifies if this interface forwards direct broadcast traffic.
<b>OperRouting</b>	Shows the routing status of the port.
<b>HighSecureEnable</b>	Enables or disables the high secure feature for this port.
<b>RmonEnable</b>	Enables or disables Remote Monitoring (RMON) on the interface. The default is disabled.
<b>FlexUniEnable</b>	Enables Flex UNI on the port. The default is disabled.
<b>IngressRateLimit</b>  <b>Note:</b> Exception: not supported on VSP 4450 Series, VSP 7400 Series, or VSP 8600 Series.	Limits the traffic rate that the specific ingress port accepts.
<b>IngressRatePeak</b>	Configures the peak rate in Kbps. The default is 0.
<b>IngressRateSvc</b>	Configures the service rate in Kbps. The default is 0.
<b>EgressRateLimitState</b>	Enables or disables egress port-based shaping to bind the maximum rate at which traffic leaves the port. The default is disabled.
<b>EgressRateLimit</b>  <b>Note:</b> Exception: not supported on VSP 7400 Series, VSP 8600 Series, or XA1400 Series.	Specifies the egress rate limit in Kbps. Different hardware platforms support different egress rate limits, depending on the port with the highest speed available on the platform. You cannot configure the egress shaper rate to exceed the port capability. If you configure this value to 0, shaping is disabled on the port.
<b>TxFlowControl</b>  <b>Note:</b> Exception: not supported on VSP 8600 Series	Configures if the port sends pause frames. By default, an interface does not send pause frames. You must also enable the flow control feature globally before an interface can send pause frames.

Name	Description
<b>TxFlowControlOperState</b>	Shows the operational state of flow control.
<b>BpduGuardTimerCount</b>	Shows the time, starting at 0, since the port became disabled. When the BpduGuardTimerCount reaches the BpduGuardTimeout value, the port is enabled. Displays in 1/100 seconds.
<b>BpduGuardTimeout</b>	Specifies the value to use for port-state recovery. After a BPDU guard disables a port, the port remains in the disabled state until this timer expires. The default is 120 seconds. If you configure the value to 0, the expiry is infinity.
<b>BpduGuardAdminEnabled</b>	Enables BPDU Guard on the port. The default is disabled.
<b>ForwardErrorCorrection</b>	Configures one of the following options for Forward Error Correction (FEC) on the port: <ul style="list-style-type: none"> <li>• CL 91</li> <li>• CL 108</li> <li>• CL 74</li> <li>• disable</li> <li>• auto</li> </ul> The disable option disables this configuration on the port.
<b>ForwardErrorCorrectionApplicability</b>	Displays whether FEC is applicable on the interface.
<b>OperAutoNegotiate</b>	Shows the operational state of Auto-Negotiation.
<b>OperForwardErrorCorrection</b>	Shows the negotiated operational FEC clause. If the value is off, the port supports FEC and is up but not configured for FEC. If the value is notApplicable, the port does not support FEC. If the value is unknown, the port supports FEC but is down.
<b>IsPortShared</b>	Indicates whether the port is combo or not. <ul style="list-style-type: none"> <li>• portShared—Combo port.</li> <li>• portNotShared—Not a combo port.</li> </ul>
<b>PortActiveComponent</b>	Specifies whether the copper port is active or fabric port is active if port is a combo port. <ul style="list-style-type: none"> <li>• fixed port—Copper port is active.</li> <li>• gbic port—Fabric port is active.</li> </ul>

Name	Description
<b>Action</b>	Performs one of the following actions on the port <ul style="list-style-type: none"> <li>• none - none of the following actions</li> <li>• flushMacFdb - flush the MAC forwarding table</li> <li>• flushArp - flush the ARP table</li> <li>• flushIp - flush the IP route table</li> <li>• flushAll - flush all tables</li> <li>• triggerRipUpdate — manually triggers a RIP update</li> </ul> The default is none.
<b>Result</b>	Displays the result of the selected action. The default is none.
<b>AutoSense</b> <b>Note:</b> Exception: not supported on VSP 8600 Series and XA1400 Series.	Enables or disables Auto-sense on the specific port. The default value is disabled for existing configurations but enabled for new Zero Touch Fabric Configuration deployments.
<b>AutoSenseKeepAutoConfig</b> <b>Note:</b> Exception: not supported on VSP 8600 Series and XA1400 Series.	Retains the Auto-sense configuration if you disable Auto-sense on the port. The dynamic configuration becomes a manual configuration and is visible in the <b>show running-config</b> output.
<b>CustomAutoNegAdOrigin</b>	Specifies the origin of Custom Auto Negotiation Advertisements (CANA) configuration on the port. The supported values are: <ul style="list-style-type: none"> <li>• config - Set by the user.</li> <li>• radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.</li> </ul>
<b>BpduGuardOrigin</b>	Specifies the origin of BPDU Guard configuration on the port. The supported values are: <ul style="list-style-type: none"> <li>• config - Set by the user.</li> <li>• radius - Set by the Remote Authentication Dial-In User Service (RADIUS) attribute.</li> </ul>
<b>AutoSenseState</b> <b>Note:</b> Exception: not supported on VSP 8600 Series and XA1400 Series.	Displays the Auto-sense port state.

Name	Description
<b>LinkDebounce</b> <b>Note:</b> Exception: not supported on VSP 8600 Series and XA1400 Series.	Specifies the extended debounce timer on the port. The value 0 milliseconds disables debounce time. The default value is 1000.
<b>AutoSenseDataI Sid</b> <b>Note:</b> Exception: not supported on VSP 8600 Series and XA1400 Series.	Specifies the Auto-sense data I-SID per port.
<b>AutoSenseWaitInterval</b> <b>Note:</b> Exception: not supported on XA1400 Series.	Specifies the Auto-sense Wait Interval for the port. The default is 35.

## Configuring RSTP global parameters

Perform this procedure to configure the RSTP global parameters.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **RSTP**.
3. Configure the parameters as required.
4. Click **Apply**.

### *Globals field descriptions*

Use the data in the following table to use the **Globals** tab.

Name	Description
<b>PathCostDefault</b>	Specifies the version of the spanning tree default path costs that are used by this bridge. A value of 8021d1998 indicates the use of the 16-bit default path costs from IEEE Std. 802.1d-1998. A value of stp8021t2001 indicates the use of the 32-bit default path costs from IEEE Std. 802.1t.
<b>TxHoldCount</b>	Specifies the value used by the port transmit state machine to limit the maximum transmission rate. The default is 3.

Name	Description
<b>Version</b>	Specifies the version of STP that the bridge currently runs. The value <code>stpCompatible</code> indicates that the Spanning Tree Protocol as specified in IEEE 802.1d is in use; <code>rstp</code> indicates that the Rapid Spanning Tree Protocol as specified in IEEE 802.1w is in use.
<b>EnableStp</b>	Indicates whether the spanning tree protocol is active in this STG. The default is enabled.
<b>Priority</b>	Specifies the RSTP bridge priority.
<b>BridgeMaxAge</b>	Specifies the value that all bridges use for <code>MaxAge</code> while this bridge acts as the root.
<b>BridgeHelloTime</b>	The value that all bridges use for <code>HelloTime</code> while this bridge acts as the root.
<b>BridgeForwardDelay</b>	Specifies the value that all bridges use for forward delay while this bridge acts as the root.
<b>DesignatedRoot</b>	Specifies the unique bridge identifier of the bridge recorded as the root in the configuration BPDUs transmitted by the designated bridge for the segment to which the port is attached.
<b>RootCost</b>	Specifies the cost of the path to the root from this bridge.
<b>RootPort</b>	Specifies the port number of the port which offers the lowest cost path from this bridge to the root bridge.
<b>MaxAge</b>	Specifies the maximum age of Spanning Tree Protocol information in hundredths of a second learned from the network on any port before the port is discarded.
<b>HelloTime</b>	Specifies the amount of time in hundredths of a second between the transmission of configuration bridge PDUs by this node on any port while it is the root of the spanning tree (or trying to become the root).

Name	Description
<b>ForwardDelay</b>	Specifies a time value, measured in hundredths of a second, controls how fast a port changes its spanning state after moving towards the forwarding state. The value determines how long the port stays in each of the listening and learning states, which precede the forwarding state. This value is also used after a topology change is detected, and is underway, to age all dynamic entries in the forwarding database.
<b>RstpUpCount</b>	Specifies the number of times the RSTP module is enabled. A trap is generated on the occurrence of this event.
<b>RstpDownCount</b>	Specifies the number of times the RSTP module is disabled. A trap is generated on the occurrence of this event.
<b>NewRootIdCount</b>	Specifies the number of times this bridge detects a root identifier change. A trap is generated on the occurrence of this event.
<b>TimeSinceTopology Change</b>	Specifies the time (in hundredths of a second) since the TcWhile Timer for any port in this bridge was nonzero for Common Spanning Tree.
<b>TopChanges</b>	Specifies the number of times that there was at least one nonzero TcWhile Timer on this bridge for Common Spanning Tree.

## Configuring RSTP ports

Configure RSTP to reduce the recovery time after a network breakdown.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **RSTP**.
3. Click the **RSTP Ports** tab.
4. Use the fields in the **RSTP Ports** tab to configure the RSTP ports.
5. Click **Apply**.

**RSTP Ports** field descriptions

Use the data in the following table to use the **RSTP Ports** tab.

Name	Description
<b>Port</b>	Specifies a unique value, greater than zero, indicating the port number.
<b>Priority</b>	Specifies the value of the priority field.
<b>PathCost</b>	Specifies the contribution of this port to the path cost of paths towards the root that includes this port.
<b>ProtocolMigration</b>	Specifies a port to transmit RSTP BPDUs if operating in RSTP mode. Any other operation on this object has no effect, and RSTP mode returns false if read.
<b>AdminEdgePort</b>	Specifies the administrative value of the Edge Port parameter. A value of true indicates that this port is an edge-port, and a value of false indicates that this port is a nonedge-port.
<b>OperEdgePort</b>	Specifies the operational value of the Edge Port parameter. The object is initialized to the value of AdminEdgePort and is configured to false on reception of a BPDU.
<b>AdminPointToPoint</b>	Specifies the administrative point-to-point status of the LAN segment attached to this port. A value of forceTrue indicates that this port is treated as if it is connected to a point-to-point link. A value of forceFalse indicates that this port is treated as having a shared media connection. A value of auto indicates that this port is considered to have a point-to-point link if it is an aggregator and all of its members are aggregatable, or if the MAC entity is configured for full-duplex operation, either through autonegotiation or by management means.
<b>OperPointToPoint</b>	Specifies the operational point-to-point status of the LAN segment attached to this port. It indicates whether a port is considered to have a point-to-point connection or not. The value is determined by management or by autodetection as described in the AdminPointToPoint object.
<b>OperVersion</b>	Indicates if the port is in MSTP mode, RSTP mode or STP-compatible mode. MSTP mode transmits MST BDUs, RSTP mode transmits RST BPDUs and STP-compatible transmits Config/TCN BPDUs.

## Viewing RSTP port status

View the RSTP port status to ensure proper functioning of RSTP.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **RSTP**.
3. In the RSTP tab, click the **RSTP Status** tab.

### *RSTP Status* field descriptions

Use the data in the following table to use the **RSTP Status** tab.

Name	Description
<b>Port</b>	Specifies a unique value, greater than zero, indicating the port number.
<b>State</b>	Specifies the current state of the port as defined by application of the Spanning Tree Protocol. This state controls what action a port takes on reception of a frame.
<b>Role</b>	Indicates the current port role assumed by this port.
<b>OperVersion</b>	Indicates whether the port is operationally in the RSTP- or STP-compatible mode; that is, whether the port transmits RSTP BPDUs or Config/TCN BPDUs.
<b>EffectivePortState</b>	Specifies the effective operational state of the port. This object is configured to true if the port is operationally up in the Interface Manager, and if Force Port State for this port and the specified port state is enabled. Otherwise, this object is configured to false.

## Viewing RSTP Status Statistics

### About This Task

You can view status statistics for Rapid Spanning Tree Protocol (RSTP).

### Procedure

1. In the navigation pane, expand the **Configuration > VLAN > Spanning Tree** folders.
2. Click **RSTP**.
3. In the **RSTP Status** tab, select a port, and then click **Graph**.

**RSTP Status** *Field Descriptions*

The following table describes the **RSTP Status** fields.

Name	Description
<b>RxRstBpduCount</b>	Specifies the number of RSTP BPDUs this port received.
<b>RxConfigBpduCount</b>	Specifies the number of configuration BPDUs this port received.
<b>RxTcnBpduCount</b>	Specifies the number of TCN BPDUs this port received.
<b>TxRstBpduCount</b>	Specifies the number of RSTP BPDUs this port transmitted.
<b>TxConfigBpduCount</b>	Specifies the number of Config BPDUs this port transmitted.
<b>TxTcnBpduCount</b>	Specifies the number of TCN BPDUs this port transmitted.
<b>InvalidRstBpduRxCount</b>	Specifies the number of invalid RSTP BPDUs this port received. A trap is generated on the occurrence of this event.
<b>InvalidConfigBpduRx Count</b>	Specifies the number of invalid configuration BPDUs this port received. A trap is generated on the occurrence of this event.
<b>InvalidTcnBpduRxCount</b>	Specifies the number of invalid TCN BPDUs this port received. A trap is generated on the occurrence of this event.
<b>ProtocolMigrationCount</b>	Specifies the number of times this port migrated from one STP protocol version to another. The relevant protocols are STP-Compatible and RSTP. A trap is generated on the occurrence of this event.

## Viewing Port Spanning Tree Statistics

View port spanning tree statistics to manage network performance.

**Procedure**

1. In the Device Physical View, select a port.
2. In the navigation pane, expand the **Configuration** > **Graph** folders.
3. Click **Port**.
4. Click the **Spanning Tree** tab.

**Spanning Tree** *Field Descriptions*

The following table describes parameters on the **Spanning Tree** tab.

Name	Description
<b>InConfigBpdus</b>	The number of Config BPDUs received.
<b>InTcnBpdus</b>	The number of Topology Change Notifications BPDUs received.

Name	Description
<b>InBadBpdus</b>	The number of unknown or malformed BPDUs received.
<b>OutConfigBpdus</b>	The number of Config BPDUs transmitted.
<b>OutTcnBpdus</b>	The number of Topology Change Notifications BPDUs transmitted.

## Configuring MSTP global parameters

Configure the global MSTP parameters to determine how MSTP operates for the system. Interface-level parameters override global settings.

### Before You Begin

- The system must be in MSTP mode.

### Procedure

- In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
- Click **MSTP**.
- Click the **Globals** tab.
- Configure MSTP as required.
- Click **Apply**.

### *Globals* field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
<b>PathCostDefaultType</b>	Specifies the version of the spanning tree default path costs to be used by this bridge. A value of 8021d1998 denotes the use of the 16-bit default path costs from IEEE 802.1d-1998. A value of stp8021t2001 denotes the use of the 32-bit default path costs from IEEE 802.1t.
<b>TxHoldCount</b>	Specifies the value used by the port transmit state to limit the maximum transmission rate. The default is 3.
<b>MaxHopCount</b>	Assigns the MSTP bridge maximum hop count. The range is 100 to 4000 one hundredths of a second. The original MIB erroneously designated the value in hundredths of a second, when it should have been in hops. The replacement MIB kept the range at 100-4000 to remain backwards compatible. To convert this value to hops, divide by 100 so 100-4000 equals 1-40 hops.

Name	Description
<b>NoOfInstancesSupported</b>	Indicates the maximum number of spanning tree instances supported.
<b>MstpUpCount</b>	The number of times the MSTP module is enabled. A trap is generated on the occurrence of this event.
<b>MstpDownCount</b>	The number of times the MSTP module is disabled. A trap is generated on the occurrence of this event.
<b>ForceProtocolVersion</b>	<p>Specifies the version of Spanning Tree Protocol that the bridge currently runs. stpCompatible indicates that the Spanning Tree Protocol as specified in IEEE 802.1d is in use; rstp indicates that the Rapid Spanning Tree Protocol as specified in IEEE 802.1w is in use; and mstp indicates that the multiple spanning tree protocol as specified in IEEE 802.1s is in use.</p> <p>Although STP and MSTP are variations of the same spanning tree protocol, they communicate information differently. A switch in MSTP mode cannot recognize the spanning tree groups running on a chassis configured with STP. MSTP spanning tree groups are not the same as STP spanning tree groups. Using a switch in MSTP mode with a chassis in STP mode can create a loop in the network.</p> <p>The default is MSTP.</p>
<b>BrgAddress</b>	Specifies the MAC address used by this bridge if it must be referred to in a unique fashion. This should be the numerically smallest MAC address of all ports that belong to this bridge. If concatenated with MstCistBridgePriority or MstBridgePriority, a unique bridge identifier is formed, which is used in the STP.
<b>Root</b>	Specifies the bridge identifier of the root of the common spanning tree as determined by the STP by this node. This value is used as the CIST root identifier parameter in all configuration bridge PDUs originated by this node.
<b>RegionalRoot</b>	Specifies the bridge identifier of the root of the multiple spanning tree region as determined by the STP as executed of this node. This value is used as the common and internal spanning tree (CIST) regional root identifier parameter in all configuration bridge PDUs originated by this node.

Name	Description
<b>RootCost</b>	Specifies the cost of the path to the CIST root from this bridge.
<b>RegionalRootCost</b>	Specifies the cost of the path to the CIST regional root from this bridge.
<b>RootPort</b>	Specifies the port number of the port which offers the lowest path cost from this bridge to the CIST root bridge.
<b>BridgePriority</b>	Specifies the value of the writable portion of the bridge identifier comprising the first two octets. The values you enter for bridge priority must be in steps of 4096. The default is 32768.
<b>BridgeMaxAge</b>	Specifies the value that all bridges use for MaxAge while this bridge acts as the root. The granularity of this timer is specified as 1 second. An agent can return a bad value error if you attempt to configure a value which is not a whole number of seconds. The default is 2000.
<b>BridgeForwardDelay</b>	Specifies the value that all bridges use for forward delay if this bridge acts as the root. Note that 802.1d specifies that the range for this parameter is related to the value of BridgeMaxAge. The granularity of this timer is specified as 1 second. An agent can return a bad value error if you attempt to configure a value which is not a whole number of seconds. The default is 1500.
<b>HoldTime</b>	Determines the interval length in hundredths of a second during which no more than two configuration bridge PDUs can be transmitted by this node.
<b>MaxAge</b>	Specifies the maximum age of Spanning Tree Protocol information learned from the network on any port before it is discarded. This is the value that this bridge currently uses.
<b>ForwardDelay</b>	Specifies the time value, measured in units of hundredths of a second, that controls how fast a port changes its spanning state after moving towards the forwarding state. This value determines how long the port stays in a particular state before moving to the next state.
<b>TimeSinceTopology Change</b>	Specifies the time (in hundredths of a second) since the TcWhile Timer for any port in this bridge was nonzero for Common Spanning Tree.

Name	Description
<b>TopChanges</b>	Specifies the number of times that there was at least one nonzero TcWhile Timer on this bridge for Common Spanning Tree.
<b>NewRootBridgeCount</b>	Specifies the number of times this bridge detects a root bridge change for Common Spanning Tree. A trap is generated on the occurrence of this event.
<b>RegionName</b>	Specifies the name for the region configuration. By default, the region name is equal to the bridge MAC Address.
<b>RegionVersion</b>	Specifies the version of the MST region.
<b>ConfigIdSel</b>	Specifies the configuration identifier format selector used by the bridge. This has a fixed value of 0 to indicate RegionName. RegionVersions are specified as in the standard.
<b>ConfigDigest</b>	Specifies the configured MD5 digest value for this region, which must be 16 octets long.
<b>RegionConfigChange Count</b>	Specifies the number of times a region configuration identifier change is detected. A trap is generated on the occurrence of this event.

## Configuring CIST ports for MSTP

Configure Common and Internal Spanning Tree (CIST) ports to configure ports for MSTP.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **MSTP**.
3. Click the **CIST Port** tab.

#### Note

The MSTP, CIST Port tab contains information for each port that is common to all bridge and spanning tree instances.

4. Use the fields in the **CIST Port** box to configure the MSTP CIST port.
5. Click **Apply**.

**CIST Port** field descriptions

Use the data in the following table to use the **CIST Port** tab.

Name	Description
<b>Port</b>	Specifies the port number of the port for which this entry contains spanning tree information.
<b>PathCost</b>	Specifies the contribution of this port to the path cost of paths towards the CIST root that includes this port.
<b>Priority</b>	Specifies the four most significant bits of the port identifier of the spanning tree instance which are modified by setting the CistPortPriority value. The values that are configured for port priority must be in steps of 16. Although port priority values can range from 0 to 255, only the following values are used: 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, 240. The default is 128.
<b>DesignatedRoot</b>	Specifies the unique bridge identifier of the bridge recorded as the CIST root in the configuration BPDUs transmitted.
<b>DesignatedCost</b>	Specifies the path cost of the designated port of the segment that connects to this port.
<b>DesignatedBridge</b>	Specifies the unique bridge identifier of the bridge which that port considers to be the designated bridge for the ports segment.
<b>DesignatedPort</b>	Specifies the port identifier of the port on the designated bridge for this port segment.
<b>RegionalRoot</b>	Specifies the unique bridge identifier of the bridge recorded as the CIST regional root identifier in the configuration BPDUs transmitted.
<b>RegionalPathCost</b>	Specifies the contribution of this port to the path cost of paths towards the CIST regional root that include this port.

Name	Description
<b>ProtocolMigration</b>	Indicates the protocol migration state of this port. If you chose true, the option initiates protocol migration for a port. If you chose false, the option terminates protocol migration for a port. An MSTP-compatible port transmits and receives only RSTP BPDUs. If an MSTP port receives an STP BPDU, it becomes an STP port. User intervention is required to change this port back to MSTP mode. This process is called Port Protocol Migration. You must configure protocol migration to true on all spanning-tree enabled interfaces when you change the spanning tree version from STP-compatible to MSTP for those interfaces to work in the proper mode.
<b>AdminEdgeStatus</b>	Specifies the administrative value of the Edge Port parameter. A value of true indicates that this port is an edge-port, and a value of false indicates that this port is a nonedge-port.
<b>OperEdgeStatus</b>	Specifies the operational value of the Edge Port parameter. The object is initialized to the value of AdminEdgeStatus and is configured to false on reception of a BPDU.
<b>AdminP2P</b>	Specifies the administrative point-to-point status of the LAN segment attached to this port. A value of forceTrue indicates that this port is treated as if it connects to a point-to-point link. A value of forceFalse indicates that this port is treated as having a shared media connection. A value of auto indicates that this port is considered to have a point-to-point link if it is an aggregator and all of its members are aggregatable, or if the MAC entity is configured for full-duplex operation, either through autonegotiation or by management means.
<b>OperP2P</b>	Specifies the operational point-to-point status of the LAN segment attached to this port. It indicates whether a port is considered to have a point-to-point connection or not. The value is determined by management or by autodetection as described in the AdminP2P object.
<b>HelloTime</b>	Specifies the amount of time in hundredths of a second between the transmission of configuration bridge PDUs by this node on this port.

Name	Description
<b>OperVersion</b>	Indicates whether the port is operationally in the MSTP mode, the RSTP mode, or the STP-compatible mode; that is, whether the port transmits MST BPDUs, RST BPDUs, or Config/TCN BPDUs. Although STP and MSTP are variations of the same spanning tree protocol, they communicate information differently. A switch in MSTI mode cannot recognize the spanning tree groups running on a chassis configured with STP. MSTP spanning tree groups are not the same as STP spanning tree groups. Using a switch in MSTP mode with another chassis in STP mode can create a loop in the network.
<b>EffectivePortState</b>	Specifies the effective operational state of the port for CIST. This is true only if the port is operationally up at the interface and protocol levels for CIST. This is configured to false for all other conditions.
<b>State</b>	Specifies the current state of the port as defined by the common spanning tree protocol. It can be disabled, discarding, learning, or forwarding.
<b>ForcePortState</b>	Specifies the current state of the port. You can change the port to either Disabled or Enabled for the base spanning tree instance.
<b>SelectedPortRole</b>	Specifies the selected port role of the port for this spanning tree instance.
<b>CurrentPortRole</b>	Specifies the current port role of the port for this spanning tree instance.

## Configuring MSTI bridges for MSTP

Perform this procedure to configure multiple spanning tree instance (MSTI) bridges for MSTP.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **MSTP**.
3. Click the **MSTI Bridges** tab.

#### Note

The systems generates MSTI bridge instances after you create a VLAN in MSTP mode.

4. Use the fields in the **MSTI Bridges** box to configure the MSTP bridge.
5. Click **Apply**.

#### **MSTI Bridges** field descriptions

Use the data in the following table to use the **MSTI Bridges** tab.

Name	Description
<b>Instance</b>	Specifies the spanning tree instance to which this information belongs.
<b>RegionalRoot</b>	Specifies the MSTI regional root identifier value for the instance. This value is used as the MSTI regional root identifier parameter in all configuration bridge PDUs originated by this node.
<b>Priority</b>	Specifies the writable portion of the MSTI bridge identifier comprising the first two octets. The values that are configured for bridge priority must be in steps of 4096. The default is 32768.
<b>RootCost</b>	Specifies the cost of the path to the MSTI regional root as seen by this bridge.
<b>RootPort</b>	Specifies the port number of the port that offers the lowest path cost from this bridge to the MSTI region root bridge.
<b>TimeSinceTopologyChange</b>	Specifies the time (in hundredths of a second) since the TcWhile Timer for any port in this bridge was nonzero for this spanning tree instance.
<b>TopChanges</b>	Specifies the number of times that there was at least one nonzero TcWhile Timer on this bridge for this spanning tree instance.
<b>NewRootCount</b>	Specifies the number of times this bridge detects a root bridge change for this spanning tree instance. A trap is generated on the occurrence of this event.
<b>InstanceUpCount</b>	Specifies the number of times a new spanning tree instance is created. A trap is generated on the occurrence of this event.
<b>InstanceDownCount</b>	Specifies the number of times a spanning tree instance is deleted. A trap is generated on the occurrence of this event.

## Configuring MSTI ports for MSTP

Perform the following procedure to configure MSTI ports for MSTP.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > VLAN > Spanning Tree**.
2. Click **MSTP**.
3. Click the **MSTI Port** tab.

#### Note

Port members you select on the VLAN, the system displays **Basic** tab in the **MSTI Port** tab.

4. Use the fields in the **MSTI Port** box to configure the MSTP.
5. Click **Apply**.

### *MSTI Port Field Descriptions*

Use the data in the following procedure to use the **MSTI Port** tab.

Name	Description
<b>Port</b>	Specifies the port number of the port for which this entry contains spanning tree information.
<b>Instance</b>	Specifies the spanning tree instance to which the information belongs.
<b>PathCost</b>	Specifies the contribution of this port to the path cost of paths towards the MSTI root that includes this port.
<b>Priority</b>	Specifies the four most significant bits of the port identifier for a given spanning tree instance can be modified independently for each spanning tree instance supported by the bridge. The values configured for port priority must be in steps of 16. The default is 128.
<b>DesignatedRoot</b>	Specifies the unique bridge identifier of the bridge recorded as the MSTI regional root in the configuration BPDUs transmitted.
<b>DesignatedBridge</b>	Specifies the unique bridge identifier of the bridge that this port considers to be the designated bridge for the port segment.
<b>DesignatedPort</b>	Specifies the port identifier of the port on the designated bridge for this port segment.
<b>State</b>	Specifies the current state of the port, as defined by the MSTP. A port which is in forwarding state in one instance can be in discarding (blocking) state in another instance.

Name	Description
<b>ForcePortState</b>	Specifies the current state of the port, that is changed to either disabled or enabled for the specific spanning tree instance.
<b>DesignatedCost</b>	Specifies the path cost of the designated port of the segment connected to this port.
<b>CurrentPortRole</b>	Specifies the current port role of the port for this spanning tree instance.
<b>EffectivePortState</b>	Specifies the effective operational state of the port for a specific instance. This is configured to true if the port is operationally up at the interface and protocol levels for the specific instance. This is configured to false at all other times.

## Viewing VLAN and Spanning Tree CIST Statistics

### About This Task

View CIST port statistics to manage network performance.

### Procedure

1. In the navigation pane, expand the **Configuration > VLAN > Spanning Tree** folders.
2. Click **MSTP**.
3. Click the **CIST Port** tab.
4. Select a port, and then click **Graph**.

### CIST Field Descriptions

The following table describes parameters on the **CIST** tab.

Name	Descriptions
<b>ForwardTransitions</b>	Specifies the number of times this port has transitioned to the forwarding state.
<b>RxMstBpduCount</b>	Specifies the number of MSTP BPDUs received on this port.
<b>RxRstBpduCount</b>	Specifies the number of RSTP BPDUs received on this port.
<b>RxConfigBpduCount</b>	Specifies the number of configuration BPDUs received on this port.
<b>RxTcnBpduCount</b>	Specifies the number of TCN BPDUs received on this port.
<b>TxMstBpduCount</b>	Specifies the number of MSTP BPDUs transmitted from this port.

Name	Descriptions
<b>TxRstBpduCount</b>	Specifies the number of RSTP BPDUs transmitted from this port.
<b>TxConfigBpduCount</b>	Specifies the number of configuration BPDUs transmitted from this port.
<b>TxTcnBpduCount</b>	Specifies the number of TCN BPDUs transmitted from this port.
<b>InvalidMstBpduRxCount</b>	Specifies the number of Invalid MSTP BPDUs received on this port.
<b>InvalidRstBpduRxCount</b>	Specifies the number of Invalid RSTP BPDUs received on this port.
<b>InvalidConfigBpduRxCount</b>	Specifies the number of invalid configuration BPDUs received on this port.
<b>InvalidTcnBpduRxCount</b>	Specifies the number of invalid TCN BPDUs received on this port. The number of times this port has migrated from one STP protocol version to another. The relevant protocols are STP-compatible and RSTP/MSTP. A trap is generated on the occurrence of this event.
<b>ProtocolMigrationCount</b>	Specifies the number of times this port has migrated from one STP protocol version to another. The relevant protocols are STP-compatible and RSTP. A trap is generated on the occurrence of this event.

## Viewing VLAN and Spanning Tree MSTI Statistics

### About This Task

View multiple spanning tree instance (MSTI) port statistics to manage network performance.

### Procedure

1. In the navigation pane, expand the **Configuration > VLAN > Spanning Tree** folders.
2. Click **MSTP**.
3. Click the **MSTI Port** tab.
4. Select a port, and then click **Graph**.

### *MSTI Field Descriptions*

The following table describes parameters on the **MSTI** tab.

Name	Description
<b>ForwardTransitions</b>	Specifies the number of times this port has transitioned to the forwarding state for this specific instance.
<b>ReceivedBPDUs</b>	Specifies the number of BPDUs received by this port for this spanning tree instance.

Name	Description
<b>TransmittedBPDUs</b>	Specifies the number of BPDUs transmitted on this port for this spanning tree instance.
<b>InvalidBPDUsRcvd</b>	Specifies the number of invalid BPDUs received on this port for this spanning tree instance.

SPB-PIM Gateway configuration includes controller and gateway nodes, and Multicast Source Discovery Protocol (MSDP) configuration.

The following topics provide necessary concepts and procedures to configure SPB-PIM Gateway.

## SPB-PIM Gateway fundamentals

This section provides conceptual content to help you configure and customize SPB-PIM Gateway (SPB-PIM GW) on the switch.

### IP Multicast over Fabric Connect in Protocol Independent Multicast networks

IP Multicast over Fabric Connect provides simplicity in provisioning and deploying IP multicast bridging and routing. Also, due to the fact that only one control plane protocol (IS-IS) exists, convergence times in the event of a network failure, are typically sub second.

#### *IP Multicast over Fabric Connect*

IP Multicast over Fabric Connect introduces extensions to the SPBM IS-IS control plane to exchange IP multicast stream advertisement and membership information. IP Multicast over Fabric Connect uses these extensions, along with the Internet Group Management Protocol (IGMP) Snooping and Querier functions at the edge of the SPBM cloud, to create sub-trees of the VSN SPB for each multicast group to transport IP multicast data.

With IP Multicast over Fabric Connect, the switch supports the following:

- Layer 2 Virtual Services Network with IGMP support on the access networks for optimized forwarding of IP multicast traffic in a bridged network (Layer 2 VSN with IP Multicast over Fabric Connect). Example application: Multicast in data centers.
- IP multicast routing support for IP Shortcuts using SPBM in the core and IGMP on the access (IP Shortcuts with IP Multicast over Fabric Connect). Example applications: Video surveillance, TV/Video/Ticker/Image distribution, VX-LAN.
- Layer 3 Virtual Services Network with VRF based routing support for IP Multicast over Fabric Connect in the core and IGMP on the access (Layer 3 VSN with IP Multicast over Fabric Connect). Example applications: Video surveillance, TV/Video/Ticker/Image Distribution, VXLAN, Multi-tenant IP multicast.

#### Important

Sources must be IGMP enabled to support discovery functions specific to the multicast applications in use.

#### *IP Multicast over Fabric Connect restrictions*

- IP Multicast over Fabric Connect cannot connect to an IP Multicast router outside the SPB network.
- You can only deploy IP Multicast over Fabric Connect in environments where there are no multicast routers between the edge of the SPB network and the IP Multicast hosts that connect to the network.
- An existing network which is Protocol Independent Multicast (PIM) based cannot participate in the SPB network either by connecting to SPB originated streams or by injecting PIM network streams into the SPB network.
- In certain environments it is not possible to deploy an SPB network all the way to the point where the SPB network directly connects to an IGMP edge.

You encounter these restrictions during the following typical deployment scenarios:

- **Scenario 1:** You deployed IP Multicast using PIM and want to expand the network by deploying SPB for the new portion of the network. You want multicast applications to work across the old and new portion of the network.
- **Scenario 2:** Multicast traffic is exchanged between independent network operators at the boundary between their networks. PIM is the multicast routing protocol. A network operator wants to upgrade or replace the existing network to an SPB network. The inter-domain multicast traffic exchanges with other networks should not be disrupted.

The following figure shows the traditional Multicast over Fabric Connect environment with no PIM routers.

**Figure 241: IP Multicast over Fabric Connect streams**

In the above figure, sources and receivers on the edges of the SPB network are IGMP hosts and sources of multicast data. Hence, the traditional Multicast over Fabric Connect host-to-host deployment works.

The following figure shows the traditional Multicast over Fabric Connect environment with PIM routers.

**Figure 242: IP Multicast over Fabric Connect Streams**

In the above figure, sources and receivers on the edges of the SPB network, which are IGMP or source hosts can communicate over the SPB network. Sources and receivers connected to PIM routers cannot participate in the SPB network.

## SPB-PIM Gateway

Multicast over Fabric Connect cannot connect to a PIM router that is external to the SPB network. When a receiver joins the SPB network for a specific group, the receiver must receive multicast streams in the neighboring multicast domains (PIM network). Similarly, a receiver in the neighboring multicast domain (PIM network) must receive multicast streams from sources in the SPB network. SPB-PIM Gateway (SPB-PIM GW) provides multicast inter-domain communication between an SPB network and a PIM network. SPB-PIM GW accomplishes this inter-domain communication across a special gateway VLAN. The gateway VLAN communicates with the PIM network through a subset of the full protocol messaging required for RFC 4601 compliance of a PIM interface, and translates the PIM network requirements into SPB language and vice versa.

SPB-PIM GW provides the following functionality:

- One or more SPB domains can share streams with one or more PIM domains.

- SPB-PIM GW can connect two independent SPB domains. The independent SPB domains connected by SPB-PIM GW share a subset of multicast streams without a PIM network in between.

SPB-PIM GW is supported in the GRT and in VRFs.

*Multicast over Fabric Connect with SPB-PIM GW*

In a Multicast over Fabric Connect environment with SPB-PIM GW, the SPB network connects sources and receivers from one or more PIM networks. The multicast traffic is then delivered across the domain boundaries through a path that transports the multicast traffic.

Multicast over Fabric Connect with SPB-PIM GW functionality consists of SPB nodes, which act as SPB-PIM Controller nodes and SPB-PIM Gateway nodes. The SPB Controller uses the Multicast Source Discovery Protocol (MSDP) to discover foreign sources.

The following figure shows the Multicast over Fabric Connect environment with SPB-PIM GW.

**Figure 243: Multicast over Fabric Connect with SPB-PIM GW**

### SPB-PIM GW components

SPB-PIM GW has two functional components:

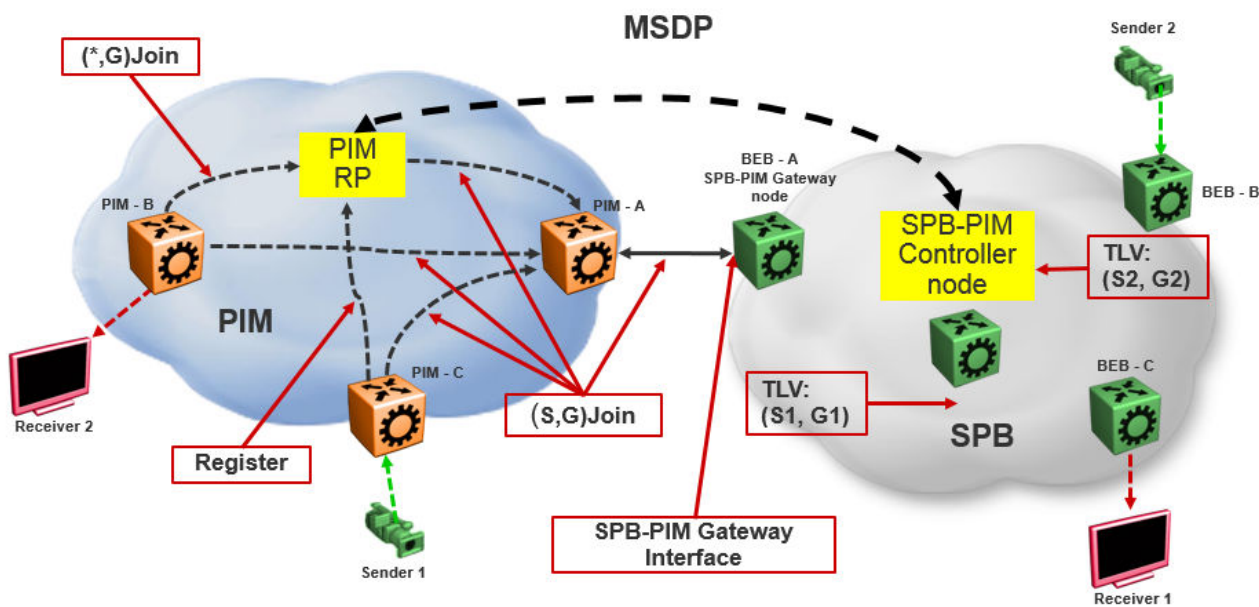

- SPB-PIM Gateway Controller Nodes (Controller), which are used for multicast source discovery.
- SPB-PIM Gateway Nodes (Gateway), on which the SPB-PIM Gateway interfaces reside.

**Note**

The Controller and Gateway can reside in a single node.

The following figure shows the SPB-PIM GW components.

**Figure 244: SPB-PIM GW components**

#### SPB-PIM Gateway Controller Node

SPB-PIM Gateway Controller Node (Controller) shares stream information between the local SPB domain and a foreign domain. The foreign domain is the PIM network Rendezvous point (RP) or another SPB domain Controller.

The Controller functionality is outlined below:

- The Controller discovers PIM sources for a specific multicast group and distributes them to the Gateways.

**Note**

PIM source discovery is either through MSDP or static configuration of foreign streams at the Controller.

- The Controller advertises local SPB originated streams through MSDP to another PIM domain or another SPB domain.
- The Controller references the Unicast IP route table to determine which Gateway has the best route to the PIM source. The Controller then assigns the stream to the selected Gateway.

The Controller Node has the following components:

- Source Discovery (MSDP and static configuration)
- Gateway Selection Controller

#### Source Discovery (MSDP and static configuration)

MSDP resides in the Controller BEB or Controller BCB and PIM network RP that wish to advertise multicast source information between domains.

You can implement SPB-PIM GW under the following scenarios:

- The multicast source resides in the Protocol Independent Sparse Module (PIM-SM) domain. The multicast source must be discovered by MSDP residing on the Gateway Controller in the SPB domain.
- The multicast source resides in the SPB domain. The multicast source must be advertised to the neighboring PIM domain through MSDP peers.

For more information on MSDP, see [MSDP overview](#) on page 3483.

#### Note

You can also configure multicast sources statically on the Controller. Static configuration is useful for SSM multicast group range streams in the foreign domain, which are not advertised by MSDP. Static configuration is also useful for when two SPB domains are connected through a PIM Gateway, and want to only advertise a subset of streams to each other, without enabling MSDP.

#### Gateway Selection Controller

The Gateway Selection Controller resides in the Controller BEB or Controller BCB node in the SPB network. The Gateway Selection Controller receives source information from MSDP or through static configuration. The source information consists of the following components:

- Sender IP address (S)
- Group IP address (G)
- VRF ID of the stream
- RP of the source (optional)

Gateway Selection Controller finds the best BEB (Gateway Node) in the SPB network through which the sender sends traffic to group G. The Gateway Selection Controller performs the following tasks:

- The Gateway Selection Controller uses Layer 3 reachability information to reach S, which is retrieved from the ISIS IP Shortcuts (IPSC) database.
- The VSN identifier (I-SID) is determined by using the VRF ID provided by MSDP.

- The Gateway Selection Controller uses the VRF ID and searches the IP shortcut database to determine which Gateway is closest to S.

**Note**

If multiple BEBs have a route to S, the BEB with the lowest Layer 3 metric is selected as the Gateway.

**Note**

If a Gateway link fails or the cost of the route changes, the selection process identifies the link failure as a route change and selects another best Gateway BEB.

The selected Gateway BEB for a stream must satisfy the following criteria:

- The selected Gateway BEB for a stream must announce a route to the source of the foreign stream through ISIS.

**Note**

Among all the routes to the source of the foreign stream announced by different BEBs through ISIS, the route announced by the selected Gateway has the longest prefix match and has the lowest external route metric.

- If multiple BEBs meet the Gateway selection criteria, a deterministic hash function of system ID, source IP address, and group IP address is used. The deterministic hash function is computed for each of the BEBs that meet the Gateway selection criteria. The BEB that generates the lowest hash value is selected as the Gateway for the stream.

The result of the Gateway selection process is saved in the Gateway assignment table. The Gateway assignment table consists of VSN identifier or I-SID, S, G, and the selected Gateway BEB. Having only one selected Gateway BEB ensures that traffic from source S is drawn into the SPB network by only one BEB, the selected Gateway BEB. The selection Controller then distributes the Gateway assignment table information to all the Gateway nodes.

### *SPB-PIM Gateway Node*

The SPB-PIM Gateway Node (Gateway) has the following components:

- Gateway Selection Agent
- SPB-PIM Gateway interface

#### **Gateway Selection Agent**

The Gateway Selection Agent (Agent) resides in the Gateway BEB Node in the SPB network. The Gateway BEB has connections into the foreign network over SPB-PIM Gateway Interfaces. The Agent receives foreign network source information from the Controller BEB or the Controller BCB Node. The source information consists of the following components:

- Sender IP address (S)
- Group IP address (G)

- VSN identifier (I-SID)
- Gateway assigned to the stream

The Agent interacts with SPB-PIM Gateway interface and creates the multicast path. The Agent receives foreign source information from the Controller and creates a foreign source address (SA) cache after validating the reachability to S. The Agent interacts with the SPB-PIM Gateway interface to validate that the next-hop ip address toward the source is a valid PIM adjacency. The foreign SA cache includes the following components:

- Source IP address (information received from the Gateway Controller)
- Group IP address (information received from the Gateway Controller)
- Ingress port (The port through which S is accessible)
- Upstream IP address (The next-hop IP address, which is also the PIM neighbor across the SPB-PIM Gateway interface which is used to reach S as indicated by the unicast routing entry)
- Ingress VLAN ID

If multiple next-hops are available, then the first valid PIM neighbor next-hop is used for the upstream.

**Note**

If the Agent receives the same source information from multiple Controllers, then the Agent takes action only for the information received from the preferred Controller. The Controller with the lowest system ID is the preferred Controller.

**SPB-PIM Gateway interface**

The SPB-PIM Gateway interface provides inter-domain multicast services. The SPB-PIM Gateway interface connects senders and receivers of multicast streams across a PIM Domain and a SPB network boundary over a Gateway interface. The SPB-PIM Gateway interface provides the following functionality:

- PIM HELLO exchanges
- Issuing Joins and Leaves
- Process received Joins and Leaves
- Implements the Gateway assignment table by acting as the Ingress BEB for streams for which the SPB-PIM Gateway interface is the selected Gateway
- Enforces the Gateway assignment table and does not forward streams for which the SPB-PIM Gateway interface is not the selected Gateway
- Forwards local and remote SPB streams to satisfy stream requests from neighboring multicast domains
- SPB-PIM Gateway Interfaces supports both SM and SSM multicast group range joins and prunes. \*G joins are only supported in SM group range.

The PIM Gateway interface resides in the SPB-PIM Gateway Node (Gateway). The SPB-PIM Gateway interface connects to a PIM router in a PIM network or to another Gateway BEB in an SPB network. Local hosts (IGMP member hosts and multicast data source hosts) are not supported on SPB-PIM Gateway interfaces, only PIM Routers or

another SPB BEB with SPB-PIM Gateway interface configured. Multicast data from local source hosts and IGMP reports from local hosts are dropped. An SPB Node must be configured as a SPB-PIM Gateway Node if the SPB Node is connected to a foreign PIM network or a foreign SPB network. A single Gateway Node can have multiple SPB-PIM Gateway interfaces. The SPB-PIM Gateway interface can be a VLAN or a brouter port, can reside on an MLT and is fully virtualized. The SPB-PIM Gateway interface is a translation mechanism between the PIM protocol and SPB TLVs.

**Note**

- Only PIM protocol messages are communicated over the SPB-PIM Gateway interface
- Only SPB TLVs are communicated over Fabric Connect over SPB
- The SPB-PIM Gateway interface is the only component that handles the translation mechanism

The SPB-PIM Gateway interface communicates with the PIM router through the standard PIM protocol messaging HELLO, JOIN, and PRUNE. The SPB-PIM Gateway interface then forms a normal PIM adjacency with the PIM router or another SPB Gateway Node. The SPB-PIM Gateway Interface processes received SG joins and prunes, \*G joins and prunes, and SG-RPT joins and prunes. The SPB-PIM Gateway interface transmits SG joins and prunes, but never \*G joins. The SPB-PIM Gateway Interface does not have RP capabilities, and therefore has no need for group-to-RP mapping configurations. A \*G JOIN received on a SPB-PIM Gateway Interface is accepted if the destination IP is the IP address of the interface or of a neighbor on the interface if the neighbor is learned on another port in the interface. However, the RP address within the \*G JOIN message is ignored by the SPB-PIM Gateway Interface.

## MSDP overview

MSDP enables advertisement of multicast source information between different PIM-SM domains. This function of MSDP in SPB-PIM GW topologies is to advertise multicast source information between SPB domains and PIM domains. MSDP routers in a PIM-SM or SPB domain have a peering relationship with MSDP peers in another domain. The peering relationship is a TCP connection in which the control information is exchanged. The TCP connection between peers uses the underlying unicast routing system.

### *Source Active messages*

In a PIM domain, MSDP enabled routers are RPs. MSDP routers form adjacencies through TCP port 639 to share multicast source information. This functionality is similar to the Border Gateway Protocol (BGP). When an MSDP router receives multicast source information, the routers use reachability information to perform Reverse Path Forwarding (RPF) checks. The reachability information is exchanged through BGP or any other unicast routing protocol.

When a RP router learns of a new (S,G), the RP router saves the (S,G) information and the RP address in the MSDP Source Active (SA) local cache. The RP router learns the new (S,G) through a directly connected source or PIM register message. The RP router

then sends an SA update message which contains (S,G,RP) information to the MSDP peers. The MSDP peers broadcast the SA to RPs in their local domains and to their MSDP peers in other PIM-SM domains.

**Note**

A PIM domain is a set of routers in a single Autonomous System (AS), which uses the same RP for any given multicast group.

When an SPB-PIM Gateway Controller in the SPB domain learns of a new (S,G) in its own domain, the Controller saves the (S,G) information in the local SA cache. The Controller learns the new (S,G) through a directly connected source or Intermediate-System-to-Intermediate-System (IS-IS). The controller sends an SA update message to the MSDP peers in the PIM domain. SA uses the CLIP address configured on the controller as the RP address.

**Note**

Configure CLIP before you enable MSDP. Peer connections use the CLIP address as the local address.

### *Reverse Path Forwarding check*

When an MSDP peer receives the SA from a peer, the MSDP performs an RPF check. The RPF check ensures that the SA received from the MSDP peer is the closest to the originating RP. An RPF check prevents SA loops.

**Note**

This RPF check is different from the multicast routing RPF check.

If the RPF checks pass, then the receiving MSDP enabled router saves the SA information in the SA foreign cache and makes it available to the local domain. Each MSDP peer floods the SA information away from the originating RP. The flooding process is called peer RPF flooding.

### *SA redistribution and filtering*

Redistribution and filtering is used to control SA flooding. The MSDP redistribute policy is applied on the MSDP node that originates the SAs to control which SAs are advertised on all MSDP peers. An SA filter is applied to a specific MSDP peer in the inbound direction or outbound directions or both inbound and outbound direction on any MSDP router. Filtering is multicast group based.

When configuring MSDP redistribution, use prefix lists to create the route policies. When a route policy is created it must match the group prefix with the name of the prefix list created for the group address. If deny action is set for the lists in the route-policy, the policy blocks the matching groups from all the sources. If permit action is set for the lists in the route-policy, the policy accepts the matching groups from all the sources. MSDP redistribution does not refer to the redistribution of SPB domain

sources to MSDP. MSDP redistribution refers to SAs which needs to be redistributed to other MSDP peers.

**Note**

MSDP redistribution is applied globally to all MSDP peers. SA filtering is used to filter SAs on a peer-to-peer level.

*MSDP and SPB-PIM GW*

The SPB-PIM GW functional component for MSDP resides in the SPB-PIM Gateway Controller node (Controller).

**Overview**

Controllers from an SPB network discover sources through MSDP sessions with RPs from a PIM network. Once the SA packed is received at the MSDP module of the Controller, the IP routing table is examined to determine which peer is the next hop towards the originating RP of the SA message. Once the SA RPF test passes, the SA packet is saved in the foreign cache and passed to the Controller.

The Controller nodes also distribute the sources from an SPB domain to a PIM domain through an MSDP session with RPs in the PIM network. Similar to RP, when a Controller in the SPB domain learns of a new (S,G), through a directly connected source or ISIS, the Controller saves the new (S,G) in its local SA cache. The Controller then transmits an SA update message for this source to its MSDP peers in the PIM domain. The Controller that sends the SA to the MSDP is viewed as the RP (circuitless IP interface is used).

**MSDP as part of SPB-PIM GW**

MSDP does not work with the traditional PIM implementation. MSDP communicates only with the Controller and should be configured as an IP endpoint.

MSDP configuration considerations:

- A circuitless IP interface (CLIP) is used in the context of global router or VRF, hence at least one CLIP in each VRF should be configured.
- MSDP should use a single CLIP address as the source for establishing all MSDP connections in the same VRF.
- For SPB sources, this CLIP is used as the RP in all SA messages advertised.

- MSDP source IP address should be one of the CLIP interfaces pre-configured on the global router or VRF.
- The originator-id should be configured before enabling MSDP.

**Note**

MSDP transmits encapsulated multicast data packets inside forwarded MSDP messages. If the received SA is an encapsulated SA, then the switch parses the TTL value of the encapsulated data and compares it against the configured value. If the configured value is less than or equal to the parsed value, then the switch forwards the encapsulated data along with the SA, otherwise the switch forwards the SA alone by stripping the encapsulate data. By default, MSDP forwards encapsulated data along with the SA message. MSDP does not forward the encapsulated data to the local receivers.

When MSDP generates SA messages for SPB sources, the local cache miss data cannot be encapsulated into the SA messages that are sent to the peers.

The switch supports forwarding SA messages with encapsulated data from sources to MSDP peers but not from MSDP peers to the receivers.

For more information on MSDP configuration, see [Multicast Source Discovery Protocol configuration](#) on page 3487.

### *Full mesh group*

MSDP mesh groups are full mesh of MSDP peers and is a subset of MSDP speakers. MSDP mesh groups are used for SA flooding which is similar to the BGP route reflector concept. MSDP floods the SA to all the members of the mesh group when:

- The MSDP peers are fully meshed
- The MSDP enabled router learns a new SA from a non-member of its mesh group
- The SA passes the RPF check

The receiving routers accept the SA and forwards it only to any non-mesh Group MSDP peers.

The SPB-PIM Gateway is deployed in two models:

- Model 1: All multicast networks have peering agreements with one another. The full mesh MSDP is setup.
- Model 2 : An inter-domain multicast provider exists. All multicast networks setup MSDP peering with the provider.

The controllers relay SA messages between individual networks.

#### Note

Consider the following when you deploy SPB-PIM Gateway:

- Use mesh group of MSDP peers (PIM RP's and SPB-PIM Gateway Controller nodes) to avoid flooding and RPF failure.

#### Note

Since MSDP uses CLIP interface in its peering relation, the MSDP peer may not fall in any of the RFC rules and the MSDP SA messages will be rejected.

- Controllers from the same SPB network must not have MSDP sessions with each other, regardless of whether mesh groups are used or not.
- When using mesh groups, all Controllers within one SPB domain should peer with the same set of RPs and Controllers in adjacent domains, ie, one Controller should not peer with an RP that the other Controllers do not peer with.

## Multicast Source Discovery Protocol configuration

This section provides procedures to configure Multicast Source Discovery Protocol (MSDP) using the Command Line Interface (CLI) and Enterprise Device Manager (EDM).

### Basic MSPD configuration using the CLI

This section provides procedures to configure Basic MSDP using the command line interface (CLI).

#### *Configuring the MSDP originator ID*

Configure the originator ID to set the Rendezvous Point (RP) address inside the Source Active (SA) message. The RP address must be a pre-configured CLIP interface on the global router or a VRF. The RP address is also the local IP address in all peer relations.

#### Note

To delete the originator ID, you must first disable MSDP.

#### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the MSDP originator ID:

```
ip msdp originator-id {A.B.C.D}
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp originator-id 2.0.2.2
```

**Variable definitions**

The following table defines parameters for the **ip msdp originator-id** command.

Variable	Value
{A.B.C.D}	Specifies the MSDP source IP address. The IP address must be one of the CLIP interfaces configured on the global router or a VRF.

*Configuring MSDP on a VRF*

Create an MSDP instance on a user defined VRF to allow further configuration to take place. This command does not exist in the Global Configuration mode because the MSDP instance for a default VRF is created by default.

**Procedure**

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Create the MSDP instance:

```
ip msdp
```

*Enabling MSDP globally*

Enable or disable MSDP globally on the device to allow further configuration to take place.

**Procedure**

1. Enter Global Configuration mode:

```
enable

configure terminal
```

2. Enable MSDP globally on the switch:

```
ip msdp enable
```

### Creating an MSDP peer

Create an MSDP peer to establish a peer relationship between the local MSDP enabled router and a peer in another domain.

**Important**

Do not enable more than 20 active peers.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Create an MSDP peer:

```
ip msdp peer {A.B.C.D}
```

3. Enable an MSDP peer:

```
ip msdp peer {A.B.C.D} enable
```

**Note**

MSDP peer is disabled by default.

4. (Optional) Specify the remote autonomous system (AS) number of the MSDP peer:

```
ip msdp peer {A.B.C.D} remote-as WORD<0-11>
```

### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp peer 21.0.0.2
Switch:1(config)#ip msdp peer 21.0.0.2 enable
Switch:1(config)#ip msdp peer remote-as 1
```

### Variable definitions

The following table defines parameters for the `ip msdp peer` command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the MSDP peer IP address.
<code>WORD&lt;0-11&gt;</code>	Specifies the AS number of the MSDP peer, 0-65535 (2-Byte AS) 0-4294967295 (4-Byte AS).

## MSDP Peer Configuration using the CLI

This section provides procedures to configure MSDP peer using the command line interface (CLI).

### Configuring a peer description

Configure a peer description to add descriptive text to an MSDP peer for easy identification of a peer.

#### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the peer description:

```
ip msdp description {A.B.C.D} WORD<1-255>
```

#### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp peer 21.0.0.2 primary
```

#### Variable definitions

The following table defines parameters for the `ip msdp description` command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the MSDP peer IP address.
<code>WORD&lt;1-255&gt;</code>	Specifies a descriptive text to a MSDP peer in the range of 1-255 characters. To include spaces in the peer description, enclose the text string in quotation marks.

### Securing control messages

Configure Message Digest (MD) 5 authentication to secure control messages on the TCP connection between MSDP peers.

#### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Enable MD5 authentication:

```
ip msdp md5-authentication {A.B.C.D} [enable]
```

3. Specify the case sensitive password for MD5 authentication:

```
ip msdp password peer {A.B.C.D} WORD<1-80>
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp md5-authentication 21.0.0.2 enable
Switch:1(config)#ip msdp password peer 21.0.0.2 helloworld
```

**Variable definitions**

The following table defines parameters for the **ip msdp** command.

Variable	Value
<i>{A.B.C.D}</i>	Specifies the MSDP peer IP address.
<i>WORD&lt;1-80&gt;</i>	Specifies the MD5 authentication password.

*Configuring the MSDP peer SA limit*

Configure the SA limit to limit the number of SA messages from an MSDP peer that the router saves in the SA cache. The default value is 6,144 messages.

**Procedure**

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the SA limit:

```
ip msdp sa-limit {A.B.C.D} <0-6144>
```

**Example**

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#ip msdp sa-limit 21.0.0.2 6100
```

**Variable definitions**

The following table defines parameters for the **ip msdp sa-limit** command.

Variable	Value
<i>{A.B.C.D}</i>	Specifies the MSDP peer IP address.
<i>&lt;0-6144&gt;</i>	Specifies the maximum number of SA messages to keep in SA cache.

*Limiting which packets the router sends*

Configure the time-to-live (TTL) threshold to limit which multicast data packets the router encapsulated in SA Messages forwarded to an MSDP peer. The TTL limits the number of hops a packet can take before the router drops the packet. The router sends out SA Messages with encapsulated data only if TTL equals or exceeds the value you

configure. If the TTL is lower than the value you configure, the router drops the data packet and forwards the SA Message without the encapsulated data.

### Note

MSDP transmits encapsulated multicast data packets inside forwarded MSDP messages. If the received SA is an encapsulated SA, then the switch parses the TTL value of the encapsulated data and compares it against the configured value. If the configured value is less than or equal to the parsed value, then the switch forwards the encapsulated data along with the SA, otherwise the switch forwards the SA alone by stripping the encapsulate data. By default, MSDP forwards encapsulated data along with the SA message. MSDP does not forward the encapsulated data to the local receivers.

When MSDP generates SA messages for SPB sources, the local cache miss data cannot be encapsulated into the SA messages that are sent to the peers.

The switch supports forwarding SA messages with encapsulated data from sources to MSDP peers but not from MSDP peers to the receivers.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the MSDP peer TTL threshold:

```
ip msdp ttl-threshold {A.B.C.D} <1-255>
```

### Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#ip msdp ttl-threshold 21.0.0.2 10
```

### Variable definitions

The following table defines parameters for the `ip msdp ttl-threshold` command.

Variable	Value
{A.B.C.D}	Specifies the MSDP peer IP address.
<1-255>	Specifies the TTL value. Default value is 1.

### Configuring the MSDP peer keep alive messages

Configure keepalive messages to adjust the interval in seconds at which an MSDP peer sends keep alive messages (default is 60 seconds) and the interval at which the MSDP

peer waits for keep alive messages from other peers before it declares them down (default is 75 seconds).

#### Note

In a peer relationship, the keep alive interval configured on one peer must be at least 1 second less than the hold time configured on the other side of the peer relationship. This is not applicable when the hold time is set to 0 seconds.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the MSDP peer keep alive interval:

```
ip msdp keepalive {A.B.C.D} <0-21845> <0-65535>
```

### Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#ip msdp keepalive 21.0.0.2 70 71
```

### Variable definitions

The following table defines parameters for the `ip msdp keepalive` command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the MSDP peer IP address.
<code>&lt;0-21845&gt;</code>	Specifies the keep alive interval in seconds. The default is 60 seconds.
<code>&lt;0-65535&gt;</code>	Specifies the hold time interval in seconds. The default is 75 seconds.  <b>Note:</b> 0 seconds means the peer never expires. Values 1 and 2 are not allowed.

### Configuring the MSDP peer connect-retry period

Configure the connect-retry period to specify the amount of time, in seconds, between connection attempts for peering sessions. The default is 30 seconds.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the MSDP peer connect-retry period:

```
ip msdp connect-retry {A.B.C.D} <1-65535>
```

### Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#ip msdp connect-retry 21.0.0.2 40
```

### Variable definitions

The following table defines parameters for the `ip msdp connect-retry` command.

Variable	Value
{A.B.C.D}	Specifies the MSDP peer IP address.
<1-65535>	Specifies the connect-retry interval in seconds. The default is 30 seconds.

### Clearing the peer connection

Clear the peer connection to clear the TCP connection to the specified MSDP peer, and reset all MSDP message counters.

#### Note

This procedure does not clear the SA cache entries the router learns from the peer.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Clear the peer connection:

```
clear ip msdp peer {A.B.C.D} [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

### Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#clear ip msdp peer 21.0.0.2
```

## Variable definitions

The following table defines parameters for the `clear ip msdp peer` command.

Variable	Value
<code>{A.B.C.D}</code>	Specifies the MSDP peer IP address.
<code>vrf WORD&lt;0-16&gt;</code>	Specifies the VRF name.
<code>vrfids WORD&lt;0-512&gt;</code>	Specifies the VRF ID.

### Deleting an MSDP peer

Use this procedure to delete an MSDP peer.

#### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Clear the peer connection:  
no ip msdp peer `{A.B.C.D}`

#### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#no ip msdp peer 21.0.0.2
```

## MSDP Message Control using the CLI

### Filtering PIM routes

Filter SPB routes to filter which (S,G,RP) entries sent out to all MSDP peers. This procedure applies only to the rendezvous point (RP) that originates the MSDP SA messages and not the intermediate MSDP peers that forward the received SA messages.

#### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:  
enable  
  
configure terminal  
  
Optional: router vrf `WORD<1-16>`
2. Create the MSDP filter:  
ip msdp redistribute
3. Create the route policy name:  
ip msdp redistribute route-policy `WORD<1-64>`

4. Apply the redistribution filters:  

```
ip msdp apply redistribute
```

### Example

```
Switch:1>enable

Switch:1#configure terminal

Switch:1(config)#ip msdp redistribute

Switch:1(config)#ip msdp redistribute route-policy helloworld

Switch:1(config)#ip msdp apply redistribute
```

### Variable definitions

The following table defines parameters for the **clear ip redistribute** command.

Variable	Value
<i>WORD</i> <1-64>	Specifies the route policy name.

### Filtering SA messages

Filter SA messages to determine which SA messages to accept from a peer and which SA messages to send to a peer. By default, no inbound or outbound filter exists.

### Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:  

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`
2. Create the inbound filter:  

```
ip msdp sa-filter in {A.B.C.D}
```
3. Create the inbound filter route policy name:  

```
ip msdp sa-filter in {A.B.C.D} route-policy WORD<1-64>
```
4. Create the outbound filter:  

```
ip msdp sa-filter out {A.B.C.D}
```
5. Create the outbound filter route policy name:  

```
ip msdp sa-filter out {A.B.C.D} route-policy WORD<1-64>
```

### Example

```
Switch:1>enable

Switch:1#configure terminal

Switch:1(config)#ip msdp sa-filter in 21.0.0.2 route-policy helloworld
```

## Variable definitions

The following table defines parameters for the **ip msdp sa-filter** command.

Variable	Value
<i>{A.B.C.D}</i>	Specifies the MSDP peer IP address.
<i>route-policy WORD&lt;1-64&gt;</i>	Specifies the route policy name for an inbound or outbound filter.

## Configuring MSDP mesh groups

Configure mesh groups to reduce SA flooding. A mesh group does not forward SA messages to other group members. The originator, which is also a mesh group member, forwards SA messages to all group members. Create MSDP mesh groups from a group of meshed MSDP speakers from a domain.

### Note

The MSDP router does not belong to any mesh group by default.

## Procedure

1. Enter either Global Configuration mode or VRF Router Configuration mode for a specific VRF context:

```
enable
```

```
configure terminal
```

Optional: `router vrf WORD<1-16>`

2. Configure the MSDP mesh group:

```
ip msdp mesh-group WORD<1-64> {A.B.C.D}
```

## Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#ip msdp mesh-group helloworld 21.0.0.2
```

## Variable definitions

The following table defines parameters for the **ip msdp mesh-group** command.

Variable	Value
<i>WORD&lt;1-64&gt;</i>	Specifies the mesh group name.
<i>{A.B.C.D}</i>	Specifies the MSDP peer IP address.

### Clearing the MSDP SA cache

Clear the SA cache to clear the SA entries the router learns from all peers or a specific peer.

**Note**

This procedure clears the foreign cache. This procedure does not clear the local cache.

### Procedure

1. Enter Privileged EXEC mode:

```
enable
```

2. Clear the SA cache for all peers:

```
clear ip msdp sa-cache [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

3. Clear the SA cache for a specific peer:

```
clear ip msdp sa-cache peer {A.B.C.D} [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

4. Clear the SA cache for a specific group range, source range, and RP.

```
clear ip msdp sa-cache [source prefix/len] [group prefix/len] [rp {A.B.C.D}] [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

### Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#clear ip msdp sa-cache peer 21.0.0.2
```

### Variable definitions

The following table defines parameters for the **clear ip msdp sa-cache** command.

Variable	Value
<i>{A.B.C.D}</i>	Specifies the MSDP peer IP address.
<i>vrf WORD&lt;0-16&gt;</i>	Specifies the VRF names.
<i>vrfids WORD&lt;0-512&gt;</i>	Specifies the VRF ID.

## MSDP Verification using the CLI

This section provides procedures to verify MSDP using the command line interface (CLI).

### Displaying the peer information

Use the following procedure to display the peer configuration and SA message information.

## Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display the peer information:  
show ip msdp peer {A.B.C.D} [vrf WORD<0-16>] [vrfids WORD<0-512>]

## Example

```
Switch:#enable
Switch:1#show ip msdp peer 2.2.2.2
=====
MSDP Peer - GlobalRouter
=====
MSDP Peer 2.2.2.2, AS 109Admin Status: Enabled
Operational Status: Enabled
Description:
Connection status:
FSM State: Established, Establish Count: 9,
Connection source: 2.2.2.17
Uptime (Downtime): 1d10h, Messages sent/received:
436765/429062
Connection and counters cleared 1w2d ago

## Variable definitions

The following table defines parameters for the **show ip msdp peer** command.

Variable	Value
{A.B.C.D}	Specifies the MSDP peer IP address.
vrf WORD<0-16>	Displays configuration info for a particular VRF.
vrfids WORD<0-512>	Displays configuration info for a particular VRF ID.

## Displaying the SA cache

Use the following procedure to display the (S,G) state learned from MSDP peers and the local (S,G) state. The local (S,G) is the SPB (S,G) sent to MSDP.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display the SA cache:  
show ip msdp sa-cache [local] [vrf WORD<0-16>] [vrfids WORD<0-512>]  
[group {A.B.C.D}] [rp {A.B.C.D}] [source {A.B.C.D}]

### Example

```
Switch:#enable
Switch:1#show ip msdp sa-cache local
=====

**Variable definitions**

The following table defines parameters for the `show ip msdp sa-cache` command.

Variable	Value
<code>group{A.B.C.D}</code>	Displays all SA cache entries that match the group IP address.
<code>local</code>	Displays the local SA cache.
<code>rp{A.B.C.D}</code>	Displays all SA cache entries that match the RP IP address.
<code>source{A.B.C.D}</code>	Displays all SA cache entries that match the source IP address.
<code>vrf WORD&lt;0-16&gt;</code>	Displays configuration information for a particular VRF.
<code>vrfids WORD&lt;0-512&gt;</code>	Displays configuration information for a particular VRF ID.

*Displaying the MSDP count*

Use the following procedure to display the number of sources and groups sent and received.

**Procedure**

1. Enter Privileged EXEC mode:  
enable
2. Display the MSDP count:  
show ip msdp count [*vrf WORD<0-16>*] [*vrfids WORD<0-512>*] [*<0-65535>*]

**Example**

```
Switch:#enable
Switch:1#show ip msdp count

## Variable definitions

The following table defines parameters for the **show ip msdp show-all** command.

Variable	Value
<i>file</i> WORD<1-99>	Specifies the file name to save the display output.
<i>vrf</i> WORD<0-16>	Displays configuration information for a particular VRF.
<i>vrfids</i> WORD<0-512>	Displays configuration information for a particular VRF ID.

## Clearing IPv4 MSDP Statistics

Use the following procedure to clear all IPv4 Multicast Source Discovery Protocol (MSDP) statistics for all peers or a specific peer.

### About This Task

The switch supports this command for local management VRF or global routing table (GRT). If you do not specify a VRF or VRF ID, the switch defaults to GRT.

### Procedure

1. Enter Privileged EXEC mode:
 

```
enable
```
2. Clear IPv4 MSDP statistics for all peers:
 

```
clear ip msdp statistics [vrf WORD<0-16>] [vrfids WORD<0-512>]
```
3. Clear IPv4 MSDP statistics for a specific peer:
 

```
clear ip msdp statistics {A.B.C.D.} [vrf WORD<0-16>] [vrfids WORD<0-512>]
```

## Variable Definitions

Use the data in the following table to use the **clear ip msdp statistics** command.

Variable	Value
vrf WORD<0-16>	Specifies a VRF instance by VRF name.
vrfids WORD<0-512>	Specifies the ID of the VRF.
{A.B.C.D.}	Specifies the IPv4 MSDP address for a specific peer.

## Basic MSDP configuration using the EDM

This section provides procedures to configure basic MSDP using the EDM.

*Configure the MSDP Originator ID*

Configure the originator ID to set the RP address inside the SA message. The RP address must be a pre-configured CLIP interface on the global router or a VRF. The RP address is also the local IP address in all peer relations.

**Note**

Originator ID cannot be deleted if MSDP is enabled.

**Before You Begin**

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

**Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Globals** tab.
4. In the **RPAddress** box, type the IP address to use as the originator ID.
5. Select **Apply**.

**Global field descriptions**

Use the data in the following table to use the **Globals** tab.

Name	Description
<b>Enabled</b>	Enables MSDP. If you clear this check box, you disable MSDP. The default setting is clear (disabled).
<b>CacheLifetime</b>	Configures the lifetime given to SA cache entries when created or refreshed.
<b>NumSACacheEntries</b>	Displays the total number of entries in the SA cache.
<b>RPAddress</b>	Specifies the IP address to use as the originator ID. If the address is not a system local address, the system rejects the configuration.
<b>RouteMapName</b>	Specifies the name of the optional route policy to create or modify. You do not need to create a route policy to use the redistribution filter.  <b>Note:</b> To delete the route map name, clear the field and click <b>Apply</b> .
<b>RedistributeFilterEnabled</b>	Filters the (S,G,RP) entries provided by PIM to MSDP. The default is clear (disabled).

Name	Description
<b>RedistributeFilterApply</b>	Applies the changes made to the redistribute filter.
<b>StatsClear</b>	Clears MSDP statistics.

### Enable MSDP

Enable or disable MSDP globally on the switch to permit further configuration to take place.

#### Before You Begin

- You must configure the originator ID before you enable MSDP.
- To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

#### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Globals** tab.
4. Select **Enabled** to enable MSDP.
5. Select **Apply**.

#### Global field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
<b>Enabled</b>	Enables MSDP. If you clear this check box, you disable MSDP. The default setting is clear (disabled).
<b>CacheLifetime</b>	Configures the lifetime given to SA cache entries when created or refreshed.
<b>NumSACacheEntries</b>	Displays the total number of entries in the SA cache.
<b>RPAddress</b>	Specifies the IP address to use as the originator ID. If the address is not a system local address, the system rejects the configuration.

Name	Description
<b>RouteMapName</b>	Specifies the name of the optional route policy to create or modify. You do not need to create a route policy to use the redistribution filter.  <b>Note:</b> To delete the route map name, clear the field and click <b>Apply</b> .
<b>RedistributeFilterEnabled</b>	Filters the (S,G,RP) entries provided by PIM to MSDP. The default is clear (disabled).
<b>RedistruteFilterApply</b>	Applies the changes made to the redistribute filter.
<b>StatsClear</b>	Clears MSDP statistics.

### Create an MSDP Peer

Create an MSDP peer to establish a peer relationship between the local MSDP enabled router and a peer in another domain.

#### Important

Do not enable more than 20 active peers.

### Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. Select **Insert**.
5. In **RemoteAddress**, type the IP address of the peer.
6. Select **Insert**.

## Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
<b>RemoteAddress</b>	Shows the IP address of the remote MSDP peer.
<b>State</b>	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
<b>AdminEnabled</b>	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
<b>ClearPeer</b>	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
<b>ConnectRetryInterval</b>	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
<b>HoldTimeConfigured</b>	The default value is 75 seconds.
<b>KeepAliveConfigured</b>	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
<b>DataTtl</b>	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
<b>InSAFilterEnabled</b>	Activates the inbound SA filter for the peer.
<b>InSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
<b>OutSAFilterEnabled</b>	Activates the outbound SA filter for the peer.

Name	Description
<b>OutSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
<b>Description</b>	Specifies the text description, up to 255 characters, for the peer.
<b>SALimit</b>	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0-6144; the default value is 6144.
<b>Md5AuthEnabled</b>	Activates MD5 authentication on the TCP connection between peers. The default is false.
<b>Md5AuthPassword</b>	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
<b>RemotePort</b>	Shows the remote port for the TCP connection between the MSDP peers.
<b>LocalPort</b>	Shows the local port for the TCP connection between the MSDP peers.
<b>OperEnabled</b>	Shows the operational status of the peer.
<b>RPFFailures</b>	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAs</b>	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAs</b>	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSARequests</b>	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
<b>OutSARequests</b>	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAResponses</b>	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAResponses</b>	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InControlMessages</b>	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutControlMessages</b>	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InDataPackets</b>	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutDataPackets</b>	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>FsmEstablishedTransitions</b>	Shows the total number of times the BGP transitioned to the established state.
<b>FsmEstablishedTime</b>	Shows the time when the peer transitioned to the established state.
<b>InMessageTime</b>	Shows the time when the last MSDP message was received from the peer.
<b>ConnectionAttempts</b>	Shows the number of times the state machine has transitioned from inactive to connecting.

Name	Description
<b>DiscontinuityTime</b>	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
<b>AsNumber</b>	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
<b>TooShortMessages</b>	Shows the number of short messages received from this peer.
<b>InBadMessages</b>	Shows the number of bad MSDP messages received from this peer.
<b>InKeepAliveMessages</b>	Shows the number of keepalive messages received from this peer.
<b>OutKeepAliveMessages</b>	Shows the number of keepalive messages transmitted to this peer.
<b>SAsLearnedFromThisPeer</b>	Shows the total number of SAs learned from this peer.
<b>SAsAdvertisedToThisPeer</b>	Shows the total number of SAs advertised from this peer.
<b>UpOrDownTime</b>	Shows the duration a peer has been up or down.
<b>ConnAndStatsClearedTime</b>	Shows the duration of connection and statistics cleared.

## MSDP Peer Configuration using the EDM

This section provides procedures to configure MSDP peer using the EDM.

### *Secure Control Messages*

Configure Message Digest (MD) 5 authentication to secure control messages on the TCP connection between MSDP peers.

## Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

## Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. In the row for the peer, double-click **Md5AuthEnabled**, and then select true.
5. In the row for the peer, double-click **Md5AuthPassword**, and then type a password.
6. Select **Apply**.

## Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
<b>RemoteAddress</b>	Shows the IP address of the remote MSDP peer.
<b>State</b>	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
<b>AdminEnabled</b>	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
<b>ClearPeer</b>	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
<b>ConnectRetryInterval</b>	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
<b>HoldTimeConfigured</b>	The default value is 75 seconds.
<b>KeepAliveConfigured</b>	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.

Name	Description
<b>DataTtl</b>	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
<b>InSAFilterEnabled</b>	Activates the inbound SA filter for the peer.
<b>InSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
<b>OutSAFilterEnabled</b>	Activates the outbound SA filter for the peer.
<b>OutSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
<b>Description</b>	Specifies the text description, up to 255 characters, for the peer.
<b>SALimit</b>	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
<b>Md5AuthEnabled</b>	Activates MD5 authentication on the TCP connection between peers. The default is false.
<b>Md5AuthPassword</b>	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
<b>RemotePort</b>	Shows the remote port for the TCP connection between the MSDP peers.
<b>LocalPort</b>	Shows the local port for the TCP connection between the MSDP peers.
<b>OperEnabled</b>	Shows the operational status of the peer.
<b>RPFFailures</b>	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
<b>InSAs</b>	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAs</b>	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSARequests</b>	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSARequests</b>	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAResponses</b>	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAResponses</b>	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InControlMessages</b>	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutControlMessages</b>	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InDataPackets</b>	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutDataPackets</b>	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
<b>FsmEstablishedTransitions</b>	Shows the total number of times the BGP transitioned to the established state.
<b>FsmEstablishedTime</b>	Shows the time when the peer transitioned to the established state.
<b>InMessageTime</b>	Shows the time when the last MSDP message was received from the peer.
<b>ConnectionAttempts</b>	Shows the number of times the state machine has transitioned from inactive to connecting.
<b>DiscontinuityTime</b>	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
<b>AsNumber</b>	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
<b>TooShortMessages</b>	Shows the number of short messages received from this peer.
<b>InBadMessages</b>	Shows the number of bad MSDP messages received from this peer.
<b>InKeepAliveMessages</b>	Shows the number of keepalive messages received from this peer.
<b>OutKeepAliveMessages</b>	Shows the number of keepalive messages transmitted to this peer.
<b>SAsLearnedFromThisPeer</b>	Shows the total number of SAs learned from this peer.
<b>SAsAdvertisedToThisPeer</b>	Shows the total number of SAs advertised from this peer.
<b>UpOrDownTime</b>	Shows the duration a peer has been up or down.
<b>ConnAndStatsClearedTime</b>	Shows the duration of connection and statistics cleared.

*Configure the MSDP Peer SA Limit*

Configure the SA limit to limit the number of SA messages from an MSDP peer. The router saves the SA messages in the local cache.

**Before You Begin**

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

**Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. In the row for the peer, double-click **SALimit**, and then type a value.
5. Select **Apply**.

**Peers field descriptions**

Use the data in the following table to use the **Peers** tab.

Name	Description
<b>RemoteAddress</b>	Shows the IP address of the remote MSDP peer.
<b>State</b>	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
<b>AdminEnabled</b>	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
<b>ClearPeer</b>	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
<b>ConnectRetryInterval</b>	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
<b>HoldTimeConfigured</b>	The default value is 75 seconds.

Name	Description
<b>KeepAliveConfigured</b>	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
<b>DataTtl</b>	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
<b>InSAFilterEnabled</b>	Activates the inbound SA filter for the peer.
<b>InSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
<b>OutSAFilterEnabled</b>	Activates the outbound SA filter for the peer.
<b>OutSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
<b>Description</b>	Specifies the text description, up to 255 characters, for the peer.
<b>SALimit</b>	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
<b>Md5AuthEnabled</b>	Activates MD5 authentication on the TCP connection between peers. The default is false.
<b>Md5AuthPassword</b>	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
<b>RemotePort</b>	Shows the remote port for the TCP connection between the MSDP peers.
<b>LocalPort</b>	Shows the local port for the TCP connection between the MSDP peers.
<b>OperEnabled</b>	Shows the operational status of the peer.

Name	Description
<b>RPFFailures</b>	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAs</b>	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAs</b>	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSARequests</b>	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSARequests</b>	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAResponses</b>	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAResponses</b>	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InControlMessages</b>	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutControlMessages</b>	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
<b>InDataPackets</b>	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutDataPackets</b>	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>FsmEstablishedTransitions</b>	Shows the total number of times the BGP transitioned to the established state.
<b>FsmEstablishedTime</b>	Shows the time when the peer transitioned to the established state.
<b>InMessageTime</b>	Shows the time when the last MSDP message was received from the peer.
<b>ConnectionAttempts</b>	Shows the number of times the state machine has transitioned from inactive to connecting.
<b>DiscontinuityTime</b>	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
<b>AsNumber</b>	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
<b>TooShortMessages</b>	Shows the number of short messages received from this peer.
<b>InBadMessages</b>	Shows the number of bad MSDP messages received from this peer.
<b>InKeepAliveMessages</b>	Shows the number of keepalive messages received from this peer.
<b>OutKeepAliveMessages</b>	Shows the number of keepalive messages transmitted to this peer.

Name	Description
<b>SAsLearnedFromThisPeer</b>	Shows the total number of SAs learned from this peer.
<b>SAsAdvertisedToThisPeer</b>	Shows the total number of SAs advertised from this peer.
<b>UpOrDownTime</b>	Shows the duration a peer has been up or down.
<b>ConnAndStatsClearedTime</b>	Shows the duration of connection and statistics cleared.

### Configure a Peer Description

Configure a peer description to add a descriptive text to an MSDP peer, for easy identification of a peer.

#### Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

#### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. In the row for the peer, double-click **Description**, and then type a description for the peer.
5. Select **Apply**.

#### Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
<b>RemoteAddress</b>	Shows the IP address of the remote MSDP peer.
<b>State</b>	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
<b>AdminEnabled</b>	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).

Name	Description
<b>ClearPeer</b>	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
<b>ConnectRetryInterval</b>	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
<b>HoldTimeConfigured</b>	The default value is 75 seconds.
<b>KeepAliveConfigured</b>	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
<b>DataTtl</b>	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
<b>InSAFilterEnabled</b>	Activates the inbound SA filter for the peer.
<b>InSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
<b>OutSAFilterEnabled</b>	Activates the outbound SA filter for the peer.
<b>OutSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
<b>Description</b>	Specifies the text description, up to 255 characters, for the peer.
<b>SALimit</b>	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
<b>Md5AuthEnabled</b>	Activates MD5 authentication on the TCP connection between peers. The default is false.

Name	Description
<b>Md5AuthPassword</b>	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
<b>RemotePort</b>	Shows the remote port for the TCP connection between the MSDP peers.
<b>LocalPort</b>	Shows the local port for the TCP connection between the MSDP peers.
<b>OperEnabled</b>	Shows the operational status of the peer.
<b>RPFFailures</b>	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAs</b>	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAs</b>	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSARequests</b>	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSARequests</b>	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAResponses</b>	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAResponses</b>	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InControlMessages</b>	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
<b>OutControlMessages</b>	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InDataPackets</b>	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutDataPackets</b>	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>FsmEstablishedTransitions</b>	Shows the total number of times the BGP transitioned to the established state.
<b>FsmEstablishedTime</b>	Shows the time when the peer transitioned to the established state.
<b>InMessageTime</b>	Shows the time when the last MSDP message was received from the peer.
<b>ConnectionAttempts</b>	Shows the number of times the state machine has transitioned from inactive to connecting.
<b>DiscontinuityTime</b>	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
<b>AsNumber</b>	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
<b>TooShortMessages</b>	Shows the number of short messages received from this peer.
<b>InBadMessages</b>	Shows the number of bad MSDP messages received from this peer.

Name	Description
<b>InKeepAliveMessages</b>	Shows the number of keepalive messages received from this peer.
<b>OutKeepAliveMessages</b>	Shows the number of keepalive messages transmitted to this peer.
<b>SAsLearnedFromThisPeer</b>	Shows the total number of SAs learned from this peer.
<b>SAsAdvertisedToThisPeer</b>	Shows the total number of SAs advertised from this peer.
<b>UpOrDownTime</b>	Shows the duration a peer has been up or down.
<b>ConnAndStatsClearedTime</b>	Shows the duration of connection and statistics cleared.

### Configure the MSDP Peer Time-to-Live Threshold

Configure the time-to-live (TTL) threshold to limit which multicast data packets the router encapsulated in SA Messaged forwarded to an MSDP peer. The TTL limits the number of hops a packet can take before the router drops the packet. The router sends out SA Messages with encapsulated data only if TTL equals or exceeds the value you configure. If the TTL is lower than the value you configure, the router drops the data packet and forwards the SA Message without the encapsulated data.

#### Note

MSDP transmits encapsulated multicast data packets inside forwarded MSDP messages. If the received SA is an encapsulated SA, then the switch parses the TTL value of the encapsulated data and compares it against the configured value. If the configured value is less than or equal to the parsed value, then the switch forwards the encapsulated data along with the SA, otherwise the switch forwards the SA alone by stripping the encapsulate data. By default, MSDP forwards encapsulated data along with the SA message. MSDP does not forward the encapsulated data to the local receivers.

When MSDP generates SA messages for SPB sources, the local cache miss data cannot be encapsulated into the SA messages that are sent to the peers.

The switch supports forwarding SA messages with encapsulated data from sources to MSDP peers but not from MSDP peers to the receivers.

### Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.

3. Select the **Peers** tab.
4. In the row for the peer, double-click **Md5AuthEnabled**, and then select true.
5. In the row for the peer, double-click **DataTtl**, and then type a value.
6. Select **Apply**.

### Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
<b>RemoteAddress</b>	Shows the IP address of the remote MSDP peer.
<b>State</b>	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
<b>AdminEnabled</b>	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
<b>ClearPeer</b>	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
<b>ConnectRetryInterval</b>	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
<b>HoldTimeConfigured</b>	The default value is 75 seconds.
<b>KeepAliveConfigured</b>	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
<b>DataTtl</b>	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
<b>InSAFilterEnabled</b>	Activates the inbound SA filter for the peer.
<b>InSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.

Name	Description
<b>OutSAFilterEnabled</b>	Activates the outbound SA filter for the peer.
<b>OutSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
<b>Description</b>	Specifies the text description, up to 255 characters, for the peer.
<b>SALimit</b>	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
<b>Md5AuthEnabled</b>	Activates MD5 authentication on the TCP connection between peers. The default is false.
<b>Md5AuthPassword</b>	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
<b>RemotePort</b>	Shows the remote port for the TCP connection between the MSDP peers.
<b>LocalPort</b>	Shows the local port for the TCP connection between the MSDP peers.
<b>OperEnabled</b>	Shows the operational status of the peer.
<b>RPFFailures</b>	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAs</b>	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAs</b>	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSARequests</b>	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
<b>OutSARequests</b>	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAResponses</b>	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAResponses</b>	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InControlMessages</b>	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutControlMessages</b>	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InDataPackets</b>	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutDataPackets</b>	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>FsmEstablishedTransitions</b>	Shows the total number of times the BGP transitioned to the established state.
<b>FsmEstablishedTime</b>	Shows the time when the peer transitioned to the established state.
<b>InMessageTime</b>	Shows the time when the last MSDP message was received from the peer.
<b>ConnectionAttempts</b>	Shows the number of times the state machine has transitioned from inactive to connecting.

Name	Description
<b>DiscontinuityTime</b>	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
<b>AsNumber</b>	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
<b>TooShortMessages</b>	Shows the number of short messages received from this peer.
<b>InBadMessages</b>	Shows the number of bad MSDP messages received from this peer.
<b>InKeepAliveMessages</b>	Shows the number of keepalive messages received from this peer.
<b>OutKeepAliveMessages</b>	Shows the number of keepalive messages transmitted to this peer.
<b>SAsLearnedFromThisPeer</b>	Shows the total number of SAs learned from this peer.
<b>SAsAdvertisedToThisPeer</b>	Shows the total number of SAs advertised from this peer.
<b>UpOrDownTime</b>	Shows the duration a peer has been up or down.
<b>ConnAndStatsClearedTime</b>	Shows the duration of connection and statistics cleared.

### Configuring the MSDP peer keepalive messages

Configure keepalive messages to adjust the interval in seconds at which an MSDP peer sends keep alive messages (default is 60 seconds) and the interval at which the MSDP peer waits for keep alive messages from other peers before it declares them down (default is 75 seconds).

#### Note

In a peer relationship, the keep alive interval configured on one peer must be at least 1 second less than the hold time configured on the other side of the peer relationship. This is not applicable when the hold time is set to 0 seconds.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **MSDP**.
3. Click the **Peers** tab.
4. In the row for the peer, double-click the **KeepAliveConfigured** field, and then type the interval at which to send keepalive messages.
5. In the row for the peer, double-click the **HoldTimeConfigured** field, and then type the interval at which to wait for keepalive messages.
6. Click **Apply**.

### Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
<b>RemoteAddress</b>	Shows the IP address of the remote MSDP peer.
<b>State</b>	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
<b>AdminEnabled</b>	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
<b>ClearPeer</b>	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
<b>ConnectRetryInterval</b>	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
<b>HoldTimeConfigured</b>	The default value is 75 seconds.
<b>KeepAliveConfigured</b>	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
<b>DataTtl</b>	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
<b>InSAFilterEnabled</b>	Activates the inbound SA filter for the peer.

Name	Description
<b>InSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
<b>OutSAFilterEnabled</b>	Activates the outbound SA filter for the peer.
<b>OutSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
<b>Description</b>	Specifies the text description, up to 255 characters, for the peer.
<b>SALimit</b>	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
<b>Md5AuthEnabled</b>	Activates MD5 authentication on the TCP connection between peers. The default is false.
<b>Md5AuthPassword</b>	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
<b>RemotePort</b>	Shows the remote port for the TCP connection between the MSDP peers.
<b>LocalPort</b>	Shows the local port for the TCP connection between the MSDP peers.
<b>OperEnabled</b>	Shows the operational status of the peer.
<b>RPFFailures</b>	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAs</b>	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
<b>OutSAs</b>	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSARequests</b>	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSARequests</b>	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAResponses</b>	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAResponses</b>	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InControlMessages</b>	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutControlMessages</b>	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InDataPackets</b>	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutDataPackets</b>	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>FsmEstablishedTransitions</b>	Shows the total number of times the BGP transitioned to the established state.
<b>FsmEstablishedTime</b>	Shows the time when the peer transitioned to the established state.

Name	Description
<b>InMessageTime</b>	Shows the time when the last MSDP message was received from the peer.
<b>ConnectionAttempts</b>	Shows the number of times the state machine has transitioned from inactive to connecting.
<b>DiscontinuityTime</b>	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
<b>AsNumber</b>	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
<b>TooShortMessages</b>	Shows the number of short messages received from this peer.
<b>InBadMessages</b>	Shows the number of bad MSDP messages received from this peer.
<b>InKeepAliveMessages</b>	Shows the number of keepalive messages received from this peer.
<b>OutKeepAliveMessages</b>	Shows the number of keepalive messages transmitted to this peer.
<b>SAsLearnedFromThisPeer</b>	Shows the total number of SAs learned from this peer.
<b>SAsAdvertisedToThisPeer</b>	Shows the total number of SAs advertised from this peer.
<b>UpOrDownTime</b>	Shows the duration a peer has been up or down.
<b>ConnAndStatsClearedTime</b>	Shows the duration of connection and statistics cleared.

#### *Configure the MSDP Peer connect-retry Period*

Configure the connect-retry period to specify the amount of time, in seconds, between connection attempts for peering sessions. The default is 30 seconds.

## Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

## Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. In the row for the peer, double-click **ConnectRetryInterval**, and then type the interval.
5. Select **Apply**.

## Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
<b>RemoteAddress</b>	Shows the IP address of the remote MSDP peer.
<b>State</b>	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
<b>AdminEnabled</b>	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
<b>ClearPeer</b>	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
<b>ConnectRetryInterval</b>	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
<b>HoldTimeConfigured</b>	The default value is 75 seconds.
<b>KeepAliveConfigured</b>	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.

Name	Description
<b>DataTtl</b>	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
<b>InSAFilterEnabled</b>	Activates the inbound SA filter for the peer.
<b>InSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
<b>OutSAFilterEnabled</b>	Activates the outbound SA filter for the peer.
<b>OutSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
<b>Description</b>	Specifies the text description, up to 255 characters, for the peer.
<b>SALimit</b>	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
<b>Md5AuthEnabled</b>	Activates MD5 authentication on the TCP connection between peers. The default is false.
<b>Md5AuthPassword</b>	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
<b>RemotePort</b>	Shows the remote port for the TCP connection between the MSDP peers.
<b>LocalPort</b>	Shows the local port for the TCP connection between the MSDP peers.
<b>OperEnabled</b>	Shows the operational status of the peer.
<b>RPFFailures</b>	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
<b>InSAs</b>	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAs</b>	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSARequests</b>	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSARequests</b>	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAResponses</b>	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAResponses</b>	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InControlMessages</b>	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutControlMessages</b>	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InDataPackets</b>	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutDataPackets</b>	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
<b>FsmEstablishedTransitions</b>	Shows the total number of times the BGP transitioned to the established state.
<b>FsmEstablishedTime</b>	Shows the time when the peer transitioned to the established state.
<b>InMessageTime</b>	Shows the time when the last MSDP message was received from the peer.
<b>ConnectionAttempts</b>	Shows the number of times the state machine has transitioned from inactive to connecting.
<b>DiscontinuityTime</b>	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
<b>AsNumber</b>	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
<b>TooShortMessages</b>	Shows the number of short messages received from this peer.
<b>InBadMessages</b>	Shows the number of bad MSDP messages received from this peer.
<b>InKeepAliveMessages</b>	Shows the number of keepalive messages received from this peer.
<b>OutKeepAliveMessages</b>	Shows the number of keepalive messages transmitted to this peer.
<b>SAsLearnedFromThisPeer</b>	Shows the total number of SAs learned from this peer.
<b>SAsAdvertisedToThisPeer</b>	Shows the total number of SAs advertised from this peer.
<b>UpOrDownTime</b>	Shows the duration a peer has been up or down.
<b>ConnAndStatsClearedTime</b>	Shows the duration of connection and statistics cleared.

*Change the MSDP Peer Status*

Change the peer status to administratively enable or disable a configured peer. Disable the peer to stop the peering relationship.

**Before You Begin**

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

**Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. In the row for the peer, double-click **AdminEnabled**, and then select true.
5. Select **Apply**.

**Peers field descriptions**

Use the data in the following table to use the **Peers** tab.

Name	Description
<b>RemoteAddress</b>	Shows the IP address of the remote MSDP peer.
<b>State</b>	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
<b>AdminEnabled</b>	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
<b>ClearPeer</b>	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
<b>ConnectRetryInterval</b>	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
<b>HoldTimeConfigured</b>	The default value is 75 seconds.

Name	Description
<b>KeepAliveConfigured</b>	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
<b>DataTtl</b>	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
<b>InSAFilterEnabled</b>	Activates the inbound SA filter for the peer.
<b>InSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
<b>OutSAFilterEnabled</b>	Activates the outbound SA filter for the peer.
<b>OutSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
<b>Description</b>	Specifies the text description, up to 255 characters, for the peer.
<b>SALimit</b>	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
<b>Md5AuthEnabled</b>	Activates MD5 authentication on the TCP connection between peers. The default is false.
<b>Md5AuthPassword</b>	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
<b>RemotePort</b>	Shows the remote port for the TCP connection between the MSDP peers.
<b>LocalPort</b>	Shows the local port for the TCP connection between the MSDP peers.
<b>OperEnabled</b>	Shows the operational status of the peer.

Name	Description
<b>RPFFailures</b>	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAs</b>	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAs</b>	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSARequests</b>	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSARequests</b>	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAResponses</b>	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAResponses</b>	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InControlMessages</b>	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutControlMessages</b>	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
<b>InDataPackets</b>	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutDataPackets</b>	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>FsmEstablishedTransitions</b>	Shows the total number of times the BGP transitioned to the established state.
<b>FsmEstablishedTime</b>	Shows the time when the peer transitioned to the established state.
<b>InMessageTime</b>	Shows the time when the last MSDP message was received from the peer.
<b>ConnectionAttempts</b>	Shows the number of times the state machine has transitioned from inactive to connecting.
<b>DiscontinuityTime</b>	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
<b>AsNumber</b>	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
<b>TooShortMessages</b>	Shows the number of short messages received from this peer.
<b>InBadMessages</b>	Shows the number of bad MSDP messages received from this peer.
<b>InKeepAliveMessages</b>	Shows the number of keepalive messages received from this peer.
<b>OutKeepAliveMessages</b>	Shows the number of keepalive messages transmitted to this peer.

Name	Description
<b>SAsLearnedFromThisPeer</b>	Shows the total number of SAs learned from this peer.
<b>SAsAdvertisedToThisPeer</b>	Shows the total number of SAs advertised from this peer.
<b>UpOrDownTime</b>	Shows the duration a peer has been up or down.
<b>ConnAndStatsClearedTime</b>	Shows the duration of connection and statistics cleared.

### Clear the MSDP Peer Connection

Clear the TCP connection to the specified MSDP peer, and reset all MSDP message counters.

The default is disabled (false).

### Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. In the row for the peer, double-click **ClearPeer**, and then select true.
5. Select **Apply**.

### Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
<b>RemoteAddress</b>	Shows the IP address of the remote MSDP peer.
<b>State</b>	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
<b>AdminEnabled</b>	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).

Name	Description
<b>ClearPeer</b>	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
<b>ConnectRetryInterval</b>	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
<b>HoldTimeConfigured</b>	The default value is 75 seconds.
<b>KeepAliveConfigured</b>	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
<b>DataTtl</b>	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
<b>InSAFilterEnabled</b>	Activates the inbound SA filter for the peer.
<b>InSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
<b>OutSAFilterEnabled</b>	Activates the outbound SA filter for the peer.
<b>OutSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
<b>Description</b>	Specifies the text description, up to 255 characters, for the peer.
<b>SALimit</b>	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
<b>Md5AuthEnabled</b>	Activates MD5 authentication on the TCP connection between peers. The default is false.

Name	Description
<b>Md5AuthPassword</b>	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
<b>RemotePort</b>	Shows the remote port for the TCP connection between the MSDP peers.
<b>LocalPort</b>	Shows the local port for the TCP connection between the MSDP peers.
<b>OperEnabled</b>	Shows the operational status of the peer.
<b>RPFFailures</b>	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAs</b>	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAs</b>	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSARequests</b>	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSARequests</b>	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAResponses</b>	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAResponses</b>	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InControlMessages</b>	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
<b>OutControlMessages</b>	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InDataPackets</b>	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutDataPackets</b>	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>FsmEstablishedTransitions</b>	Shows the total number of times the BGP transitioned to the established state.
<b>FsmEstablishedTime</b>	Shows the time when the peer transitioned to the established state.
<b>InMessageTime</b>	Shows the time when the last MSDP message was received from the peer.
<b>ConnectionAttempts</b>	Shows the number of times the state machine has transitioned from inactive to connecting.
<b>DiscontinuityTime</b>	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
<b>AsNumber</b>	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
<b>TooShortMessages</b>	Shows the number of short messages received from this peer.
<b>InBadMessages</b>	Shows the number of bad MSDP messages received from this peer.

Name	Description
<b>InKeepAliveMessages</b>	Shows the number of keepalive messages received from this peer.
<b>OutKeepAliveMessages</b>	Shows the number of keepalive messages transmitted to this peer.
<b>SAsLearnedFromThisPeer</b>	Shows the total number of SAs learned from this peer.
<b>SAsAdvertisedToThisPeer</b>	Shows the total number of SAs advertised from this peer.
<b>UpOrDownTime</b>	Shows the duration a peer has been up or down.
<b>ConnAndStatsClearedTime</b>	Shows the duration of connection and statistics cleared.

### Delete an MSDP Peer

#### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. Select a row from the peer to delete.
5. Select **Delete**.
6. Select **Yes**.

### Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
<b>RemoteAddress</b>	Shows the IP address of the remote MSDP peer.
<b>State</b>	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
<b>AdminEnabled</b>	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
<b>ClearPeer</b>	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
<b>ConnectRetryInterval</b>	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.

Name	Description
<b>HoldTimeConfigured</b>	The default value is 75 seconds.
<b>KeepAliveConfigured</b>	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
<b>DataTtl</b>	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
<b>InSAFilterEnabled</b>	Activates the inbound SA filter for the peer.
<b>InSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
<b>OutSAFilterEnabled</b>	Activates the outbound SA filter for the peer.
<b>OutSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
<b>Description</b>	Specifies the text description, up to 255 characters, for the peer.
<b>SALimit</b>	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
<b>Md5AuthEnabled</b>	Activates MD5 authentication on the TCP connection between peers. The default is false.
<b>Md5AuthPassword</b>	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
<b>RemotePort</b>	Shows the remote port for the TCP connection between the MSDP peers.
<b>LocalPort</b>	Shows the local port for the TCP connection between the MSDP peers.
<b>OperEnabled</b>	Shows the operational status of the peer.

Name	Description
<b>RPFFailures</b>	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAs</b>	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAs</b>	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSARequests</b>	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSARequests</b>	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAResponses</b>	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAResponses</b>	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InControlMessages</b>	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutControlMessages</b>	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
<b>InDataPackets</b>	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutDataPackets</b>	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>FsmEstablishedTransitions</b>	Shows the total number of times the BGP transitioned to the established state.
<b>FsmEstablishedTime</b>	Shows the time when the peer transitioned to the established state.
<b>InMessageTime</b>	Shows the time when the last MSDP message was received from the peer.
<b>ConnectionAttempts</b>	Shows the number of times the state machine has transitioned from inactive to connecting.
<b>DiscontinuityTime</b>	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
<b>AsNumber</b>	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
<b>TooShortMessages</b>	Shows the number of short messages received from this peer.
<b>InBadMessages</b>	Shows the number of bad MSDP messages received from this peer.
<b>InKeepAliveMessages</b>	Shows the number of keepalive messages received from this peer.
<b>OutKeepAliveMessages</b>	Shows the number of keepalive messages transmitted to this peer.

Name	Description
<b>SAsLearnedFromThisPeer</b>	Shows the total number of SAs learned from this peer.
<b>SAsAdvertisedToThisPeer</b>	Shows the total number of SAs advertised from this peer.
<b>UpOrDownTime</b>	Shows the duration a peer has been up or down.
<b>ConnAndStatsClearedTime</b>	Shows the duration of connection and statistics cleared.

## MSDP Message Control using the EDM

This section provides procedures to configure MSDP message control using the EDM.

### *Filter PIM Routes*

Configure MSDP global filter for which the SA local cache are distributed to all MSDP peers. All SA local cache entries generate SA messages.

#### **Before You Begin**

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

#### **Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Globals** tab.
4. Select **RedistributeFilterEnabled**.
5. Type the name of the route policy in **RouteMapName**.
6. Select **RedistributeFilterApply** to apply the changes to the redistribute filter.

You do not need to apply the changes in the following situations:

- You create the redistribute filter without a route policy.
- You disable the redistribute filter.
- You remove a route policy from the redistribute filter.

7. Select **Apply**.

## Global field descriptions

Use the data in the following table to use the **Globals** tab.

Name	Description
<b>Enabled</b>	Enables MSDP. If you clear this check box, you disable MSDP. The default setting is clear (disabled).
<b>CacheLifetime</b>	Configures the lifetime given to SA cache entries when created or refreshed.
<b>NumSACacheEntries</b>	Displays the total number of entries in the SA cache.
<b>RPAddress</b>	Specifies the IP address to use as the originator ID. If the address is not a system local address, the system rejects the configuration.
<b>RouteMapName</b>	Specifies the name of the optional route policy to create or modify. You do not need to create a route policy to use the redistribution filter.  <b>Note:</b> To delete the route map name, clear the field and click <b>Apply</b> .
<b>RedistributeFilterEnabled</b>	Filters the (S,G,RP) entries provided by PIM to MSDP. The default is clear (disabled).
<b>RedistruteFilterApply</b>	Applies the changes made to the redistribute filter.
<b>StatsClear</b>	Clears MSDP statistics.

### Filter SA Messages

Filter SA messages to determine which SA messages to accept from a peer and which SA messages to send to a peer. By default, no inbound or outbound filter exists.

#### Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

#### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.
4. In the row for the peer, double-click **InSAFilterEnabled**, and then select true.
5. In the row for the peer, double-click **InSAFilterRouteMapName**, and then type the route map name for the IN SA Filter of the peer.

6. In the row for the peer, double-click **OutSAFilterEnabled**, and then select true.
7. In the row for the peer, double-click **OutSAFilterRouteMapName**, and then type the route map name for the OUT SA Filter of the peer.
8. Select **Apply**.

### Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
<b>RemoteAddress</b>	Shows the IP address of the remote MSDP peer.
<b>State</b>	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
<b>AdminEnabled</b>	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
<b>ClearPeer</b>	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
<b>ConnectRetryInterval</b>	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
<b>HoldTimeConfigured</b>	The default value is 75 seconds.
<b>KeepAliveConfigured</b>	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
<b>DataTtl</b>	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
<b>InSAFilterEnabled</b>	Activates the inbound SA filter for the peer.
<b>InSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.

Name	Description
<b>OutSAFilterEnabled</b>	Activates the outbound SA filter for the peer.
<b>OutSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
<b>Description</b>	Specifies the text description, up to 255 characters, for the peer.
<b>SALimit</b>	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0–6144; the default value is 6144.
<b>Md5AuthEnabled</b>	Activates MD5 authentication on the TCP connection between peers. The default is false.
<b>Md5AuthPassword</b>	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
<b>RemotePort</b>	Shows the remote port for the TCP connection between the MSDP peers.
<b>LocalPort</b>	Shows the local port for the TCP connection between the MSDP peers.
<b>OperEnabled</b>	Shows the operational status of the peer.
<b>RPFFailures</b>	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAs</b>	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAs</b>	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSARequests</b>	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
<b>OutSARequests</b>	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAResponses</b>	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAResponses</b>	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InControlMessages</b>	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutControlMessages</b>	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InDataPackets</b>	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutDataPackets</b>	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>FsmEstablishedTransitions</b>	Shows the total number of times the BGP transitioned to the established state.
<b>FsmEstablishedTime</b>	Shows the time when the peer transitioned to the established state.
<b>InMessageTime</b>	Shows the time when the last MSDP message was received from the peer.
<b>ConnectionAttempts</b>	Shows the number of times the state machine has transitioned from inactive to connecting.

Name	Description
<b>DiscontinuityTime</b>	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
<b>AsNumber</b>	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
<b>TooShortMessages</b>	Shows the number of short messages received from this peer.
<b>InBadMessages</b>	Shows the number of bad MSDP messages received from this peer.
<b>InKeepAliveMessages</b>	Shows the number of keepalive messages received from this peer.
<b>OutKeepAliveMessages</b>	Shows the number of keepalive messages transmitted to this peer.
<b>SAsLearnedFromThisPeer</b>	Shows the total number of SAs learned from this peer.
<b>SAsAdvertisedToThisPeer</b>	Shows the total number of SAs advertised from this peer.
<b>UpOrDownTime</b>	Shows the duration a peer has been up or down.
<b>ConnAndStatsClearedTime</b>	Shows the duration of connection and statistics cleared.

### *Configure the MSDP Mesh Groups*

Configure mesh groups to reduce SA flooding. A mesh group does not forward SA messages to other group members in the same mesh group. The originator, which is also a mesh group member, forwards SA messages to all group members. Create MSDP mesh groups from a group of meshed MSDP speakers from a domain. Do not create MSDP peerings between Controllers within the same SPB domain.

### Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Mesh Group** tab.
4. Select **Insert**.
5. In **Name**, type a name for the mesh group.
6. In **PeerAddress**, type the IP address of the peer to add the mesh group.
7. Select **Insert**.

### Mesh Group field descriptions

Use the data in the following table to use the **Mesh Group** tab.

Name	Description
<b>Name</b>	Specifies the mesh group ID; the name of the mesh group from 1-64 characters.
<b>PeerAddress</b>	Specifies the IP address of the MSDP router that is the peer.

### Clear the MSDP SA Cache

Clear the SA cache to clear the SA entries the router learns from all the peers or a specific peer.

### Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **SA-Cache** tab.
4. Select **Clear SA-Cache**.

### SA-Cache field descriptions

Use the data in the following table to use the **SA-Cache** tab.

Name	Description
<b>GroupAddr</b>	Shows the group IP address of the SA cache entry.
<b>SourceAddr</b>	Shows the source IP address of the SA cache entry.
<b>OriginRP</b>	Shows the RP address of the SA cache entry.
<b>PeerLearnedFrom</b>	Shows the peer from which this SA cache entry was accepted.
<b>RPFPeer</b>	Shows the peer from which an SA message corresponding to the cache entry is accepted.
<b>InSAs</b>	Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InDataPackets</b>	Shows the number of MSDP encapsulated data packets received that are relevant to this cache entry.
<b>UpTime</b>	Shows the time since this entry was first placed in the SA cache.
<b>ExpiryTime</b>	Shows the time remaining before this entry expires from the SA cache.

## MSDP Verification using the EDM

This section provides procedures to verify MSDP using the EDM.

### *View Peer Information*

#### **Before You Begin**

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

#### **Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Peers** tab.

## Peers field descriptions

Use the data in the following table to use the **Peers** tab.

Name	Description
<b>RemoteAddress</b>	Shows the IP address of the remote MSDP peer.
<b>State</b>	Shows the state of the default peer. An MSDP node only accepts SA messages from an operational default peer. Only one default peer can be operational; the configured default peers provide redundancy.
<b>AdminEnabled</b>	Changes the peer status to administratively enable or disable a configured peer. The default value is disabled (false).
<b>ClearPeer</b>	Clears the TCP connection to the specified MSDP peer and resets all MSDP message counters. The default value is disabled (false).
<b>ConnectRetryInterval</b>	Specifies the connection retry period, in seconds, for this peer. The default value is 30 seconds.
<b>HoldTimeConfigured</b>	The default value is 75 seconds.
<b>KeepAliveConfigured</b>	Specifies the keepalive period, in seconds, configured for this MSDP speaker with this peer. If the value is 0 seconds, no periodic keepalive messages are sent to the peer after the MSDP connection is established. The default value is 60 seconds.
<b>DataTtl</b>	Specifies the time-to-live value, from 1–255. The default value is 1, which means that the router forwards all SA messages with encapsulated data.
<b>InSAFilterEnabled</b>	Activates the inbound SA filter for the peer.
<b>InSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter accepts only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all inbound SA messages from this peer.
<b>OutSAFilterEnabled</b>	Activates the outbound SA filter for the peer.

Name	Description
<b>OutSAFilterRouteMapName</b>	Specifies the name of the route map. If you configure the route map name, the filter sends only the SA messages that meet the match criteria in the route map map-name with a permit keyword. If you do not configure the route map name, the system blocks all outbound SA messages from this peer.
<b>Description</b>	Specifies the text description, up to 255 characters, for the peer.
<b>SALimit</b>	Specifies the maximum number of SA messages from an MSDP peer to keep in the SA cache. The valid values are from 0-6144; the default value is 6144.
<b>Md5AuthEnabled</b>	Activates MD5 authentication on the TCP connection between peers. The default is false.
<b>Md5AuthPassword</b>	Specifies a case-sensitive password, up to 80 characters, for MD5 authentication.
<b>RemotePort</b>	Shows the remote port for the TCP connection between the MSDP peers.
<b>LocalPort</b>	Shows the local port for the TCP connection between the MSDP peers.
<b>OperEnabled</b>	Shows the operational status of the peer.
<b>RPFFailures</b>	Shows the number of SA messages received from this peer that failed the Peer-RPF check. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAs</b>	Shows the number of MSDP SA messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAs</b>	Shows the number of MSDP SA messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSARquests</b>	Shows the number of MSDP SA-Request messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.

Name	Description
<b>OutSARequests</b>	Shows the number of MSDP SA-Request messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InSAResponses</b>	Shows the number of MSDP SA-Response messages received on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutSAResponses</b>	Shows the number of MSDP SA-Response messages sent on this connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InControlMessages</b>	Shows the total number of MSDP messages received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutControlMessages</b>	Shows the total number of MSDP messages transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>InDataPackets</b>	Shows the total number of encapsulated packets received on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>OutDataPackets</b>	Shows the total number of encapsulated packets transmitted on this TCP connection. Discontinuities in the value of this counter can occur at reinitialization of the management system.
<b>FsmEstablishedTransitions</b>	Shows the total number of times the BGP transitioned to the established state.
<b>FsmEstablishedTime</b>	Shows the time when the peer transitioned to the established state.
<b>InMessageTime</b>	Shows the time when the last MSDP message was received from the peer.
<b>ConnectionAttempts</b>	Shows the number of times the state machine has transitioned from inactive to connecting.

Name	Description
<b>DiscontinuityTime</b>	Shows the sysUpTime value (the time, in hundredths of a second, since the network management portion of the system last reinitialized) when one or more of the counters for this entry suffered a discontinuity. Discontinuities can occur at peer connection establishment. If no discontinuities occurred since the last reinitialization of the local management subsystem, the value is zero.
<b>AsNumber</b>	Specifies the autonomous system number of the MSDP peer. A peer can appear to be in another autonomous system (other than the one in which it really resides) if you use an MSDP peering session but do not use a Border Gateway Protocol peer session with that peer. If another autonomous system injects the prefix of the peer, the system displays the prefix as the autonomous system number of the peer.
<b>TooShortMessages</b>	Shows the number of short messages received from this peer.
<b>InBadMessages</b>	Shows the number of bad MSDP messages received from this peer.
<b>InKeepAliveMessages</b>	Shows the number of keepalive messages received from this peer.
<b>OutKeepAliveMessages</b>	Shows the number of keepalive messages transmitted to this peer.
<b>SAsLearnedFromThisPeer</b>	Shows the total number of SAs learned from this peer.
<b>SAsAdvertisedToThisPeer</b>	Shows the total number of SAs advertised from this peer.
<b>UpOrDownTime</b>	Shows the duration a peer has been up or down.
<b>ConnAndStatsClearedTime</b>	Shows the duration of connection and statistics cleared.

#### *View the Local SA Cache*

View the local SA cache to display the (S, G) state the router learns from local Protocol Independent Multicast - Sparse Mode (PIM-SM) entries.

#### **Before You Begin**

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **SA-Cache-Records** tab.

### SA-Cache-Records field descriptions

Use the data in the following table to use the **SA-Cache-Records** tab.

Name	Description
<b>TypeInformation</b>	Shows the SA cache type. The SA cache type can be local or foreign cache.
<b>GroupAddr</b>	Shows the group IP address of the SA cache entry.
<b>SourceAddr</b>	Shows the source IP address of the SA cache entry.
<b>OriginRP</b>	Shows the RP address of the SA cache entry.
<b>OriginatorAsNumber</b>	Shows the AS number of the originator.
<b>RouteType</b>	Shows the type of route used for Reverse Path Forwarding checking. The value can be rip (1), ospf (2), static (3), bgp (4), isis(5) or none (6).

### *View the Foreign SA Cache*

View the foreign SA cache to display the (S, G) state the router learns from SA messages.

### Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **SA-Cache-Records** tab.

### SA-Cache-Records field descriptions

Use the data in the following table to use the **SA-Cache-Records** tab.

Name	Description
<b>TypeInformation</b>	Shows the SA cache type. The SA cache type can be local or foreign cache.
<b>GroupAddr</b>	Shows the group IP address of the SA cache entry.
<b>SourceAddr</b>	Shows the source IP address of the SA cache entry.
<b>OriginRP</b>	Shows the RP address of the SA cache entry.
<b>OriginatorAsNumber</b>	Shows the AS number of the originator.
<b>RouteType</b>	Shows the type of route used for Reverse Path Forwarding checking. The value can be rip (1), ospf (2), static (3), bgp (4), isis(5) or none (6).

#### *View the Mesh Group*

Configure Message Digest (MD) 5 authentication to secure control messages on the TCP connection between MSDP peers.

#### Before You Begin

To perform this procedure on a non-default VRF, you must first change the VRF instance. For information about how to use EDM for a non-default VRF, see [Select and Launch a VRF Context View](#) on page 4203. All parameters might not be available in non-default VRFs.

#### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Select **MSDP**.
3. Select the **Mesh Group** tab.

### Mesh Group field descriptions

Use the data in the following table to use the **Mesh Group** tab.

Name	Description
<b>Name</b>	Specifies the mesh group ID; the name of the mesh group from 1-64 characters.
<b>PeerAddress</b>	Specifies the IP address of the MSDP router that is the peer.

## Controller configuration

This section provides procedures to configure the Controller using Command Line Interface (CLI) and Enterprise Device Manager (EDM).

The Controller functionality is configured at the global (switch-wide) level.

### Controller Configuration using the CLI

This section provides procedures to configure controller using the command line interface (CLI).

#### Enabling the Controller

Enable the Controller globally.

#### Procedure

1. Enter IS-IS Router Configuration mode:

```
enable
configure terminal
router isis
```

2. Enable the Controller globally:

```
spbm <1-100> multicast spb-pim-gw controller enable
```

#### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 multicast spb-pim-gw controller enable
```

#### Variable definitions

The following table defines parameters for the **spb** command.

Variable	Value
<1-100>	Specifies the isis spbm instance-id to create the spbm instance.
<i>controller enable</i>	Enables the SPB-PIM Gateway Controller.

#### Displaying the Controller admin status

Use the following procedure to display the admin status of the Controller.

#### Procedure

1. To enter User EXEC mode, log on to the switch.

## 2. Display the Controller Status:

```
show isis spbm
```

**Example****Note**

The SPB-PIM-GW column displays either Controller, Gateway, or Controller/Gateway if the Controller and or Gateway functionality is configured.

```
Switch:1>show isis spbm

*Displaying the active Controller and Gateway Nodes*

Use the following procedure to display the active Controllers and Gateways in the SPBM domain.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway active Controller and Gateway Nodes:  

```
show ip spb-pim-gw node [controller | gateway] [spb-node-as-mac]
```

**Example**

Display all node lists:

```
Switch:1>show ip spb-pim-gw node
```

```

=====
                               Spb-pim-gw Active Controller/Gateway
=====
HOST-NAME      Role
-----
BEB3-4037      Gateway
BEB5-4011      Controller

Total Number of Nodes = 2/2
=====
    
```

Display Controller node lists only:

```

Switch:1>show ip spb-pim-gw node controller

=====
                               Spb-pim-gw Active Controller/Gateway
=====
HOST-NAME      Role
-----
BEB5-4011      Controller

Total Number of Nodes = 1/2
=====
    
```

Display Gateway node lists only:

```

Switch:1>show ip spb-pim-gw node gateway

=====
                               Spb-pim-gw Active Controller/Gateway
=====
HOST-NAME      Role
-----
BEB3-4037      Gateway

Total Number of Nodes = 1/2
=====
    
```

Display all node lists with MAC address:

```

Switch:1>show ip spb-pim-gw node spb-node-as-mac

=====
                               Spb-pim-gw Active Controller/Gateway

Total Number of Nodes = 1/2
-----

```

### Configuring a static foreign source on the global router

Configure a static foreign source on the global router. Configuration is done at the Controller. Statically configure foreign sources, such as streams in a Source Specific Multicast (SSM) group range that are not advertised by the foreign network through MSDP. Non-SSM range group multicast address streams are advertised by MSDP and do not need to be statically configured.

#### Procedure

1. Enter Global Configuration mode:
 

```
enable
```

```
configure terminal
```
2. Configure a static foreign source:
 

```
ip spb-pim-gw foreign-source {A.B.C.D} group {A.B.C.D}
```

#### Example

```
Switch:1>enable
```

```
Switch:1#configure terminal
```

```
Switch:1(config)#ip spb-pim-gw foreign-source 10.0.0.1 group 240.0.0.1
```

#### Variable definitions

The following table defines parameters for the **ip spb-pim-gw** command.

Variable	Value
<code>foreign-source {A.B.C.D}</code>	Specifies the multicast foreign source IP address.
<code>group {A.B.C.D}</code>	Specifies the group IP address.

*Configuring a static foreign source on a VRF*

Configure a static foreign source on a VRF, configuration is done at the Controller.

**Procedure**

1. Enter VRF Router Configuration mode for a specific VRF context:

```
enable

configure terminal

router vrf WORD<1-16>
```

2. Configure a static foreign source:

```
ip spb-pim-gw foreign-source {A.B.C.D} group {A.B.C.D}
```

**Example**

In the following example, vrf-10 is configured with vrf id 10.

```
Switch:1>enable

Switch:1#configure terminal

Switch:1(config)#router vrf vrf-10

Switch:1(router-vrf)#ip spb-pim-gw foreign-source 10.0.0.1 group
240.0.0.1
```

**Variable definitions**

The following table defines parameters for the **ip spb-pim-gw** command.

Variable	Value
<i>foreign-source</i> {A.B.C.D}	Specifies the multicast foreign source IP address.
<i>group</i> {A.B.C.D}	Specifies the group IP address.

*Displaying foreign sources*

Use the following procedure to display the foreign sources learned from MSDP or statically configured at the Controller.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the foreign source information:

```
show ip spb-pim-gw foreign-source [all] [controller | gateway] [vrf
WORD<0-16>] [vrfids WORD<0-512>] [source {A.B.C.D}] [group {A.B.C.D}]
[static | msdp] [spb-node-as-mac]
```

## Example

### Note

The command **show ip spb-pim-gw**, which specifies the parameter *controller*, the OWNER column displays the RP address of the MSDP peer from which the foreign source was learned. If the *gateway* parameter is specified, then the OWNER column displays MSDP rather than the actual RP address.

```
Switch:1>show ip spb-pim-gw foreign-source controller
=====
==
SPB-PIM-GW Controller Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF      OWNER
-----
--
10.0.0.1    240.0.0.1  beeb-1          GlobalRouter 47.17.0.1
10.0.0.2    240.0.0.2  beeb-1          GlobalRouter static
10.0.0.3    240.0.0.3  -               GlobalRouter 47.17.0.2
-----
--
```

Display the foreign sources from a specific VRF:

```
Switch:1>show ip spb-pim-gw foreign-source controller vrf green
=====
==
SPB-PIM-GW Controller Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF      OWNER
-----
--
10.0.0.1    240.0.0.1  beeb-1          green    47.17.0.1
10.0.0.2    240.0.0.2  beeb-1          green    static
10.0.0.3    240.0.0.3  -               green    47.17.0.2
-----
--
```

Display all the foreign sources at the Controller with the Gateway in the SPB-PIM-GW shown as a mac address rather than a nickname:

```
Switch:1>show ip spb-pim-gw foreign-source controller vrf green spb-node-as-mac
=====
==
SPB-PIM-GW Controller Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF      OWNER
-----
--
10.0.0.1    240.0.0.1  00:0b:eb:00:00:a1 green    47.17.0.1
10.0.0.2    240.0.0.2  00:0b:eb:00:00:a1 green    static
10.0.0.3    240.0.0.3  -               green    47.17.0.2
-----
--
```

### Variable definitions

The following table defines parameters for the `show ip spb-pim-gw foreign source` command.

Variable	Value
<code>all</code>	Displays information for all the VRF IDs from the Controller and Gateway foreign source database.
<code>controller</code>	Displays information from the Controller foreign source database. Only displays information on nodes configured as Controller.
<code>gateway</code>	Displays information from the Gateway foreign source database. Only displays information on nodes configured as Gateway.
<code>vrf WORD&lt;0-16&gt;</code>	Displays information from the Controller foreign source database for a specific VRF name.
<code>vrfids WORD&lt;0-512&gt;</code>	Displays information from the Controller foreign source database for a range of VRF IDs.  <b>Note:</b> Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.
<code>source {A.B.C.D}</code>	Displays information for the specific source IP address from the Controller foreign source database.
<code>group {A.B.C.D}</code>	Displays information for the specific multicast group IP address from the Controller foreign source database.
<code>static</code>	Displays information from the Controller foreign source database that is configured statically.
<code>msdp</code>	Displays information from the Controller foreign source database that is learned through MSDP.
<code>spb-node-as-mac</code>	Displays the MAC address for the assigned SPB-PIM Gateway.

### Displaying Multicast over Fabric Connect sources

Use the following procedure to display all the SPB Multicast over Fabric Connect sources distributed to MSDP. This procedure is only valid on a Controller node.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB source information:

```
show ip spb-pim-gw spbmc-source [vrf WORD<1-32>] [vrffids WORD<0-512>]
[source {A.B.C.D}] [group {A.B.C.D}] [originator WORD<1-32>] [spb-
node-as-mac]
```

## Example

```
Switch:1>show ip spb-pim-gw spbmc-source
```

```
=====
==
SPB-PIM-GW SPB Source
=====
==
SOURCE          GROUP          VRF          ORIGINATOR
-----
--
10.0.0.1        240.0.0.1     GlobalRouter bcb-1
10.0.0.2        240.0.0.2     GlobalRouter bcb-2
10.0.0.3        240.0.0.3     GlobalRouter bcb-2
-----
--
```

Display the SPB Multicast over Fabric Connect from a specific VRF:

```
Switch:1>show ip spb-pim-gw spbmc-source vrf green
```

```
=====
SPB-PIM-GW Foreign Source
=====

10.0.0.3        240.0.0.3     green        00:0b:cb:00:00:c2
-----
---
```

## Variable definitions

The following table defines parameters for the `show ip spb-pim-gw spbmc-source` command.

Variable	Value
<code>vrf WORD&lt;1-32&gt;</code>	Displays SPB originated sources for a specific VRF.
<code>vrfids WORD&lt;0-512&gt;</code>	Displays SPB originated sources for a range of VRF IDs.  <b>Note:</b> Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.
<code>source {A.B.C.D}</code>	Displays information for a specific source IP address from SPB originated sources database.
<code>group {A.B.C.D}</code>	Displays information for a specific multicast group IP address from SPB originated sources database.
<code>originator WORD&lt;0-32&gt;</code>	Displays information for a specific originator host name from SPB originated sources database.
<code>spb-node-as-mac</code>	Displays the originator of SPB originated sources as a MAC address rather than a nickname.

## Controller Configuration using the EDM

This section provides procedures to configure controller using the EDM.

### Enabling the Controller

Enable the Controller globally.

#### Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. In the row for the SPBM, double click the **McastSpbPimGwControllerEnable** field, and then select true.
4. Select **Apply**.

**SPBM field descriptions**

Use the data in the following table to use the **SPBM** tab.

Name	Description
<b>McastSpbPimGwControllerEnable</b>	Enables or disables the ISIS multicast SPM-PIM Gateway Controller node.
<b>McastSpbPimGWGatewayEnable</b>	Enables or disables the ISIS multicast SPM-PIM Gateway node.

*Displaying the Controller and Gateway admin status*

Use the following procedure to display the admin status of the Controller and Gateway.

**Procedure**

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. Select the **SPBM** tab.

*Displaying active Controller and Gateway nodes*

Use the following procedure to display the active Controllers and Gateways in the SPBM domain.

**Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Node** tab.

**Node field descriptions**

Use the data in the following table to use the **Node** tab.

Name	Description
<b>MacAddress</b>	Shows the MAC address of the active node.
<b>HostName</b>	Shows the host name of the active node.
<b>RoleType</b>	Shows the role of the active node: either gateway, controller, or both.

*Configuring a static foreign source globally*

Configure a static foreign source on the global router. Configuration is done at the Controller.

**Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Controller-Foreign-Source** tab.

4. Click **Insert**.
5. In the **SourceAddress** box, type the multicast foreign source IP address.
6. In the **GroupAddress** box, type the group IP address.
7. Click **Insert**.

#### Controller-Foreign-Source field descriptions

Use the data in the following table to use the **Controller-Foreign-Source** tab.

Name	Description
<b>SourceAddress</b>	Specifies the source IP address from a foreign multicast domain.
<b>GroupAddress</b>	Specifies the multicast group IP address associated with the foreign source.
<b>GatewaySysId</b>	Displays the system ID of the node selected as the Gateway for this foreign source. <b>GatewaySysId</b> field will have a valid value if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is 0.
<b>GatewayHostName</b>	Displays the host name of the node selected as the Gateway for this foreign source. <b>GatewayHostName</b> field will have valid values if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is NULL.
<b>Type</b>	Displays the owner type for this source.
<b>Owner</b>	Displays the IP address of the MSDP peer if the foreign source is MSDP.

#### Configuring a static foreign source on a VRF

Configure a static foreign source on a VRF. Configuration is done at the Controller.

##### Procedure

1. In the navigation pane, expand **Configuration > VRF Context View**.
2. Click **Set VRF Context view**.
3. Select a row and click **Launch VRF Context view**.
4. Select a switch port in the **Device Physical View** tab.
5. In the navigation pane, expand **Configuration > IP**.
6. Click **SPB-PIM-GW**.
7. Click the **Controller-Foreign-Source** tab.
8. Click **Insert**.
9. In the **SourceAddress** box, type the multicast foreign source IP address.
10. In the **GroupAddress** box, type the group IP address.
11. Click **Insert**.

**Controller-Foreign-Source field descriptions**

Use the data in the following table to use the **Controller-Foreign-Source** tab.

Name	Description
<b>SourceAddress</b>	Specifies the source IP address from a foreign multicast domain.
<b>GroupAddress</b>	Specifies the multicast group IP address associated with the foreign source.
<b>GatewaySysId</b>	Displays the system ID of the node selected as the Gateway for this foreign source. <b>GatewaySysId</b> field will have a valid value if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is 0.
<b>GatewayHostName</b>	Displays the host name of the node selected as the Gateway for this foreign source. <b>GatewayHostName</b> field will have valid values if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is NULL.
<b>Type</b>	Displays the owner type for this source.
<b>Owner</b>	Displays the IP address of the MSDP peer if the foreign source is MSDP.

*Displaying foreign sources*

Use the following procedure to display the foreign sources learned from MSDP or statically configured at the Controller.

**Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Controller-Foreign-Source** tab.

**Controller-Foreign-Source field descriptions**

Use the data in the following table to use the **Controller-Foreign-Source** tab.

Name	Description
<b>SourceAddress</b>	Specifies the source IP address from a foreign multicast domain.
<b>GroupAddress</b>	Specifies the multicast group IP address associated with the foreign source.
<b>GatewaySysId</b>	Displays the system ID of the node selected as the Gateway for this foreign source. <b>GatewaySysId</b> field will have a valid value if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is 0.

Name	Description
<b>GatewayHostName</b>	Displays the host name of the node selected as the Gateway for this foreign source. <b>GatewayHostName</b> field will have valid values if the Gateway is assigned to a source. If the Gateway is not assigned to a source the value is NULL.
<b>Type</b>	Displays the owner type for this source.
<b>Owner</b>	Displays the IP address of the MSDP peer if the foreign source is MSDP.

### *Displaying Multicast over Fabric Connect sources*

Use the following procedure to display all the SPB Multicast over Fabric Connect sources distributed to MSDP.

#### **Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **spbm-source** tab.

#### **Spbmc-Source field descriptions**

Use the data in the following table to use the **Spbmc-Source** tab.

Name	Description
<b>SourceAddress</b>	Displays the source IP address from SPBM multicast domain.
<b>GroupAddress</b>	Displays the multicast group IP address associated with the SPBM source.
<b>OriginatorSysId</b>	Displays the system ID of the node from which the source originates.
<b>OriginatorHostName</b>	Displays the host name of the node from which the source originates.

## Gateway configuration

This section provides procedures to configure the Gateway using Command Line Interface (CLI) and Enterprise Device Manager (EDM).

The Gateway functionality is configured at the global (switch-wide) level. SPB-PIM Gateway Interfaces are configured at the interface level. For more information on SPB-PIM Gateway Interfaces configuration, see [SPB-PIM Gateway interface configuration](#) on page 3586.

## Gateway Configuration using the CLI

This section provides procedures to configure gateway using the command line interface (CLI).

### Enabling the Gateway

Enable the Gateway at the global (switch-wide) level.

#### Procedure

1. Enter IS-IS Router Configuration mode:  

```
enable

configure terminal

router isis
```
2. Enable the Gateway globally:  

```
spbm <1-100> multicast spb-pim-gw gateway enable
```

#### Example

```
Switch:1>enable

Switch:1#configure terminal

Switch:1(config)#router isis

Switch:1(config-isis)#spbm 1 multicast spb-pim-gw gateway enable
```

### Variable definitions

The following table defines parameters for the **spb** command.

Variable	Value
<1-100>	Specifies the isis spbm instance-id to create the spbm instance.
<i>gateway enable</i>	Enables the SPB-PIM Gateway.

### Displaying the Gateway admin status

Use the following procedure to display the admin status of the Gateway.

#### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the Gateway admin status:  

```
show isis spbm
```

#### Example

```
Switch:1>show isis spbm
```

```

*Displaying foreign sources information*

Use the following procedure to display the Gateway foreign sources database. If executed on a Gateway node, it displays the foreign sources assigned to the Gateway by the Controller. Foreign sources are originally learned from MSDP or statically configured on the Controller.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the foreign sources information:

```
show ip spb-pim-gw foreign-source [all] [controller | gateway] [vrf
WORD<0-16>] [vrfids WORD<0-512>] [source {A.B.C.D}] [group {A.B.C.D}]
[from-controller <0x00:0x00:0x00:0x00:0x00:0x00> | preferred][static |
msdp] [spb-node-as-mac]
```

**Example**

```
Switch:1>show ip spb-pim-gw foreign-source gateway
=====
==
SPB-PIM-GW Gateway Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF          PORT  VLAN  CONTROLLER      OWNER
-----
--
10.0.0.1    240.0.0.1  beb-2           GlobalRouter 1/1    200   bcb-2           msdp
10.0.0.2    240.0.0.2  beb-2           GlobalRouter 1/1    200   bcb-2           static
10.0.0.3    240.0.0.3  beb-2           GlobalRouter -     -     bcb-2           msdp
-----
--
```

**Note**

The SPB-PIM-GW column displays the node that is selected as the Gateway for the particular source or group stream. The OWNER column displays either msdp or static depending on how the source was originally learned at the assigning Controller. The PORT and VLAN columns represent the port or VLAN toward the source.

Display the foreign sources from a specific VRF:

```
Switch:1>show ip spb-pim-gw foreign-source gateway vrf green
=====
==
SPB-PIM-GW Gateway Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF          PORT  VLAN  CONTROLLER      OWNER
-----
--
10.0.0.1    240.0.0.1  beb-2           green        1/1    200   bcb-2           msdp
10.0.0.2    240.0.0.2  beb-2           green        1/1    200   bcb-2           static
10.0.0.3    240.0.0.3  beb-2           green        -     -     bcb-2           msdp
-----
--
```

Display all the foreign sources available at the Gateway with SPB-PIM-GW and Controller as mac:

```
Switch:1>show ip spb-pim-gw foreign-source gateway vrf green spb-node-as-mac
=====
==
SPB-PIM-GW Gateway Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF      PORT  VLAN  CONTROLLER      OWNER
-----
--
10.0.0.1    240.0.0.1  00:0b:eb:00:00:a2 green    1/1    200   00:0b:cb:00:00:c2 msdp
10.0.0.2    240.0.0.2  00:0b:eb:00:00:a2 green    1/1    200   00:0b:cb:00:00:c2 static
10.0.0.3    240.0.0.3  00:0b:eb:00:00:a2 green    -      -     00:0b:cb:00:00:c2 msdp
-----
--
```

Display all the foreign sources available at the Gateway which are statically configured at the Controller:

```
Switch:1>show ip spb-pim-gw foreign-source gateway vrf green static
=====
==
SPB-PIM-GW Gateway Foreign Source
=====
==
SOURCE      GROUP      SPB-PIM-GW      VRF      PORT  VLAN  CONTROLLER      OWNER
-----
--
10.0.0.2    240.0.0.2  beb-2           green    1/1    200   bcb-2           static
-----
--
```

**Variable definitions**

The following table defines parameters for the **show ip spb-pim-gw foreign source** command.

Variable	Value
<i>all</i>	Displays information for all the VRF IDs from the Controller and Gateway foreign source database.
<i>controller</i>	Displays information from the Controller foreign source database. Only displays information on nodes configured as Controller.
<i>gateway</i>	Displays information from the Gateway foreign source database. Only displays information on nodes configured as Gateway.
<i>vrf WORD&lt;0-16&gt;</i>	Displays information from the Gateway foreign source database for a specific VRF name.

Variable	Value
<code>vrfids WORD&lt;0-512&gt;</code>	Displays information from the Gateway foreign source database for a range of VRF IDs.  <b>Note:</b> Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.
<code>source {A.B.C.D}</code>	Displays information for the specific source IP address from the Gateway foreign source database.
<code>group {A.B.C.D}</code>	Displays information for the specific multicast group IP address from the Gateway foreign source database.
<code>from-controller 0x00:0x00:0x00:0x00:0x00:0x00</code>	Displays information filtering on a specific Controllers assignments, where the Controller is specified as a mac address.
<code>from-controller preferred</code>	Displays information from Gateway source database filtering on a preferred Controller or chosen by the Gateway.
<code>static</code>	Displays information from the Gateway foreign source database that is configured statically at the assigning Controller.
<code>msdp</code>	Displays information from the Gateway foreign source database that is learned through MSDP.
<code>spb-node-as-mac</code>	Displays the MAC address for the assigned PIM-GW.

## Gateway Configuration using the EDM

This section provides procedures to configure gateway using the EDM.

### Enabling the Gateway globally

Use this procedure to enable the Gateway at the global (switch-wide) level.

#### Procedure

1. In the navigation pane, expand **Configuration > Fabric**.
2. Select **SPBM**.
3. In the row for the SPMB, double click the **McastSpbPimGwGatewayEnable** field, and then select true.
4. Select **Apply**.

**SPBM field descriptions**

Use the data in the following table to use the **SPBM** tab.

Name	Description
<b>McastSpbPimGwControllerEnable</b>	Enables or disables the ISIS multicast SPM-PIM Gateway Controller node.
<b>McastSpbPimGWGatewayEnable</b>	Enables or disables the ISIS multicast SPM-PIM Gateway node.

*Displaying foreign sources*

Use the following procedure to display the Gateway foreign source database. Foreign sources are originally learned from MSDP or statically configured on the Controller.

**Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Gateway-Foreign-Source** tab.

**Gateway-Foreign-Source field descriptions**

Use the data in the following table to use the **Gateway-Foreign-Source** tab.

Name	Description
<b>SourceAddress</b>	Displays the foreign source IP address.
<b>GroupAddress</b>	Displays the multicast group IP address associated with the foreign source.
<b>ControllerSysId</b>	Displays the system ID of the controller node that sends this foreign source.
<b>ControllerHostName</b>	Displays the host name of the controller node that sends this foreign source.
<b>GatewaySysId</b>	Displays the system ID of the node selected as the gateway for this foreign source.
<b>GatewayHostName</b>	Displays the host name of the node selected as the gateway for this foreign source.
<b>InVid</b>	Displays the VLAN ID of the SPB-PIM Gateway interface through which the source of this source is reachable.
<b>InPort</b>	Displays the physical interface through which the source of this source is reachable.
<b>OwnerType</b>	Displays if the owner is MSDP or static.

## SPB-PIM Gateway interface configuration

---

This section provides procedures to configure the SPB-PIM Gateway interface using the Command Line Interface (CLI) and Enterprise Device Manager (EDM).

The SPB-PIM Gateway interface is either a VLAN or a Brouter port interface. An SPB-PIM Gateway interface is configured separately from the global (switch-wide) Gateway functionality. The global Gateway configuration does not affect the administrative or the operational state of the SPB-PIM Gateway interfaces which function independently. However, the Gateway node functionality works in conjunction with the Gateway Interface functionality. Configure SPB-PIM Gateway on an interface that connects to a router in a foreign PIM or SPB multicast domain.

### SPB-PIM Gateway Interface Configuration using the CLI

This section provides procedures to configure SPB-PIM gateway interface using the command line interface (CLI).

#### *Enabling SPB-PIM Gateway on a VLAN*

Enable SPB-PIM Gateway on a VLAN interface.

#### **Procedure**

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Enable SPB-PIM Gateway on a VLAN:

```
ip spb-pim-gw enable
```

#### **Note**

SPB-PIM Gateway cannot be enabled under the following circumstances:

- If the IP interface does not exist on the VLAN. An IP Address must first be configured on the VLAN.
- If the **spbm\_config\_mode** boot flag is set to false.
- If the VLAN is configured with a circuitless IP.
- If the interface is a management VLAN.
- If **ip igmp snooping** is enabled.
- If the spb-multicast is enabled on the VLAN.
- If the VLAN has SMLT ports.
- If the VLAN has an i-sid configured.
- If the VLAN is a vIST VLAN.

*Enabling SPB-PIM Gateway on a brouter port interface*

Enable SPB-PIM Gateway on a brouter port.

**Procedure**

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

**Note**

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.

2. Enable SPB-PIM Gateway on a brouter port:

```
ip spb-pim-gw enable
```

**Note**

SPB-PIM Gateway cannot be enabled under the following circumstances:

- If the IP interface is not configured using the **brouter** command
- If the IP interface does not exist on the brouter port
- If the **spbm\_config\_mode** boot flag is set to false
- If **ip igmp snooping** is enabled
- If the spb-multicast is enabled on the brouter port
- If the brouter port is part of an SMLT or vIST Vlan
- If the brouter port has an i-sid configured

*Configuring the SPB-PIM Gateway VLAN optional parameters*

Configure the SPB-PIM Gateway interface parameters on a VLAN.

**Procedure**

1. Enter VLAN Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface vlan <1-4059>
```

2. Configure the SPB-PIM Gateway VLAN HELLO interval:

```
ip spb-pim-gw hello-interval <0-18724>
```

3. Configure the SPB-PIM Gateway VLAN JOIN PRUNE interval:

```
ip spb-pim-gw ip join-prune-interval <1-18724>
```

## Variable definitions

The following table defines parameters for the `ip spb-pim-gw` command.

Variable	Value
<code>hello-interval&lt;0-18724&gt;</code>	Specifies the HELLO interval in seconds. The default value is 30 seconds.
<code>join-prune-interval&lt;1-18724&gt;</code>	Specifies the JOIN PRUNE interval in seconds. The default value is 60 seconds.

### Configuring the SPB-PIM Gateway router port optional parameters

Configure the SPB-PIM Gateway interface parameters on a router port.

#### Procedure

1. Enter GigabitEthernet Interface Configuration mode:

```
enable
```

```
configure terminal
```

```
interface GigabitEthernet {slot/port[/sub-port] [-slot/port[/sub-port]]
[,...]}
```

#### Note

If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format `slot/port/sub-port`.

2. Configure the SPB-PIM Gateway router port HELLO interval:

```
ip spb-pim-gw hello-interval <0-18724>
```

3. Configure the SPB-PIM Gateway router port JOIN PRUNE interval:

```
ip spb-pim-gw join-prune-interval <1-18724>
```

## Variable definitions

The following table defines parameters for the `ip spb-pim-gw` command.

Variable	Value
<code>hello-interval&lt;0-18724&gt;</code>	Specifies the HELLO interval in seconds. The default value is 30 seconds.
<code>join-prune-interval&lt;1-18724&gt;</code>	Specifies the JOIN PRUNE interval in seconds. The default value is 60 seconds.

### Displaying the SPB-PIM Gateway interface default values

Use the following procedure to display the default values used for the SPB-PIM Gateway interface HELLO and JOIN PRUNE intervals unless specifically configured on the individual interface.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway interface default values:

```
show ip spb-pim-gw
```

## Example

```
Switch:1>show ip spb-pim-gw
=====
                        Spb-pim-gw General Group
=====
Hello Interval           : 30
Join-Prune Interval      : 60
```

### Displaying the SPB-PIM Gateway brouter port information

Use the following procedure to display the SPB-PIM Gateway brouter port information. This procedure displays the administrative (configured) state of the interface as well as the operational state, and the HELLO and JOIN PRUNE intervals. An interface can be administratively ENABLED but operationally DISABLED if, for example, mvpn is not enabled on the VRF, or **spbm <spbm-instance> multicast enable** is not configured.

## Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway interface information:

```
show ip spb-pim-gw interface [gigabitethernet {slot/port[/sub-port]} [-
slot/port[/sub-port]] [,...]]] [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

## Example

```
Switch:1#show ip spb-pim-gw interface gigabitethernet 1/2
=====
                        Port Ip Spb-pim-gw
=====
ORT-NUM  OPSTATE    ADMINSTATE  HELLOINT  JPINT
=====
1/2      Disabled    Enabled     30        60
```

**Variable definitions**

The following table defines parameters for the **show ip spb-pim-gw interface** gigabit command.

Variable	Value
<code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code>	Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.
<code>vrf WORD&lt;1-16&gt;</code>	Displays SPB-PIM Gateway interface information for a specific VRF.
<code>vrfids WORD&lt;0-512&gt;</code>	Displays SPB-PIM Gateway interface information for a range of VRF IDs.  <b>Note:</b> Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.

*Displaying the SPB-PIM Gateway VLAN information*

Use the following procedure to display the SPB-PIM Gateway VLAN interface information.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway VLAN interface information:

```
show ip spb-pim-gw interface [vlan]
```

**Example**

```
Switch:1>show ip spb-pim-gw interface
=====
===
                               Spb-pim-gw Interface - GlobalRouter
=====
===
IF          ADDR          MASK          JPINT    HELLOINT  OPSTATE  ADMINSTATE
Vlan50     50.1.1.1      255.255.255.0  60       30        Disabled Enabled
Vlan123    123.1.1.1     255.255.255.0  60       30        Disabled Disabled
Vlan142    142.1.1.1     255.255.255.0  60       30        Enabled  Enabled
Vlan400    100.1.1.2     255.255.255.0  60       30        Disabled Disabled

Total spb-pim-gw Interfaces Displayed 4/4
```

**Variable definitions**

The following table defines parameters for the **show ip spb-pim-gw interface** command.

Variable	Value
vlan-id	The VLAN ID of an interface to display.

*Displaying the SPB-PIM Gateway neighbor information*

Use the following procedure to display the SPB-PIM Gateway interfaces neighbor information.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway neighbor information:

```
show ip spb-pim-gw neighbor [vrf WORD<1-16>] [vrfids WORD<0-512>]
```

**Example**

```
Switch:1>show ip spb-pim-gw neighbor
=====
                        Spb-pim-gw Neighbor - GlobalRouter
=====
INTERFACE ADDRESS      UPTIME                EXPIRE
Vlan26      26.1.1.10            0 day(s), 00:11:36    0 day(s), 00:01:28

Total SPB-PIM-GW Neighbors Displayed = 1/1
=====
```

**Variable definitions**

The following table defines parameters for the **show ip spb-pim-gw neighbor** command.

Variable	Value
vrf WORD<1-16>	Displays the SPB-PIM Gateway interface neighbor information for a specific VRF name.
vrfids WORD<0-512>	Displays the SPB-PIM Gateway interface neighbor information for a range of VRF IDs.  <b>Note:</b> Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.

*Displaying the SPB-PIM Gateway multicast routes*

Use the following procedure to display the SPB-PIM Gateway multicast routes. This procedure displays upstream (toward the foreign source) information and downstream

(receiver) information on the SPB-PIM Gateway interfaces. This command does not display the following information:

- Upstream information for streams ingressing on spb-multicast interfaces
- Upstream information for streams ingressing from a remote SPB node
- Receivers in spb-multicast interfaces

Use the **show isis spbm ip-multicast-route** command to display information on all multicast streams and the multicast streams ingress interfaces and egress interfaces.

Use the **show ip spb-pim-gw mroute** command to display information only on SPB-PIM Gateway interfaces.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display the SPB-PIM Gateway multicast routes:

```
show ip spb-pim-rw mroute [source {A.B.C.D}] [group {A.B.C.D}] [vrf
WORD<1-16>] [vrfrids WORD<0-512>]
```

### Example

#### Note

The **show ip spb-pim-gw mroute** command displays active upstream information and active downstream information per (\*,g) and (s,g) per port, which includes \*G Join or Prune pending state, SG join or prune pending state, and SG Rpt PRUNE or PRUNE pending state.. There can be upstream information for a specific SG and no downstream, and vice-versa, as the information in the command **show ip spb-pim-gw mroute** reflects only information known on the SPB-PIM Gateway interfaces. For example, there might be downstream receivers on a SPB-PIM Gateway Interface for a particular stream which is ingressing on an spb-multicast interface; thus, the upstream information will not be displayed using this command.

```
Switch:1>show ip spb-pim-gw mroute
=====
                Spb-pim-gw Active PIM Multicast Route - GlobalRouter

```

**Variable definitions**

The following table defines parameters for the **show ip spb-pim-gw mroute** command.

Variable	Value
<i>vrf</i> WORD<1-16>	Displays the SPB-PIM Gateway mroute information for a specific VRF name.
<i>vrfids</i> WORD<0-512>	Displays the SPB-PIM Gateway interface mroute information for a range of VRF IDs.  <b>Note:</b> Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.
<i>group</i> {A.B.C.D}	Displays mroute information specific to a group IP address.
<i>source</i> {A.B.C.D}	Displays mroute information specific to a source IP address.

*Display the IP mroute Routes*

Use the following procedure to display multicast routes ingressing on either SPB-PIM Gateway interfaces or SPB multicast interfaces.

**Procedure**

1. To enter User EXEC mode, log on to the switch.
2. Display the multicast routes:  

```
show ip mroute mroute
```

**Example**

**Note**

The UPSTREAM\_NBR field is populated only if the stream was learned across a spb-pim-gw interface, and the upstream neighbor is the PIM neighbor IP address toward the source. The PROT field equals spb-pim-gw when the stream's source is learned on a VLAN configured for protocol spb-pim-gw. If the stream's source is learned on a VLAN configured for spb-multicast, the PROT field equals spb.

```
Switch:1>show ip mroute route

=====
Mroute Route - GlobalRouter

Total 4
```

**Variable definitions**

The following table defines parameters for the **show ip mroute route** command.

Variable	Value
<code>vrf WORD&lt;1-32&gt;</code>	Displays the multicast mroute information for a specific VRF name.
<code>vrfids WORD&lt;0-512&gt;</code>	Displays the multicast mroute information for a range of VRF IDs.  <b>Note:</b> Enter a single VRF ID or multiple VRF IDs separated by ',' or enter a range of VRF IDs 'x-y'.

**SPB-PIM Gateway Interface Configuration using the EDM**

This section provides procedures to configure SPB-PIM gateway interface using the EDM.

*Enabling SPB-PIM Gateway on a VLAN*

Enable SPB-PIM Gateway on a VLAN interface.

**Procedure**

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Click the **Advanced** tab.

4. In the row for the VLANs, double click the **SpbPimGatewayMulticast** field, and then select enable from the drop down menu.
5. Click **Apply**.

#### *Enabling SPB-PIM Gateway on a Brouter port interface*

Enable SPB-PIM Gateway on a Brouter port.

#### **Procedure**

1. In the Device Physical View tab, select the port you need to configure.
2. In the navigation pane, expand **Configuration > Edit > Port**.
3. Click **IP**.
4. Click the **SPB-PIM-GW** tab.
5. Select the **Enable** check box to enable SPB-PIM Gateway on a Brouter port interface.
6. Click **Apply**.

#### **SPB-PIM-GW field descriptions**

Use the data in the following table to use the **SPB-PIM-GW** tab.

Name	Description
<b>Enable</b>	Enables SPB-PIM Gateway on the interface. The default is disabled.
<b>OperState</b>	Displays the current operational state of this SPB-PIM Gateway interface.
<b>Address</b>	Displays the primary IP address of this router on this SPB-PIM Gateway interface.
<b>AddressMask</b>	Displays the primary IP address mask of this router on this SPB-PIM Gateway interface.
<b>HelloInterval</b>	Configures the PIM HELLO transmission interval.
<b>JoinPruneInterval</b>	Configures the PIM JOIN PRUNE transmission interval.

#### *Configuring SPB-PIM Gateway VLAN optional parameters*

Configure the SPB-PIM Gateway interface parameters on a VLAN.

#### **Procedure**

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANs**.
3. Select a row from the VLAN and click the **IP** tab.
4. Click the **SPB-PIM-GW** tab.
5. In the **HelloInterval** field, type the hello transmission interval.
6. In the **JoinPruneInterval** field, type the join prune transmission interval.
7. Click **Apply**.

**SPB-PIM-GW field descriptions**

Use the data in the following table to use the **SPB-PIM-GW** tab.

Name	Description
<b>OperState</b>	Displays the current operational state of this SPB-PIM Gateway interface.
<b>Address</b>	Displays the primary IP address of this router on this SPB-PIM Gateway interface.
<b>AddressMask</b>	Displays the primary IP address mask of this router on this SPB-PIM Gateway interface.
<b>HelloInterval</b>	Configures the PIM HELLO transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global SPB-PIM Gateway HELLO interval setting. Setting the HELLO Interval to 0 causes the neighbors to never expire its neighborship with this local SPB-PIM Gateway interface.
<b>JoinPruneInterval</b>	Configures the PIM JOIN PRUNE transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global level JOIN PRUNE transmission interval setting.

*Configuring the SPB-PIM Gateway optional parameters*

Perform this procedure to configure the optional parameters on existing SPB-PIM Gateway interfaces.

**Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Interfaces** tab.
4. In the row for the interfaces, double-click the **HelloInterval** box, and then type the hello interval in seconds.
5. In the row for the interfaces, double-click the **JoinPruneInterval** box, and then type the join prune interval in seconds.

**Interfaces field descriptions**

Use the data in the following table to use the **Interfaces** tab.

Name	Description
<b>IfIndex</b>	Shows the interface index.
<b>OperState</b>	Shows the operational state of the interface.
<b>AddressType</b>	Shows the address type of the interface.

Name	Description
<b>Address</b>	Shows the address assigned to the interface.
<b>AddressMask</b>	Shows the address mask associated with the interface address.
<b>HelloInterval</b>	Configures the PIM HELLO transmission interval. The default is 30 seconds.
<b>JoinPruneInterval</b>	Configures the PIM JOIN PRUNE transmission interval. The default is 60 seconds.

#### *Displaying the SPB-PIM Gateway interface default values*

Use the following procedure to display the default values used for the SPB-PIM Gateway interface HELLO and JOIN PRUNE intervals unless specifically configured on the individual interface.

#### **Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Globals** tab.

#### **Globals field descriptions**

Use the data in the following table to use the **Globals** tab.

Name	Description
<b>HelloInterval</b>	Displays the PIM HELLO transmission interval.
<b>JoinPruneInterval</b>	Displays the PIM JOIN PRUNE transmission interval.

#### *Displaying the SPB-PIM Gateway router port information*

Use the following procedure to display the SPB-PIM Gateway interface information.

#### **Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Interfaces** tab.

**Interfaces field descriptions**

Use the data in the following table to use the **Interfaces** tab.

Name	Description
<b>IfIndex</b>	Displays the VLAN ID.
<b>OperState</b>	Displays the current operational state of this SPB-PIM Gateway interface.
<b>AddressType</b>	Displays the address type of this SPB-PIM Gateway interface.
<b>Address</b>	Displays the primary IP address of this router on this SPB-PIM Gateway interface.
<b>AddressMask</b>	Displays the primary IP address mask of this router on this SPB-PIM Gateway interface.
<b>HelloInterval</b>	Configures the PIM HELLO transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global SPB-PIM Gateway HELLO interval setting. Setting the HELLO Interval to 0 causes the neighbors to never expire its neighborhood with this local SPB-PIM Gateway interface.
<b>JoinPruneInterval</b>	Configures the PIM JOIN PRUNE transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global level JOIN PRUNE transmission interval setting.

*Displaying the SPB-PIM Gateway VLAN information*

Use the following procedure to display the SPB-PIM Gateway VLAN information.

**Procedure**

1. In the navigation pane, expand **Configuration > VLAN**.
2. Click **VLANS**.
3. Select a row from the VLAN and click the **IP** tab.
4. Click the **SPB-PIM-GW** tab.

**SPB-PIM-GW field descriptions**

Use the data in the following table to use the **SPB-PIM-GW** tab.

Name	Description
<b>OperState</b>	Displays the current operational state of this SPB-PIM Gateway interface.
<b>Address</b>	Displays the primary IP address of this router on this SPB-PIM Gateway interface.

Name	Description
<b>AddressMask</b>	Displays the primary IP address mask of this router on this SPB-PIM Gateway interface.
<b>HelloInterval</b>	Configures the PIM HELLO transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global SPB-PIM Gateway HELLO interval setting. Setting the HELLO Interval to 0 causes the neighbors to never expire its neighborship with this local SPB-PIM Gateway interface.
<b>JoinPruneInterval</b>	Configures the PIM JOIN PRUNE transmission interval. This SPB-PIM Gateway VLAN level interval setting overrides the inherited global level JOIN PRUNE transmission interval setting.

*Displaying the SPB-PIM Gateway neighbor information*

### About This Task

Use the following procedure to display the SPB-PIM Gateway neighbor information

### Procedure

1. In the navigation pane, expand **Configuration > IP**.
2. Click **SPB-PIM-GW**.
3. Click the **Neighbors** tab.

### Neighbors field descriptions

Use the data in the following table to use the **Neighbors** tab.

Name	Description
<b>IfIndex</b>	Specifies the IfIndex for the interface which is used to reach this SPB-PIM Gateway neighbor.
<b>AddressType</b>	Specifies the address type of this SPB-PIM Gateway neighbor.
<b>Address</b>	Specifies the primary IP address of this router on this SPB-PIM Gateway neighbor.
<b>UpTime</b>	Specifies the time since this SPB-PIM Gateway neighbor last became a neighbor of the local router.
<b>ExpiryTime</b>	Specifies the minimum time remaining before this SPB-PIM Gateway neighbor times out.

*Displaying the IP mroute routes*

Use the following procedure to display multicast routes ingressing on either SPB-PIM Gateway interfaces or SPB multicast interfaces.

**Procedure**

1. In the navigation pane, expand **Configuration > IP**.
2. Click **Multicast**.
3. Click the **Routes** tab.

**Routes field descriptions**

Use the data in the following table to use the **Routes** tab.

Name	Description
<b>Group</b>	Displays the IP multicast group address for this entry that contains multicast routing information.
<b>Source</b>	Displays the network address that, when combined with the corresponding route SourceMask value, identifies the source that contains multicast routing information.
<b>SourceMask</b>	Displays the network mask that, when combined with the corresponding route Source value, identifies the multicast source.
<b>UpstreamNeighbor</b>	Shows the address of the upstream neighbor from which the IP datagrams from these sources are received. The address is 0.0.0.0 if the network is local.
<b>Interface</b>	Displays the interface, slot and portnumber, or VLAN ID where IP datagrams sent by these multicast sources to this multicast address are received.
<b>ExpiryTime</b>	Displays the amount of time that remains before this entry ages out. The value 0 indicates that the entry is not subject to aging.
<b>Protocol</b>	Displays the protocol as one of the following: <ul style="list-style-type: none"> <li>• other(1): none of the following</li> <li>• local(2): manually configured</li> <li>• netmgmt(3): configured by a network management protocol</li> <li>• pimSparseMode(8): PIM-SMv2</li> <li>• igmpOnly(10)</li> <li>• pimSsmMode(11)</li> <li>• spb (12)</li> <li>• spbpimgw(13)</li> </ul>

## SPB-PIM Gateway Interface Deployment Scenarios

---

This section provides information about different deployment scenarios for SPB-PIM gateway interface.

## SPB-PIM Gateway Base Case Deployment Scenario

There are several different customer topology scenarios for the SPB-PIM Gateway (SPB-PIM GW) feature deployment . One of these scenarios, shown in [Figure 5](#), is fully described here, along with configuration details, and display information.

The deployment scenario described here has two domains:

- SPB domain
- PIM domain

The PIM network has 5 PIM routers:

- RP
- PIM-A1
- PIM-A2
- PIM-B
- PIM-C

The RP router is the PIM-SM rendezvous point. PIM router PIM-B has receiver host R2 attached to it and source S1 is connected to PIM router PIM-C.

The SPB domain has the following components:

- SPB-PIM Gateway Controller node
- Two Gateway nodes, BEB-A1 and BEB-A2
- BEB-A1 is connected to the PIM network through a SPB-PIM Gateway interface to the PIM router PIM-A1
- BEB-A2 is connected to the PIM network through a SPB-PIM Gateway interface to the PIM router PIM-A2

**Note**

PIM-A1 and PIM-A2 routers attached to the BEBs SPB-PIM Gateway interface have standard PIM configured on their side of the interface.

- The SPB cloud has a BEB-B to which the source S2 is connected
- The SPB cloud has a BEB-C to which a receiver R1 is connected

**Note**

You can place the controller anywhere in the SPB cloud. The controller can be in the boundary or the core. Anywhere there is a connection into the PIM network from the SPB network, there must be a Gateway node(s) and Gateway interface(s).

**Figure 245: SPB-PIM Gateway base case configuration**

The SPB-PIM Gateway nodes BEB-A1 and BEB-A2 from the SPB cloud are connected to the PIM network. The connection is established by SPB-PIM Gateway interface connections to PIM routers PIM-A1 and PIM-A2. A MSDP connection is established between the RP from the PIM domain and the SPB-PIM Gateway Controller from the SPB domain. A MSDP connection is established to exchange the multicast source information between the RP and the SPB Controller. Unicast routing or reachability is setup before establishing the MSDP connection between the RP and the Gateway controller. The Unicast setup is not shown in the above figure.

*SPB-PIM Gateway base case configuration example*

**Before You Begin**

- The Shortest Path Bridging (SPB) infrastructure must be configured and setup in the SPB domain (not shown in this example)
- Protocol Independent Multicast (PIM) infrastructure must be configured and setup in the PIM domain (not shown in this example)
- Unicast routing table must be setup in the PIM domain to ensure reachability of the Multicast Source Discovery Protocol (MSDP) peer and source S2 from the SPB network
- Unicast routing table must be setup in the SPB domain to ensure reachability of the MSDP peer and source S1 from the PIM network

## Example

### Node: Gateway controller

Configure ISIS and SPBM:

```
Switch:1#configure terminal
Switch:1(config)#spbm
Switch:1(config)#router isis
Switch:1(config-isis)#system-id 0026.0026.0026
Switch:1(config-isis)#manual-area 01.0202.0303.04
Switch:1(config-isis)#spbm 1
Switch:1(config-isis)#spbm 1 nick-name 0.00.26
Switch:1(config-isis)#spbm 1 b-vid 10,20 primary 10
Switch:1(config-isis)#vlan create 10 name bvlan1 type spbm-bvlan
Switch:1(config)#vlan create 20 name bvlan2 type spbm-bvlan
Switch:1(config)#router isis enable
```

NNI Configuration:

```
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config-if)#isis
Switch:1(config-if)#isis spbm 1
Switch:1(config-if)#isis enable
Switch:1(config-if)#no shutdown
```

- Enable IPSC to setup Unicast route table. This setup ensures reachability of Rendezvous Point (RP) in the PIM network
- Create a loopback interface 2.0.2.2 to enable IPSC and MSDP originator-id
- Enable Multicast over Fabric Connect
- Configure static route and direct route redistribution
- Apply the static route and direct route redistribution

#### Note

Static route is used to reach RP for the below sample configuration.

```
Switch:1(config)#interface loopback 1
Switch:1(config-if)#ip address 2.0.2.2/32
Switch:1(config)#router isis
Switch:1(config-isis)#ip-source-address 2.0.2.2
Switch:1(config-isis)#spbm 1 ip enable
Switch:1(config-isis)#spbm 1 multicast enable
Switch:1(config-isis)#
Switch:1(config-isis)#redistribute static
Switch:1(config-isis)#redistribute static enable
Switch:1(config-isis)#redistribute direct
Switch:1(config-isis)#redistribute direct enable
Switch:1(config-isis)#
Switch:1(config-isis)#end
Switch:1#isis apply redistribute static
Switch:1#isis apply redistribute direct
```

MSDP Configuration:

Create an instance for the MSDP session. This IP interface is used for establishing an MSDP session with an RP in the PIM network. The source IP address used for the MSDP session must not be the newly created IP interface. The originator-id specifically configured for MSDP is used as the source IP address to establish the MSDP session.

The originator-id is also used by the RP in the source active (SA) messages sent to the MSDP peers. The CLIP configured earlier is used as the originator-id.

```
Switch:1#configure terminal
Switch:1(config)#vlan create 2100 type port-mstprstp 0
Switch:1(config)#vlan members add 2100 1/3 portmember
Switch:1(config)#interface vlan 2100
Switch:1(config-if)#ip address 21.0.0.1/24
Switch:1(config-if)#exit

Switch:1(config)#ip msdp originator-id 2.0.2.2
Switch:1(config)#ip msdp enable
Switch:1(config)#ip msdp peer 21.0.0.2
Switch:1(config)#ip msdp peer 21.0.0.2 enable
```

SPB-PIM Gateway Controller configuration:

Enable SPB-PIM Gateway Controller

```
Switch:1(config)#router isis
Switch:1(config-isis)#spbm 1 multicast spb-pim-gw controller enable
```

**Node: BEB-A1 (SPB-PIM Gateway)**

Configure ISIS and SPBM:

```
Switch:1#configure terminal
Switch:1(config)#spbm
Switch:1(config)#
Switch:1(config)#router isis
Switch:1(config-isis)#system-id 0015.0015.0015
Switch:1(config-isis)#manual-area 01.0202.0303.04
Switch:1(config-isis)#spbm 1
Switch:1(config-isis)#spbm 1 nick-name 0.00.15
Switch:1(config-isis)#spbm 1 b-vid 10,20 primary 10
Switch:1(config-isis)#
Switch:1(config-isis)#vlan create 10 name bvlan1 type spbm-bvlan
Switch:1(config)#vlan create 20 name bvlan2 type spbm-bvlan
Switch:1(config)#router isis enable
```

NNI Configuration:

```
Switch:1(config)#interface gigabitEthernet 1/1
Switch:1(config-if)#isis
Switch:1(config-if)#isis spbm 1
Switch:1(config-if)#isis enable
Switch:1(config-if)#no shutdown
```

- Enable IP Shortcuts (IPSC) to setup Unicast route table. This setup ensures reachability of sources in the PIM network
- Create a loopback interface 1.0.1.1 to enable IPSC
- Enable Multicast over Fabric Connect

- Configure static route and direct route redistribution
- Apply the static route and direct route redistribution

### Note

Static route is used to reach sources in the PIM network for the below sample configuration.

```
Switch:1(config)#interface loopback 1
Switch:1(config-if)#ip address 1.0.1.1/32
Switch:1(config-if)#router isis
Switch:1(config-isis)#ip-source-address 1.0.1.1
Switch:1(config-isis)#spbm 1 ip enable
Switch:1(config-isis)#spbm 1 multicast enable
Switch:1(config-isis)#
Switch:1(config-if)#router isis
Switch:1(config-isis)#redistribute static
Switch:1(config-isis)#redistribute static enable
Switch:1(config-isis)#redistribute direct
Switch:1(config-isis)#redistribute direct enable
Switch:1(config-isis)#
Switch:1(config-isis)#end
Switch:1#isis apply redistribute static
Switch:1#isis apply redistribute direct
```

SPB-PIM Gateway interface configuration:

- Create an IP interface
- Enable SPB-PIM Gateway on the IP interface

### Note

For the sample configuration below, the SPB-PIM Gateway interface is on VLAN 2000 with IP address 20.0.0.1

```
Switch:1#configure terminal
Switch:1(config)#vlan create 2000 type port-mstprstp 0
Switch:1(config)#vlan members add 2000 1/1 portmember
Switch:1(config)#interface vlan 2000
Switch:1(config-if)#ip address 20.0.0.1/24
Switch:1(config-if)#ip spb-pim-gw enable
```

Enable SPB-PIM Gateway node functionality:

```
Switch:1(config-if)#router isis
Switch:1(config-isis)#spbm 1 multicast spb-pim-gw gateway enable
```

Similar configuration is done for the SPB-PIM Gateway node BEB-A2.

PIM Sparse Mode (PIM-SM) is enabled at the PIM routers PIM-A1 and PIM-A2 on the interfaces connecting SPB-PIM Gateway nodes BEB-A1 and BEB-A2. The SPB-PIM Gateway nodes BEB-A1 and BEB-A2 see the PIM routers PIM-A1 and PIM-A2 as PIM neighbors. The PIM routers PIM-A1 and PIM-A2 see the SPB-PIM Gateway nodes as PIM neighbors. The SPB-PIM Gateway nodes BEB-A1 and BEB-A2 have IP reachability to the PIM source S1 with PIM neighbors as the next hop.

The route to reach source S1 is distributed to the Gateway controller through IPSC. The Gateway controller uses this route information to select only one of the Gateways to which the source S1 will be assigned for a specific group. The Gateway node is the only node that can draw the source S1 stream into the SPB network on behalf of SPB receivers, by sending an SG Join across a Gateway Interface to the nexthop toward the source S1. This ensures that the data is not duplicated from multiple ingress interfaces from the PIM network. Other Gateway nodes that are not assigned as the Gateway to the source S1 will not establish multicast path.

When S1 from the PIM network sends traffic to G1, RP from the PIM network sends MSDP SA message for (S1,G1) to the Gateway Controller. If the Gateway Controller selects BEB-A1 as the Gateway for the foreign source S1 and group G1, the Gateway Controller assigns BEB-A1 to (S1,G1). The Gateway Controller then sends the Gateway assignment information to all the nodes. When BEB-A1 receives the assignment information, it sees that it is assigned as the Gateway to (S1,G1). The BEB-A1 then checks if the next hop to reach S1 is a valid PIM neighbor. If the next hop is a valid PIM neighbor, the BEB-A1 interacts with Multicast over Fabric Connect and advertises a sender TLV for the (S1,G1) into the SPB cloud. The BEB-A2 also receives the Gateway assignment information but silently saves the received Gateway assignment information since it is not the selected Gateway. If the interested receiver R1 is found at BEB-C, as part of Multicast over Fabric Connect processing, BEB-C sends receiver TLV for the group G1 to the advertising node, BEB-A1. Upon receiving this receiver TLV, BEB-A1 establishes the multicast stream through its Gateway interface which is upstream towards the PIM neighbor, by sending out a PIM SG Join message toward the source S1. This causes PIM-A1 node to forward multicast data from S1 to BEB-A1.

When the local source S2 (local to the SPB network) at BEB-B in the SPB network sends traffic to group G1, BEB-B advertises a sender TLV for (S1,G1). The controller sees this sender TLV and sends an MSDP SA message for (S2,G1) to the RP in the PIM network.

**Note**

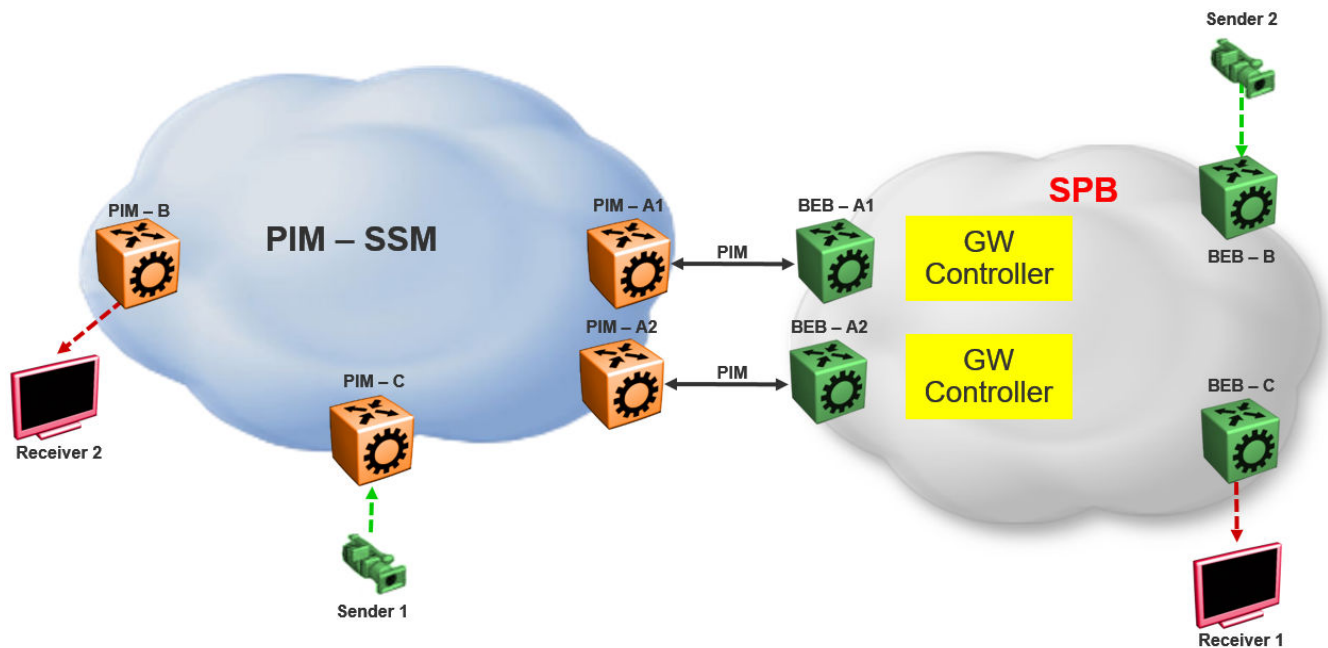

The controller does not send SA messages for (S1,G1) to the PIM network since S1 is a foreign source.

When PIM network receiver R2 is interested in group G1, the PIM router PIM-B sends PIM a (\*,G) Join message to the RP. RP in turn sends (S2,G1) Join towards the source S2. The unicast IP reachability to source S2 which is setup in the RP is used for sending (S2,G1) joins hop-by-hop towards the source. From the RP point of view, the next hop to reach the source S2 is one of the PIM routers PIM-A1 or PIM-A2 (depending on the unicast route table next hop address). For this example, the next hop is PIM-A1. The RP sends the (S2,G1) Join message towards the PIM-A1. PIM-A1 then sends an SG Join to BEB-A1. Upon receiving the Join for (S2,G1) from the PIM network, BEB-A1 sends a receiver TLV into the SPB network to the S2 advertising router BEB-B. When the BEB-B receives the receiver TLV, the BEB-B establishes the multicast stream from source S2 toward the receiver.

### Source Specific Multicast

PIM-SSM does not use a Rendezvous Point to centralize the receivers and sources. A PIM-SSM router which has a receiver for a group multicast address in the SSM address range joins directly to a source for that group by sending an SG join toward the source, not a \*G join toward the RP for the group. Because of this, MSDP is not required in order for the PIM Network to learn of an SSM range stream in the SPB network. However, in order for the SPB network to know where a PIM SSM source resides, it must statically configure S1,SSM-G1 at the controllers. In this way, a Gateway can be chosen for the stream, even in the absence of MSDP.

The following figure shows a non-MSDP SSM environment where stream PIM network source S1, for an SSM group, must be statically configured at the SPB Controllers:

**Figure 246: Static configuration of SSM groups in Controllers**

### Peer Mesh Group

The following figure shows the Peer Mesh Group configuration:

**Note**

Controllers within a single SPB network must never peer with each other, regardless of whether mesh groups exist. In addition, both Controllers must have the same peerings configured with other networks RPs.

**Figure 247: Peer Mesh Group**

*MSDP Peer Mesh Group configuration example*

### Example

Configure MSDP:

If the MSDP speakers are fully meshed, the speakers can be configured into a mesh group in order to prevent excessive SA forwarding and RPF checks. To configure a mesh group, specify a name along with the MSDP peer. For example, on router RP1, configure a mesh group which includes RP2, RP3, and both Gateway controllers. On RP2, configure the same mesh group with members RP1, RP3, and both Gateway controllers. On RP3, configure the same mesh group with members RP1, RP2, and both Gateway controllers. On each Gateway controller, configure the same mesh group with members RP1, RP2, and RP3, but never with another Gateway controller in the same SPB domain.

```
Switch:1(config)#ip msdp originator-id 2.0.2.2
Switch:1(config)#ip msdp enable
Switch:1(config)#ip msdp peer 21.0.0.2 enable
Switch:1(config)#ip msdp mesh-group mgTest 21.0.0.2
```

### Multi domain

The following figure shows a multi domain scenario, where two PIM domains and one SPB domain share multicast streams:

**Figure 248: Multi domain configuration**

### SPB domain interconnect

The following figure shows the SPB domain interconnect configuration. In this scenario, two SPB domains are connected by PIM Gateway interfaces, and there is no traditional PIM Network involved. The Controllers from each SPB domain form MSDP adjacencies with the Controllers in the other domain (but not within the same domain) in order to share their multicast sources. The SPB-PIM Gateway nodes see the other SPB-PIM Gateway nodes as PIM neighbors on the SPB-PIM Gateway interfaces.

Figure 249: SPB domain interconnect

# System Access

---

[System access fundamentals](#) on page 3611

[System access configuration using CLI](#) on page 3625

[System access configuration using EDM](#) on page 3652

The following sections describe how to access the switch, create users, and user passwords.

## System access fundamentals

---

This section contains conceptual information about how to access the switch and create users and user passwords for access.

### Logging On to the System

After the startup sequence is complete, the system opens the login prompt.

#### Note

With enhanced secure mode enabled, the person in the role-based authentication level of administrator configures the login and password values for the other role-based authentication levels. The administrator initially logs on to the switch using the default login of `admin` and the default password of `admin`. After the initial login, the switch prompts the administrator to create a new password.

The administrator then configures default logins and passwords for the other users based on the role-based authentication levels of the user. For more information on enhanced secure mode, see [System access security enhancements](#) on page 3638.

The following table shows the default values for login and password for the console and Telnet sessions.

**Table 252: Access levels and default logon values**

Access level	Description	Default logon	Default password
Read-only	Permits view only configuration and status information. This access level is equivalent to Simple Network Management Protocol (SNMP) read-only community access.	ro	ro
Layer 1 read-write	View most switch configuration and status information and change physical port settings.	l1	l1
Layer 2 read-write	View and change configuration and status information for Layer 2 (bridging and switching) functions.	l2	l2
Layer 3 read-write	View and change configuration and status information for Layer 2 and Layer 3 (routing) functions.	l3	l3
Read-write	View and change configuration and status information across the switch. Read-write access does not allow you to change security and password settings. This access level is equivalent to SNMP read-write community access.	rw	rw
Read-write-all	Permits all the rights of read-write access and the ability to change security settings. This access level allows you to change the command line interface (CLI) and web-based management user names and passwords and the SNMP community strings.	rwa	rwa

You can enable or disable users with particular access levels, eliminating the need to maintain large numbers of access levels and passwords for each user.

The system denies access to a user with a disabled access level who attempts to log on. The system displays the following error message after a user attempts to log on with a blocked access level:

```
CPU1 [mm/dd/yy hh:mm:ss] 0x0019bfff GlobalRouter CLI WARNING Slot 1: Blocked unauthorized cli access
```

The system logs the following message to the log file:

```
User <user-name> tried to connect with blocked access level <access-level> from <src-  
ipaddress> via <login type>.
```

The system logs the following message for the console port:

```
User <user-name> tried to connect with blocked access level <access-level> from console  
port.
```

### *RADIUS authentication*

Remote Authentication Dial-in User Service (RADIUS) authentication takes precedence over the local configuration. If you enable RADIUS authentication on the switch, the user can access the switch even if you block an access level on the switch.

#### **Important**

When you enable RADIUS on the switch and configure a RADIUS server to be used by CLI or EDM, the server authenticates the connection, whether it is FTP, HTTPS, SSH, or TELNET. However, in the event that the RADIUS server is unresponsive or is unreachable, the switch will fall back to the local authentication, so that you can access the switch using your local login credentials.

If you disable an access level, all running sessions, except FTP sessions, with that access level to the switch terminate.

#### **Important**

Only the RWA user can disable an access level on the switch. You cannot disable the RWA access level on the switch.

The system preserves these configurations across restarts.

### *hsecure mode boot configuration flag*

The switch supports a configurable flag called high secure (hsecure). Use the hsecure flag to enable the following password features:

- 10 character enforcement
- aging time
- limitation of failed login attempts
- protection mechanism to filter designated IP addresses

If you activate the **hsecure** flag, the software enforces the 10-character rule for all passwords. The password must contain a minimum of two uppercase characters, two lowercase characters, two numbers, and two special characters.

If you enable hsecure for the first time and the password file does not exist, then the device creates a normal default username (rwa) and password (rwa). In this case, the password does not meet the minimum requirements for hsecure and as a result the system prompts you to change the password.

For more information about the hsecure flag, see [hsecure Mode](#) on page 3269.

#### *Enhanced secure mode*

If you enable enhanced secure mode, the system uses different authentication levels. Enhanced secure mode allows the system to:

- Provide role-based access levels
- Stronger password requirements
- Stronger rules on password length
- Stronger rules on password complexity
- Stronger rules on password change intervals
- Stronger rules on password reuse
- Stronger password maximum age use

For more information on enhanced secure mode, see [System access security enhancements](#) on page 3638.

#### *Default Web-Server Behavior*

The default switch configuration enforces the following restrictions for web-server access:

- The web-server password must be a minimum of 8 characters.
- Secure communications with the web server use Transport Layer Security (TLS) version 1.2 and above.
- The switch does not support the RC4 cipher. The switch supports the following ciphers:
  - TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA
  - TLS\_RSA\_WITH\_AES\_256\_CBC\_SHA
  - TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA256
  - TLS\_RSA\_WITH\_AES\_256\_CBC\_SHA256

For information about how to enable and configure the web server, see [Configure the Web Server](#) on page 275 or [Configure the Web Management Interface](#) on page 295. For information about supported browser versions, see [Supported Browsers](#) on page 283.

## Managing the System using Different VRF Contexts

You can use the Enterprise Device Manager (EDM) to manage the system using different Virtual Router Forwarding (VRF) contexts.

- Using the GlobalRouter (VRF 0), you can manage the entire system. GlobalRouter is the default view at log in
- Using a VRF context other than the GlobalRouter (VRF 0), you have limited functionality to manage the system. For instance you can only manage the ports assigned to the specified VRF instance

Specify the VRF instance name on the EDM screen when you launch a VRF context view. You can use the context names (SNMPv3) and community strings (SNMPv1/v2) to

assign different VRFs to manage selected components, such as ports and VLANs. For more information about context names and community strings, see [Simple Network Management Protocol \(SNMP\)](#) on page 3388.

## CLI Passwords

The switch ships with default passwords configured for access to CLI through a console or Telnet session. If you possess read-write-all access authority, and you use SNMPv3, then you can change passwords in encrypted format. If you use EDM, then you can also specify the number of allowed Telnet sessions.

### Important

Be aware that the default passwords and community strings are documented and well known. Change the default passwords and community strings immediately after the first logon.

For security, if you fail to log on correctly in three consecutive instances, then the device locks for 60 seconds.

The switch stores passwords in encrypted format and not in the configuration file.

### *Subscriber or Administrative Interaction*

As a network administrator, you can configure the RADIUS server for user authentication to override user access to commands. You must still provide access based on the existing access levels in the switch, but you can customize user access by allowing and denying specific commands.

You must configure the following three returnable attributes for each user:

- Access priority (single instance)—the access levels currently available on the switch (ro, l1, l2, l3, rw, rwa)
- Command access (single instance)—indicates whether the user has access to the commands on the RADIUS server
- CLI commands (multiple instances)—the list of commands that the user can or cannot use

## Access Policies for Services

You can control access to the switch by creating an access policy. An access policy specifies the hosts or networks that can access the switch through various services, such as Telnet, Simple Network Management Protocol (SNMP), Hypertext Transfer Protocol (HTTP), and Secure Shell version 2 (SSHv2). You can enable or disable access services by configuring flags.

Use access policies for in-band management to secure access to the switch. When configuring an access policy, a lower precedence takes higher priority if you use multiple policies. For example, preference 120 has priority over preference 128.

You can define network stations that can access the switch or stations that cannot access the switch. For each service you can also specify the level of access, such as read-only or read-write-all.

When you configure access policies, you can perform either of the following actions:

- Globally enable the access policy feature, and then create and enable individual policies. Each policy takes effect immediately after you enable it.
- Create and enable individual access policies, and then globally enable the access policy feature to activate all the policies at the same time.

HTTP and SSH support IPv4 and IPv6 with no difference in configuration or functionality.

## Web interface passwords

The switch includes a web-management interface, Enterprise Device Manager (EDM), that you can use to monitor and manage the device through a supported web browser from anywhere on the network. For more information on supported web browsers, see [Supported Browsers](#) on page 283.

A security mechanism protects EDM and requires you to log on to the device using a user name and password. The default user name is `admin` and the default password is `password`.

### Important

For security reasons, EDM is disabled by default.

By default, the minimum password length for the web server is 8 characters but you can override this value. For more information about how to enable and configure the web server, see [Configure the Web Server](#) on page 275 or [Configure the Web Management Interface](#) on page 295.

### *Password encryption*

The switch handles password encryption in the following manner:

- After the device starts, the system restores the web-server passwords and community strings from the hidden file.
- After you modify the web-server username and password or SNMP community strings, the system makes the modifications to the hidden file.

## Multiple CLI Users for Each Role

**Table 253: Multiple CLI Users product support**

Feature	Product	Release introduced
Multiple CLI users per role	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7
	7520 Series	Fabric Engine 8.10
	7720 Series	Fabric Engine 8.10
	VSP 4450 Series	VOSS 7.0
	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 7.0
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 7.0
	VSP 8400 Series	VOSS 7.0
	VSP 8600 Series	VSP 8600 8.0 demonstration feature
	XA1400 Series	VOSS 8.0.50

### Note

DEMO FEATURE - Multiple CLI Users Per Role is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [Fabric Engine and VOSS Feature Support Matrix](#).

You can create up to a maximum of 10 CLI users for each role, which includes:

- 3 default users (rwa, rw, and ro)—User Type = default
- 7 user defined users (rwa or rw or ro)—User Type = userDefined

Username for default users (rwa, rw, and ro) can be changed; however, usernames for user defined users cannot be changed.

Users require a username and password to connect to the switch. Users can log on through the local serial port, Telnet, SSH, or ftp. When a user is created, authentication is enabled, by default.

For security reasons, if a login attempt fails, the error feedback does not indicate if the failed login is due to an invalid user name or an invalid password. Response times

for invalid user name and invalid user name/password pair are identical to prevent identification of which of the two failed.

**Note**

Multiple CLI users for each role does not apply in enhanced secure mode.

## Enhanced Secure Mode

**Table 254: Enhanced Secure Mode product support**

Feature	Product	Release introduced
Enhanced Secure mode	5320 Series	Fabric Engine 8.6
	5420 Series	VOSS 8.4
	5520 Series	VOSS 8.2.5
	5720 Series	Fabric Engine 8.7

	VSP 8400 Series	VOSS 8.5
	VSP 8600 Series	Not supported
	XA1400 Series	VOSS 8.5

#### *Authentication Levels*

After you enable enhanced secure mode with the **boot config flags `enhancedsecure-mode`** command, the switch supports role-based authentication levels. With enhanced secure mode enabled, the switch supports the following authentication access levels for local authentication, Remote Authentication Dial-In User Service (RADIUS), and Terminal Access Controller Access Control System Plus (TACACS+) authentication:

- Administrator
- Privilege
- Operator
- Auditor
- Security

Each username is associated with a certain role in the product and appropriate authorization rights for viewing and executing commands are available for that role.

With enhanced secure mode enabled, the person in the role-based authentication level of administrator configures the login and password values for the other role-based authentication levels. The administrator access level cannot be disabled on VOSS switches.

The administrator initially logs on to the switch using the default login of `admin` and the default password of `admin`. After the initial login, the switch prompts the administrator to create a new password.

The following displays an example of the initial login to the switch by the administrator after enhanced secure mode is enabled.

```

Login: admin
Password: *****
      This is an initial attempt using the default user name and password.
      Please change the user name and password to continue.
Enter the new name : rwa
Enter the New password : *****
Re-enter the New password : *****
Password changed successfully
      Last Successful Login:Wed Oct 14 12:20:42 2015
      Unsuccessful Login attempts from last login is: 0

```

The administrator then configures default logins and passwords for the other users based on the role-based authentication levels of the user.

#### *Access Level and Login Details*

Access level	Description	Login location
Administrator	The administrator access level permits all read-write access, and can change security settings. The administrator access level can configure CLI and web-based management user names, passwords, and the SNMP community strings. The administrator access level can also view audit logs. The administrator access level can be disabled on VSP 8600 Series only.	SSH/Telnet (in band/mgmt)/console
Privilege	The privilege access level has the same access permission as the administrator; however, the privilege access level cannot use RADIUS or TACACS+ authentication. The privilege access level is known as the emergency-admin on VSP 8600 Series only.	SSH/Telnet(in band/mgmt)/console/
Operator	The operator access level can view most switch configurations and status information. The operator access level can change physical port settings at layer 2 and layer 3. The operator access level cannot access audit logs or security settings.	SSH/Telnet(in band/mgmt)/console/
Auditor	The auditor access level can view configuration information, status information, and audit logs.	SSH/Telnet(in band/mgmt)/console/
Security	The security access level can change security settings only. The security access level also has permission to view configuration and status information.	SSH/Telnet(in band/mgmt)/console/

#### *Password Requirements*

After you enable enhanced secure mode on the switch, the password requirements are stronger. The individual in the administrator access level role configures and provides a temporary user name and password. After you log in for the first time with the temporary user name and temporary password, the system forces you to change the temporary password. After you change the temporary password, you cannot use the password again in subsequent sessions.

The following topics discuss the enhanced password requirements.

### Password Complexity Rule

After you enable enhanced secure mode, the system checks each password change request to ensure the new password meets the password complexity required.

The default for the password complexity rule includes the following:

- Two uppercase characters, from the range: ABCDEFGHIJKLMNOPQRSTUVWXYZ
- Two lowercase characters, from the range: abcdefghijklmnopqrstuvwxyz
- Two numeric characters, from the range: 1234567890
- Two special characters, from the range: `~!@#\$%^&\*()\_-+={[]|\:;'"<,.>?/

### Password Length Rule

The system enforces a minimum password length of 15 characters after you enable enhanced secure mode.

If the password is not long enough, the system displays the following message:

```
Password change aborted. The new password does not meet the minimum
complexity requirement. Please select another password that meets the
change interval, length, complexity, no consecutive repeating characters
or history requirements of the domain.
```

### Password Change Interval Rule

The system enforces a minimum password change interval, which defines the minimum amount of time before you can change to a new password. By default, the minimum change interval is 24 hours between changing from one password to a new password. When you attempt to change your password, the system checks the timestamp for your password to determine if enough time has passed to enable you to change the password.

If you attempt to change the password and not enough time has passed, the system rejects the request, and the system informs you that the password was recently changed. Any password change outside of the enforced interval requires the Administrator to approve the change.

If you try to change the password before the change interval allows, the system displays the following message:

```
Password change aborted. The new password does not meet the minimum
complexity requirement. Please select another password that meets the
change interval, length, complexity, no consecutive repeating characters
or history requirements of the domain.
```

### Minimum Password Change

#### Note

Product Notice: This section does not apply to VSP 8600 Series.

The system enforces a minimum password change requirement, which defines that 8 characters must differ within the same position from the old password.

If the new password does not have at least 8 characters changed within the same position from the old password, the system rejects the password and displays the following message:

```
The password change failed, less than eight characters were changed.
```

#### **Password Reuse Rule**

After you enable enhanced secure mode, the administrator access level can define the number of old passwords that cannot be reused. The password reuse rule ensures that recently used passwords are not reused immediately, which reduces the risk of someone unlawfully gaining access to the system. The default number of prohibited recently used passwords is 3, but you can define up to 99.

The system saves the password history and stores the history in an encrypted format, along with the user name and date of change. If a particular user attempts to change a password, the system checks the new password against the stored passwords the user has previously used. If the password is on the list of previously used passwords, the system rejects the password change, and displays the following message:

```
Old password not allowed.
```

#### **Password Maximum Age Rule**

The system enforces automatic password renewal and password lockout after the expiration period because long-term usage of the same password can cause the system to be vulnerable to hacking.

You can configure the password expiration period to a range of 1 to 365 days. The default password expiration period is 90 days.

#### **Password Max-Session**

The password max-sessions value indicates the maximum number of times a particular type of role-based user can log in to the switch through the SSH session at the same time. The max-sessions value applies only for SSH sessions, and only with enhanced secure mode enabled.

After the maximum session number is reached that particular type of user cannot login. For example, if the max-sessions for an auditor user is configured as 5, then the auditor user can log in to only five SSH sessions at the same time. The default is 3.

#### **Password Pre-Notification Interval and Post-Notification Interval Rule**

After enhanced secure mode is enabled, the switch enforces password expiry. To ensure a user does not lose access, the switch offers pre- and post-notification messages explaining when the password will expire.

The administrator can define pre- and post-notification intervals to between one to 99 days.

The system maintains the password with a time stamp for when the password expiration. When you log in, the system checks the password time stamp and the notification timer values. If the administrator configures the pre-notification to 30 days, when you log in, the system checks the time stamp and notification timer values, and if the password expiry is due in 30 days, the system displays the first notification.

The pre-notification intervals provide messages to warn users that their passwords will expire within a particular timeframe:

- interval 1—By default, interval 1 is 30 days.
- interval 2—By default, interval 2 is 7 days.
- interval 3—By default, interval 3 is 1 day.

The post-notification intervals provide notification to users that their passwords have expired within a particular timeframe:

- interval 1—By default, interval 1 is 1 day.
- interval 2—By default, interval 2 is 7 days.
- interval 3—By default, interval 3 is 30 days.

If you do not change the password before the expiry date, the system locks your account. When your account is locked, only the administrator can unlock the account. The administrator creates a temporary password, and then you can login with the temporary password. If the administrator password expires and the configured notification interval lapses, access to SSH/Telnet/FTP connections is denied. The administrator must connect to the console port using a serial connection to change the password.

### *Sensitive File Protection*

#### **Note**

Sensitive file protection does not apply to VSP 8600 Series.

For certain switches in enhanced secure mode, sensitive files and paths are protected. The home directory for enhanced secure mode is `/intflash/shared`. You cannot access sensitive files using Telnet, SSH, FTP, SFTP, TFTP, and SCP connections. You cannot access sensitive files using CLI commands. Files transferred on the switch through the default path are saved in `/intflash/shared`.

The following sensitive files and paths are protected in enhanced secure mode:

- `/intflash/cert`
- `/intflash/ike_psk.txt`
- `/intflash/ospf_key.txt`
- `/intflash/ospf_vrfif_key.txt`
- `/intflash/ospf_vrfvif_key.txt`
- `/intflash/isis_md5key.txt`
- `/intflash/isis_sha2key.txt`
- `/intflash/isis_simplekey.txt`

- /intflash/shadovfedmoc.txt
- /intflash/snmp\_usm\_moc.txt
- /intflash/snmp\_usm\_moc\_fed.txt
- /intflash/snmp\_comm\_moc.txt
- /intflash/snmp\_comm\_moc\_fed.txt
- /intflash/.radsec/profile
- /intflash/ssh/ssh\_rsa.key
- /intflash/ssh/ssh\_dss.key
- /intflash/ssh/moc\_sshc\_rsa\_file
- /intflash/ssh/moc\_sshc\_dsa\_file
- /intflash/ssh/id\_dsa\_\*
- /intflash/ssh/id\_rsa\_\*
- /intflash/server.pem
- /intflash/app/server.pem
- /intflash/app/restweb/certs/privkey.pem
- /intflash/app/restweb/certs/server.pem
- /intflash/app/restweb/certs/cert.pem
- /intflash/app/slamon/certs/trustcerts.txt
- /intflash/ovsdb/keys/privatekey.pem
- /intflash/ovsdb/keys/sc-cert.pem
- /intflash/shadov.txt
- /intflash/ntp\_keys.txt

Sensitive files cannot be accessed using the following CLI commands:

- **cd**
- **copy**
- **move**
- **move**
- **rename**
- **remove**
- **delete**
- **more**
- **edit**
- **dir**
- **mkdir**

#### Operational Considerations

- If you attempt to change the value of the enhancedsecure-mode flag when the system is running, you are prompted to continue or to cancel the action. If

you decide to continue, all sensitive files are deleted. You must save the current configuration and then reset the switch for the change to take effect.

- When you upgrade the software from versions earlier than VOSS 8.5, even if the `enhancedsecure-mode` flag is changed, no sensitive files are deleted.

If you upgrade the software to VOSS 8.5, if the `enhancedsecure-mode` flag is changed, all sensitive files are deleted.

- If you enable the `boot config flags factorydefaults` configuration flag to return an existing switch to factory default configuration, in enhanced secure mode, all sensitive files are deleted. When you enable the factory default optional parameters with default configuration, it preserves the user security files and security mode. For more information, see [Enable Factory Default Behavior](#) on page 237.
- When the switch resets after you enable enhanced secure mode or you upgrade the switch software, all configuration files, such as the runtime, primary, and backup configuration files are copied to `/intflash/shared`. The system displays the following message:

```
GlobalRouter SW INFO The runtime config file /intflash/config.cfg is
copied to /intflash/shared/config.cfg due to changing ESM mode/upgrade
version.
```

When the switch resets after you disable enhanced secure mode or after you downgrade the switch software, the switch uses the same configuration files as it used before the switch reset, either from `/intflash/shared` or from `/intflash`.

---

## System access configuration using CLI

---

The section provides procedures to manage system access through configurations such as usernames, passwords, and access policies.

### Change the Default Username

You can change usernames for default users (`rwa`, `rw`, and `ro`) for the specified access level. You cannot change usernames for user-defined users.

#### Before You Begin

Only the `rwa` user can change the default username.

#### About This Task

Perform this procedure to change the default username for the specified access level.

#### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```

## 2. Change the default username:

```
username WORD <1-20> level {l1|l2|l3|ro|rw|rwa}
```

The system displays the following message:

```
Do you want to change username for the default RO user ?
```

3. Type *y*.

## 4. Enter the old password.

## 5. Enter the new password.

## 6. Re-enter the new password.

**Example**

Change the default username:

```
Switch:1>enable
Switch:1#config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#username EXUser ?
    level Which access level
Switch:1(config)#username EXUser level ?
    l1 Change Layer 1 read write enable password
    l2 Change Layer 2 read write enable password
    l3 Change Layer 3 read write enable password
    ro Change read only enable password
    rw Change read write enable password
    rwa Change read write all enable password

Switch:1(config)#username EXUser level ro

Do you want to change username for the default RO user ? (y/n) ? y

Enter the old password : **
Enter the New password : *****
Re-enter the New password : *****
```

*Variable Definitions*

The following table defines parameters for the **username** command.

**Table 255:**

Variable	Value
<i>WORD</i> <1-20>	Specifies the user logon name.
<i>level</i> l1 l2 l3 ro rw rwa	Specifies the access level.

**Enabling CLI access levels**

Enable CLI access levels to control the configuration actions of various users.

## About This Task

### Important

Only the RWA user can disable an access level on the switch. You cannot disable the RWA access level on the switch.

The system preserves these configurations across restarts.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable an access level:  

```
password access-level WORD<2-8>
```

## Example

Block CLI access to Layer 1:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no password access-level 11
```

## Variable Definitions

The following table defines parameters for the **password access-level** command.

Variable	Value
<i>WORD</i> <2-8>	<p>Permits or blocks this access level. The available access level values are as follows:</p> <ul style="list-style-type: none"> <li>• 11 — Specifies Layer 1.</li> <li>• 12 — Specifies Layer 2.</li> <li>• 13 — Specifies Layer 3.</li> <li>• ro — Specifies read-only.</li> <li>• rw — Specifies read-write.</li> <li>• rwa — Specifies read-write-all.</li> </ul> <p>To set this option to the default value, use the <b>default</b> operator with the command. By default, the system permits all access levels. To block an access level, use the <b>no</b> operator with the command.</p>

## Changing passwords

Configure new passwords for each access level, or change the logon or password for the different access levels of the switch. After you receive the switch, use default passwords to initially access CLI. If you use Simple Network Management Protocol version 3 (SNMPv3), you can change encrypted passwords.

### Before You Begin

- You must use an account with read-write-all privileges to change passwords. For security, the switch saves passwords to a hidden file.

### About This Task

If you enable the hsecure flag, after the aging time expires, the system prompts you to change your password. If you do not configure the aging time, the default is 90 days.

### Procedure

- Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

- Change a password:

```
cli password WORD<1-20> {layer1|layer2|layer3|read-only|read-write|read-write-all}
```

- Enter the old password.
- Enter the new password.
- Enter the new password a second time.

- Configure password options:

```
password [access-level WORD<2-8>] [aging-time <1-365>] [default-lockout-time <60-65000>] [lockout WORD<0-46> time <60-65000>] [min-passwd-len <10-20>] [password-history <3-32>]
```

### Example

Change a password, and then set the password to an access level of read-write-all and the expiration period for the password to 60 days:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#cli password smith read-write-all
Switch:1(config)#Enter the old password : winter
Switch:1(config)#Enter the New password : summer
Switch:1(config)#Re-enter the New password : summer
Switch:1(config)#password access-level rwa aging-time 60
```

### Variable Definitions

The following table defines parameters for the **cli password** command.

Variable	Value
<i>layer1 layer2 layer3 read-only read-write read-write-all</i>	Changes the password for the specific access level.
<i>WORD&lt;1-20&gt;</i>	Specifies the user logon name.

Use the data in the following table to use the **password** command.

Variable	Value
<code>access level WORD&lt;2-8&gt;</code>	Permits or blocks this access level. The available access level values are as follows: <ul style="list-style-type: none"> <li>• ll</li> <li>• l2</li> <li>• l3</li> <li>• ro</li> <li>• rw</li> <li>• rwa</li> </ul>
<code>aging-time &lt;1-365&gt;</code>	Configures the expiration period for passwords in days, from 1–365. The default is 90 days.
<code>default-lockout-time &lt;60-65000&gt;</code>	Changes the default lockout time after three invalid attempts. Configures the lockout time, in seconds, and is in the 60–65000 range. The default is 60 seconds. To configure this option to the default value, use the <b>default</b> operator with the command.
<code>lockout WORD&lt;0-46&gt; time &lt;60-65000&gt;</code>	Configures the host lockout time. <ul style="list-style-type: none"> <li>• <code>WORD&lt;0-46&gt;</code> is the host IP address in the format a.b.c.d.</li> <li>• <code>&lt;60-65000&gt;</code> is the lockout-out time, in seconds, in the 60–65000 range. The default is 60 seconds.</li> </ul>
<code>min-passwd-len &lt;10-20&gt;</code>	Configures the minimum length for passwords in high-secure mode. The default is 10 characters. To configure this option to the default value, use the <b>default</b> operator with the command.
<code>password-history &lt;3-32&gt;</code>	Specifies the number of previous passwords the switch stores. You cannot reuse a password that is stored in the password history. The default is 3. To configure this option to the default value, use the <b>default</b> operator with the command.

## Configure an Access Policy

Configure an access policy to control access to the switch.

### About This Task

You can permit network stations to access the switch or forbid network stations to access the switch.

For each service, you can also specify the level of access; for example, read-only or read-write-all.

If you configure the access policy mode to *deny*, the system checks the mode and service, and if they match the system, denies the connection. With the access policy mode configured to *deny*, the system does not check *accesslevel* and *access-strict* information.

If you configure the access policy mode to *allow*, the system continues to check the *accesslevel* and *access-strict* information.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create an access policy by assigning it a number:

```
access-policy <1-65535>
```

3. Restrict the access to a specific level:

```
access-policy <1-65535> access-strict
```

4. Configure access for an access policy:

```
access-policy <1-65535> accesslevel <ro|rwa|rw>
```

5. Configure the access policy mode, network, and precedence:

```
access-policy <1-65535> [mode <allow|deny>] [precedence <1-128>]
[network <A.B.C.D> <A.B.C.D>]
```

6. (Optional) Configure access protocols for an access policy:

```
access-policy <1-65535> [ftp] [http] [ssh] [telnet] [tftp]
```

7. (Optional) Configure trusted access for an access policy:

```
access-policy <1-65535> host WORD<0-46>
```

8. (Optional) Configure SNMP parameters for an access policy:

### Note

If you configure an access policy for SNMPv3, you must create an SNMP group and add that group as part of the access policy configuration. For more information about how to create an SNMP group, see [Create a New User Group](#) on page 3403.

- `access-policy <1-65535> [snmpv3]`
- `access-policy <1-65535> [snmp-group WORD<1-32> <snmpv1|snmpv2c|usm>]`

9. Enable the access policy:

```
access-policy <1-65535> enable
```

10. Enable access policies globally:

```
access-policy
```

### Examples

Assuming no access policies exist, start with policy 3 and name the policy policy3. Add the read-write-all access level and the usm group group\_example. Enable access strict, and finally, enable the policy.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#access-policy 3
Switch:1(config)#access-policy 3 name policy3
Switch:1(config)#access-policy 3 accesslevel rwa
Switch:1(config)#access-policy 3 snmp-group group_example usm
Switch:1(config)#access-policy 3 access-strict
Switch:1(config)#access-policy 3 enable
```

Create an SNMPv3 policy that references an existing SNMP group.

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#access-policy 1
Switch:1(config)#access-policy 1 snmpv3
Switch:1(config)#access-policy 1 snmp-group Test usm
```

### Variable Definitions

The following table defines parameters for the **access-policy** command.

Variable	Value
<i>access-strict</i>	Restrains access to criteria specified in the access policy. <ul style="list-style-type: none"> <li>• true—The system accepts only the currently configured access level.</li> <li>• false—The system accepts access up to the configured level.</li> </ul>
<i>accesslevel</i> <ro  rwa  rw>	Specifies the level of access if you configure the policy to allow access.
<i>enable</i>	Enables the access policy.
<i>ftp</i>	Activates or disables FTP for the specified policy. Because FTP derives its login and password from the CLI management filters, FTP works for read-write-all (rwa) and read-write (rw) access, but not for the read-only (ro) access.
<i>host</i> WORD<0-46>	For remote login access, specifies the trusted host address as an IP address. The switch supports access-policies over IPv4 and IPv6 with no difference in functionality or configuration.
<i>http</i>	Activates the HTTP and HTTPS for this access policy.

Variable	Value
<code>mode &lt;allow deny&gt;</code>	Specifies whether the designated network address is allowed access to the system through the specified access service. The default is allow. If you configure the access policy mode to <i>deny</i> , the system checks the mode and service, and if they match, the system denies the connection. With the access policy mode configured to <i>deny</i> , the system does not check <i>accesslevel</i> and <i>access-strict</i> information. If you configure the access policy mode to allow, the system continues to check the <i>accesslevel</i> and <i>access-strict</i> information.
<code>name WORD&lt;0-15&gt;</code>	Specifies the access policy name.
<code>network &lt;A.B.C.D&gt; &lt;A.B.C.D&gt;</code>	Specifies the IP address and subnet mask for IPv4, or the IP address and prefix for IPv6, that can access the system through the specified access service. The switch supports access-policies over IPv4 and IPv6 with no difference in functionality or configuration.
<code>precedence &lt;1-128&gt;</code>	Specifies a precedence value for a policy, expressed as a number from 1–128. The precedence value determines which policy the system uses if multiple policies apply. Lower numbers take higher precedence. The default value is 10.
<code>snmp-group WORD&lt;1-32&gt; &lt;snmpv1 snmpv2c usm&gt;</code>	Adds an SNMP version 3 group under the access policy. <i>WORD&lt;1-32&gt;</i> is the SNMP version 3 group name consisting of 1–32 characters. <i>&lt;snmpv1 snmpv2c usm&gt;</i> is the security model; either <i>snmpv1</i> , <i>snmpv2c</i> , or <i>usm</i> .
<code>snmpv3</code>	Activates SNMP version 3 for the access policy.
<code>ssh</code>	Activates SSH for the access policy.
<code>telnet</code>	Activates Telnet for the access policy. Use the <b>no</b> operator to remove this configuration.
<code>tftp</code>	Activates the Trivial File Transfer Protocol (TFTP) for this access policy.

## Specifying a name for an access policy

### Before You Begin

The policy must exist before you can name it.

### About This Task

Assign a name to an existing access policy to uniquely identify the policy.

### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Assign a name to the access policy:  
access-policy <1-65535> name WORD<0-15>

### Example

Assign a name to an access policy:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#access-policy 10 name useraccounts
```

### Variable Definitions

The following table defines parameters for the **access-policy** command.

Variable	Value
name WORD<0-15>	Specifies a name expressed as a string from 0-15 characters.

## Allowing a network access to the switch

### About This Task

Specify the network to which you want to allow access.

### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Specify the network:  
access-policy <1-65535> [mode <allow|deny>] [network <A.B.C.D>  
<A.B.C.D>]

### Example

Specify the network to which you want to allow access:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#access-policy 5 mode allow network 192.192.192.0 24
```

## Variable Definitions

The following table defines parameters for the **access-policy** command.

Variable	Value
<code>mode &lt;allow deny&gt;</code>	Specifies whether a designated network address is allowed or denied access through the specified access service. The default is allow.
<code>network &lt;A.B.C.D&gt; &lt;A.B.C.D&gt;</code>	Specifies the IPv4 address and subnet mask, or the IPv6 address and prefix-length, permitted or denied access through the specified access service.

## Configuring access policies by MAC address

### About This Task

Configure access-policies by MAC address to allow or deny local MAC addresses on the network management port after an access policy is activated. If the source MAC does not match a configured entry, the default action is taken. For connections coming in from a different subnet, the source MAC of the last hop is used in decision making. Configuring access-policies by MAC address does not perform MAC or Forwarding Database (FDB) filtering on data ports.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Add the MAC address and configure the action for the policy:
 

```
access-policy by-mac <0x00:0x00:0x00:0x00:0x00:0x00> <allow|deny>
```
3. Specify the action for a MAC address that does not match the policy:
 

```
access-policy by-mac action <allow|deny>
```

### Example

Add the MAC address:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#access-policy by-mac 00-C0-D0-86-BB-E7 allow
```

## Variable Definitions

The following table defines parameters for the **access-policy by-mac** command.

Variable	Value
<0x00:0x00:0x00:0x00:0x00:0x00>	Adds a MAC address to the policy. Enter the MAC address in hexadecimal format.
<allow deny>	Specifies the action to take for the MAC address.

## Creating multiple CLI users

### Note

DEMO FEATURE - Multiple CLI Users Per Role is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [Fabric Engine and VOSS Feature Support Matrix](#).

You can create up to seven new CLI users on the switch, in addition to the three default CLI users. The username must be unique. If you enable the hsecure flag, password complexity rules apply to all users.

### Before You Begin

You must use an account with read-write-all privileges to create new CLI users.

### About This Task

### Note

When a new CLI user is created, the specified username and access level cannot be changed later.

### Procedure

1. Enter Global Configuration mode:  
enable  
  
configure terminal
2. Create a new CLI user:  
username add {<WORD 1-20> level [ro|rw|rwa] enable}
3. Enter a password.
4. Enter the password a second time.

### Example

Create a new CLI user:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#username add smith level rwa enable
```

```
Enter password : *****
Re-enter password : *****
Switch:1(config)#
```

### Variable Definitions

The following table defines parameters for the **username** command.

Variable	Value
<code>add WORD&lt;1-20&gt;</code>	Specifies the username to create.
<code>enable</code>	Enables the new CLI user.
<code>level &lt;ro   rw   rwa&gt;</code>	Specifies the level assigned to the new CLI user: <ul style="list-style-type: none"> <li>• ro: Read-only level</li> <li>• rw: Read-write level</li> <li>• rwa: Read-write-all level</li> </ul>

## Deleting a username

### About This Task

#### Note

DEMO FEATURE - Multiple CLI Users Per Role is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [Fabric Engine and VOSS Feature Support Matrix](#).

Use this task to delete a username. Default ro, rw, and rwa users cannot be deleted.

### Before You Begin

You must use an account with read-write-all privileges to delete a user.

### Procedure

1. Enter Global Configuration mode:

```
enable

configure terminal
```
2. Delete the username:

```
no username <WORD 1-20>
```

### Example

Delete a user:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#no username smith
The specified username will be deleted! Continue (y/n) ? Y
```

```
Switch:1(config)#show cli username smith
Username does not exist
```

### Variable Definitions

The following table defines parameters for the **no username** command.

Variable	Value
<i>WORD</i> <1-20>	Specifies the username to delete.
<i>enable</i>	Disables the username.

## Displaying CLI usernames and roles

### About This Task

#### Note

DEMO FEATURE - Multiple CLI Users Per Role is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [Fabric Engine and VOSS Feature Support Matrix](#).

Use this task to display CLI usernames and roles.

### Procedure

1. To enter User EXEC mode, log on to the switch.
2. Display CLI usernames and roles:

```
show cli username
```

### Example

```
Switch:1>show cli username

=====
UserName          AccessLevel      State           Type
=====
ro                ro               enable         default
rw                rw               enable         default
rwa               rwa              NA              default
smith             rw               enable         userDefined
```

## Enable a CLI User

DEMO FEATURE - Multiple CLI Users Per Role is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [Fabric Engine and VOSS Feature Support Matrix](#).

## About This Task

Perform this procedure to enable a user after you disable it using the Command Line Interface (CLI).

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable the user:  

```
username WORD<1-20> enable
```

### Example

Enable the CLI user after disabling it on the switch:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#username add test level rwa enable
Switch:1(config)#no username test enable
Switch:1(config)#username test enable
```

### Variable Definitions

The following table defines parameters for the **username** command.

Variable	Value
<i>WORD</i> <1-20>	Specifies the username to enable.
<i>enable</i>	Enables the username.

## System access security enhancements

The section provides information on security enhancements after you enable enhanced secure mode.

### Display the Boot Config Flags Status

Use the following procedure to display the boot config flags status.

If enhanced secure mode is enabled, the status displays whether the JITC or non-JITC sub-mode is enabled. If enhanced secure mode is disabled, the status displays as false.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. View the boot flags status:  

```
show boot config flags
```

## Example

In the following example, the status displays that enhanced secure mode is disabled.

### Note

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
flags block-snmp false
flags debug-config false
flags debugmode false
flags dvr-leaf-mode false
flags enhancedsecure-mode false
flags factorydefaults false
flags flow-control-mode true
flags ftpd true
flags hsecure false
flags ipv6-egress-filter true
flags ipv6-mode false
flags linerate-directed-broadcast false
flags logging true
flags nni-mstp false
flags reboot true
flags spanning-tree-mode mstp
flags spbm-config-mode true
flags sshd true
flags syslog-rfc5424-format true
flags telnetd true
flags tftpd true
flags trace-logging false
flags urpf-mode true
flags verify-config true
flags vrf-scaling true
flags vxlan-gw-full-interworking-mode false
```

### *Enabling enhanced secure mode*

Use the following procedure to enable enhanced secure mode. Enhanced secure mode is disabled by default.

### About This Task

### Note

When you migrate your switch from enhanced secure mode enabled to disabled, or from disabled to enabled, you must build a new configuration. Do not use a configuration created in either enhanced secure mode disabled or enabled, and expect it to transfer over to the new mode.

The configuration file cannot be guaranteed if you transfer between enhanced secure mode enabled to disabled, or from enhanced secure mode disabled to enabled.

After you enable the enhanced secure mode, the system provides role-based access levels, stronger password requirements, and stronger rules on password length, password complexity, password change intervals, password reuse, and password maximum age use. The enhanced secure mode boot flag supports two sub-modes namely JITC and non-JITC.

After you disable enhanced secure mode, the authentication, access-level, and password requirements work similarly to any of the existing commercial releases.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Enable enhanced secure mode:

```
boot config flags enhancedsecure-mode [jitc | non-jitc]
```

#### Note

As a best practice, enable the enhanced secure mode in the non-JITC sub-mode, because the JITC sub-mode is more restrictive and prevents the use of some CLI commands that are commonly used for troubleshooting.

3. (Optional) Disable enhanced secure mode:

```
no boot config flags enhancedsecure-mode
```

4. (Optional) Configure the enhanced secure mode to the default value:

```
default boot config flags enhancedsecure-mode
```

5. Save the configuration:

```
save config
```

#### Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

6. Restart the switch:

```
boot [config WORD<1-99>] [-y]
```

#### Note

If you enter the **boot** command with no arguments, you cause the switch to start using the current boot choices defined by the **boot config choice** command.

If you enter a boot command and the configuration filename without the directory, the device uses the configuration file from `/intflash/`.

### Example

Enable the enhanced secure non-JITC sub-mode:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags enhancedsecure-mode non-jitc
Switch:1(config)#save config
Switch:1(config)#exit
Switch:1(config)#boot config /intflash/config.cfg -y
```

Enable the enhanced secure JITC sub-mode:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#boot config flags enhancedsecure-mode jitc
Switch:1(config)#save config
Switch:1(config)#exit
Switch:1(config)#boot config /intflash/config.cfg -y
```

### Variable definitions

Use the data in the following table to use the **boot config flags enhancedsecure-mode** command.

Variable	Value
<i>jitc</i>	Enables the JITC enhanced secure mode. The JITC mode is more restrictive and prevents the use of some CLI commands that are commonly used for troubleshooting.
<i>non-jitc</i>	Enables the non-JITC enhanced secure mode.

### Create Accounts for Different Access Levels

Use the following procedure to create accounts for different access levels in enhanced secure mode. You must be the administrator to configure the different access levels.

#### Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

#### Procedure

- Enter Global Configuration mode:
 

```
enable

configure terminal
```
- Create accounts on the switch for different access levels:
 

```
password create-user {auditor|operator|privilege|security} WORD<1-255>
```
- Save the configuration:
 

```
save config
```

#### Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

## Example

Create an account at the auditor level for jsmith:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password create-user auditor jsmith
Switch:1(config)#save config
```

## Variable definitions

Use the data in the following table to use the **password create-user** command.

Variable	Value
<i>{auditor operator privilege security}</i>	Specifies the access level for the user.
<i>WORD&lt;1-255&gt;</i>	Specifies the user name.

## Deleting Accounts in Enhanced Secure Mode

Use the following procedure to delete accounts in enhanced secure mode.

### Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.
- You must be an admin or privilege user to delete accounts.

### Procedure

- Enter Global Configuration mode:
 

```
enable

configure terminal
```
- Delete an account on the switch:
 

```
password delete-user username WORD<1-255>
```
- Save the configuration:
 

```
save config
```

### Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

## Example

Delete an account for jsmith:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password delete-user user-name jsmith
Switch:1(config)#save config
```

## Variable definitions

Use the data in the following table to use the **password delete-user** command.

Variable	Value
<code>user-name WORD&lt;1-255&gt;</code>	Specifies the user name.

### Configuring a password for a specific user

Configure a new password for a user if the password has expired or locked. Only the administrator can configure a password for a user.

#### Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

#### Procedure

- Enter Global Configuration mode:  

```
enable

configure terminal
```
- Create accounts on the switch for different access levels:  

```
password set-password user-name WORD<1-255>
```
- Save the configuration:  

```
save config
```

#### Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

#### Example

Configure a password for jsmith:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password set-password user-name jsmith
Enter the New password : *****
Switch:1(config)#Password modified for user jsmith
Switch:1(config)#save config
```

## Variable definitions

Use the data in the following table to use the **password set-password** command.

Variable	Value
<code>user-name WORD&lt;1-255&gt;</code>	Specifies the user for which to configure the password.

### *Return the System to the Factory Defaults*

To return the system to factory defaults, run the **boot config flags factorydefaults** command.

For more information about the factorydefaults boot flag, see the following sections:

- [Boot Sequence](#) on page 164
- [Enable Factory Default Behavior](#) on page 237
- [Configure Boot Flags](#) on page 645

### *Configuring the Password Complexity Rule*

#### About This Task

Use the following procedure to configure the password complexity rule.

The password complexity rule default is to use at least two uppercase, two lowercase, two numeric, and two special character to meet the password criteria.

#### Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

#### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure the password complexity rule:  

```
password password-rule <1-2> <1-2> <1-2> <1-2>
```
3. (Optional) Configure the password complexity rule to the default:  

```
default password password-rule
```
4. Save the configuration:  

```
save config
```

#### Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

## Example

Configure the password complexity rule to require two uppercase, two lowercase, two numeric and two special characters in each password:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password password-rule 2 2 2 2
Switch:1(config)#save config
```

## Variable definitions

Use the data in the following table to use the **password password-rule** command.

Variable	Value
<1-2> <1-2> <1-2> <1-2>	Configures the minimum password rule. The first variable defines the number of uppercase characters required. The second <1-2> variable defines the number of lowercase characters required. The third <1-2> variable defines the number of numeric characters required. The fourth <1-2> variable defines the number of special characters required. The default for each of these is 2.

## Configuring the password length rule

### About This Task

Configure the password length rule after you enable enhanced secure mode. By default, the minimum password length is 15.

### Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

### Procedure

- Enter Global Configuration mode:
 

```
enable

configure terminal
```
- Configure the password length rule option:
 

```
password min-passwd-len <8-32>
```
- (Optional) Configure the password length rule to the default:
 

```
default password min-passwd-len
```

## 4. Save the configuration:

```
save config
```

**Note**

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

**Example**

Configure the password length rule to 20:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password min-passwd-len 20
Switch:1(config)#save config
```

**Variable definitions**

Use the data in the following table to use the **password min-passwd-len** command.

Variable	Value
<8-32>	Configures the minimum character length required. The default is 15.

*Configuring the change interval rule***About This Task**

Use the following procedure to configure the change interval rule. The system enforces a minimum password change interval, which defines the minimum amount of time before you can change to a new password. By default, the minimum change interval is 24 hours between changing from one password to a new password.

**Before You Begin**

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

**Procedure**

- Enter Global Configuration mode:
 

```
enable

configure terminal
```
- Configure the change interval rule option:
 

```
password change-interval <1-999 hours>
```
- (Optional) Configures the change interval rule to the default:
 

```
default password change-interval
```

## 4. Save the configuration:

```
save config
```

**Note**

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

**Example**

Configure the change interval rule to 72 hours:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password change-interval 72
Switch:1(config)#save config
```

**Variable definitions**

Use the data in the following table to use the **password change-interval** command.

Variable	Value
<1-999>	Configures the minimum interval between consecutive password changes. The default is 24 hours.

*Configuring the reuse rule*

Use the following procedure to configure the password reuse rule. The default password reuse rule is 3.

**Before You Begin**

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

**Procedure**

- Enter Global Configuration mode:
 

```
enable

configure terminal
```
- Configure the password reuse rule option:
 

```
password password-history <3-32>
```
- (Optional) Configure the password reuse rule to the default:
 

```
default password password-history
```

## 4. Save the configuration:

```
save config
```

**Note**

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

**Example**

Configure the reuse rule to 30:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password password-history 30
Switch:1(config)#save config
```

**Variable definitions**

Use the data in the following table to use the **password password-history** command.

Variable	Value
<3-32>	Configures the minimum number of previous passwords to remember. The default is 3.

*Configuring the maximum number of sessions*

Use the following procedure to configure the maximum number of sessions on the switch. The max-sessions value configures the number of times a particular role-based user can log in to the switch through the SSH session at the same time. The default max-sessions value is 3.

The max-sessions value applies only for SSH sessions, and only with enhanced secure mode enabled.

**Before You Begin**

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

**Procedure**

- Enter Global Configuration mode:
 

```
enable

configure terminal
```
- Configure the maximum number of sessions:
 

```
password max-sessions <1-8> user-name WORD<1-255>
```
- (Optional) Configure the password reuse rule to the default:
 

```
default password max-sessions
```

## 4. Save the configuration:

```
save config
```

**Note**

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

**Example**

Configure the reuse rule to 5:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password max-sessions 5 user-name jsmith
Switch:1(config)#save config
```

**Variable definitions**

Use the data in the following table to use the **password max-sessions** command.

Variable	Value
<1-8>	Specifies the maximum number of sessions. The default is 3.
user-name <i>WORD</i> <1-255>	Specifies the user-name.

*Configuring the maximum age rule*

Use the following procedure to configure the maximum age rule.

If enhanced secure mode is enabled, the individual with the administrator access level role can configure the aging-time for each user. If you configure the aging time for each user, the aging time must be more than the global change interval value. The default is 90 days.

If you do not enable enhanced secure mode, the aging time is a global value for all users.

**Before You Begin**

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

**Procedure**

## 1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

## 2. Configure the maximum age rule option:

```
password aging-time day <1-365> [user WORD<1-255>]
```

- (Optional) Configure the maximum age rule to the default:

```
default password aging-time [user WORD<1-255>]
```

- Save the configuration:

```
save config
```

#### Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

### Example

Configure the maximum age rule option to 100 days for user jsmith:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#password aging-time day 100 user jsmith
Switch:1(config)#save config
```

### Variable definitions

Use the data in the following table to use the **password aging-time** command.

Variable	Value
<i>day</i> <1-365>	Configures the password aging time in days. The default is 90 days.
<i>user</i> WORD<1-255>	Specifies a particular user.

### Configuring the Pre-notification and Post-notification Rule

Use the following procedure to configure the pre-notification and post-notification rule.

After enhanced secure mode is enabled, the switch enforces password expiry. To ensure a user does not lose access, the switch offers pre- and post-notification messages explaining when the password will expire.

The administrator can define pre- and post-notification intervals to between one to 99 days.

#### Before You Begin

- You must enable enhanced secure mode in either the JITC or non-JITC sub-modes. As a best practice, use the non-JITC sub-mode because the JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

#### About This Task

The pre-notification intervals provide messages to warn users that their passwords will expire within a particular timeframe:

The post-notification intervals provide notification to users that their passwords have expired within a particular timeframe:

- interval 1—By default, interval 1 is 1 day.
- interval 2—By default, interval 2 is 7 days.
- interval 3—By default, interval 3 is 30 days.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the pre-notification rule option:

```
password pre-expiry-notification-interval <1-99> <1-99> <1-99>
```

3. Configure post-notification rule option:

```
password post-expiry-notification-interval <1-99> <1-99> <1-99>
```

4. Configure the pre-notification rule to the default:

```
default password pre-expiry-notification-interval
```

5. Configure the post-notification rule to the default:

```
default password post-expiry-notification-interval
```

6. Save the configuration:

```
save config
```

#### Note

The **save config** command saves the configuration file with the filename configured as the primary configuration filename in **boot config**. Use the command **show boot config choice** to view the current primary and backup configuration filenames.

### Example

Configure the pre- and post-notification rules to the default:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#default password pre-expiry-notification-interval
Switch:1(config)#default password post-expiry-notification-interval
Switch:1(config)#save config
```

### Variable definitions

Use the data in the following table to use the **pre-expiry-notification-interval** command.

Variable	Value
<1-99> <1-99> <1-99>	<p>Configure the pre-notification intervals to provide messages to warn the users that their passwords will expire within a particular timeframe.</p> <p>The first &lt;1-99&gt; variable specifies the first notification, the second &lt;1-99&gt; specifies the second notification, and the third &lt;1-99&gt; variable specifies the third interval.</p> <p>By default, the first interval is 30 days, the second interval is 7 days, and the third interval is 1 day.</p>

Use the data in the following table to use the **post-expiry-notification-interval** command.

Variable	Value
<1-99> <1-99> <1-99>	<p>Configure the post-notification intervals to provide notification to the users that their passwords have expired within a particular timeframe.</p> <p>The first &lt;1-99&gt; variable specifies the first notification, the second &lt;1-99&gt; specifies the second notification, and the third &lt;1-99&gt; variable specifies the third interval.</p> <p>By default, the first interval is 1 day, the second interval is 7 days, and the third interval is 30 days.</p>

## System access configuration using EDM

The section provides procedures you can use to manage system access by using Enterprise Device Manager (EDM). Procedures include configurations for usernames, passwords, and access policies.

### Configuring CLI Access using EDM

Use the following procedures to perform CLI access configuration tasks such as:

- Enable access levels
- Change passwords
- Configure the logon banner

#### *Enable Access Levels*

##### **About This Task**

Enable access levels to control the configuration actions of various users.

##### **Important**

Only the RWA user can disable an access level on the switch. You cannot disable the RWA access level on the switch.

The system preserves these configurations across restarts.

##### **Procedure**

1. In the navigation pane, expand **Configuration > Security > Control Path**.

2. Click **General**.
3. Click the **CLI** tab.
4. Select the enable check box for the required access level.
5. Click **Apply**.

### *Change Passwords*

#### **About This Task**

Configure new passwords for each access level, or change the logon or password for the different access levels of the system to prevent unauthorized access. After you receive the switch, use default passwords to initially access CLI. If you use Simple Network Management Protocol version 3 (SNMPv3), you can change passwords in encrypted format.

#### **Procedure**

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **CLI** tab.
4. Specify the username and password for the appropriate access level.
5. Click **Apply**.

### *Configure the Logon Banner*

#### **About This Task**

Configure the logon banner using EDM to display a warning message to users on the CLI before authentication.

#### **Procedure**

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **CLI** tab.
4. Enter the banner text in the **CustomBannerText** field.
5. Check the **CustomBannerEnable** check box.
6. Click **Apply**.

#### **CLI Field Descriptions**

The following table defines parameters for the **CLI** tab.

Name	Description
<b>RWAUserName</b>	Specifies the user name for the read-write-all CLI account.
<b>RWAPassword</b>	Specifies the password for the read-write-all CLI account.
<b>RWEnable</b>	Activates the read-write access. The default is enabled.

Name	Description
<b>RWUserName</b>	Specifies the user name for the read-write CLI account.
<b>RWPassword</b>	Specifies the password for the read-write CLI account.
<b>RWL3Enable</b>	Activates the read-write Layer 3 access. The default is enabled.
<b>RWL3UserName</b>	Specifies the user name for the Layer 3 read-write CLI account.
<b>RWL3Password</b>	Specifies the password for the Layer 3 read-write CLI account.
<b>RWL2Enable</b>	Activates the read-write Layer 2 access. The default is enabled.
<b>RWL2UserName</b>	Specifies the user name for the Layer 2 read-write CLI account.
<b>RWL2Password</b>	Specifies the password for the Layer 2 read-write CLI account.
<b>RWL1Enable</b>	Activates the read-write Layer 1 access. The default is enabled.
<b>RWL1UserName</b>	Specifies the user name for the Layer 1 read-write CLI account.
<b>RWL1Password</b>	Specifies the password for the Layer 1 read-write CLI account.
<b>ROEnable</b>	Activates the read-only CLI account. The default is enabled.
<b>ROUserName</b>	Specifies the user name for the read-only CLI account.
<b>ROPassword</b>	Specifies the password for the read-only CLI account.
<b>MaxTelnetSessions</b>	Specifies the maximum number of concurrent Telnet sessions in a range from 0–8. The default is 8.
<b>Timeout</b>	Specifies the number of seconds of inactivity for a Telnet before the system initiates automatic timeout and disconnect, expressed in a range from 30–65535. The default is 900 seconds.
<b>NumAccessViolations</b>	Indicates the number of CLI access violations detected by the system. This variable is a read-only field.

Name	Description
<b>CustomBannerText</b>  <b>Note:</b> Exception: not supported on VSP 8600 Series.	Specifies the text message that is displayed to users on the CLI before authentication. The message can be company information, such as company name and contact, or a warning message for the users of CLI. With character limitation from 1-1800, the text box displays 79 characters per line.
<b>CustomBannerEnable</b>  <b>Note:</b> Exception: not supported on VSP 8600 Series.	Specifies whether custom logon banner is enabled or disabled. The default is enabled.

## Create an Access Policy

### About This Task

Create an access policy to control access to the switch. An access policy specifies the hosts or networks that can access the switch through various services, such as Telnet, SNMP, HTTP, and SSH.

You can allow network stations to access the switch or forbid network stations to access the switch. For each service, you can also specify the level of access, such as read-only or read-write-all.

HTTP and HTTPS support IPv4 and IPv6 addresses.

If you configure the access policy mode to **deny**, the system checks the mode and service, and if they match the system denies the connection. With the access policy mode configured to **deny**, the system does not check **AccessLevel** and **AccessStrict** information. If you configure the access policy mode to allow, the system continues to check the **AccessLevel** and **AccessStrict** information.

#### Important

EDM does not provide SNMPv3 support for an access policy. If you modify an access policy with EDM, SNMPV3 is disabled.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **Access Policies**.
3. Select the **Access Policies** tab.
4. Select **Insert**.
5. In **ID**, type the policy ID.
6. In **Name**, type the policy name.
7. Select **PolicyEnable**.
8. Select the **Mode** option to allow or deny a service.

9. From the **Service** options, select a service.
10. In **Precedence**, type a precedence number for the service (lower numbers mean higher precedence).
11. Select the **NetInetAddrType**.
12. In **NetInetAddress**, type an IP address.
13. In **NetInetAddressPrefixLen**, type the prefix length.
14. Select an **AccessLevel** for the service.
15. Select **AccessStrict**, if required.

#### Important

If you select **AccessStrict**, you specify that a user must use an access level identical to the one you select.

16. Select **Insert**.

### **Access Policies** Field Descriptions

Use the data in the following table to use the **Access Policies** tab.

Name	Description
<b>Id</b>	Specifies the policy ID.
<b>Name</b>	Specifies the name of the policy.
<b>PolicyEnable</b>	Activates the access policy. The default is enabled.
<b>Mode</b>	Indicates whether a packet with a source IP address matching this entry is permitted to enter the device or is denied access. The default is allow. If you configure the access policy mode to <b>deny</b> , the system checks the mode and service, and if they match the system denies the connection. With the access policy mode configured to <b>deny</b> , the system does not check <b>AccessLevel</b> and <b>AccessStrict</b> information. If you configure the access policy mode to allow, the system continues to check the <b>AccessLevel</b> and <b>AccessStrict</b> information.
<b>Service</b>	Indicates the protocol to which this entry applies. The default is no service enabled.
<b>Precedence</b>	Indicates the precedence of the policy expressed in a range from 1–128. The lower the number, the higher the precedence. The default is 10.
<b>NetInetAddrType</b>	Indicates the source network Internet address type as one of the following. <ul style="list-style-type: none"> <li>• any</li> <li>• IPv4</li> <li>• IPv6</li> </ul> <p>IPv4 is expressed in the format a.b.c.d. Express IPv6 in the format x:x:x:x:x:x.</p>

Name	Description
<b>NetInetAddress</b>	Indicates the source network Inet address (prefix/network). If the address type is IPv4, you must enter an IPv4 address and its mask length. If the type is IPv6, you must enter an IPv6 address. You do not need to provide this information if you select the NetInetAddressType of <b>any</b> .
<b>NetInetAddressPrefixLen</b>	Indicates the source network Inet address prefix-length/mask. If the type is IPv4, you must enter an IPv4 address and mask length. If the type is IPv6, you must enter an IPv6 address and prefix length. You do not need to provide this information if you select the NetInetAddressType of <b>any</b> .
<b>TrustedHostInetAddress</b>  <b>Note:</b> Exception: rlogin and rsh are only supported on VSP 8600 Series.	Indicates the trusted address of a host performing a login to the device. You do not need to provide this information if you select the NetInetAddressType of <b>any</b> .  <b>Important:</b> You cannot use wildcard entries in <b>TrustedHostInetAddress</b> .  If the type is IPv4, you must enter an IPv4 address and mask length. If the type is IPv6, you must enter an IPv6 address and prefix length.
<b>AccessLevel</b>	Specifies the access level of the trusted host as one of the following: <ul style="list-style-type: none"> <li>• readOnly</li> <li>• readWrite</li> <li>• readWriteAll</li> </ul> The default is readOnly.

Name	Description
<b>Usage</b>	Counts the number of times this access policy applies.
<b>AccessStrict</b>	<p>Activates or disables strict access criteria for remote users. If selected, a user must use an access level identical to the one you selected in the dialog box to use this service.</p> <ul style="list-style-type: none"> <li>• selected (true): The system accepts only the currently configured access level.</li> <li>• cleared (false): The system accepts access up to the configured level.</li> </ul> <p><b>Note:</b> If you configure <b>Mode</b> to <b>allow</b>, the system checks <b>AccessStrict</b> information. If you configure <b>Mode</b> to <b>deny</b>, the system does not check <b>AccessStrict</b> information.</p> <p><b>Important:</b> If you do not select true or false, user access is governed by criteria specified in the policy table. For example, a user with an rw access level specified for a policy ID in the policy table is granted rw access, and ro is denied access.</p> <p>The default is false (cleared).</p>

## Enable an Access Policy

### About This Task

Enable the access policy feature globally to control access across the switch.

You can create an access policy to control access to the switch. An access policy specifies the hosts or networks that can access the switch through access services; for example Telnet, SNMP, and Hypertext Transfer Protocol (HTTP).

### Procedure

1. In the Device Physical View tab, select the Device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Select **Chassis**.
4. Select the **System Flags** tab.
5. Select **EnableAccessPolicy**.
6. Select **Apply**.

## Creating Multiple Users

### Note

DEMO FEATURE - Multiple CLI Users Per Role is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [Fabric Engine and VOSS Feature Support Matrix](#).

You can create up to seven new CLI user roles on the switch, in addition to the three default CLI user roles. The username must be unique. If you enable the hsecure flag, password complexity rules apply to all users.

### Before You Begin

You must use an EDM account with read-write-all privileges to create new CLI users.

### About This Task

Use this task to create multiple CLI users on the switch using EDM.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Multiple Users** tab.
4. Click **Insert**.
5. Type the ID.
6. Type a unique user name.
7. Type a password.
8. Select the access level.
9. Select **Enable** to activate the user account.
10. Click **Insert**.

### **Multiple Users** field descriptions

Use the data in the following table to use the **Multiple Users** tab.

Name	Description
<b>Id</b>	Specifies the unique ID.
<b>Name</b>	Specifies the username.
<b>Password</b>	Specifies the password.
<b>Level</b>	Specifies the user access level. <ul style="list-style-type: none"> <li>• ro</li> <li>• rw</li> <li>• rwa</li> </ul>

Name	Description
Enable	Enables the user access on the switch.
Type	Specifies the user type.

## Modify User Passwords

### About This Task

#### Note

DEMO FEATURE - Multiple CLI Users Per Role is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [Fabric Engine and VOSS Feature Support Matrix](#).

Use this task to modify user account passwords using EDM.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Multiple Users** tab.
4. To change the user account password, double-click the **Password** field.
5. Click **Apply**.

## Disable a User Account

### About This Task

#### Note

DEMO FEATURE - Multiple CLI Users Per Role is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [Fabric Engine and VOSS Feature Support Matrix](#).

Use this task to disable a user account using EDM.

#### Note

Users with rwa access rights cannot be disabled. Only users with ro and rw access rights can be disabled.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Multiple Users** tab.

4. View whether the user account is enabled. To modify, double-click on the cell and select false from the list.
5. Click **Apply**.

## Delete a User Account

### About This Task

#### Note

DEMO FEATURE - Multiple CLI Users Per Role is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [Fabric Engine and VOSS Feature Support Matrix](#).

Use this task to delete a user account using EDM. You cannot delete default ro, rw, and rwa users.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **General**.
3. Click the **Multiple Users** tab.
4. Select the row with the user account to delete and click **Delete**.
5. Click **Yes** to confirm.

## System access security enhancements using EDM

The section provides information to enable enhanced secure mode.

### *Enable Enhanced Secure Mode*

Use the following procedure to enable enhanced secure mode in either the JITC or non-JITC sub-modes.

The enhanced secure mode is disabled by default.

### About This Task

After you enable enhanced secure mode, the system can provide role-based access levels, stronger password requirements, and stronger rules on password length, password complexity, password change intervals, password reuse, and password maximum age use.

After you disable enhanced secure mode, the authentication, access-level, and password requirements work similarly to any of the existing commercial releases.

#### Note

You can use EDM to enable or disable enhanced secure mode. To configure the security enhancements this feature provides, you must use CLI.

## Procedure

1. On the Device Physical View, select the device.
2. In the navigation pane, expand **Configuration > Edit**.
3. Click **Chassis**.
4. Click the **Boot Config** tab.
5. In the **EnableEnhancedsecureMode** option box, select either **jitc** or **non-jitc** to enable the enhanced secure mode in one of these sub-modes. Select **disable** to disable the enhanced secure mode.

### Note

As a best practice, enable the non-JITC sub-mode. The JITC sub-mode is more restrictive and prevents the use of some troubleshooting utilities.

6. Click **Apply**.
7. Save the configuration, and restart the switch.

# TACACS+

	VSP 4900 Series	VOSS 8.1
	VSP 7200 Series	VOSS 5.1.2
	VSP 7400 Series	VOSS 8.0
	VSP 8200 Series	VOSS 5.1.2
	VSP 8400 Series	VOSS 5.1.2
	VSP 8600 Series	VSP 8600 8.0 demonstration feature
	XA1400 Series	VOSS 8.0.50

**Note**

DEMO FEATURE - Secure AAA server communication, which includes TACACS+ secure communication for IPv4, is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information on feature support, see [Fabric Engine and VOSS Feature Support Matrix](#).

## TACACS+ Fundamentals

The switch supports the TACACS+ client. TACACS+ is a remote authentication protocol that provides centralized validation of users who attempt to gain access to a router or Network Access Server (NAS).

The TACACS+ feature is a client and server-based protocol that allows the switch to accept a user name and password and send a query to a TACACS+ authentication server, sometimes called a TACACS+ daemon. The TACACS+ server allows access or denies access based on the response by the client.

The TACACS+ feature facilitates the following services:

- Login authentication and authorization for CLI access through Secure Shell (SSH), Telnet, or serial port.
- Login authentication for web access through EDM.

- Command authorization for CLI through SSH, Telnet, or serial port.
- Accounting of CLI through SSH, Telnet, and serial port.

The following figure displays the basic layout of the switch and the TACACS+ server for a remote user connection.

**Figure 250: Switch and TACACS+ server**

The TACACS+ feature uses Transmission Control Protocol (TCP) for its transport to ensure reliable delivery of packets. TACACS+ provides security by encrypting all traffic between the switch, which acts as the Network Access Server, and the TACACS+ server.

TACACS+ is a newer version of TACACS and provides separate authentication, authorization, and accounting (AAA) services. TACACS+ does not support earlier versions of TACACS.

TACACS+ is a base license feature. The TACACS+ feature is disabled by default.

## TACACS+ Operation

The switch acts as an NAS to provide a connection to a single user, to a network, subnetwork or interconnected networks. The switch acts as a gateway to guard access to the TACACS+ server and network. Encryption relies on a secret key that is known to the client and the TACACS+ server.

Similar to the Remote Access Dial-In User Services (RADIUS) protocol, TACACS+ provides the ability to centrally manage the users who want to access a remote device. TACACS+ provides management of remote and local users who try to access a device through:

- Secure Shell (SSHv2)
- Telnet
- serial port
- web management

A TACACS+ daemon, which typically runs on a UNIX or Windows NT workstation, maintains the TACACS+ authentication, authorization, and accounting services.

You configure users in the TACACS+ server. If you enable authentication, authorization, and accounting services, the following occurs:

- During the logon process, the TACACS+ client initiates the TACACS+ authentication session with the TACACS+ server.
- After successful authentication the TACACS+ client initiates the TACACS+ authorization session with the TACACS+ server. This is transparent to the user. The switch receives the user access level after a successful TACACS+ authorization. The TACACS+ server authorizes every command the user issues if TACACS+ command authorization is enabled for that user access level.

- After successful authorization, if you enable TACACS+ accounting, the TACACS+ client sends accounting information to the TACACS+ server.

A TACACS+ session establishes with the server in one of two ways:

- Multi-connection mode (also known as per-session): For every authentication, authorization, and accounting (AAA) request the switch establishes a session with the TACACS+ server, and then after the request finishes, the session is torn down. Multi-connection mode is the default mode.
- Single-connection mode: The first AAA request establishes the session, which is only torn down if TACACS+ is disabled or due to inactivity.

## TACACS+ Architecture

You can connect the TACACS+ server to the switch:

- In-band through one of the data ports.
- Out-of-band through the management port.

Connect the TACACS+ server through a local interface. Management PCs can reside on an out-of-band management Ethernet port, or on the corporate network. Place the TACACS+ server on the corporate network so you can route it to the switch.

Before you configure the switch, you must configure at least one TACACS+ server and a key.

The TACACS+ server and the switch must have the same:

- Encryption key
- Connection mode (single connection or per-session connection. Per-session connection is the same as multi-connection mode.)
- TCP port number

You can configure a secondary TACACS+ server for backup authentication. You specify the primary authentication server when you configure the switch.

## Authentication, authorization, and accounting

A fundamental feature of TACACS+ is the separation of authentication, authorization, and accounting (AAA) services, which allows you to selectively implement one or more TACACS + services.

### *TACACS+ authentication*

TACACS+ authentication provides control of authentication through login and password.

Authentication uses a database of users and passwords to determine:

- who a user is

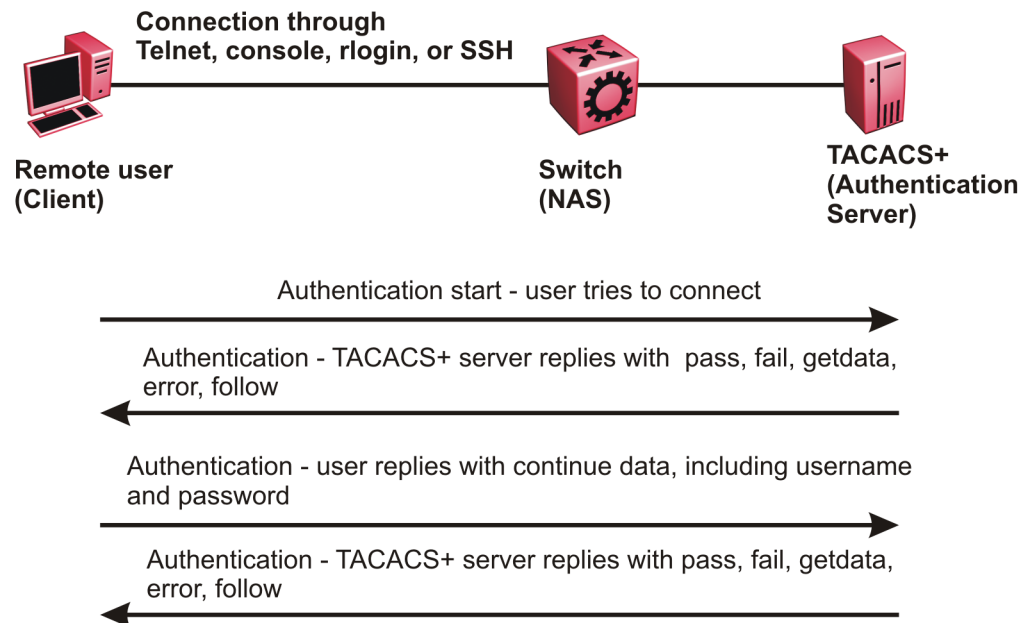

- whether to allow the user access to the NAS

### Important

Prompts for log on and password occur prior to the authentication process. If TACACS+ fails because no valid servers exist, the device uses the user name and password from the local database. If TACACS+ or the local database returns an access denied packet, the authentication process stops. The device attempts no other authentication methods.

The following figure illustrates the authentication process.

**Figure 251: Authentication process**

### TACACS+ authorization

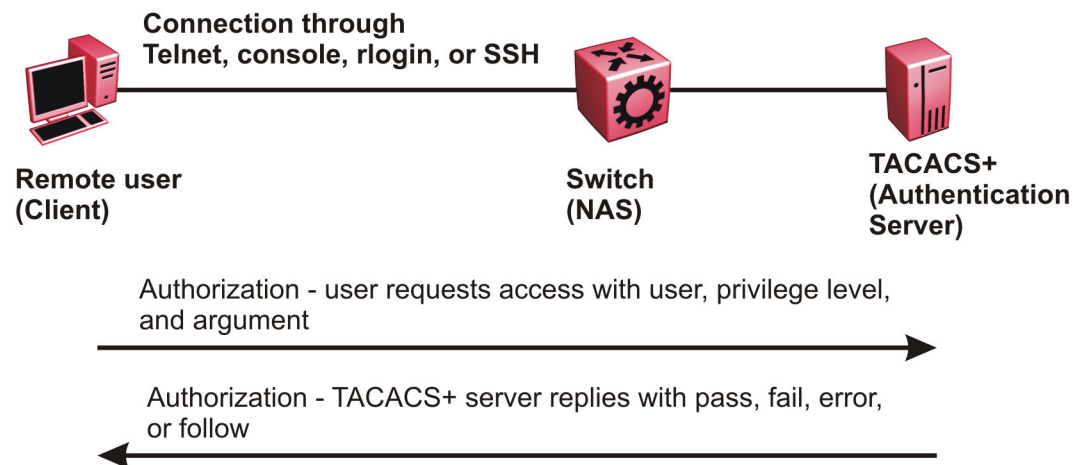

The transition from TACACS+ authentication to the authorization phase is transparent to the user. After successful completion of the authentication session, an authorization session starts with the authenticated user name. The authorization session provides access level functionality.

Authorization cannot occur without authentication.

Authorization:

- determines what a user can do
- allows administrators fine-grained control over the capabilities of users during sessions

The following figure illustrates the authorization process.

**Figure 252: Authorization process**

Authorization determines what a user can do. Authorization gives you the ability to limit network services to certain users and to limit the use of certain commands to certain users. The TACACS+ feature enhances the security by tightly policing the command execution for a particular user. After you enable command authorization, all commands, no matter the access level to which they belong, are sent to the TACACS+ server for authorization. Authorization cannot occur without first enabling authentication. You must configure command authorization globally and at individual access levels.

Two kinds of authorization requests exist:

1. Login authorization: Login authorization happens immediately after authentication and is transparent to the user. When the user logs on to the device, authorization provides the user access level. With log on, the device does not send a command to the TACACS+ server. You cannot configure login authorization.
2. Command authorization: When you configure command authorization for a particular level, all commands that you issue are sent to the TACACS+ server for authorization. The device can only issue the commands the TACACS+ server

authorizes. You need to configure command authorization globally and at individual access levels, which are visible to the users.

**Note**

You must verify that the switch can reach the TACACS+ server and that you configure TACACS+ properly before you enable command authorization.

If a user is TACACS+ authenticated and command authorization is enabled for that level, then if the switch cannot reach the TACACS+ server, the switch does not allow the user to issue any command that has privilege level command authorization enabled. In such a case, the user can only issue logout and exit commands.

If a user tries to log in and the TACACS+ server does not exist or is not reachable, then, as discussed before, a local database in the switch authenticates the user. The switch authorizes a locally authenticated user and a locally authenticated user is not eligible for TACACS+ command authorization.

After the switch requests authorization, the logon credentials are sent to the TACACS+ daemon for authorization. If logon authorization fails, the user receives a permission denied message.

If TACACS+ logon authorization succeeds, the switch uses information from the user profile, which exists in the local user database or on the TACACS+ server, to configure the session for the user.

After you enable TACACS+ command authorization all commands are visible to all users; however, the user can only issue those commands that the TACACS+ server configuration allows.

The switch cannot enforce command access level. The TACACS+ server returns an access level to the switch. The switch allows the user to access the switch according to the access level. The device grants the user access to a command only if the profile for the user allows the access level.

You preconfigure command authorization on the TACACS+ server. You specify a list of regular expressions that match command arguments, and you associate each command with an action to deny or permit.

All members in a group have the same authorization. If you place a user in a group, the daemon looks in the group for authorization parameters if it cannot find them in the user profile.

### *TACACS+ Accounting*

TACACS+ accounting enables you to track the services users access and the amount of network resources users consume.

TACACS+ accounting allows you to track:

- what a user does
- when a user does certain actions

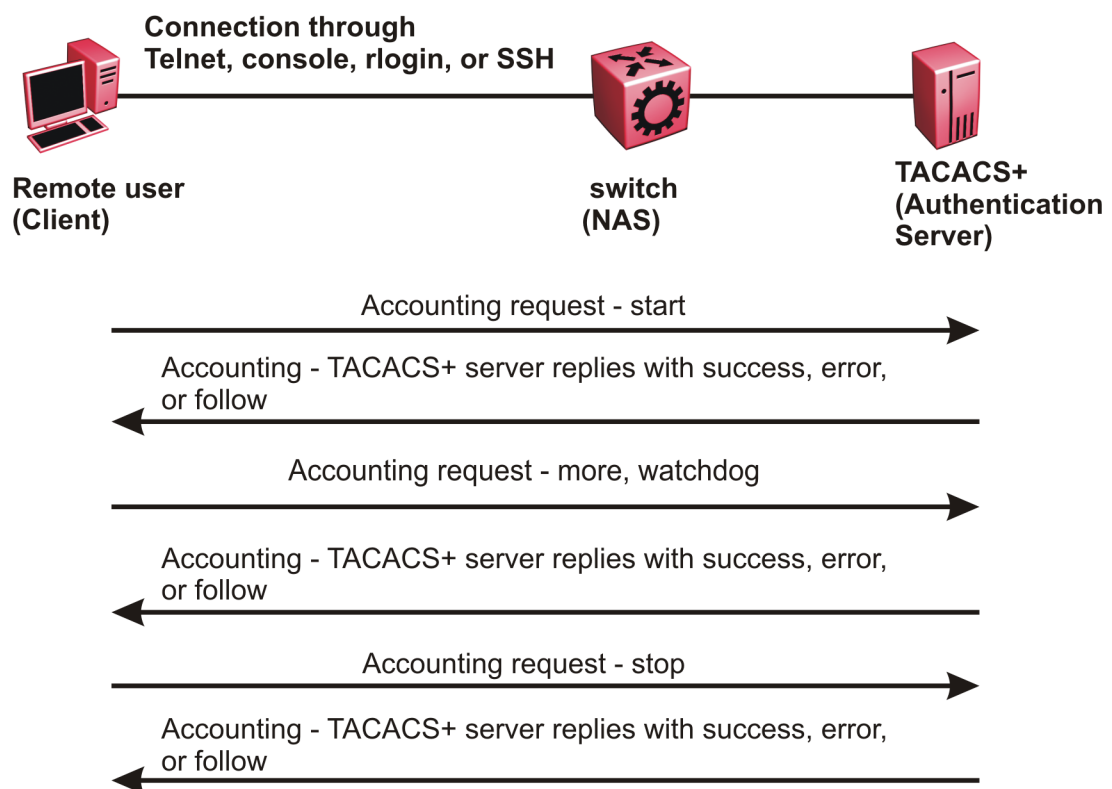

The accounting record includes the following information:

- User name
- Date
- Start/stop/elapsed time
- Access server IP address
- Reason

You can use accounting for an audit trail, to bill for connection time or resources used, or for network management. TACACS+ accounting provides information about user sessions using the following connection types: Telnet, SSH, and web-based management.

With separation of AAA, accounting can occur independently from authentication and authorization.

The following figure illustrates the accounting process.

**Figure 253: Accounting process**

After you enable accounting, the switch reports user activity to the TACACS+ server in the form of accounting records. Each accounting record contains accounting attribute value (AV) pairs. AV pairs are strings of text in the form “attribute-value” sent between the switch and a TACACS+ daemon as part of the TACACS+ protocol. The TACACS+ server stores the accounting records.

You cannot customize the set of events the switch monitors and logs with TACACS+ accounting. TACACS+ accounting logs the following events:

- User logon and logoff
- Logoff generated because of activity timeout
- Unauthorized command
- Telnet session closed (not logged off)

## Privilege Level Changes at Runtime

You can change your privilege level at runtime with the **tacacs switch level** command.

You need to configure separate profiles in the TACACS+ server configuration file for the switch level. The switch supports only levels 1 to 6 and level 15. The switch uses the profile when you issue the command **tacacs switch level <1-15>**. As part of the profile, you specify a user name, level, and password. To preconfigure a dummy user for that level on the TACACS+ daemon, the format of the user name for the dummy user is **\$enab<n>\$**, where **<n>** is the privilege level to which you want to allow access.

The following is an example of a TACACS+ server profile, which you configure on the TACACS+ server:

```
user = $enab6$ {
member = level6
login = cleartext get-me-on-6
}
```

The following table maps user accounts to TACACS+ privilege level.

Switch access level	TACACS+ privilege level	Description
NONE	0	If the TACACS+ server returns an access level of 0, the user is denied access. You cannot log into the device if you have an access level of 0.
READ ONLY	1	Permits you to view only configuration and status information.
LAYER 1 READ WRITE	2	Permits you to view most of the switch configuration and status information and change physical port settings.
LAYER 2 READ WRITE	3	Permits you to view and change configuration and status information for Layer 2 (bridging and switching) functions.

Switch access level	TACACS+ privilege level	Description
LAYER 3 READ WRITE	4	Permits you to view and change configuration and status information for Layer 2 and Layer 3 (routing) functions.
READ WRITE	5	Permits you to view and change configuration and status information across the switch. This level does not allow you to change security and password settings.
READ WRITE ALL	6	Permits you to have all the rights of read-write access and the ability to change security settings, including command line interface (CLI) and web-based management user names and passwords, and the SNMP community strings.

Switch access level	TACACS+ privilege level	Description
NONE	7 to 14	If the TACACS+ server returns an access level of 7 to 14, the user is denied access. You cannot log into the device if you have an access level of 7 to 14.
READ WRITE ALL	15	Permits you to have all the rights of read-write access and the ability to change security settings, including command line interface (CLI) and web-based management user names and passwords, and the SNMP community strings.  <b>Note:</b> Access level 15 is internally mapped to access level 6, which ensures consistency with other vendor implementations. The switch does not differentiate between an access level of 6 and an access level of 15.

#### Note

If you enable enhanced secure mode with the **boot config flags `enhancedsecure-mode`** command, you enable different access levels, along with stronger password complexity, length, and minimum change intervals. With enhanced secure mode enabled, the switch supports the following access levels for RADIUS authentication:

- Administrator
- Privilege
- Operator
- Auditor
- Security

The switch associates each username with a certain role and appropriate authorization rights to view and configure commands. For more information, see [Enhanced Secure Mode](#) on page 3618.

#### *TACACS+ command authorization*

After you enable TACACS+ authorization, the current privilege-level to command mapping on the switch is no longer relevant because the TACACS+ server has complete

responsibility for command authorization. TACACS+ authorization provides access to the system based on username, not based on privilege level.

After you enable TACACS+ command authorization for a particular privilege level, and a user with that privilege level logs on, the user can access commands based on his user name.

#### *TACACS+ switch level and TACACS+ switch back commands*

The user can only issue the **tacacs switch level** command after TACACS+ authenticates the user. Locally authenticated users, which means users authenticated only by the switch and not by the TACACS+ server, cannot use the **tacacs switch level** command.

Consider a user, called X, with a privilege level of 4, who uses the **tacacs switch level <1-15>** command to change the privilege level from 4 to 6.

If user X successfully changes the switch level to 6, the user name changes from X to "\$enab6\$", and the privilege level changes from 4 to 6. If TACACS+ command authorization is enabled for privilege level 6, then the TACACS+ server authorizes commands issued based on the rules defined for (dummy) user "\$enab6\$".

If TACACS+ command authorization is not enabled for privilege level 6, then the switch locally authorizes the user X based on the privilege level of the user.

The user can return to his previous privilege level using the **tacacs switch back** command. In the preceding scenario, if the user issues the **tacacs switch back** command, the user name changes for user X from "\$enab6\$" to X, and the privilege level changes from 6 to 4.

TACACS+ switch level supports up to eight levels, and TACACS+ switch level allows a user to switch level up to eight times from his original privilege level. The switch stores all of the previous privilege levels in the same order in which the user switches levels. After switching eight times, if the user tries to switch a level the ninth time, the following error message displays:

```
Only allowed to switch level 8 times!
```

The user can switch back to his previous privilege levels using the **tacacs switch back** command. The **tacacs switch back** command switches back in the reverse order in which you issued the **tacacs switch level** command. Consider a user who switched levels from 4 to 5, and then to 6. If the user used the **tacacs switch back** command, the user first moves from 6 to 5, and then using the **tacacs switch back** command again moves from 5 to 4.

#### Note

If you want to switch to a privilege level 'X' using **tacacs switch level <1-15>** command, you must create a user "\$enabX\$" on the TACACS+ server. X is the privilege level that you want to change.

*TACACS+ switch level functionality:*

The following table explains TACACS+ switch level functionality.

User logs in with	TACACS+ server available	Result
TACACS+ authentication	Yes	The user can issue the <b>tacacs switch level &lt;1-15&gt;</b> command.
Local authentication	No	The user cannot issue the <b>tacacs switch level &lt;1-15&gt;</b> command.
Local authentication	Yes	Even if a TACACS+ server becomes reachable, the user remains locally authenticated and cannot issue the <b>tacacs switch level &lt;1-15&gt;</b> command.

*TACACS+ command authorization functionality:*

The following table explains TACACS+ command authorization functionality.

User logs in with	Command authorization	Result
Local authentication		The switch authorizes the user locally.
TACACS+ authentication	Not enabled for the logged-in level.	The switch authorizes the user locally. If the server connection is lost, the switch authorizes the user locally.
TACACS+ authentication	Enabled for the logged-in level.	The TACACS+ server authorizes the user. If the server connection is lost, the user can only issue <b>exit</b> and <b>logout</b> commands.

#### Note

A user who configures TACACS+ is locally authenticated and authorized by the switch, so even after the user configures TACACS+, the switch continues to locally authorize the user.

## TACACS+ and RADIUS differences

TACACS+ and RADIUS are security protocols that you can use on network devices.

You can enable TACACS+ and RADIUS together. However, TACACS+ has a higher priority. If the TACACS+ server is not available the authentication is sent to RADIUS, if RADIUS is enabled. However, if TACACS+ authentication fails, then requests are not sent to RADIUS.

Following is a list of differences between TACACS+ and RADIUS.

TACACS+	RADIUS
Separates Authorization, Authentication and Accounting (AAA). As a result, you can selectively implement one or more TACACS+ services. With TACACS+ you can use different servers for each service.	Combines authentication and authorization.
Uses TCP. TCP is connection-oriented. TCP immediately indicates if a server crashes or is not running. TCP offers an acknowledgement that a request has been received.	Uses UDP. UDP is best-effort delivery. RADIUS uses re-transmit attempts and timeouts to make up for the support TCP has.
Encrypts the entire body of the packet, which includes the password and username.	Encrypts only the password from the client to the server.
Used for administrator access. Usually used for administrator access to network devices.	Used for subscriber access. Usually used to authenticate remote users to a network.
Can control which access level of commands a user or group can access.	Cannot control which access level of commands can be used.

## TACACS+ Feature Limitations

TACACS+ does not support the following features:

- Point-to-Point Protocol (PPP) authentication and accounting
- IPv6 for TACACS+
- S/KEY (One Time Password) authentication
- PAP/CHAP/MSCHAP authentication methods
- The FOLLOW response of a TACACS+ server, in which the AAA services are redirected to another server. The response is interpreted as an authentication failure.
- User capability to change passwords at runtime over the network. The system administrator must change user passwords locally, on the server.
- TACACS+ command authorization when the user accesses the switch through EDM and SNMP.
- Restriction of command authorization for a specific kind of access. After you enable command authorization, command authorization applies for Telnet, SSH, and serial-port access. You cannot restrict command authorization to just one kind of access.

If a user is TACACS+ authenticated and command authorization is enabled for that level, then if the switch cannot reach the TACACS+ server, the switch does not permit the user to execute any command that has privilege level command authorization enabled.

## TACACS+ configuration using CLI

This section provides procedures to configure TACACS+ using the command line interface (CLI).

## Enabling TACACS+

Enable TACACS+ globally on the switch.

The switch supports the TACACS+ client. TACACS+ is a security application implemented as a client and server-based protocol that provides centralized validation of users who attempt to gain access to a router or network access server (the switch).

By default, TACACS+ is disabled.

### Before You Begin

- You must have access to and you must configure a TACACS+ server before the TACACS+ features on your switch are available.

### Procedure

1. Enter Global Configuration mode:  
`enable`  
`configure terminal`
2. Enable TACACS+ globally:  
`tacacs protocol enable`
3. Disable TACACS+ globally:  
`no tacacs protocol enable`  
`default tacacs protocol enable`

### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs protocol enable
```

## Add a TACACS+ Server

Add a primary and secondary TACACS+ server and specify the authentication process.

If you have a backup server configured, the AAA request goes to the backup server if the primary server is not available.

### About This Task

The TACACS+ server and the switch must have the same:

- Encryption key
- Connection mode (single connection or per-session connection. Per-session connection is the same as multi-connection mode)
- TCP port number

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Add a primary TACACS+ server with an encryption key:

```
tacacs server host {A.B.C.D} key WORD<0-128>
```

3. (Optional) Configure the parameters for the primary TACACS+ server as required.

- a. (Optional) Specify a single connection to maintain a constant connection between the switch and the TACACS+ daemon:

```
tacacs server host {A.B.C.D} single-connection
```

### Note

The TACACS+ daemon must also support this mode. If you do not configure this, the switch uses the default connection type, which is the per-session connection. Per-session is the same as multi-connection mode.

- b. (Optional) Specify the TCP port to use when the switch connects to the TACACS+ daemon:

```
tacacs server host {A.B.C.D} port <1-65535>
```

The default port is 49.

- c. (Optional) Specify the period of time (in seconds) the switch waits for a response from the TACACS+ daemon before it times out and shows an error:

```
tacacs server host {A.B.C.D} timeout <10-30>
```

- d. (Optional) Designate a fixed source IP address for all outgoing TACACS+ packets and enable this option:

```
tacacs server host {A.B.C.D} source {A.B.C.D}source-ip-interface  
enable
```

### Note

This step applies to VSP 8600 Series only.

4. Specify the IP address of the secondary TACACS+ server and specify an encryption key:

```
tacacs server secondary-host {A.B.C.D} key WORD<0-128>
```

5. (Optional) Configure the optional parameters on the secondary TACACS+ server as required.

- a. (Optional) Specify a single connection for the secondary TACACS+ server to maintain a constant connection between the switch and the TACACS+ daemon:
- ```
tacacs server secondary-host {A.B.C.D} single-connection
```

#### Note

The TACACS+ daemon must also support this mode. If you do not configure this, the switch uses the default connection type, which is the per-session connection. Per-session is the same as multi-connection mode.

- b. (Optional) Specify the TCP port to use when the switch connects to the TACACS+ daemon:

```
tacacs server secondary-host {A.B.C.D} port <1-65535>
```

- c. (Optional) Specify the period of time (in seconds) the switch waits for a response from the TACACS+ daemon before it times out and shows an error:

```
tacacs server secondary-host {A.B.C.D} timeout<10-30>
```

- d. (Optional) Designate a fixed source IP address for all outgoing TACACS+ packets and enable this option:

```
tacacs server secondary-host {A.B.C.D} source {A.B.C.D} source-ip-interface enable
```

#### Note

This step applies to VSP 8600 Series only.

6. Display the status of the TACACS+ configuration:

```
show tacacs
```

7. (Optional) Delete a primary TACACS+ server:

```
no tacacs server host {A.B.C.D} [single-connection] [source source-ip-interface enable]
```

8. (Optional) Delete a backup TACACS+ server:

```
no tacacs server secondary-host {A.B.C.D} [single-connection] [source source-ip-interface enable]
```

9. (Optional) Configure a primary TACACS+ server or secondary TACACS+ server to the default settings:

```
default tacacs server {A.B.C.D} [port] [single-connection] [source source-ip-interface enable] [timeout]
```

## Example

Configure the primary server with the IP address 192.0.2.1 and the encryption key 1dt4ly. Configure the secondary server with the IP address 198.51.100.2 with the same encryption key 1dt4ly. Display the configuration to ensure proper configuration.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs server host 192.0.2.1 key 1dt4ly
Switch:1(config)#tacacs server secondary-host 198.51.100.2 key 1dt4ly
```

```

Switch:1(config)#show tacacs

Global Status:

    global enable : true

    authentication enabled for : cli

    accounting enabled for : none

    authorization : disabled

    User privilege levels set for command authorization : None

Server:

        create :

Prio      Status  Key      Port  IP address      Timeout Single Source
SourceEnabled
Primary   Conn    *        49    192.0.2.1      10     false  0.0.0.0
false
Backup   NotConn *        49    198.51.100.2   10     false  0.0.0.0
false

Switch:1(config)#no tacacs server host 192.0.2.1
Switch:1(config)#no tacacs server secondary-host 198.51.100.2

```

### Variable Definitions

The following table defines parameters for the **tacacs server host** and the **tacacs server secondary-host** commands.

| Variable                      | Value                                                                                                                                                                                                                                                                         |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{A.B.C.D}</i>              | Specifies the IP address of the TACACS+ server you want to add. Only IPv4 addresses are valid.                                                                                                                                                                                |
| <i>key WORD &lt;0-128&gt;</i> | Configures the authentication and encryption key for all TACACS+ communications between the device and the TACACS+ server. If the key length is zero, that indicates no encryption is used. You must configure the same encryption key for the TACACS+ server and the switch. |
| <i>port &lt;1-65535&gt;</i>   | Configures the TCP port, on which the client establishes a connection to the server. A value of 0 indicates the system specified default value is used. The default is 49. You must configure the same TCP port for the TACACS+ server and the switch.                        |

| Variable                                                                                                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>single-connection</i>                                                                                    | <p>Specifies if the TCP connection between the device and the TACACS+ server is a single connection. If you specify the single connection parameter, the connection between the switch and the TACACS+ daemon remains open, which is more efficient because it allows the daemon to handle a higher number of TACACS+ operations. The single-connection is torn down if TACACS+ is disabled due to inactivity.</p> <p>If you do not configure this, the switch uses the default connection type, which is the multi-connection. With the multi-connection, the connection opens and closes each time the switch and TACACS+ daemon communicate.</p> <p><b>Note:</b><br/>You must configure the same connection mode for the TACACS+ server and the switch.<br/>To enable single-connection, the TACACS+ daemon has to support this mode as well.</p> |
| <i>source {A.B.C.D}</i><br><br><b>Note:</b><br>Exception: only supported on VSP 8600 Series only.           | <p>Designates a fixed source IP address for all outgoing TACACS+ packets, which is useful if the router has many interfaces and you want to make sure all TACACS+ packets from a certain router have the same IP address.</p> <p>If you do not configure an address, the system uses 0.0.0.0 as the default.<br/>Only IPv4 addresses are valid.</p> <p><b>Note:</b><br/>If you configure a valid source IP address that is not 0.0.0.0 without enabling source-ip-interface, the source IP address returns to 0.0.0.0.</p>                                                                                                                                                                                                                                                                                                                           |
| <i>source-ip-interface enable</i><br><br><b>Note:</b><br>Exception: only supported on VSP 8600 Series only. | <p>Enables the source address. You must enable this parameter if you configure a valid source IP address. The default is disabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>timeout &lt;10-30&gt;</i>                                                                                | <p>Configures the maximum time, in seconds, to wait for this TACACS+ server to reply before it times out. The default value is 10 seconds.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Configuring TACACS+ authentication

Configure what application TACACS+ authenticates: CLI, web, or all.

TACACS+ authentication provides control of authentication through login and password.

By default, CLI authentication is enabled.

## Before You Begin

- You must enable TACACS+ globally for TACACS+ authentication to function.

## Procedure

- Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
- Configure TACACS+ authentication:  

```
tacacs authentication <all/cli/web>
```
- (Optional) Disable TACACS+ authentication:  

```
no tacacs authentication <all/web>
```
- (Optional) Configure TACACS+ authentication to the default settings (default is cli authentication enabled):  

```
default tacacs authentication <all/cli/web>
```
- Display the configuration:  

```
show tacacs
```

## Example

Configure TACACS+ to authenticate CLI and display the configuration.

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs authentication cli
Switch:1(config)#show tacacs
Global Status:

  global enable : true

  authentication enabled for : cli

  accounting enabled for : none

Server:
      create :

Prio   Status  Key      Port  IP address  Timeout  SingleSource  Source  Enabled
-----
Primary Conn   *****  49    192.0.2.1   10      false        0.0.0.0  false
Backup NotConn *****  49    198.51.100.2 10      false        0.0.0.0  false
```

### Variable Definitions

The following table defines parameters for the **tacacs authentication** command.

| Variable   | Value                                                                                                     |
|------------|-----------------------------------------------------------------------------------------------------------|
| <i>all</i> | Specifies TACACS+ authentication for all applications. By default, CLI authentication is enabled.         |
| <i>cli</i> | Specifies TACACS+ authentication for command line connections. By default, CLI authentication is enabled. |
| <i>web</i> | Specifies TACACS+ authentication for web connections. By default, CLI authentication is enabled.          |

## Configuring TACACS+ accounting

Determines for which applications TACACS+ collects accounting information. Use TACACS+ accounting to track the services that users access and the amount of network resources that users consume. If unassigned, TACACS+ does not perform the accounting function.

If enabled, TACACS+ accounting logs the following events:

- User log on and log off
- Log off generated because of activity timeout
- Unauthorized command
- Telnet session closed (not logged off)

If unassigned, TACACS+ does not perform the accounting function. No default value exists.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Enable TACACS+ accounting:
 

```
tacacs accounting enable cli
```
3. (Optional) Disable TACACS+ accounting:
 

```
no tacacs accounting cli

tacacs accounting disable [cli]
```

### Example

Enable TACACS+ accounting:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs accounting enable cli
```

## Configuring command authorization with TACACS+

Use this procedure to enable TACACS+ authorization for a particular privilege level. Use this option to limit the use of certain commands to certain users.

If command authorization fails, the following log message displays: Command <command> not authorized for user <username>.

By default, command authorization is disabled on the switch. The default for the command authorization level is none.

### Before You Begin

- You must have access to and you must configure a TACACS+ server before the TACACS+ features on your switch are available. You must verify that the switch can reach the TACACS+ server and that you configure TACACS+ properly before you enable command authorization. If a user is TACACS+ authenticated and command authorization is enabled for that level, then if the switch cannot reach the TACACS+ server, the switch does not allow you to issue any command that has privilege level command authorization enabled. If the switch cannot reach the TACACS+ server, you can only issue logout and exit commands.
- To use TACACS+ authorization, you must enable TACACS+ authentication.

### About This Task

Two kinds of authorization requests exist:

1. Login authorization: Login authorization happens immediately after authentication when the user logs on to the device, authorization provides the user access level. You cannot configure login authorization.
2. Command authorization: When you configure command authorization for a particular level, all commands that you issue are sent to the TACACS+ server for authorization. You need to configure command authorization globally and at individual access levels.

### Procedure

1. Enter Global Configuration mode:  

```
enable  
  
configure terminal
```
2. Enable TACACS+ authorization:  

```
tacacs authorization enable
```
3. Configure TACACS+ privilege level for TACACS+ command authorization:  

```
tacacs authorization level <1-6>  
  
tacacs authorization level all  
  
tacacs authorization level none
```
4. (Optional) Disable TACACS+ authorization:  

```
tacacs authorization disable  
  
default tacacs authorization
```

### Example

```
Switch:1>enable  
Switch:1#configure terminal
```

```
Switch:1(config)#tacacs authorization enable
Switch:1(config)#tacacs authorization level 6
```

### Variable Definitions

The following table defines parameters for the **tacacs authorization** command.

| Variable                 | Value                                                                                                                  |
|--------------------------|------------------------------------------------------------------------------------------------------------------------|
| <i>level &lt;1-6&gt;</i> | Enables command authorization for a specific privilege level. The default for the command authorization level is none. |
| <i>level all</i>         | Enables command authorization for all privilege levels. The default for the command authorization level is none.       |
| <i>level none</i>        | Disables command authorization for all privilege levels. The default for the command authorization level is none.      |

## Changing privilege levels at runtime

Users can change their privilege levels at runtime. The privilege level determines what commands a user can access through TACACS+ server authorization.

A user can only use the **tacacs switch level** command, after TACACS+ authenticates the user. Locally authenticated users, which means users authenticated only by the switch and not by the TACACS+ server, cannot use the **tacacs switch level** command.

### Before You Begin

- You need to configure separate profiles in the TACACS+ server configuration file for switch level. As part of the profile, you specify a user name, level, and password.

### About This Task

After you enable TACACS+ authorization, the current privilege-level to command mapping on the switch is no longer relevant because the TACACS+ server has complete responsibility for command authorization. TACACS+ authorization provides access to the system based on username, not based on privilege level.

After you enable TACACS+ command authorization for a particular privilege level, and a user with that privilege level logs on, the user can access commands based on his user name.

#### Note

If you want to switch to a privilege level 'X' using **tacacs switch level <1-15>** command, you must create a user "\$enabX\$" on the TACACS+ server. X is the privilege level to which you want to change.

## Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Change the privilege level for a user at runtime:
 

```
tacacs switch level <1-15>
```
3. Return to the original privilege level:
 

```
tacacs switch back
```

## Example

Change the privilege level for a user at runtime. Return to the original privilege level:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#tacacs protocol enable
Switch:1(config)#tacacs switch level 5
Password:*****
```

Return to the original privilege level:

```
Switch:1(config)#tacacs switch back
```

## Variable Definitions

The following table defines parameters for the **tacacs switch** command.

| Variable            | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>level</i> <1-15> | Specifies the privilege level you want to access. You can change your privilege level at runtime by using this parameter. You are prompted to provide the required password. If you do not specify a level in the command, the administration level is selected by default.<br><br><b>Note:</b><br>For switch level, you need to configure separate profiles in the TACACS+ server configuration file. As part of the profile, you specify a username, level, and password. To preconfigure a dummy user for that level on the TACACS+ daemon, the format of the username for the dummy user is <b>\$enab&lt;n&gt;\$</b> , where <n> is the privilege level to which you want to allow access. |
| <i>back</i>         | Specifies that you want to return to the original privilege level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## TACACS+ configuration using EDM

This section provides procedures to configure TACACS+ using Enterprise Device Manager (EDM).

## Configure TACACS+ Globally

Enable TACACS+ globally on the switch. TACACS+ is a security application implemented as a client and server-based protocol that provides centralized validation of users. By default, TACACS+ is disabled.

### Before You Begin

- You must have access to and you must configure a TACACS+ server before the TACACS+ features on your switch (network access server) are available.

You must verify that the switch can reach the TACACS+ server and that you configure TACACS+ properly before you enable command authorization.

- If a user is TACACS+ authenticated and command authorization is enabled for that level, then if the switch cannot reach the TACACS+ server, the switch does not allow the user to issue any command that has privilege level command authorization enabled. In such a case, the user can only issue logout and exit commands.
- You must enable TACACS+ globally for TACACS+ authentication to function.
- You must enable TACACS+ authentication for TACACS+ authorization to function.

### About This Task

Configure what application TACACS+ authenticates. TACACS+ authentication provides control of authentication through login and password dialog, challenge and response. By default, CLI authentication is enabled.

After authentication is complete, the switch starts the authorization process. By default, command authorization is disabled on the switch. The default for the command authorization level is none. If command authorization fails, the following log message displays: `Command <command> not authorized for user <username>.`

Two kinds of authorization requests exist:

1. Login authorization: Login authorization happens immediately after authentication when the user logs on to the device, authorization provides the user access level. You cannot configure login authorization.
2. Command authorization: When you configure command authorization for a particular level, all commands that you issue are sent to the TACACS+ server for authorization. You need to configure command authorization globally and at individual access levels.

Enable TACACS+ accounting function and determine which application TACACS+ accounts. After you enable accounting, the switch reports user activity to the TACACS+ server in the form of accounting records. The default for accounting is none.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **TACACS+**.
3. Click the **TACACS+ Globals** tab.
4. Select the **GlobalEnable** check box to enable TACACS+ globally.

5. Select the **cli** check box to enable the **Accounting** option.
6. Select the **cli** or **web** check box to enable the **Authentication** option.
7. Click the **CliCommandAuthorizationEnabled** box to enable TACACS+ authorization.
8. Select the level in the **CliCommandAuthorizationLevels** box.
9. Click **Apply**.

### **TACACS+ Globals** field descriptions

Use the data in the following table to use the **TACACS+ Globals** tab.

| Name                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GlobalEnable</b>    | Enables or disables the TACACS+ feature globally.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Accounting</b>      | <p>Determines for which applications TACACS+ collects accounting information. Use TACACS+ accounting to track the services that users access and the amount of network resources that users consume. If unassigned, TACACS+ does not perform the accounting function. The default is none.</p> <p>If enabled, TACACS+ accounting logs the following events:</p> <ul style="list-style-type: none"> <li>• User log on and log off</li> <li>• Log off generated because of activity timeout</li> <li>• Unauthorized command</li> <li>• Telnet session closed (not logged off)</li> </ul> |
| <b>Authentication</b>  | <p>Configures what application TACACS+ authenticates. The options include:</p> <ul style="list-style-type: none"> <li>• cli</li> <li>• web</li> </ul> <p>TACACS + authentication provides control of authentication through login and password dialog, challenge and response. By default, CLI authentication is enabled.</p>                                                                                                                                                                                                                                                          |
| <b>LastUserName</b>    | Displays the last user for which the system attempted authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>LastAddressType</b> | Displays the type of address to access the TACACS+ server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>LastAddress</b>     | Displays the last address to access the TACACS+ server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Name                                  | Description                                                                                                                                                                                                                                                                                                               |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CliCommandAuthorizationEnabled</b> | Enables TACACS+ authorization for a particular privilege level. Use this option to limit the use of certain commands to certain users. To use TACACS+ authorization, you must also use TACACS+ authentication.<br>The switch allows the user to access the switch according to the access level. The default is disabled. |
| <b>CliCommandAuthorizationLevels</b>  | Enables command authorization for a specific privilege level.<br>The default for the command authorization level is none.                                                                                                                                                                                                 |

## Add a TACACS+ Server

Add a TACACS+ server, configure the TACACS+ server, and specify the authentication process.

If you have a secondary server configured, the AAA request goes to the backup server if the primary server is not available.

### Before You Begin

You must have access to and you must configure a TACACS+ server before the TACACS+ features on your switch are available.

### About This Task

The TACACS+ server and the switch must have the same:

- Encryption key
- Connection mode (single connection or per-session connection. Per-session is the same as multi-connection mode.)
- TCP port number

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Select **TACACS+**.
3. Select the **TACACS+ Servers** tab.
4. Select **Insert**.
5. In the **AddressType** box, select **ipv4**.
6. In the **Address** field, type the IP address of the TACACS+ server.
7. (Optional) In the **PortNumber** field, type the TCP port on which the client establishes a connection to the TACACS+ server.
8. (Optional) In the **ConnectionType** box, select either **singleConnection** or **perSessionConnection** to specify the TCP connection type between the switch and TACACS+ server.

9. (Optional) In the **Timeout** field, type the period of time (in seconds) the switch waits for a response from the TACACS+ server.
10. In the **Key** field, enter the key that the switch and the TACACS+ server share.
11. (Optional) Select **SourceInterfaceEnabled**, if you want to enable the switch to designate a fixed source IP address for all outgoing TACACS+ packets.

**Note**

This step applies to VSP 8600 Series only.

12. In the **SourceInterfaceType** box, select **ipv4**.

**Note**

This step applies to VSP 8600 Series only.

13. (Optional) In the **SourceInterface** field, type a fixed source IP address if you want to designate a fixed source IP address for all outgoing TACACS+ packets.

**Note**

This step applies to VSP 8600 Series only.

14. In the **Priority** box, select either **primary** or **backup** to determine the order the switch uses the TACACS+ servers.
15. Select **Insert**.

### **TACACS+ Servers** field descriptions

Use the data in the following table to use the **TACACS+ Servers** tab.

| Name               | Description                                                                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AddressType</b> | Specifies the type of IP address to use on the TACACS+ server. You must set the value to IPv4.                                                                                                                                                                |
| <b>Address</b>     | Specifies the IP address of the TACACS+ server.                                                                                                                                                                                                               |
| <b>PortNumber</b>  | Configures the TCP port on which the client establishes a connection to the server. The default is 49. A value of 0 indicates that the system specified default value is used.<br>You must configure the same TCP port for the TACACS+ server and the switch. |

| Name                                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ConnectionType</b>                                                                             | <p>Specifies if the TCP connection between the device and the TACACS+ server is a single connection. If you specify the single connection parameter, the connection between the switch and the TACACS+ daemon remains open, which is more efficient because it allows the daemon to handle a higher number of TACACS+ operations. The single-connection session is torn down if TACACS+ is disabled due to inactivity.</p> <p>If you do not configure this parameter, the switch uses the default connection type, which is the multi-connection. With the multi-connection, the connection opens and closes each time the switch and TACACS+ daemon communicate.</p> <p><b>Note:</b><br/>You must configure the same connection mode for the TACACS+ server and the switch.<br/>To enable single-connection, the TACACS+ daemon has to support this mode as well.</p> |
| <b>ConnectionStatus</b>                                                                           | <p>Specifies if the TCP connection between the device and TACACS+ server is connected or not connected.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Timeout</b>                                                                                    | <p>Configures the maximum time, in seconds, to wait for this TACACS+ server to reply before it times out. The default value is 10 seconds.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Key</b>                                                                                        | <p>Configures the authentication and encryption key for all TACACS+ communications between the device and the TACACS+ server. If the key length is zero, that indicates no encryption is used. You must configure the same encryption key for the TACACS+ server and the switch.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SourceInterfaceEnabled</b><br><br><b>Note:</b><br>Exception: only supported on VSP 8600 Series | <p>Enables the source address specification. If <b>SourceInterfaceEnabled</b> is true (the check box is selected), and you change <b>SourceInterfaceEnabled</b> to false (the check box is cleared), the <b>SourceInterface</b> is reset to 0.0.0.0. ## Modify a TACACS+ Configuration

Modify an existing TACACS+ configuration to customize the server.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Control Path**.
2. Click **TACACS+**.
3. Click **TACACS+ Servers** tab.
4. Double-click in the fields that you want to modify.  
 In some of the fields, the text becomes bold, which indicates that you can edit them.  
 In other fields, the system displays a list.
5. In the fields that you can edit, type the desired values.
6. In the fields with lists, select the desired option.
7. Click **Apply**.

## TACACS+ Configuration Example

This section provides a configuration example to configure the switch to use TACACS+.

**Figure 254: Switch connects to the TACACS+ server**

## TACACS+ Configuration on the Switch

The following section shows the steps required to configure TACACS+ on the switch.

The example displays how to:

- Configure a key to be used by the TACACS+ server and the switch. In the example, the key is configured to the word `secret`.
- Configure an IP address for the TACACS+ server. In the example the IP address for the primary server is 192.0.2.8, which is accessible by the Management Router VRF.
- Configure the TACACS+ server to authenticate CLI sessions.
- Enable TACACS+.

*Switch*

```
TACACS CONFIGURATION

tacacs server host 192.0.2.8 key *****
tacacs protocol enable
tacacs accounting enable cli
tacacs authorization enable
tacacs authorization level 6
```

*Verify your configuration*

The **show tacacs** output must show as `global enable: true` to confirm TACACS is enabled.

The output for the **show tacacs** command must display the IP addresses for the TACACS+ server. The IP addresses must be accessible to the Management Router VRF on the switch.

If you want to use the TACACS+ server to authenticate sessions in CLI, the output must display as `authentication enabled for: cli`. If you want to authenticate EDM sessions, the output must display as `authentication enabled for: web`.

Ensure the other parameters match what you have configured.

```
Global Status:
```

```
global enable : true

authentication enabled for : cli

accounting enabled for : cli

authorization : enabled

User privilege levels set for command authorization : rwa

Server:
        create :

Prio      Status  Key      Port  IP address  Timeout Single Source
SourceEnabled
Primary  Conn  *      49    192.0.2.8   10     false  0.0.0.0
false
```

# Traffic Filtering

---

[Traffic filtering fundamentals](#) on page 3695

[Access control list configuration using EDM](#) on page 3740

[Access Control Entry Configuration using CLI](#) on page 3752

[Access Control Entry Configuration using EDM](#) on page 3779

Traffic filtering can generally provide a mechanism to accurately manage and secure network flows or prioritize crucial information over other network traffic.

The following topics provide necessary concepts and procedures to configure an access control list (ACL) and access control entry (ACE) to filter traffic.

## Traffic filtering fundamentals

---

Use the information in this section to help you understand filtering. This section describes a range of features that you can use with the switch to allocate network resources to apply filters.

In a large and busy network, traffic management is very important and can be complex. Traffic filtering can generally provide a mechanism to accurately manage and secure network flows or prioritize crucial information over other network traffic. Some of the primary uses of filtering are:

- Manage traffic flows.
- Implement security permissions on network traffic.
- Prioritize mission critical traffic flows.
- Redirect traffic to firewalls or other devices to efficiently manage bandwidth.

## Overview of Traffic Filtering

Traffic filtering on the switch is based on ACL filter implementation. Access Control List (ACL) based filters are a means to provide predictable and flexible traffic filtering. ACL Traffic filters can be configured using the Command Line Interface (CLI) or the Enterprise Device Manager (EDM). ACL filters set a list of criteria for the network traffic to be matched against, performing a predefined set of actions. Access Control Lists and Action Control Entries provide traffic filtering services on the switch.

Traffic filtering supports IPv6 ingress and egress port/vlan security and QoS ACL/filters. IPv6 egress QoS ACL/filters are not supported.

## QoS and Filters

The switch has functions you can use to provide appropriate QoS levels to traffic for each customer, application, or packet. These functions include port-based shapers, DiffServ access or core port settings, and ingress port-rate limiting or policing. The switch also provides access control list (ACL)-based filters. You do not need to use filters to provide QoS; however, filters aid in prioritizing customer traffic. Filters also provide protection by blocking unwanted traffic.

Port rate limiting or policing apply at ingress; shapers apply at egress. ACL-based filters apply at ingress and egress.

There are four ingress filter groups:

- Port-based Security ACEs
- Port-based QoS ACEs
- VLAN-based Security ACEs
- VLAN-based QoS ACEs

### Note

The VSP 7400 Series supports two ingress filter groups, where each type can hold both Security and QoS actions in both Primary Bank and Secondary Bank ranges.

Filters help you provide QoS by permitting or dropping traffic based on the parameters you configure. You can use filters to mark packets for specific treatment.

Typically, filters act as firewalls or are used for Layer 3 redirection. In more advanced cases, traffic filters can identify Layer 3 and Layer 4 traffic streams. The filters cause the streams to be re-marked and classified to attain a specific QoS level at both Layer 2 (802.1p) and Layer 3 (DSCP).

Traffic filtering is a key QoS feature. The switch, by default, determines incoming packet 802.1p or DiffServ markings, and forwards traffic based on their assigned QoS levels. However, situations exist where the markings are incorrect, or the originating user application does not have 802.1p or DiffServ marking capabilities. Also, you can give a higher priority to select users (executive class). In these situations, use filters to prioritize specific traffic streams.

You can use filters to assign QoS levels to devices and applications. To help you decide whether to use a filter, key questions include:

1. Does the user or application have the ability to mark QoS information on data packets?
2. Is the traffic source trusted? Are the QoS levels configured appropriately for each data source?

Users can maliciously configure QoS levels on their devices to take advantage of higher priority levels.

3. Do you want to prioritize traffic streams?

This decision-making process is outlined in the following figure.

**Figure 255: Filter decision-making process**

Configure filters through the use of Access Control Lists (ACL) and Access Control Entries (ACE), which are implemented in hardware. An ACL can include both security and QoS type ACEs.

The following steps summarize the filter configuration process:

1. Determine your desired match fields.
2. Create an ACL.
3. Create an ACE within the ACL.
4. Configure the desired precedence, traffic type, and action.

You determine the traffic type by creating an ingress or egress ACL.

5. Modify the parameters for the ACE.

## Access Control Lists

**Table 257: Access Control List product support**

| Feature                                                                                                                                  | Product         | Release introduced |
|------------------------------------------------------------------------------------------------------------------------------------------|-----------------|--------------------|

|                         | XA1400 Series   | Not Supported                       |

Apply rules to incoming and outgoing traffic. The total number of ACLs that you can configure differs depending on the switch.

An ACL can filter either IPv6 or non-IPv6 packets. By default, an ACL filters non-IPv6 packets. You must specify the packet type as IPv6 at the ACL level to enable IPv6 filtering. You cannot change the packet type for the ACL after you configure it. If you need a different packet type, you must delete the ACL, and then re-create it with the other packet type.

You can associate an ACL with the following interfaces:

- Ingress port (inPort)
- Ingress VLAN (inVLAN)
- Ingress VSN (inVSN)
- Egress port (outPort)

**Note**

VLAN-based ACL filters are not supported on a DvR Leaf node.

**Note**

All ACLs are enabled when a DvR Leaf node is created. When creating the DvR Leaf node, or when you enable IS-IS globally, the message `dvr leaf [x]` displays in CLI. If the DvR Leaf node is reset or reconnects to the DvR domain, this message does not display but the same principle applies. As a best practice, delete ACLs not used on DvR Leaf nodes, rather than disable them, because the ACLs re-enable without warning after a DvR domain transition caused by reset, or protocol or link bounce.

**Note**

The VSP 8600 Series Segmented Management Instance does not support ACL based filters or use of ping with -Q option to change the internal priority of management traffic.

The ingress VLAN ACL associations apply to all active port members of a VLAN. An ACL is created in the enabled state by default.

The InVSN Filter is an Access Control List (ACL) that can be used with MAC-in-MAC (MIM) encapsulated packets that are received on the NNI ingress ports and are routed or bridged to UNI ports or terminated on the fabric node. The InVSN Filter matches and filters IPv4 and IPv6 packet headers coming on UNI ports only, NNI ports only, or both UNI and NNI ports. The InVSN Filter does not filter packets that arrive on NNI ingress ports but are bridged to other NNI ports or are for transit traffic.

An ACL can contain multiple filter rules called Access Control Entries (ACE). ACEs provide match criteria and rules for ACL-based filters. An ACE can provide actions such as dropping a packet, monitoring a packet, or remarking QoS on a packet. Complete lists of actions are provided in the Access Control Entries section. After an ingress or egress packet meets the match criteria specified in ACEs within an ACL, the system executes the predefined action.

ACLs provide the ability to configure default and global actions. A default action is applied when no filter rule (ACE) matches on a packet flow. The global action is executed when any filter rule (ACE) matches on a packet flow. The default action mode for ACLs is permit. ACL global actions are:

- monitor-dst-mlt
- monitor-dst-ports

The following figure shows the relationships between ACEs and VLAN- and port-based ACLs.

**Figure 256: ACE and ACL relationships**

## Access Control Entries

**Table 258: Access Control Entry product support**

| Feature                          | Product         | Release introduced |
|----------------------------------|-----------------|--------------------|
| QoS Access Control Entries (ACE) | 5320 Series     | Fabric Engine 8.6  |
|                                  | 5420 Series     | VOSS 8.4           |
|                                  | 5520 Series     | VOSS 8.2.5         |

|                                                           | XA1400 Series   | Not Supported                                                                                            |

The switch filter rules are defined using Access Control Entries (ACE). An ACE is an ordered set of filter rules contained in an Access Control List (ACL). ACE rules are divided into the following three components:

- Operators
- Attributes
- Actions

An ACE generally operates on fields in a packet. If a packet field matches an ACE rule, the system executes the action specified. As each packet enters through an interface with an associated ACL, the system scans the ACE list configured on that ACL and matches on the packet fields. If multiple ACE rules are associated with the ACL, the lower ACE ID will have a higher precedence.

### *Operators*

ACEs use operators to match on packet fields. The switch supports the following operators:

- Equal-to

This rule operator looks for an exact match with the field defined. If the field matches exactly with the rule, the system will return a match (hit). If the rule does not match, the search continues and at the end of the search a miss is returned.

- Mask

ACL-based filters provide the mask operator to match on Layer 2, Layer 3, and Layer 4 packet fields. The mask operator is used to mask bits in packet fields during a search or to match on a partial value of a packet field. This section provides examples of the mask operator.

If a mask bit is set to 1, it means it is not part of the match criteria (treated as do not care), and a mask bit of 0 means that the value represented is part of the match criteria. You can use the mask operator for the following attributes:

- source MAC address
- destination MAC address
- VLAN ID
- Dot1p
- IPv4/IPv6 source address
- IPv4/IPv6 destination address
- destination IP address
- DSCP
- Layer 4 source port
- Layer 4 destination port
- TCP flags

#### **Note**

MAC Address cannot be configured as attributes for IPv6 filters.

The syntax for ACL and ACE configuration of a mask is similar to the use of equal operator, except that you provide the mask value. You can specify a mask value (number) to represent the bits to mask in the attribute. You can define a mask in different ways depending on the attribute you need to mask:

- If you use a decimal number for an IP address mask, it specifies the most significant bits of the provided IP address to match on. For example, a mask of 24 used with an IP address is the same as a mask of 0.0.0.255, and a mask of 8 used with an IP address is the same as a mask of 0.255.255.255.
- If you use a decimal number for a MAC address mask, it specifies the least significant bits of the provided MAC address to ignore. For example, a mask of 32 used with a MAC address is the same as a mask of 0x0000ffffff, and a mask of 16 used with a MAC address is the same as a mask of 0x00000000ffff.

#### Note

Unlike the standard convention, for ACL filter configuration, a mask bit value of '1' specifies a do-not-care bit, and value of '0' signifies must-match bit.

The following table explains the mask operator for MAC addresses.

**Table 259: Mask operator for MAC address**

| Rule                                                                                     | Result                                                                                                                                                                                                                                                            |
|------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>filter acl ace ethernet 10 10 dst-mac mask 01:00:5e:00:00:01 0x000000FFFFFF</pre>   | The rule matches only on the most significant 24 bits as they are not masked, for example, 01:00:5e, and does not care about the least significant 24 bits because they are masked; the least significant 24 bits can have a value of 00:00:00 - FF:FF:FF.        |
| <pre>filter acl ace ethernet 10 10 dst-mac mask 0x01:00:5e:00:00:01 0xFFFFFFFF0000</pre> | The rule matches only on the least significant 16 bits because they are not masked, for example, 00:01, and does not care about the most significant 32 bits because they are masked; the most significant 32 bits can have a value of 00:00:00:00 - FF:FF:FF:FF. |
| <pre>filter acl ace ethernet 10 10 dst-mac mask 0x01:00:5e:00:00:01 0xFF00FF0000FF</pre> | The rule matches only on the unmasked bits, for example, 0xXX:00:XX:00:00:XX. The rule matches only on the bits not masked, for example, all the zeroes and the x represents a do not care (0xXX:00:XX:00:00:XX)                                                  |

The following table explains the mask operator for IP addresses.

**Table 260: Mask operator for IP address**

| Rule                                                                    | Result                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>filter acl ace ip 10 10 src-ip mask 2.10.10.12 0.255.255.255</pre> | The rule matches only the most significant 8 bits, and does not care about the value of the remaining 24 bits as they are considered masked. For example, 10.10.12. Packets with a source IP address of 2.15.16.122 or 2.3.4.5 match on the filter rule while packets with a source IP address of 3.10.10.12 and 4.10.10.12 do not match on the filter rule. |
| <pre>filter acl ace ip 10 10 src-ip mask 3.4.5.6 255.255.255.0</pre>    | The rule matches only the least significant 8 bits, for example, 6, and does not care about the most significant 24 bits, 3.4.5. Packets with a source IP address of 17.16.5.6 or 192.168.1.6 match on the filter rule while packets with a source IP address of 3.4.5.4 or 3.4.5.7 do not match on the filter rule.                                         |

The following table explains the mask operator for Layer 4 source port.

**Table 261: Mask operator for Layer 4 source port**

| Rule                                                           | Result                                                                                                                                                                                                                                                                |
|----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>filter acl ace protocol 10 10 src- port mask 80 0xF</pre> | The filter rule matches on Layer 4 source port 80 (1010000). The mask value 0xF (1111) masks the least significant 4 bits, which means source port 81 (1010001) through 95 (1011111) also match this filter rule. This means the range 80–95 is a match on this rule. |

The following table demonstrates the resulting action based on mask configuration and example packets.

**Table 262: Mask operator configuration examples**

| Filter configuration                                                                                                                                                                                                                                                                                | Address examples that match the filter                                                                                                  | Address examples that do not match the filter                                                       |

### Attributes

Attributes are fields in a packet (Layer 2, Layer 3, Layer 4) or other information related to the packet on which an ACE rule is applied like slot/port. The list of all the attributes and the operators that could be applied on them are listed below.

If you want to configure IPv6 attributes, you must configure an ACL to filter either IPv6 or non-IPv6 traffic. You can only configure IPv6 attributes for IPv6 packets. You cannot configure IPv6 attributes for non-IPv6 packets.

**Table 263: Attribute list**

| Attribute Name                      | Operator    |
|-------------------------------------|-------------|
| Slot/Port                           | Equal       |
| Destination MAC (IPv4 filters only) | Equal, Mask |
| Source MAC (IPv4 filters only)      | Equal, Mask |
| VLAN ID                             | Equal, Mask |
| .Ip bits                            | Equal, Mask |
| Ether Type                          | Equal       |
| ARP Opcode                          | Equal       |
| Source IP                           | Equal, Mask |
| Destination IP                      | Equal, Mask |

**Table 263: Attribute list (continued)**

| Attribute Name               | Operator    |
|------------------------------|-------------|
| Protocol Type                | Equal       |
| Type of Service              | Equal, Mask |
| IP Fragmentation             | Equal       |
| IP Options                   | Equal       |
| Layer 4 Destination Port     | Equal, Mask |
| Layer 4 Source Port          | Equal, Mask |
| TCP Flags                    | Equal, Mask |
| ICMP Message Type            | Equal       |
| Source IPv6 (IPv6 only)      | Equal, Mask |
| Destination IPv6 (IPv6 only) | Equal, Mask |
| Next header (IPv6 only)      | Equal       |
| Traffic class (IPv6 only)    | Equal       |
| Routed only                  | Equal       |

### Actions

Actions occur when the filter rule is hit or missed. The types of actions that the filter configuration can execute are split into two categories:

- security actions supported by the ACE IDs.
- QoS actions supported by the ACE IDs.

#### Note

- Ingress ACLs support security and QoS ACE actions. Egress ACLs do not support QoS ACEs.

The VSP 7400 Series switches use a modified implementation for IPv4 ACL filters. In this implementation, you can apply an IPv4 ACL filter ACE with both Security and QoS actions. The ACE IDs for Primary Bank range from 1-1000 and for Secondary Bank, ACE IDs range from 1001-2000. The switch performs a parallel search on both ACE lists. If actions do not conflict, both actions apply. If actions conflict, the action from the range with higher priority applies.

On all other switches, filter rules that support security actions and QoS actions are stored separately. The switch performs a parallel search, if supported, on both security and QoS ACE lists, which can result in distinct and non-conflicting actions.

If you apply multiple ACE rules, the lower ACE ID has a higher precedence.

**Note**

The ACE ID range for both security and QoS actions is different for different hardware platforms. Parallel search is not supported on all hardware platforms. For more information, see [ACL Filters Behavior Differences](#) on page 3723.

The following tables show the supported switch actions:

**Table 264: Security ACE Actions**

| Security ACE Actions | User supplied parameters | Comments                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mode                 | Permit or Deny           | Applies to both Ingress and Egress ACLs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| redirect-next-hop    | IP address, Mode         | <p>Redirects the packet to the user supplied IP address. If the switch cannot resolve ARP for the user-specified next-hop, packets that match the filter are dropped.</p> <p><b>Note:</b><br/>The filter does not redirect packets with a time-to-live (TTL) of 1 nor does it send them to the CPU where the CPU would generate ICMP TTL expired messages. IP Traceroute reports a timeout for the hop.</p> <p><b>Note:</b><br/>The filter with policer only redirects the traffic that passes the policer. For instance, if the stream is 100 Mbps and the policer peak rate is 50 Mbps, only 50 Mbps is redirected.</p> <p>Applies to ingress IPv4 ACLs only (routed and Layer 2).</p> |
| count                | None                     | Collect ACE statistics. Applies to Ingress and Egress ACLs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| monitor-dst-mlt      | mlt-id                   | Applies to Ingress ACLs only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Table 264: Security ACE Actions (continued)**

| Security ACE Actions | User supplied parameters | Comments                                                                                                                                     |
|----------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| monitor-dst-ports    | Port                     | Applies to Ingress ACLs only.                                                                                                                |
| monitor I-SID offset | None                     | The actual monitor I-SID value to which packets are mirrored.<br><br><b>Note:</b><br>This action is not supported on all hardware platforms. |

**Table 265: QoS ACE Actions**

| QoS ACE Actions                                                                                                 | User supplied parameters                                                                                         | Comments                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>• remark-dscp</li> <li>• remark-dot1p</li> <li>• internal-qos</li> </ul> | <ul style="list-style-type: none"> <li>• DCSP</li> <li>• dot1p (ingress only)</li> <li>• Internal-qos</li> </ul> | <p>Applies to Ingress ACLs.</p> <p><b>Note:</b><br/>remark-dot1p and internal-qos do not apply to IPv6 filtering.</p> <p>Each QoS action has its own user-supplied parameters.</p> <p><b>Note:</b><br/>Some hardware platforms do not support remark-dot1p and supports remark-DSCP for Layer 3 routed packets only.</p> |
| count                                                                                                           | None                                                                                                             | Applies to Ingress and Egress ACLs.                                                                                                                                                                                                                                                                                      |

When you configure an IPv6 ACL with an ACE action of remark DSCP for a mirrored packet, the mirrored copy does not include the remark DSCP value. Because of port-mirroring functionality on VSP 4900 Series, VSP 7400 Series, and VSP 8400 Series, the mirrored copy does not reflect the changes that occur in the switch to the outgoing packet. As a result, the mirrored copy is not identical to the outgoing packet. For more information, see [Port Mirroring](#) on page 3902.

#### *Internal QoS Level and Remarking*

Setting the internal QoS level is an ingress action. Remarking is an egress action.

The internal-qos action assigns a new value to the packet internal-qos. It determines the packet egress queue, outgoing packet dot1p value and egress-DSCP value.

The remark-dot1p action assigns a new dot1p value to the outgoing packet. The remark-DSCP action assigns a new DSCP value to the outgoing packet.

If a packet is filtered by a rule set to internal-qos action only, then the packet internal qos, egress queue, egress dot1p and egress DSCP will be derived from the filter internal-qos value.

If a packet is filtered by a rule set to remark-dot1p only or remark-DSCP only or both remark actions, then the packet will be remarked with the new dot1p or DSCP, or both. However, these remarked values will not have any impact on the internal-qos packet. It will be based on the native packet coming into the switch.

If a packet is filtered by a rule set with all three qos actions, then the internal-qos will determine the egress queue, but the remark-dot1p determines the egress dot1p and the remark-DSCP determines the egress DSCP.

If you want to change the internal QoS for remarked incoming packets, you have to add the **permit internal-qos** command as shown in the following ACL filter example.

```
filter acl 10 type inPort name "ACL-CTI"  
filter acl port 10 1/2-1/50  
filter acl ace 10 1302 name "CIFS-SCCM Source"  
filter acl ace action 10 1302 permit remark-dscp phbaf11 remark-dot1p 1 count  
filter acl ace action 10 1302 permit internal-qos 0  
filter acl ace ethernet 10 1302 ether-type eq ip  
filter acl ace ip 10 1302 src-ip mask 0.0.0.0 255.255.255.255  
filter acl ace ip 10 1302 ip-protocol-type eq tcp  
filter acl ace protocol 10 1302 src-port mask 0 0xffff
```

When a packet goes through the switch, the internal QoS level governs which queue the packet uses on egress. To verify which queue the packets are egressing on, use the **show qos cosq-stats interface [value]** command. For more information, see [View Port Egress CoS Queue Statistics](#) on page 2938 or [Viewing port egress CoS queue statistics](#) on page 2956.

### *Conflict and Precedence*

The switch supports both port-based and VLAN-based ACLs. A port can be associated with both Port-based ACL and a VLAN-based ACL, as shown in [Access Control Lists](#) on page 3698. Within an ACL, a rule match can generate security actions and QoS actions. The system goes through a set of precedence levels to resolve any conflicting actions between port-based ACL and VLAN-based ACL lookup.

The following table provides a list of search results and actions for all possible conflicts between port and VLAN-based ACLs and security and QoS ACE for each ACL.

**Table 266: Conflict and Precedence resolution**

| Port-based ACL look up                                |                          | Actions performed on Port-based ACL   |                                  | If VLAN-based ACL is enabled                            |                                                              | Actions performed on VLAN-based ACL search                       |                                                |
|-------------------------------------------------------|--------------------------|---------------------------------------|----------------------------------|---------------------------------------------------------|--------------------------------------------------------------|------------------------------------------------------------------|------------------------------------------------|
| Security                                              | QoS                      | Security action                       | QoS action                       | Security                                                | QoS                                                          | Security action                                                  | QoS action                                     |
| Security ACE search is a Miss and ACL mode is Permit. | QoS ACE search is a Miss | Default security statistics collected | Default QoS statistics collected | Security ACE search is a Miss and mode is set to Permit | QoS ACE search is a Miss                                     | Collect default Miss statistics                                  | Collect default Miss statistics                |
|                                                       |                          |                                       |                                  | Security ACE search is a Miss and mode is set to Permit | QoS ACE search returns a Hit                                 | Collect default Miss statistics                                  | Execute configured ACE and default ACL actions |
|                                                       |                          |                                       |                                  | Security ACE search is a Miss and mode is set to Deny   | Search result is invalid, since security mode is set to Deny | Drop packet and collect default Miss statistics                  | No action is executed                          |
|                                                       |                          |                                       |                                  | Security ACE search is a Hit and mode is set to Permit  | QoS ACE search returns a Miss                                | Execute configured ACE and default ACL actions                   | Collect default Miss statistics                |
|                                                       |                          |                                       |                                  | Security ACE search is a Hit and mode is set to Permit  | QoS ACE search is a Hit                                      | Execute configured ACE and default ACL actions                   | Execute configured ACE and default ACL actions |
|                                                       |                          |                                       |                                  | Security ACE search is a Hit and mode is set to Deny    | QoS ACE search returns a Hit                                 | Discard the packet and execute configured ACE and global actions | No action is executed                          |

**Table 266: Conflict and Precedence resolution (continued)**

| Port-based ACL look up                                      |                                                             | Actions performed on Port-based ACL               |                                                | If VLAN-based ACL is enabled                            |                                                                         | Actions performed on VLAN-based ACL search                       |                       |

| Security ACE search is a Hit and ACE mode is Deny   | Search result is invalid since Security mode is set to Deny | Discard the packet and collect default statistics | No action is executed                           | Port-based ACL's Security action take precedence. Security search result invalid  | Port-based ACL's QoS action take precedence. QoS search result invalid. | No action is executed                      | No action is executed                          |

### Common ACE uses and configuration

The following table describes configurations you can use to perform common actions.

**Table 267: Common ACE uses and configurations**

| Function                                               | ACE configuration                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Permit a specific host to access the network           | <ul style="list-style-type: none"> <li>Use action permit.</li> <li>Configure the source IP address to be the host IP address.</li> </ul> <pre>filter acl ace 1 5 name "Permit_access_to_198.51.100.0" filter acl ace action 1 5 permit filter acl ace ethernet 1 5 ether-type eq ip filter acl ace ip 1 5 src-ip eq 198.51.100.0 filter acl ace 1 5 enable</pre>                                |
| Deny a specific host from accessing the network        | <ul style="list-style-type: none"> <li>Use action deny.</li> <li>Configure the source IP address to be the host IP address.</li> </ul> <pre>filter acl ace 1 5 name "Deny_access_to_198.51.100.0" filter acl ace action 1 5 deny filter acl ace ethernet 1 5 ether-type eq ip filter acl ace ip 1 5 src-ip eq 198.51.100.0 filter acl ace 1 5 enable</pre>                                      |
| Permit a specific range of hosts to access the network | <ul style="list-style-type: none"> <li>Use action permit.</li> <li>Configure the source IP address to be the range of host IP addresses.</li> </ul> <pre>filter acl ace 1 5 name "Permit_access_to_1.2.3.4-1.2.3.7" filter acl ace action 1 5 permit filter acl ace ethernet 1 5 ether-type eq ip filter acl ace ip 1 5 src-ip mask 1.2.3.4 0.0.0.3 filter acl ace 1 5 enable</pre>             |
| Deny Telnet traffic                                    | <ul style="list-style-type: none"> <li>Use action deny.</li> <li>Configure the protocol as TCP and the TCP destination port to be 23.</li> </ul> <pre>filter acl ace 1 5 name "Deny_telnet" filter acl ace action 1 5 deny filter acl ace ethernet 1 5 ethertype eq ip filter acl ace ip 1 5 ip-protocol-type eq tcp filter acl ace protocol 1 5 dst-port eq 23 filter acl ace 1 5 enable</pre> |
| Deny FTP traffic                                       | <ul style="list-style-type: none"> <li>Use action deny.</li> <li>Configure the protocol as TCP and the TCP destination port to be 21.</li> </ul> <pre>filter acl ace 1 5 name "Deny_ftp" filter acl ace action 1 5 deny filter acl ace ethernet 1 5 ethertype eq ip filter acl ace ip 1 5 ip-protocol-type eq tcp filter acl ace protocol 1 5 dst-port eq 21 filter acl ace 1 5 enable</pre>    |

## Switched UNI ACL Filters

InPort and OutPort filters are supported on Switched UNI (S-UNI) and Fabric Attach ports.

**Note**

InPort and outPort filters are supported on S-UNI and Fabric Attach ports for the traffic mapped to an I-SID which does not have platform VLAN associated. The Customer VLAN-ID (CVID) can be applied as VLAN-ID qualifier in inPort and outPort filters.

**Note**

InPort, outPort, and inVLAN filters are supported on S-UNI and Fabric Attach ports for the traffic mapped to an I-SID which has platform VLAN associated. The platform VLAN should be used as VLAN-ID in inPort and inVLAN filters, and the CVID as VLAN-ID in the outPort filter.

## Traffic filter configuration

Traffic filtering manages traffic by defining filtering conditions and associating these conditions with specific actions. The following steps summarize the filtering configuration process:

1. Determine your desired match fields.
2. Configure an ACL and associate it with Ingress or Egress traffic flow.
3. Configure an ACE within the ACL.
4. Configure the desired precedence, attributes, and action.
5. Enable the ACE.

## Ingress Bandwidth Rate Limiter

**Table 268: Port-Based Rate Limiting, Policing, and Shaping product support**

| Feature                         | Product         | Release introduced |
|---------------------------------|-----------------|--------------------|
| Egress port shaper              | 5320 Series     | Fabric Engine 8.6  |
|                                 | 5420 Series     | VOSS 8.4           |
|                                 | 5520 Series     | VOSS 8.2.5         |
|                                 | 5720 Series     | Fabric Engine 8.7  |
|                                 | 7520 Series     | Fabric Engine 8.10 |
|                                 | 7720 Series     | Fabric Engine 8.10 |

|                                       | XA1400 Series   | VOSS 8.1.50        |

Ingress bandwidth rate limiter functionality handles congestion, meters traffic, and takes action based on the ACL filter rules. A policer can be attached directly to an ACL ACE entry to perform flow-based rate limiting. You can configure the service rate and peak rate. All traffic that qualifies for a filter is metered. Every packet that exceeds the service rate is marked as yellow, and every packet that exceeds the peak rate is marked as red and is dropped.

The ingress flow-based policer limits the traffic rate accepted by the specified ingress port. The port drops or re-marks violating traffic. The line rate of the port is the maximum rate that can be configured.

The ingress flow-based policer is available on the following interfaces:

- Ingress port (inPort)
- Ingress VLAN (inVLAN)
- Ingress VSN (inVSN)

#### *Operation Considerations*

The following section describes operational considerations for ingress bandwidth rate limiter functionality:

- If you configure ingress policer/port rate limiter and QoS port rate limiter on VSP 4900 Series, and a flow matches both of them, then green marked packets can be dropped.
- IPv4 policer statistics for red, yellow, and green packets and bytes are available on VSP 7400 Series.
- Only IPv4 policer statistics for red packets and bytes are available on VSP 4900 Series. Yellow and green packet counters are not supported on VSP 4900 Series.
- Egress port (outPort) interface is not supported.
- Policers are not supported on IPv6 ACLs.
- Supports QoS ACEs only.
- You can configure the default action policer within an ACL for permit action mode only.
- Drop action mode is not supported.
- **monitor-dst-ports**, **monitor-dst-mlt**, or **monitor-isid-offset** actions are supported. All traffic received is mirrored.
- The filter with policer and redirect-next-hop actions redirect only the traffic that passes the policer (if the stream is 100 Mbps, and the policer peak-rate is 50 Mbps, only 50 Mbps is redirected).
- Ingress policer/port rate limiter and QoS port rate limiter features are partially incompatible. Configuring both of these features together that can affect the same traffic can result in more traffic drop than expected. The best practices are as follows:
  - If ACL type is inPort, do not configure Qos port limiter on any of the ports that are part of ACL
  - If ACL type is inVlan, do not configure Qos port limiter on ports that are part of any VLAN in the ACL
  - If ACL type is inVsn, do not configure Qos port limiter on ports that are part of any VSN in the ACL

## ACL and ACE configuration guidelines

To find the maximum number of ACLs and ACEs that the switch supports, see the [VOSS Release Notes](#).

## ACL Filters Behavior Differences

The implementation of ACL filters is similar in all switches but there are some differences as summarized in the following tables.

### Note

The InVSN Filter shares the port-based groups in the following table.

**Table 269: Hardware filter engine resources**

| VSP 4450 Series                                                                                                      | VSP 4900 Series<br>VSP 7200 Series<br>VSP 8200 Series<br>VSP 8400 Series                                             | VSP 7400 Series                                                                                      | VSP 8600 Series                                                                                      | XA1400 Series                                            |
|----------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| If you enable Application Telemetry, IPv6 security filter commands and configurations are blocked and not available. | If you enable Application Telemetry, IPv6 security filter commands and configurations are blocked and not available. | If you enable Application Telemetry, IPv6 security filter commands and configurations are supported. | If you enable Application Telemetry, IPv6 security filter commands and configurations are supported. | Application Telemetry and IPv6 filters are not supported |
| All switches use a filter group as memory to store filter rules. The number of filter groups used can differ:        |                                                                                                                      |                                                                                                      |                                                                                                      |                                                          |

For QoS scaling and filter scaling information, see [VOSS Release Notes](#).

## Access control list configuration using CLI

Use an access control list (ACL) to specify an ordered list of access control entries (ACEs), or filter rules. The ACEs provide specific actions that you want the filter to perform.

### Creating an IPv4 ACL

Create an ACL to specify an ordered list of ACEs, or filter rules.

#### About This Task

Do not configure IPv4 egress ACL filters on NNI ports because the system-generated egress vIST filter rules and the user-created IPv4 egress rules use the same filter hardware.

#### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create an ACL:

```
filter acl <acl-id> type <inVlan|inPort|outPort|inVsn> [matchType  
<both|terminatingNNIOnly|uniOnly> ] [name WORD<0-32>] [enable]
```

3. Enable an ACL:

```
filter acl [enable]
```

4. Ensure the configuration is correct:

```
show filter acl [<acl-id>]
```

#### Variable definitions

Use the data in the following table to use **filter acl** command.

| Variable                                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <acl-id>                                    | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                                                                                                                                                                                                                                                                                                                                            |
| enable                                      | Enables the ACL state, and all associated ACEs. Enabled is the default state.                                                                                                                                                                                                                                                                                                                                                                                |
| matchType <both terminatingNNIOnly uniOnly> | For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <li>• <i>both</i> for traffic ingressing on both UNI ports and NNI ports terminating on this node</li> <li>• <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node</li> <li>• <i>uniOnly</i> for traffic ingressing on UNI ports only</li> </ul> The default value is <i>both</i> . |

| Variable                                              | Value                                                                                                                                                               |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name WORD&lt;0-32&gt;</code>                    | Specifies an optional descriptive name for the ACL.                                                                                                                 |
| <code>type &lt;inVlan inPort outPort inVsn&gt;</code> | Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL. |

## Create an IPv6 ACL

Create an IPv6 ACL to specify an ordered list of ACEs, or filter rules.

You must specify the packet type as IPv6 at the ACL level to enable IPv6 filtering. By default, an ACL filters non IPv6 packets.

### Note

You cannot change packet type for the ACL after you have configured it. If you want a different packet type, you must delete the ACL and re-create it using the other packet type.

### Before You Begin

- Application Telemetry must be disabled on VSP 4450 Series, VSP 7200 Series, VSP 8200 Series, and VSP 8400 Series.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create an IPv6 ACL:

```
filter acl <acl-id> type <inVlan|inPort|outPort|inVsn> [matchType
<both|terminatingNNIOOnly|uniOnly> ] [name WORD<0-32>] [pktType ipv6]
[name <0-32>]
```

### Note

IPv6 egress QoS ACL/Filters are not supported.

3. Enable the ACL:

```
filter acl <acl-id> enable
```

4. Ensure the configuration is correct:

```
show filter acl [<acl-id>]
```

### Variable definitions

Use the data in the following table to use the **filter acl** command.

| Variable                                                       | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;acl-id&gt;</code>                                    | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>enable</code>                                            | Enables the ACL state, and all associated ACEs. Enabled is the default state.                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>matchType &lt;both terminatingNNIOnly uniOnly&gt;</code> | For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <li><code>both</code> for traffic ingressing on both UNI ports and NNI ports terminating on this node</li> <li><code>terminatingNNIOnly</code> for traffic ingressing on NNI ports only and terminating on this node</li> <li><code>uniOnly</code> for traffic ingressing on UNI ports only</li> </ul> The default value is <code>both</code> . |
| <code>name WORD&lt;0-32&gt;</code>                             | Specifies an optional descriptive name for the ACL.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>type &lt;inVlan inPort outPort inVsn&gt;</code>          | Specifies the ACL type. The values <code>inVlan</code> , <code>inPort</code> , and <code>inVsn</code> are ingress ACLs. The value <code>outPort</code> configures IPv6 egress filters. A port-based ACL has precedence over a VLAN-based ACL.                                                                                                                                                                                                                                  |
| <code>pktType &lt;ipv6&gt;</code>                              | Specifies the IP version as IPv6. The default is <code>nonipv6</code> . <p><b>Note:</b><br/>You cannot change packet type for the ACL once you have configured it. If you want a different packet type, you must delete the ACL and re-create it using the other packet type.</p>                                                                                                                                                                                              |

## Associating VLANs with an ACL

Associate VLANs with an ACL to apply filters to VLAN traffic.

A VLAN can be part of two different ACLs of different types: IPv6 and non-IPv6.

### Before You Begin

- The ACL exists.

### Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Add VLAN interfaces to an ACL:

```
filter acl vlan <acl-id> <1-4059>
```

### 3. Remove specified VLAN interfaces from an ACL:

```
no filter acl vlan <acl-id> <1-4059>
```

#### Variable definitions

Use the data in the following table to use the **filter acl vlan** command.

| Variable | Value                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <acl-id> | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                                                                                                                                                                                                                                                                                                          |
| <1-4059> | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1. |

## Associating ports with an ACL

Associate ports with an ACL to apply filters to port traffic.

A port can be part of two different ACLs of different types: IPv6 and non-IPv6.

### Before You Begin

- The ACL exists.

### Procedure

#### 1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

#### 2. Associate port interfaces with a particular ACL:

```
filter acl port <acl-id> {slot/port[/sub-port] [-slot/port[/sub-port]]  
[,...]}
```

#### 3. Remove port interfaces from a particular ACL:

```
no filter acl port <acl-id> {slot/port[/sub-port] [-slot/port[/sub-  
port]][,...]}
```

### Variable definitions

Use the data in the following table to use the **filter acl port** command.

| Variable                                                           | Value                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;acl-id&gt;</code>                                        | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                                                                                                                                                                                                                                             |
| <code>{slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |

## Associate an I-SID with an ACL

### Note

This procedure does not apply to VSP 8600 Series or XA1400 Series.

### Before You Begin

- The inVsn ACL exists.
- This I-SID is already configured on the fabric node.

### About This Task

For inVsn ACL types, specify the I-SID associated with the customer VLAN (Layer 2 VSN), the customer VRF (Layer 3 VSN), or the IP Shortcut.

### Note

For IP Shortcut traffic, the inVsn ACL match type must be *both*. In this case, the I-SID is zero (0).

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Specify the I-SID.
 

```
filter acl i-sid <acl-id> <0-159999999>
```

*Variable definitions*

Use the data in the following table to use the **filter acl i-sid** command.

| Variable                        | Value                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;acl-id&gt;</code>     | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                                                                                                                                                                                                                                                                                                  |
| <code>&lt;0-15999999&gt;</code> | Specifies the I-SID associated with the customer VLAN (Layer 2 VSN) or the customer VRF (Layer 3 VSN). This I-SID must already be configured on the fabric node. The InVSN Filter supports IP Shortcut traffic if the inVsn ACL match type is <i>both</i> . In this case, the I-SID is zero (0).<br><br><b>Important:</b><br>You can specify a Switched UNI I-SID if the I-SID is associated with a platform VLAN. |

## Configure Global and Default Actions for an ACL

Configure the default action to specify packet treatment if a packet does not match any ACE.

Configure the global action to specify packet treatment if a packet does match an ACE.

Global action can only be configured for Ingress ACLs.

### Before You Begin

Ensure that the ACL exists.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
configure terminal
```
2. Configure the global action for an ACL:
 

```
filter acl set <acl-id> global-action [monitor-dst-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [, ...]}] [monitor-dst-mlt <1-512>]
```
3. Configure an ACL to the default global action settings:
 

```
default filter acl set <acl-id> global-action [monitor-dst-ports]
```
4. Configure the default action for an ACL:
 

```
filter acl set <acl-id> default-action <permit|deny>
```
5. Configure an ACL default policer.
 

```
filter acl set <acl-id> default-action permit policer svc-rate
<0-4000000000> peak-rate <8-4000000000>
```
6. Configure an ACL to the default action settings:
 

```
default filter acl set <acl-id> default-action
```

### Variable Definitions

The following table defines parameters for the **filter acl set** commands.

| Variable                                                                                                                                                                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;acl-id&gt;</code>                                                                                                                                                        | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>default-action &lt;permit   deny&gt;</code>                                                                                                                                  | Specifies the default action to take when none of the ACEs match. Options are <code>&lt;permit   deny&gt;</code> . The default is permit.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>monitor-dst-ports<br/>{slot/port[/sub-port]<br/>[-slot/port[/sub-port]]<br/>[,...]}</code>                                                                                   | Specifies the global action to take for matching ACEs: <ul style="list-style-type: none"> <li>monitor destination ports—Configures mirroring to a destination port or ports.</li> </ul> Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <code>monitor-dst-mlt &lt;1-512&gt;</code>                                                                                                                                         | Configures mirroring to a destination MLT in the range of 1 to 512.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>policer svc-rate<br/>&lt;0-4000000000&gt; peak-rate<br/>&lt;8-4000000000&gt;</code><br><br><b>Note:</b><br>Exception: only supported on VSP 4900 Series and VSP 7400 Series. | Specifies the policer for filter with service rate and peak transfer rate of packets. The service rate value specifies the rate of traffic committed to be delivered. Packets above the specified peak rate value are dropped on ingress.                                                                                                                                                                                                                                                                                                             |

## Renaming an ACL

Perform this procedure to change the name of an existing ACL.

### Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Rename an ACL:

```
filter acl <acl-id> name WORD<0-32>
```
- Reset the ACL name to the default name:

```
default filter acl <acl-id> name
```

*Variable definitions*

Use the data in the following table to use **filter acl** command.

| Variable                                                       | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;acl-id&gt;</code>                                    | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>enable</code>                                            | Enables the ACL state, and all associated ACEs. Enabled is the default state.                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>matchType &lt;both terminatingNNIOnly uniOnly&gt;</code> | For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <li><code>both</code> for traffic ingressing on both UNI ports and NNI ports terminating on this node</li> <li><code>terminatingNNIOnly</code> for traffic ingressing on NNI ports only and terminating on this node</li> <li><code>uniOnly</code> for traffic ingressing on UNI ports only</li> </ul> The default value is <code>both</code> . |
| <code>name WORD&lt;0-32&gt;</code>                             | Specifies an optional descriptive name for the ACL.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>type &lt;inVlan inPort outPort inVsn&gt;</code>          | Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL.                                                                                                                                                                                                                                                                                                            |

## Disabling an ACL

Perform this procedure to disable an ACL and all ACEs that belong to it.

### Procedure

- Enter Global Configuration mode:

```
enable

configure terminal
```
- Disable an ACL:

```
no filter acl <acl-id> enable
```

*Variable definitions*

Use the data in the following table to use **filter acl** command.

| Variable                    | Value                                                                             |
|-----------------------------|-----------------------------------------------------------------------------------|
| <code>&lt;acl-id&gt;</code> | Specifies the ACL ID. Use the CLI Help to see the available range for the switch. |
| <code>enable</code>         | Enables the ACL state, and all associated ACEs. Enabled is the default state.     |

| Variable                                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| matchType <both terminatingNNIOnly uniOnly> | For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <li>• <i>both</i> for traffic ingressing on both UNI ports and NNI ports terminating on this node</li> <li>• <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node</li> <li>• <i>uniOnly</i> for traffic ingressing on UNI ports only</li> </ul> The default value is <i>both</i> . |
| name WORD<0-32>                             | Specifies an optional descriptive name for the ACL.                                                                                                                                                                                                                                                                                                                                                                                                          |
| type <inVlan inPort outPort inVsn>          | Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL.                                                                                                                                                                                                                                                                                          |

## Resetting an ACL to default values

Reset an ACL to change the ACL name to the default name and the filter ACL mode to a default of enable.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Reset an ACL to default values:

```
default filter acl <acl-id>
```

### Variable definitions

Use the data in the following table to use **filter acl** command.

| Variable                                    | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <acl-id>                                    | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                                                                                                                                                                                                                                                                                                                                            |
| enable                                      | Enables the ACL state, and all associated ACEs. Enabled is the default state.                                                                                                                                                                                                                                                                                                                                                                                |
| matchType <both terminatingNNIOnly uniOnly> | For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <li>• <i>both</i> for traffic ingressing on both UNI ports and NNI ports terminating on this node</li> <li>• <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node</li> <li>• <i>uniOnly</i> for traffic ingressing on UNI ports only</li> </ul> The default value is <i>both</i> . |

| Variable                                              | Value                                                                                                                                                               |
|-------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name WORD&lt;0-32&gt;</code>                    | Specifies an optional descriptive name for the ACL.                                                                                                                 |
| <code>type &lt;inVlan inPort outPort inVsn&gt;</code> | Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL. |

## Deleting an ACL

Delete an ACL to remove an ordered list of filter rules.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Delete an ACL:

```
no filter acl <acl-id>
```

The system displays the following message:

```
WARNING: All ACE entries under this ACL will be Deleted.
Do you wish to delete this ACL? (y/n)?
```

3. Enter `y`.

### Variable definitions

Use the data in the following table to use **filter acl** command.

| Variable                                                       | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;acl-id&gt;</code>                                    | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                                                                                                                                                                                                                                                                                                                                            |
| <code>enable</code>                                            | Enables the ACL state, and all associated ACEs. Enabled is the default state.                                                                                                                                                                                                                                                                                                                                                                                |
| <code>matchType &lt;both terminatingNNIOnly uniOnly&gt;</code> | For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <li>• <i>both</i> for traffic ingressing on both UNI ports and NNI ports terminating on this node</li> <li>• <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node</li> <li>• <i>uniOnly</i> for traffic ingressing on UNI ports only</li> </ul> The default value is <i>both</i> . |

| Variable                                  | Value                                                                                                                                                               |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>name</i> WORD<0-32>                    | Specifies an optional descriptive name for the ACL.                                                                                                                 |
| <i>type</i> <inVlan inPort outPort inVsn> | Specifies the ACL type. The values inVlan, inPort, and inVsn are ingress ACLs, and outPort is an egress ACL. A port-based ACL has precedence over a VLAN-based ACL. |

## Clear ACL Statistics

Clear default ACL statistics if you no longer require previous statistics.

### Note

The ACL statistics do not support security action on some hardware platforms.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Enter the following command to clear default ACL statistics:  
clear filter acl statistics default <acl-id>
3. Enter the following command to clear global ACL statistics:  
clear filter acl statistics global <acl-id>
4. Enter the following command to clear all ACL statistics:  
clear filter acl statistics all
5. Enter the following command to clear statistics associated with a particular ACL, ACE, or ACE type:  
clear filter acl statistics <acl-id> <ace-id> [qos] [security]

### Variable Definitions

Use the information in the following table to use the **clear filter acl statistics** command.

| Variable | Value                                                                                                                                           |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <acl-id> | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                               |
| <ace-id> | Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch. |

## Enable IPv6 Egress Filters

### Note

Exception: not supported on VSP 8600 Series and XA1400 Series.

Use the **boot config flags** command to enable IPv6 egress filters and to add IPv6 egress qualifiers at startup.

### About This Task

This flag is disabled by default.

### Before You Begin

If more than 200 IPv4 egress entries exist in the configuration file, make a backup of the configuration file before you enable IPv6 egress filters. Only a maximum of 200 IPv4 egress entries are saved in the configuration file after you use the **save config** command.

For example, you can enter more than 200 IPv4 egress entries in the configuration file prior to enabling IPv6 egress filters. However, the entries are stored in ascending numerical order with ACL ID and ACE ID respectively, and not in the order in which they were added. Therefore, after you enable IPv6 egress filters and restart, and because the configuration file is read in ascending order, you receive an error message after the 200 maximum has been reached, such as:

```
CP1 [2017-09-28T00:44:24.077+05:30] 7K-Fi-94-I6:1 0x001049d4 00000000
GlobalRouter FILTER ERROR Unable to allocate data path resources for ACL
ID 12.
```

### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Enable the IPv6-egress-filter boot config flag:  
`boot config flags ipv6-egress-filter`
3. Save the configuration, and then restart the switch for the change to take effect.
4. After you restart the switch, verify that the IPv6-egress-filter boot config flag is configured to true:  
`show boot config flags`

### Example

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#boot config flags ipv6-egress-filter
Warning: Please save the configuration and reboot the switch
         for this configuration to take effect.
```

#### Note

Flag support can vary across hardware models.

```
Switch:1#show boot config flags
flags advanced-feature-bandwidth-reservation low
flags block-snmp false
flags debug-config false
```

```

flags debugmode false
flags dvr-leaf-mode false
flags enhancedsecure-mode false
flags factorydefaults false
flags flow-control-mode true
flags ftpd true
flags hsecure false
flags ipv6-egress-filter true
flags ipv6-mode false
flags linerate-directed-broadcast false
flags logging true
flags nni-mstp false
flags reboot true
flags spanning-tree-mode mstp
flags spbm-config-mode true
flags sshd true
flags syslog-rfc5424-format true
flags telnetd true
flags tftpd true
flags trace-logging false
flags urpf-mode true
flags verify-config true
flags vrf-scaling true
flags vxlan-gw-full-interworking-mode false

```

## Display Filter Access Control List Configuration

### About This Task

Perform this procedure to display the filter Access Control List (ACL) configuration on the switch.

### Procedure

1. Enter Privileged EXEC mode:  
enable
2. Display filter ACL configuration:  
show filter acl

### Example

```
Switch:1(config)#show filter acl
```

```

## Access control list configuration using EDM

Use traffic filtering to provide security by blocking unwanted traffic and prioritizing other traffic.

### Configuring an access control list

Use an access control list (ACL) to specify an ordered list of access control entries (ACE), or filter rules. The ACEs provide specific actions for the filter to perform.

#### About This Task

Do not configure IPv4 egress ACL filters on NNI ports because the system-generated egress vIST filter rules and the user-created IPv4 egress rules use the same filter hardware.

To modify an ACL parameter, double-click the parameter you wish to change. Change the value, and then click Apply. You cannot change a parameter that the system displays it dimmed; in this case, delete the ACL, and then configure a new one.

#### Procedure

1. In the navigation pane, expand the **Configuration > Security > Data Path** folders.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Click **Insert**.

5. In the **AcId** field, type an ACL ID, or accept the default value .
6. In **Type**, specify the type of ACL.
7. In the **Name** field, specify a name for the ACL.
8. Perform one of the following if the ACL is VLAN-based or port-based:
  - a. If the ACL is VLAN-based, click the **VlanList** ellipsis, and then choose a VLAN list.
  - b. If the ACL is port-based, click the **PortList** ellipsis, and then choose a port list.
9. Select the desired ports, and then click **Ok**.
10. Configure the **DefaultAction**.
11. Configure the **ControlPktAction**.

**Note**

There is no control packet action support for the InVSN Filter. Control packets go to the CPU after termination.

12. Enable or disable the **State**, as required.
13. In the **PktType** field, select the packet type to create either IPv4 or IPv6 ACLs.
14. If the ACL type is inVsn, do the following:
  - a. In the **MatchType** field, select the match type to associate with the ACL that the traffic is ingressing on.
  - b. In the **Isid** field, enter the I-SID associated with the customer VLAN (Layer 2 VSN) or the customer VRF (Layer 3 VSN) or enter 0 for IP shortcut.
15. Configure the remaining fields, as appropriate.
16. Click **Insert**.
17. To delete an ACL, select the ACL, and then click **Delete**.

**ACL field descriptions**

Use the data in the following table to use the **ACL** tab.

| Name        | Description                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b> | Specifies a unique identifier for the ACL.                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Type</b> | <p>Specifies the ACL type. Valid options are</p> <ul style="list-style-type: none"> <li>• inVlan</li> <li>• inPort</li> <li>• outPort</li> <li>• inVsn</li> </ul> <p><b>Important:</b><br/>The inVlan ACLs drop packets if you add a VLAN after ACE creation.</p> <p><b>Important:</b><br/>You can insert an inVsn ACL type for a Switched UNI only if the Switched UNI I-SID is associated with a platform VLAN.</p> |
| <b>Name</b> | Specifies a descriptive user-defined name for the ACL.                                                                                                                                                                                                                                                                                                                                                                |

| Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VlanList</b>          | For inVlan ACL types, specifies all VLANs to associate with the ACL.                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>PortList</b>          | For inPort and outPort ACL types, specifies the ports to associate with the ACL.                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DefaultAction</b>     | Specifies the action taken when no ACEs in the ACL match. Valid options are deny and permit, with permit as the default. Deny means the system drops the packets; permit means the system forwards packets.                                                                                                                                                                                                                                                |
| <b>ControlPktAction</b>  | Specifies the action taken for control packets. Valid options are deny and permit.                                                                                                                                                                                                                                                                                                                                                                         |
| <b>State</b>             | Enables or disables all of the ACEs in the ACL. The default value is enable.                                                                                                                                                                                                                                                                                                                                                                               |
| <b>PktType</b>           | Indicates the packet type to which this ACL applies.                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>MirrorMltId</b>       | Configures mirroring to a destination MLT.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>MirrorDstPortList</b> | Configures mirroring to a destination port or ports.                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>MatchType</b>         | For inVsn ACL types, specifies the match type to associate with the ACL. Valid options are: <ul style="list-style-type: none"> <li>• <i>both</i> for traffic ingressing on both UNI ports and NNI ports terminating on this node</li> <li>• <i>terminatingNNIOnly</i> for traffic ingressing on NNI ports only and terminating on this node</li> <li>• <i>uniOnly</i> for traffic ingressing on UNI ports only</li> </ul> The default value is <i>both</i> |
| <b>Isid</b>              | For inVsn ACL types, specifies the I-SID associated with the customer VLAN (Layer 2 VSN) or the customer VRF (Layer 3 VSN). This I-SID should already be configured on the fabric node.<br>The InVSN Filter supports IP Shortcut traffic if the inVsn ACL match type is <i>both</i> . In this case, the I-SID is zero (0).<br><br><b>Important:</b><br>You can specify a Switched UNI I-SID if the I-SID is associated with a platform VLAN.               |
| <b>Origin</b>            | Indicates the origin of the ACL: <ul style="list-style-type: none"> <li>• <i>config</i> - ACL created by the user.</li> <li>• <i>eap</i> - ACL created by Extensible Authentication Protocol (EAP) through Remote Authentication Dial-In User Service (RADIUS) response.</li> </ul>                                                                                                                                                                        |

| Name                                                                                                     | Description                                                                                                                            |
|----------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>DefaultSvcRate</b><br><b>Note:</b><br>Exception: Only supported on VSP 4900 Series, VSP 7400 Series.  | Specifies the service rate limit in kbps {8-4000000000}.The granularity is 8 kbps.                                                     |
| <b>DefaultPeakRate</b><br><b>Note:</b><br>Exception: Only supported on VSP 4900 Series, VSP 7400 Series. | Specifies the value when exceeded causes packets to drop on ingress. Peak rate limit in kbps {8-4000000000}.The granularity is 8 kbps. |

## Viewing ACL Statistics

### About This Task

Graph statistics for a specific ACL ID to view default statistics.

### Procedure

1. In the navigation pane, expand the **Configuration > Security > Data Path** folders.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select an ACL.
5. Click **Graph**.
6. You can click **Clear Counters** to clear the **Statistics** fields.

### Statistics Field Descriptions

Use the data in the following table to use the **Statistics** tab.

#### Note

Based on your hardware platform, the output can display the ACL packets by ACE type or Primary Bank or Secondary Bank.

| Name                                                                                            | Description                                                                                                                                          |
|-------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>                                                                                     | Specifies the ACL ID.                                                                                                                                |
| <b>MatchDefaultSecurityPkts</b><br><b>Note:</b><br>Exception: not supported on VSP 7400 Series. | Shows a security packet count of traffic that does not match an ACE rule or hits the default action if count is configured in the ACL global action. |

| Name                                                                                                    | Description                                                                                                                                                |
|---------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Clearing ACL Statistics

### About This Task

Clear ACL statistics when you want to gather a new set of statistics.

### Procedure

1. In the navigation pane, expand the **Configuration > Security > Data Path** folders.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select a field.
5. Click **ClearStats**.

## Enable IPv6 Egress Filters

Enable IPv6 egress filters to add IPv6 egress qualifiers at startup.

## About This Task

This flag is disabled by default.

## Before You Begin

If more than 200 IPv4 egress entries exist in the configuration file, make a backup of the configuration file before you enable IPv6 egress filters. Only a maximum of 200 IPv4 egress entries are saved in the configuration file after you save the configuration.

For example, you can enter more than 200 IPv4 egress entries in the configuration file prior to enabling IPv6 egress filters. However, the entries are stored in ascending numerical order with ACL ID and ACE ID respectively, and not in the order in which they were added. Therefore, after you enable IPv6 egress filters and restart, and because the configuration file is read in ascending order, you receive an error message after the 200 maximum has been reached, such as:

```
CP1 [2017-09-28T00:44:24.077+05:30] 7K-Fi-94-I6:1 0x001049d4 00000000
GlobalRouter FILTER ERROR Unable to allocate data path resources for ACL
ID 12.
```

## Procedure

1. In the navigation pane, expand the **Configuration > Edit** folders.
2. Click **Chassis**.
3. Click the **Boot Config** tab.
4. Select the **EnableIpv6EgressFilterMode** check box.
5. Click **Apply**.
6. Save the configuration, and then restart the switch for the change to take effect.

### **Boot Config** Field Descriptions

Use the data in the following table to use the **Boot Config** tab.

| Name                             | Description                                                                     |
|----------------------------------|---------------------------------------------------------------------------------|
| <b>SwVersion</b>                 | Specifies the software version that currently runs on the switch.               |
| <b>LastRuntimeConfigSource</b>   | Specifies the last source for the run-time image.                               |
| <b>PrimaryConfigSource</b>       | Specifies the primary configuration source.                                     |
| <b>PrimaryBackupConfigSource</b> | Specifies the backup configuration source to use if the primary does not exist. |

| Name                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <p><b>EnableFactoryDefaultsMode</b></p> | <p>Specifies whether the switch uses the factory default settings after you reboot the switch. The options are:</p> <ul style="list-style-type: none"> <li>• <b>false:</b> The node does not use factory default settings.</li> <li>• <b>fabric:</b> This mode is not supported.</li> <li>• <b>noFabric:</b> The node uses the factory default mode settings.</li> </ul> <p>Removes the configuration files, primary and secondary config file names, all user account passwords, digital certificates, IKE/OSPF/IS-IS keys, and SNMP communities. All ports are disabled and assigned to VLAN 1. License files are not removed.</p> <ul style="list-style-type: none"> <li>• <b>config-only</b></li> </ul> <p>Boots the switch with a blank configuration.</p> <p>This parameter preserves configuration files, primary and secondary configuration file names, user accounts and passwords, digital certificates, IKE/OSPF/IS-IS keys, license files, and SNMP communities. All ports are disabled and assigned to VLAN 1.</p> <p>Use this parameter as a temporary troubleshooting option to test or investigate if something is wrong with the configuration without permanently removing the configuration files, user accounts, and other preserved items.</p> <ul style="list-style-type: none"> <li>• <b>reset-all-files:</b></li> </ul> <p>Equivalent to a switch that ships from the factory. The switch has no configuration files, default user accounts, default security mode, Auto-sense-enabled ports, removes license files, and performs a ZTP+ configuration after reboot. The 30-day factory license is also reset.</p> <p><b>Important:</b></p> <p>Only CLI provides two options to achieve the same behavior; there is no option other than <b>reset-all-files</b> in EDM.</p> <ul style="list-style-type: none"> <li>• <b>zero-touch:</b></li> </ul> |

| Name                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            | <p>Boots the switch with a default configuration that enables Auto-sense. This parameter resets secure files but keeps the security mode and performs a ZTP+ configuration after reboot. License files are not removed.</p> <p>The default value is false. This flag is automatically reset to the default value after the switch restarts. If you select an option but then want to select a different option and have not yet rebooted the switch, you must disable the first option before you select the second option.</p> <p><b>Note:</b><br/>Exception: <b>config-only</b>, <b>reset-all-files</b>, and <b>zero-touch</b> do not apply to VSP 4450 Series, XA1400 Series, and VSP 8600 Series.</p> |
| <b>EnableDebugMode</b>     | <p>Enabling the debugmode allows a user to enable TRACE on any port by prompting the selection on the console during boot up. This allows the user start trace for debugging earlier on specified port. It only works on console connection. The default value is disabled.</p> <p><b>Important:</b><br/>Do not change this parameter.</p>                                                                                                                                                                                                                                                                                                                                                                |
| <b>EnableRebootOnError</b> | <p>Activates or disables automatic reboot on a fatal error. The default value is activated.</p> <p><b>Important:</b><br/>Do not change this parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>EnableTelnetServer</b>  | <p>Activates or disables the Telnet server service. The default value is disabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>EnableFtpServer</b>     | <p>Activates or disables the FTP server on the switch. The default value is disabled. To enable FTP, ensure that the TFTPD flag is disabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>EnableTftpServer</b>    | <p>Activates or disables Trivial File Transfer Protocol server service. | <p><b>EnableIpv6EgressFilterMode</b></p>                                                                                    | <p>Enables IPv6 egress filters. The default is disabled.</p> <p>If you change this parameter, you must restart the switch.</p>                                                                                                                                                                                                                                                                                                                                                      |
| <p><b>Slot</b></p>                                                                                                          | <p>Specifies the slot number.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Name           | Description                          |
|----------------|--------------------------------------|
| TftpHash       | Enables TFTP hashing.                |
| TftpRetransmit | Set TFTP retransmit timeout counter. |
| TftpTimeout    | Set TFTP timeout counter.            |
| User           | Configure host user.                 |
| Password       | Configure host password.             |

## Access Control Entry Configuration using CLI

Use an access control entry (ACE) to provide an ordered list of traffic filtering rules. You can configure up to 1000 ACEs in a single ACL.

### Note

For information about the supported ACE IDs ranges on all hardware platforms, see [ACL Filters Behavior Differences](#) on page 3723.

## Configure ACEs

Use an ACE to define packet attributes and the desired behavior for packets that carry the attribute or list of attributes.

### Before You Begin

- The ACL exists. If you want to use IPv6 filters, you must specify the packet type as IPv6 at the ACL level to enable IPv6 filtering.

### About This Task

ACLs are by default created in enabled state while ACEs are by default created in disabled state. Use CLI commands to enable an ACE.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Create and name an ACE:
 

```
filter acl ace <acl-id> <ace-id> [name WORD<0-32>]
```

The ACE ID determines ACE precedence (that is, the lower the ID, the higher the precedence).

### Note

For some hardware platforms, the ACE ID range is from 1 to 1000. If you try to create an ACE ID outside the range, the device displays the following error message:

```
Invalid input detected at '^' marker
```

- Configure the mode as deny or permit:

```
filter acl ace action <acl-id> <ace-id> <deny|permit>
```

#### Note

For VSP 8600 Series, the filter ACL ACE deny action does not apply to the Extensible Authentication Protocol (MKPDU), Link Layer Discovery Protocol, Virtual Link Aggregation Control Protocol, Link Aggregation Control Protocol, Topology Discovery Protocol, and Bridge Protocol Data Unit (BPDU) Guard frames. The system still snoops these packets to the Central Processing Unit (CPU) for processing.

- Configure ACE actions as required.

- Ensure the configuration is correct:

```
show filter acl ace <acl-id> <ace-id>
```

- Ensure the filter is enabled:

```
filter acl ace <acl-id> <ace-id> enable
```

- Optionally, reset an ACE to default values (reset the ACE name to the default name and the administrative state to the default value of disable):

```
default filter acl ace <acl-id> <ace-id>
```

- Optionally, delete an ACE ID:

```
no filter acl ace <acl-id> <ace-id>
```

#### Variable Definitions

Use the data in the following table to use the **filter acl ace** and the **filter acl ace action** commands.

| Variable      | Value                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <acl-id>      | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                                                                                                                                                                                                                                                                             |
| <ace-id>      | Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.                                                                                                                                                                                                                                               |
| <deny permit> | Configures the action mode for security ACEs.<br><br><b>Note:</b><br>For each Security ACE, you must define one or more actions as well as the associated action mode (permit or deny). Otherwise, the security ACE cannot be enabled. There is no default configuration for Security ACEs. With QoS ACE, the action mode is not configurable. QoS ACEs are always set to action mode permit. |

| Variable                           | Value                                                                                        |
|------------------------------------|----------------------------------------------------------------------------------------------|
| <code>enable</code>                | Enables an ACE within an ACL.<br>After you enable an ACE, to make changes, first disable it. |
| <code>name WORD&lt;0-32&gt;</code> | Specifies an optional descriptive name for the ACE that uses 0–32 characters.                |

## Configure ACE actions

### Note

DEMO FEATURE - Policy Based Routing (Redirect Next Hop) per VRF is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information, see [Fabric Engine and VOSS Feature Support Matrix](#).

Configure ACE actions to determine the process that occurs after a packet matches an ACE.

### Before You Begin

- Create ACE and ACL.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure ACE actions:

```
filter acl ace action <acl-id> <ace-id> <permit | deny>
```

### Note

For VSP 8600 Series, the filter ACL ACE deny action does not apply to the Extensible Authentication Protocol (MKPDU), Link Layer Discovery Protocol, Virtual Link Aggregation Control Protocol, Link Aggregation Control Protocol, Topology Discovery Protocol, and Bridge Protocol Data Unit (BPDU) Guard frames. The system still snoops these packets to the Central Processing Unit (CPU) for processing.

3. (Optional) Configure ACE actions to count matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> count
```

4. (Optional) Configure the QoS level for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> internal-qos
<0-7>
```

**Note**

This step does not apply to IPv6 filtering.

5. (Optional) Enable mirroring on destination MLT for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> monitor-dst-
mlt <1-512>
```

6. (Optional) Enable mirroring on a port for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> monitor-dst-
ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}
```

7. (Optional) Enable mirroring on destination I-SID for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> monitor-isid-
offset <1-1000>
```

8. (Optional) Configure the next hop IPv4 or IPv6 address for redirect mode for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> redirect-next-
hop WORD<1-45> [count | unreachable | vrf {WORD <1-16>}]
```

**Important**

Ensure you configure the ACE match rules so that you only collect the desired traffic. For example, routed packets.

9. (Optional) Configure the next hop IPv4 or IPv6 address for redirect mode for matching packets for a VRF:

**Note**

If the next hop is unreachable, you can also configure ACE actions to permit or deny packet dropping within the VRF.

```
filter acl ace action <acl-id> <ace-id> <permit | deny> redirect-next-
hop WORD<1-45> vrf WORD <1-16> unreachable <permit | deny>
```

10. (Optional) Configure the next hop IPv4 or IPv6 address for redirect mode for matching packets for a VRF:

**Note**

If the next hop is unreachable, you can also configure ACE actions to count matching packets, or to permit or deny packet dropping within the VRF

```
filter acl ace action <acl-id> <ace-id> <permit | deny> redirect-next-
hop WORD<1-45> vrf WORD <1-16> unreachable <permit | deny> count
```

## 11. (Optional) Configure the QoS dot1p priority for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> remark-dot1p
<0-7>
```

**Note**

This step does not apply to IPv6 filtering.

## 12. (Optional) Configure the QoS phb and dscp for matching packets:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> remark-dscp
[phbcs0 | phbcs1 | phbaf11 | phbaf12 | phbaf13 | phbcs2 | phbaf21 |
phbaf22 | phbaf23 | phbcs3 | phbaf31 | phbaf32 | phbaf33 | phbcs4 |
phbaf41 | phbaf42 | phbaf43 | phbcs5 | phbef | phbcs6 | phbcs7]
```

## 13. (Optional) Configure the mode when next hop is unreachable:

```
filter acl ace action <acl-id> <ace-id> <permit | deny> unreachable
[permit | deny]
```

## 14. Ensure the configuration is correct:

- `show filter acl action <acl-id> <ace-id>`
- `show filter acl config`
- `show filter acl ace`

**Example**

## Configure ACE actions:

```
Switch:1>enable
Switch:1#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch:1(config)#filter acl ace action 1 47 permit redirect-next-hop 192.0.2.5
unreachable deny count
```

Display the configuration using the **show filter ace action** command:

```
Switch:1(config)#show filter acl action

### Variable Definitions

Use the data in the following table to use the **filter acl ace action** command.

-

| Variable                    | Value                                                                                                                                           |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;acl-id&gt;</code> | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                               |
| <code>&lt;ace-id&gt;</code> | Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch. |
| <code>count</code>          | Enables the ability to count matching packets. Use this parameter with either a security or QoS ACE. The default is disabled.                   |

| Variable                                                                             | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;deny permit&gt;</code>                                                     | Configures the action mode for security ACEs.<br><br><b>Note:</b><br>For each Security ACE, you must define one or more actions as well as the associated action mode (permit or deny). Otherwise, the security ACE cannot be enabled. There is no default configuration for Security ACEs. With QoS ACEs, the action mode is not configurable. QoS ACEs are always set to action mode permit.                                                       |
| <code>monitor-isid-offset &lt;1-1000&gt;</code>                                      | Specifies the offset ID which will be mapped to the actual monitor I-SID where packets are mirrored. Monitor I-SID = base monitor I-SID + offset ID. The base monitor I-SID is 16776000.                                                                                                                                                                                                                                                             |
| <code>internal-qos &lt;0-7&gt;</code>                                                | This variable is a QoS action. The default value is 1.<br><br><b>Note:</b><br>This does not apply to IPv6 filtering.                                                                                                                                                                                                                                                                                                                                 |
| <code>monitor-dst-ports {slot/port[/sub-port] [-slot/port[/sub-port]] [,...]}</code> | Configures mirroring to a destination port or ports. This action is a security action. Identifies the slot and port in one of the following formats: a single slot and port (slot/port), a range of slots and ports (slot/port-slot/port), or a series of slots and ports (slot/port,slot/port,slot/port). If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port. |
| <code>monitor-dst-mlt &lt;1-512&gt;</code>                                           | Configures mirroring to a destination MLT in the range of 1 to 512.                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>redirect-next-hop WORD &lt;1-45&gt;</code>                                     | Specifies the nexthop IPv4 or IPv6 address for redirect node. This action is a security action.<br><br><b>Note:</b><br><b>redirect-next-hop</b> is available for demonstration purposes on some products. For more information, see <a href="#">Fabric Engine and VOSS Feature Support Matrix</a> .                                                                                                                                                  |
| <code>unreachable &lt;permit deny&gt;</code>                                         | Denies or permits packet dropping when the next hop for the packet is unreachable. The default value is deny. This action is a security action.<br><br><b>Note:</b><br><b>unreachable</b> is available for demonstration purposes on some products. For more information, see <a href="#">Fabric Engine and VOSS Feature Support Matrix</a> .                                                                                                        |

| Variable                                                                                                                                                                                                                               | Value                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>vrf WORD&lt;1-16&gt;</code>                                                                                                                                                                                                      | Specifies the direct next hop VRF name. The name must be in the ranger of 1 to 16 characters.<br><br><b>Note:</b><br><b>vrf</b> is available for demonstration purposes on some products. ## Configuring ARP ACEs

Use ACE Address Resolution Protocol (ARP) entries to ensure the filter looks for ARP requests or responses.

You cannot configure ARP attributes for IPv6 filters.

### Before You Begin

- The ACL exists.
- The ACE exists.

### Procedure

1. Enter Global Configuration mode:
 

```
enable
configure terminal
```
2. Configure an ACE for ARP packets:
 

```
filter acl ace arp <acl-id> <ace-id> operation eq <arprequest|
arpresponse>
```
3. Ensure the configuration is correct:
 

```
show filter acl arp <acl-id> <ace-id>
```

4. Optionally, delete the individual attributes from the ARP portion of the ACE:  

```
no filter acl ace arp <acl-id> <ace-id> [operation]
```
5. Optionally, delete all the attributes from the ARP portion of the ACE:  

```
default filter acl ace arp <acl-id> <ace-id>
```

### Variable Definitions

Use the data in the following table to use the **filter acl ace arp** command.

| Variable                                                                                  | Value                                                                                                                                           |
|-------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;acl-id&gt;</code>                                                               | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                               |
| <code>&lt;ace-id&gt;</code>                                                               | Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch. |
| <code>operation</code><br><code>eq &lt;arprequest </code><br><code>arpresponse&gt;</code> | Specifies the type of ARP operation to filter: arpRequest or arpResponse.                                                                       |

## Configuring an Ethernet ACE

Configure an Ethernet ACE to filter on Ethernet parameters.

You do not need to configure Ethertype for IPv6 filters. If you try to configure an Ethertype other than 0x86dd or IPv6 the device displays an error.

### Before You Begin

- The ACL exists.
- The ACE exists.

### About This Task

The `eq` and `mask` parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```

2. Configure an ACE for the destination or source MAC address attribute:

```
filter acl ace ethernet <acl-id> <ace-id> <dst-mac|src-mac> eq WORD<1-1024>
```

OR

```
filter acl ace ethernet <acl-id> <ace-id> <dst-mac|src-mac> mask WORD<1-1024> WORD<1-1024>
```

#### Note

This is supported only for IPv4 filters.

3. Configure an ACE for an Ethernet type attribute:

```
filter acl ace ethernet <acl-id> <ace-id> ether-type eq WORD<1-200>
```

4. Configure an ACE for a port attribute:

```
filter acl ace ethernet <acl-id> <ace-id> port eq {slot/port[sub-port]}
```

5. Configure an ACE for a VLAN attribute:

```
filter acl ace ethernet <acl-id> <ace-id> vlan-id eq <1-4059>
```

OR

```
filter acl ace ethernet <acl-id> <ace-id> vlan-id mask <1-4059> <0-0xFFF>
```

6. Configure an ACE for a VLAN tagged priority attribute:

```
filter acl ace ethernet <acl-id> <ace-id> vlan-tag-prio eq <0-7>
```

OR

```
filter acl ace ethernet <acl-id> <ace-id> vlan-tag-prio mask <0-7> <0-0x7>
```

7. Ensure the configuration is correct:

```
show filter acl ethernet <acl-id> <ace-id>
```

8. Optionally, delete the individual attributes from the Ethernet portion of the ACE:

```
no filter acl ace ethernet <acl-id> <ace-id>
```

9. Optionally, delete all the attributes from the Ethernet portion of the ACE:

```
default filter acl ace ethernet <acl-id> <ace-id>
```

#### Variable definitions

Use the data in the following table to use the **filter acl ace ethernet** command.

| Variable | Value                                                            |
|----------|------------------------------------------------------------------|
| <0-7>    | Specifies the priority bits (3-bit field) from the 802.1Q/p tag. |
| <0-0x7>  | Specifies the mask value for VLAN tagged priority attribute.     |

| Variable               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <0-0xFFF>              | Specifies the mask value for a VLAN attribute.<br>For example:<br>filter acl ace ethernet 10 10 vlan-id eq 10<br>filter acl ace ethernet 10 10 vlan-id mask<br>1025 0xF                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <ace-id>               | Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <acl-id>               | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <1-4059>               | Specifies the VLAN ID in the range of 1 to 4059. By default, VLAN IDs 1 to 4059 are configurable and the system reserves VLAN IDs 4060 to 4094 for internal use. On switches that support the <i>vrf-scaling</i> and <i>spbm-config-mode</i> boot configuration flags, if you enable these flags, the system also reserves VLAN IDs 3500 to 3998. VLAN ID 1 is the default VLAN and you cannot create or delete VLAN ID 1.                                                                                                                                                                                                                                               |
| {slot/port[/sub-port]} | Identifies a single slot and port. If the platform supports channelization and the port is channelized, you must also specify the sub-port in the format slot/port/sub-port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| WORD<1-200>            | Specifies an ether-type name or number: <ul style="list-style-type: none"> <li>• 0x0-0xffff</li> <li>• ip, arp, ipx802dot3, ipx802dot2, ipxSnap, ipxEthernet2, appleTalk, decLat, decOther, sna802dot2, snaEthernet2, netBios, xns, vines, ipv6, rarp, or PPPoE</li> </ul> <p><b>Note:</b><br/>Ethernet ACE filter configured with ether-type eq ipx802dot3 does not match the packet with format destination MAC address, source MAC address, length, 0xFFFF, payload and FCS.<br/>Ethernet ACE filter configured with ether-type eq ipx802dot2 does not match the packet with format destination MAC address, source MAC address, length, 0xE0E0, payload and FCS.</p> |
| WORD<1-1024>           | If the operator is mask, the WORD<1-1024> parameter is {" "[1..48 , mac address mask 0x0..FFFFFFFFFFFF] }<br>If the operator is eq, the WORD<1-1024> parameter is the destination or source MAC address: AA:BB:CC:DD:EE:FF<br>For example:<br>filter acl ace ethernet 10 10 dst-mac eq<br>0x01:00:5:00:00:01<br>filter acl ace ethernet 10 10 dst-mac mask<br>0x01:00:5:00:00:01 24<br>filter acl ace ethernet 10 10 src-mac mask<br>0x01:00:5:00:00:01 0xFFFFFFFF0000                                                                                                                                                                                                   |

## Configure an IP ACE

Configure an IP ACE to filter on the source IP address, destination IP address, DiffServ Code Point (DSCP), protocol, IP options, IP fragmentation, and routed packets only.

### Before You Begin

- The ACL exists.
- The ACE exists.

### About This Task

The *eq* and *mask* parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure an ACE for the DSCP attribute:

```
filter acl ace ip <acl-id> <ace-id> dscp
eq {<0..63>|<0x00..0x3f>|phbcs0|phbcs1|phbaf11|phbaf12|phbaf13|phbcs2|
phbaf21|phbaf22|phbaf23|phbcs3|phbaf31|phbaf32|phbaf33|phbcs4|phbaf41|
phbaf42|phbaf43|phbcs5|phbef|phbcs6|phbcs7}
```

OR

```
filter acl ace ip <acl-id> <ace-
id> dscp mask {<0..63>|<0x00..0x3f>|phbcs0|phbcs1|phbaf11|
phbaf12|phbaf13|phbcs2|phbaf21|phbaf22|phbaf23|phbcs3|phbaf31|phbaf32|
phbaf33|phbcs4|phbaf41|phbaf42|phbaf43|phbcs5|phbef|phbcs6|phbcs7}
WORD<0x0-0x40>
```

3. Configure an ACE for the destination or source IP address attribute:

```
filter acl ace ip <acl-id> <ace-id> <dst-ip|src-ip> eq WORD<1-1024>
```

OR

```
filter acl ace ip <acl-id> <ace-id> <dst-ip|src-ip> mask WORD<1-1024>
{<0-32>|null|<A.B.C.D>}
```

4. Configure an ACE for the IP fragmentation attribute:

```
filter acl ace ip <acl-id> <ace-id> ip-frag-flag eq <noFragment|
anyFragment>
```

5. Configure an ACE for the IP options attribute:

```
filter acl ace ip <acl-id> <ace-id> ip-options any
```

6. Configure an ACE for the protocol type attribute:

```
filter acl ace ip <acl-id> <ace-id> ip-protocol-type eq WORD<1-256>
```

7. Configure an ACE for routed packets only:

```
filter acl ace ip <acl-id> <ace-id> routed-only
```

#### Note

This step does not apply to VSP 8600 Series or XA1400 Series.

8. Ensure the configuration is correct:

```
show filter acl ip <acl-id> <ace-id>
```

9. (Optional) Delete all the attributes from the IP (Layer 3) portion of the ACE:

```
default filter acl ace ip <acl-id> <ace-id>
```

#### Example

```
Switch:1(config)#filter acl ace ip 1 12 dst-ip eq 198.51.100.0
```

#### Variable definitions

Use the data in the following table to use the **filter acl ace ip** command.

| Variable                 | Value                                                                                                                                                                                                                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ace-id>                 | Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.                                                                                                                                                                                   |
| <acl-id>                 | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                                                                                                                                                                                                                 |
| {<0-32> null <A.B.C.D>}  | Specifies the mask value for the destination or source IP address<br>For example:<br><pre>filter acl ace ip 10 10 dst-ip mask 198.51.100.0 25 filter acl ace ip 10 10 dst-ip mask 198.51.100.1 203.0.113.0 filter acl ace ip 10 10 src-ip mask 198.51.100.2 22 filter acl ace ip 10 10 src-ip mask 198.51.100.3 203.0.113.1</pre> |
| <noFragment anyFragment> | Specifies a match option for IP fragments noFragment or anyFragment.                                                                                                                                                                                                                                                              |

| Variable                                                                                                                                                                                                            | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Variable             | Value                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------|
| <i>WORD</i> <1-256>  | Specifies one or more IP protocol types: (1-256), or tcp, udp, ipsecesp, vrrp, snmp or undefined. |
| <i>WORD</i> <1-1024> | Specifies the destination or source IP address (a.b.c.d).                                         |

## Configure an IPv6 ACE

Configure an IPv6 ACE to filter traffic based on Source IPv6 address, Destination IPv6 address, IPv6 next header, and IPv6 traffic class, and routed packets only.

Source IPv6 and destination IPv6 support equal (eq) and mask operators. Next header and traffic class attributes support the equal (eq) operator. The equal to rule operator looks for an exact match with the field defined. If the field matches exactly with the rule, the system will return a match (hit). ACL-based filters provide the mask operator to match on Layer 2, Layer 3, and Layer 4 packet fields. The mask operator is used to mask bits in packet fields during a search or to match on a partial value of a packet field.

### Before You Begin

- Application Telemetry must be disabled on VSP 4450 Series, VSP 7200 Series, VSP 8200 Series, and VSP 8400 Series.
- The ACL exists. The ACL exists with the IPv6 packet type. You can only configure ACE IPv6 attributes to filter on an IPv6 packet.
- The ACE exists.

### About This Task

The *eq* and *mask* parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.

### Procedure

1. Enter Global Configuration mode:
 

```
enable

configure terminal
```
2. Create and name an ACE:
 

```
filter acl ace <acl-id> <ace-id> [name Word<1-32>]
```
3. Configure an ACE for the destination IPv6 address attribute:
 

```
filter acl ace ipv6 <acl-id> <ace-id> dst-ipv6 eq WORD<0-255>
```

OR

```
filter acl ace ipv6 <acl-id> <ace-id> dst-ipv6 mask WORD<1-128>
WORD<0-255>
```

4. Configure an ACE for the source IP address attribute:

```
filter acl ace ipv6 <acl-id> <ace-id> src-ipv6 eq WORD<0-255>
```

OR

```
filter acl ace ipv6 src-ipv6 <acl-id> <ace-id> mask WORD<1-128>  
WORD<0-255>
```

5. Specify the next header of the IP header:

```
filter acl ace ipv6 <acl-id> <ace-id> nxt-hdr eq {fragment|hop-by-hop|  
icmpv6|ipsecah|ipsecesp|noHdr|routing|tcp|udp|undefined}
```

You must configure next header to configure the protocol attributes.

6. Specify the traffic class attribute of the IPv6 header:

```
filter acl ace ipv6 <acl-id> <ace-id> traffic-class eq WORD<0-255>
```

7. Configure an ACE for routed packets only:

```
filter acl ace ipv6 <acl-id> <ace-id> routed-only
```

#### Note

This step does not apply to VSP 8600 Series or XA1400 Series.

8. Ensure that your configuration is correct:

```
show filter acl ipv6 <acl-id> <ace-id>
```

#### Example

```
Switch:1(config)#filter acl ace ipv6 15 15 dst-ipv6 eq 30:0:0:0:0:0:ffff/64
```

## Configuring a protocol ACE

Configure a protocol ACE to filter on the source port, destination port, ICMP and ICMPv6 message type, or TCP flags.

#### Note

For IPv6 filters, you must configure next header to configure the protocol attributes.

#### Before You Begin

- The ACL exists.
- The ACE exists.

#### About This Task

The *eq* and *mask* parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Configure an ACE for destination port attributes:  

```
filter acl ace protocol <acl-id> <ace-id> dst-port eq WORD<1-60>
```

OR

```
filter acl ace protocol <acl-id> <ace-id> dst-port mask WORD<1-60>  
WORD<1-256>
```
3. Configure an ACE for source port attributes:  

```
filter acl ace protocol <acl-id> <ace-id> src-port eq WORD<1-65535>
```

OR

```
filter acl ace protocol <acl-id> <ace-id> src-port mask WORD<1-65535>  
WORD<1-256>
```
4. Configure an ACE for ICMP message type attributes:  

```
filter acl ace protocol <acl-id> <ace-id> icmp-msg-type eq WORD<1-200>
```
5. Configure an ACE for TCP flags attributes:  

```
filter acl ace protocol <acl-id> <ace-id> tcp-flags eq WORD<1-50>
```

OR

```
filter acl ace protocol <acl-id> <ace-id> tcp-flags mask {0-0x3F|  
0-0x3F}
```
6. Ensure the configuration is correct:  

```
show filter acl protocol <acl-id> <ace-id>
```
7. (Optional) Delete the individual attributes from the protocol portion of the ACE:  

```
no filter acl ace protocol <acl-id> <ace-id> [dst-port] [icmp-msg-  
type] [icmpv6-msg-type] [routing-type] [src-port] [tcp-flags]
```
8. (Optional) Delete all the attributes from the protocol portion of the ACE:  

```
default filter acl ace protocol <acl-id> <ace-id>
```

*Specify ICMP packets:*

```
Switch:1(config)#filter acl ace protocol 1 12 icmpv6-msg-type eq echoRequest
```

**Table 274: TCP Flags Order in Packet**

|               |              |             |              |             |             |
|---------------|--------------|-------------|--------------|-------------|-------------|
| 32 (decimal)  | 16 (decimal) | 8 (decimal) | 4 (decimal)  | 2 (decimal) | 1 (decimal) |
| <b>Urgent</b> | <b>Ack</b>   | <b>Push</b> | <b>Reset</b> | <b>Syn</b>  | <b>Fin</b>  |

**Configure an ACE for TCP flags attributes: Example 1**

The mask is set for an 'ack' tcp flag bit regardless of whether any other tcp flag bits are also set:

```
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask ack ?
      <0-0x3F | 0-63> Mask value <Hex | Decimal>: This six bit mask is a reverse mask where
0:care
      about, 1:do not care about

Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask ack 0x2f
Hex Value 20 10 8 4 2 1
TCP Flags _ ack _ _ _ _
Binary Value 1 0 1 1 1 1 or in hex = 0x2F
```

### Configure an ACE for TCP flags attributes: Example 2

A packet will match this filter if the 3 tcpflag bits are set in the tcp header (and only those 3 bits).

```
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags eq ?
WORD<1-50> Tcp flags
{none | fin | syn | rst | push | ack | urg | undefined}
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags eq syn,push,urg
```

You can configure a functionally equivalent filter with the mask operator as follows:

```
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask syn,push,urg 0x0
```

### Configure an ACE for TCP flags attributes: Example 3

The mask operator provides more flexibility. For example a packet will match the following filter if the 'syn,push,urg' tcpflag bits are set, regardless of whether any other tcpflag bits are also set:

```
Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask syn,push,urg ?
      <0-0x3F | 0-63> Mask value <Hex | Decimal>: This six bit mask is a reverse mask where
0:care
      about, 1:do not care about

Switch:1(config)#filter acl ace protocol 1 1 tcp-flags mask syn,push,urg 0x15
```

### Configure an ACE for ICMP message type: Example 4

```
filter acl 1 type inPort name "ICMP_TRAFFIC_FILTER"
filter acl port 1 1/3
filter acl ace 1 1
filter acl ace action 1 1 deny count
filter acl ace ethernet 1 1 ether-type eq ip
filter acl ace ip 1 1 src-ip mask 194.183.100.64 0.0.0.15
filter acl ace ip 1 1 dst-ip eq 146.97.137.42
filter acl ace ip 1 1 ip-protocol-type eq icmp
filter acl ace protocol 1 1 icmp-msg-type eq echo-request
filter acl ace 1 1 enable
filter acl ace 1 2
filter acl ace action 1 2 deny count
filter acl ace ethernet 1 2 ether-type eq ip
filter acl ace ip 1 2 src-ip mask 194.183.100.64 0.0.0.15
filter acl ace ip 1 2 dst-ip eq 146.97.137.42
filter acl ace ip 1 2 ip-protocol-type eq icmp
filter acl ace protocol 1 2 icmp-msg-type eq echoreply
filter acl ace 1 2 enable
```

### Variable Definitions

Use the data in the following table to use the **filter acl ace protocol** command.

| Variable      | Value                                                                                                                                                                                                                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {0-0x3F}      | Specifies the mask value.                                                                                                                                                                                                                                                                                          |
| <ace-id>      | Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch.                                                                                                                                                                    |
| <acl-id>      | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                                                                                                                                                                                                  |
| WORD<1-50>    | Specifies one or more TCP flags—none, fin (finish connection), syn (synchronize), rst (reset connection), push, ack (acknowledge), urg (urgent), and undefined.                                                                                                                                                    |
| WORD<1-60>    | Specifies the destination port: (0-65535), or echo, ftpdata, ftpcontrol, ssh, telnet, dns, http, hdot323, bootpServer, bootpClient, tftp, rtp, rtcp, or undefined.                                                                                                                                                 |
| WORD<1-200>   | Specifies the ICMP message type: icmpmsg type (0-255), or echoreply, destunreach, sourcequench, redirect, echo-request, routeradv, routersolicit, time-exceeded, param-problem, timestamp-request, timestamp-reply, addressmask-request, addressmask-reply, or traceroute.                                         |
| WORD<1-200>   | Specifies the ICMPv6 message type: icmpmsg type (0-255), or destUnreach, pktTooBig, timeExceeded, paramProblem, echoRequest, echoReply, mcastListenReq, mcastListenRpt, mcastListenDone, routerSolicit, routerAdvert, neighborSolicit, neighborAdvert, redirectMsg, nodeInfoReq, nodeInfoRsp, or v2McastListenRpt. |
| WORD<1-256>   | Specifies the mask parameter, {0-0xFFFF}.                                                                                                                                                                                                                                                                          |
| WORD<0-65535> | Specifies the source port (0-65535).                                                                                                                                                                                                                                                                               |

## Configure Ingress Policer and Port Rate Limiter

### Note

This procedure only applies to VSP 4900 Series and VSP 7400 Series.

### Before You Begin

Ensure that both the ACL and the ACE exist.

## About This Task

Perform this procedure to limit the number of packets that can be attached to an ACL ACE. If you want to modify the ingress bandwidth rate limiter values, you must first disable the ACE.

### Note

You can attach one policer to ACL and ACE. Every policer is independent.

## Procedure

1. Enter the Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure an ACL and ACE policer:

```
filter acl ace policer <acl-id> <ace-id> svc-rate <0-4000000000> peak-  
rate <8-4000000000>
```

### Note

You must configure both svc-rate and peak-rate.

3. Ensure the configuration is correct:

```
show filter acl policer <acl-id> <ace-id>
```

## Variable Definitions

The following table defines parameters for the **filter acl ace policer** command.

| Variable                                                                                                                         | Value                                                                                                                                           |
|----------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;acl-id&gt;</code>                                                                                                      | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                               |
| <code>&lt;ace-id&gt;</code>                                                                                                      | Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch. |
| <code>svc-rate &lt;0-4000000000&gt;</code><br><b>Note:</b><br>Exception: only supported on VSP 4900 Series and VSP 7400 Series.  | Specifies the rate of the traffic committed to be delivered.<br>Service rate limit in kbps {0-4000000000}. The granularity is 8 kbps.           |
| <code>peak-rate &lt;8-4000000000&gt;</code><br><b>Note:</b><br>Exception: only supported on VSP 4900 Series and VSP 7400 Series. | Specifies the value when exceeded causes packets to drop on ingress.<br>Peak rate limit in kbps {8-4000000000}. The granularity is 8 kbps.      |

## Viewing ACL and ACE configuration data

View your configuration to review the information and ensure it is correct.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. View ACL information:  
`show filter acl <acl-id>`
3. View IPv6 ACL information:  
`show filter acl ipv6 <acl-id> <ace-id>`
4. View the running configuration for an ACL and corresponding ACE:  
`show filter acl config <acl-id> <ace-id>`

### Variable Definitions

Use the data in the following table to use the **show filter acl** and **show filter acl config** commands.

| Variable | Value                                                                                                                                           |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <ace-id> | Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch. |
| <acl-id> | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                               |

## View ACE Statistics

View ACE statistics to ensure that the filter operates correctly.

### Procedure

1. Enter Privileged EXEC mode:  
`enable`
2. View ACE statistics for a specific ACL, ACE, or ACE type:  
`show filter acl statistics <acl-id> <ace-id> [qos] [security]`
3. View all ACE statistics:  
`show filter acl statistics all`
4. View default ACE statistics:  
`show filter acl statistics default [<acl-id>]`
5. View global statistics for ACEs:  
`show filter acl statistics global [<acl-id>]`
6. View filter policer statistics for ACL and ACE:  
`show filter acl statistics <acl-id> <ace-id> policer`

*Examples*

View ACE statistics:

**Note**

Based on your hardware platform, the output can display the ACL packets by ACE type or Primary Bank or Secondary Bank.

```
Switch:1>enable
Switch:1#show filter acl statistics all
```

```

### Variable Definitions

The following table defines parameters for the **show filter acl statistics** command.

| Variable                                                                                                  | Value                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;acl-id&gt;</code>                                                                               | Specifies the ACL ID. Use the CLI Help to see the available range for the switch.                                                               |
| <code>&lt;ace-id&gt;</code>                                                                               | Specifies the ACE ID. Different hardware platforms support different ACE ID ranges. Use the CLI Help to see the available range for the switch. |
| <code>policer</code><br><b>Note:</b><br>Exception: only supported on VSP 4900 Series and VSP 7400 Series. | Specifies the policer parameter for the command.                                                                                                |

## Access Control Entry Configuration using EDM

Use an access control entry (ACE) to define a pattern (found in a packet) and the desired behavior for packets that carry the pattern. You can configure up to 1000 ACEs in a single ACL.

As a best practice, create access control lists (ACL) with a default action of permit, and with an ACE mode of deny. For deny or permit ACLs or ACEs, the default action and the mode must be opposite for the ACE (filter) to have meaning.

### Configure an ACE

#### Note

DEMO FEATURE - Policy Based Routing (Redirect Next Hop) per VRF is a demonstration feature on some products. Demonstration features are provided for testing purposes. Demonstration features are for lab use only and are not for use in a production environment. For more information, see [Fabric Engine and VOSS Feature Support Matrix](#).

#### Before You Begin

- The ACL exists.

#### Procedure

1. In the navigation pane, expand the **Configuration > Security > Data Path** folders.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the ACL to which to add an ACE.
5. Click **ACE**.
6. Click the **ACE Common** tab.

7. Click **Insert**.
8. Configure the ACE ID.
9. Name the ACE.
10. Choose the mode: **deny** (drop packets) or **permit** (forward packets).
11. Configure the ACE actions as required.
12. Click **Insert**.
13. Configure the ACE attributes as required.
14. To enable the ACE, in the **ACE Common** tab, configure **AdminState** to enable, and then click **Apply**.
15. To delete an ACE Common entry, select the entry, and then click **Delete**.

### **ACE Common** field descriptions

Use the data in the following table to use the **ACE Common** tab.

| Name                          | Description                                                                                                                                                         |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>                   | Specifies the ACL ID.                                                                                                                                               |
| <b>AcId</b>                   | Specifies the ACE ID.                                                                                                                                               |
| <b>Name</b>                   | Specifies a descriptive user-defined name for the ACE. The system automatically assigns a name if you do not type one.                                              |
| <b>AdminState</b>             | Indicates the status of the ACE as enabled or disabled. You can modify an ACE only if you disable it.                                                               |
| <b>OperState</b>              | Indicates the current operational state of the ACE.                                                                                                                 |
| <b>Mode</b>                   | Indicates the operating mode for this ACE. Valid options are deny and permit, with deny as the default.                                                             |
| <b>RedirectNextHop</b>        | Redirects matching IPv4/IPv6 traffic to IPv4/IPv6 nexthop.                                                                                                          |
| <b>RedirectNextHopVrfname</b> | Specifies the direct next hop VRF name. The name must be in the range of 1 to 16 characters.                                                                        |
| <b>RedirectUnreach</b>        | Denies or permits packet dropping when the next hop for the packet is unreachable. The default value is deny. This action is a security action.                     |
| <b>InternalQos</b>            | This variable is a QoS action. The default value is 1.                                                                                                              |
| <b>RemarkDscp</b>             | Specifies whether the DSCP parameter marks nonstandard traffic classes and local-use Per-Hop Behavior. The default is disable. Use this option to create a QoS ACE. |
| <b>RemarkDot1Priority</b>     | Specifies whether Dot1 Priority, as described by Layer 2 standards (802.1Q and 802.1p) is enabled. The default is disable. Use this option to create a QoS ACE.     |

## Configure ACE Actions

Configure ACE actions to determine the process that occurs after a packet matches (or does not match) an ACE. Use debug actions (flags) to use filters for troubleshooting and monitoring procedures.

### Before You Begin

- The ACE exists.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select an **Aceld**.
7. Select **Action**.
8. Configure the actions as required, and then select **Apply**.

### Action field descriptions

Use the data in the following table to use the **Action** tab.

#### Note

The table lists the options for both Security ACEs and QoS ACEs. Dependent upon the ACE, the system displays different options on the EDM interface.

| Name                      | Description                                                                                                                                                                                                                                                                       |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>               | Specifies the ACL ID.                                                                                                                                                                                                                                                             |
| <b>Aceld</b>              | Specifies the ACE ID.                                                                                                                                                                                                                                                             |
| <b>Mode</b>               | Configures the action mode for security ACEs. The default value is deny.                                                                                                                                                                                                          |
| <b>RemarkDscp</b>         | Specifies the new Per-Hop Behavior (PHB) for matching packets: phbcs0, phbcs1, phbaf11, phbaf12, phbaf13, phbcs2, phbaf21, phbaf22, phbaf23, phbcs3, phbaf31, phbaf32, phbaf33, phbcs4, phbaf41, phbaf42, phbaf43, phbcs5, phbef, phbcs6, phbcs7.<br>This action is a QoS action. |
| <b>RemarkDot1Priority</b> | Specifies the new 802.1 priority bit for matching packets: zero, one, two, three, four, five, six, or seven.<br>This action is a QoS action.<br><br><b>Note:</b><br>This does not apply to IPv6 filtering.                                                                        |

| Name                         | Description                                                                                                                                                                         |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InternalQoS</b>           | This variable is a QoS action. The default value is 1.<br><br><b>Note:</b><br>This does not apply to IPv6 filtering.                                                                |
| <b>RedirectNextHop</b>       | Specifies the next-hop IPv4 address (a.b.c.d) or IPv6 address (aaaa:bbbb:cccc:dddd:eeee:ffff:gggg:hhhh) for redirect mode.<br>Applies to ingress ACLs (routed and Layer 2 packets). |
| <b>Count</b>                 | Enables the ability to count matching packets. Use this parameter with either a security or QoS ACE. The default is disabled.                                                       |
| <b>DstPortList</b>           | Configures mirroring to a destination port or ports. This action is a security action.                                                                                              |
| <b>DstMltd</b>               | Configures mirroring to a destination MLT. This action is a security action.                                                                                                        |
| <b>MonitoringIsideOffset</b> | Configures the monitoring I-SID offset value. The offset ID is mapped to the actual monitor I-SID value to which the packets are mirrored.                                          |
| <b>MirroringQoS</b>          | Defines the Quality of Service (QoS) profiles for the mirrored packet into monitoring I-SID.                                                                                        |

## Configure ACE ARP entries

Use ACE Address Resolution Protocol (ARP) entries so that the filter looks for ARP request or response packets.

### Before You Begin

- The ACL exists.
- The ACE exists.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select a parameter for the appropriate ACL.
5. Select **ACE**.
6. Select a parameter for the appropriate ACE.
7. Select **Arp**.

8. Select **Insert**.
9. Select ARP request or response.
10. Select **Insert**.

### *ARP field descriptions*

Use the data in the following table to use the **ARP** tab.

| Name         | Description                                                                      |
|--------------|----------------------------------------------------------------------------------|
| <b>AcId</b>  | Specifies the ACL ID.                                                            |
| <b>AcId</b>  | Specifies the ACE ID.                                                            |
| <b>Type</b>  | Specifies the ACE ARP operation. The only option is operation.                   |
| <b>Oper</b>  | Specifies the operator for the ACE ARP operation. The only option is eq (equal). |
| <b>Value</b> | Specifies the ARP packet type. Valid options are arpRequest and arpResponse.     |

## View ACE ARP Entries for an ACL

View all of the ACE ARP entries associated with an ACL.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **Arp**.
6. Select the parameter and modify as you need.
7. Select **Apply**.

### *ARP field descriptions*

Use the data in the following table to use the **ARP** tab.

| Name         | Description                                                                      |
|--------------|----------------------------------------------------------------------------------|
| <b>AcId</b>  | Specifies the ACL ID.                                                            |
| <b>AcId</b>  | Specifies the ACE ID.                                                            |
| <b>Type</b>  | Specifies the ACE ARP operation. The only option is operation.                   |
| <b>Oper</b>  | Specifies the operator for the ACE ARP operation. The only option is eq (equal). |
| <b>Value</b> | Specifies the ARP packet type. Valid options are arpRequest and arpResponse.     |

## Configure an ACE Ethernet Source Address

Use this procedure to filter on specific Ethernet source addresses.

### Before You Begin

- The ACL exists.
- The ACE exists.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **Eth**.
8. Select the **Source Address** tab.
9. Select **Insert**.
10. Specify the ACE Ethernet operation.
11. In the **List** dialog box, specify the Ethernet source address.
12. Select **Insert**.

### Source Address Field Descriptions

Use the data in the following table to use the **Source Address** tab.

| Variable        | Value                                                                                                                                               |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>     | Specifies the ACL ID.                                                                                                                               |
| <b>AceId</b>    | Specifies the ACE ID.                                                                                                                               |
| <b>Oper</b>     | The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.  |
| <b>List</b>     | Specifies the MAC address to match.                                                                                                                 |
| <b>OperMask</b> | Specifies the MAC Address mask value in hexadecimal format. The value for this variable is empty or 000000000000 if the <b>Oper</b> variable is eq. |

## Configure an ACE Ethernet Destination Address

Perform this procedure to filter on specific Ethernet destination addresses.

### Before You Begin

- The ACL exists.
- The ACE exists.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **Eth**.
8. Select the **Destination Address** tab.
9. Select **Insert**.
10. Specify the ACE Ethernet operation.
11. In the **List** dialog box, specify the Ethernet source address.
12. Select **Insert**.

**Destination Address** *Field Descriptions*

Use the data in the following table to use the **Destination Address** tab.

| Variable        | Value                                                                                                                                                                     |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>     | Specifies the ACL ID.                                                                                                                                                     |
| <b>AcId</b>     | Specifies the ACE ID.                                                                                                                                                     |
| <b>Oper</b>     | The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.                        |
| <b>List</b>     | Specifies the MAC address to match.                                                                                                                                       |
| <b>OperMask</b> | Specifies the MAC address mask value in hexadecimal format if the <b>Oper</b> variable is mask. The value of this variable is empty or 000000000000 if <b>Oper</b> is eq. |

**Configure an ACE LAN Traffic Type**

Perform this procedure to filter for specific LAN traffic packets.

**Before You Begin**

- The ACL exists.
- The ACE exists.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.

6. Select the appropriate ACE.
7. Select **Eth**.
8. Select the **Ethernet Type** tab.
9. Select **Insert**.
10. Specify the operation type.
11. In the **TypeList** box, type the Ethernet types.
12. Select **Insert**.

### **Ethernet Type** field descriptions

Use the data in the following table to use the **Ethernet Type** tab.

| Name            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>     | Specifies the ACL ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>AcId</b>     | Specifies the ACE ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>TypeOper</b> | The eq parameter specifies an operator for a field match condition: equal to.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>TypeList</b> | <p>Specifies the Ethernet type. Entries include: 0 to 0xffff or ip, arp, ipx802.3, ipx802.2, ipxSnap, ipxEthernet2, appleTalk, appleTalk-ARP, sna802.2, snaEthernet2, netBios, xns, vines, ipv6, rarp, PPPoE-discovery, and PPPoE-session.</p> <p><b>Note:</b><br/>Ethernet ACE filter configured with Ethernet Type ipx802.3 does not match the packet with format destination MAC address, source MAC address, length, 0xFFFF, payload and FCS.<br/>Ethernet ACE filter configured with Ethernet Type ipx802.2 does not match the packet with format destination MAC address, source MAC address, length, 0xE0E0, payload and FCS.</p> |

## Configure an ACE Ethernet VLAN Tag Priority

Perform this procedure to filter for specific VLAN tag priorities.

### Before You Begin

- The ACL exists.
- The ACE exists.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.

5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **Eth**.
8. Select the **Vlan Tag Priority** tab.
9. Select **Insert**.
10. Specify the operation type.
11. In the **VlanTagPrio** box, select the priority bits.
12. Select **Insert**.

### **VLAN Tag Priority** field descriptions

Use the data in the following table to use the **Vlan Tag Priority** tab.

| Name               | Description                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>        | Specifies the ACL ID.                                                                                                                                                                                                                    |
| <b>AcId</b>        | Specifies the ACE ID.                                                                                                                                                                                                                    |
| <b>Oper</b>        | The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.                                                                                       |
| <b>VlanTagPrio</b> | Specifies the priority bits (3-bit field) from the 802.1Q/p tag: <ul style="list-style-type: none"> <li>• zero</li> <li>• one</li> <li>• two</li> <li>• three</li> <li>• four</li> <li>• five</li> <li>• six</li> <li>• seven</li> </ul> |
| <b>OperMask</b>    | Specifies the mask value in hexadecimal format if the <b>Oper</b> value is mask.                                                                                                                                                         |

## Configure an ACE Ethernet Port

Use ACE Ethernet port entries so that the filter looks for traffic on specific ports. You can only insert an ACE Common Ethernet port for VLAN ACL types.

### Before You Begin

- The ACL exists.
- The ACE exists.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.

4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **Eth**.
8. Select the **Port** tab.
9. Select **Insert**.
10. Specify the operation type.
11. Select the **Port** ellipses (...).
12. Choose the ports.
13. Select **OK**.
14. Select **Insert**.

### *Port field descriptions*

Use the data in the following table to use the **Port** tab.

| Name        | Description                                                                   |
|-------------|-------------------------------------------------------------------------------|
| <b>AcId</b> | Specifies the ACL ID.                                                         |
| <b>AcId</b> | Specifies the ACE ID.                                                         |
| <b>Oper</b> | The eq parameter specifies an operator for a field match condition: equal to. |
| <b>Port</b> | Specifies the port or port list on which to perform a match.                  |

## Configure an ACE Ethernet VLAN ID

Use ACE Ethernet VLAN ID entries so that the filter looks for traffic on specific VLANs. You can insert an ACE Ethernet VLAN ID only for ACL VLAN types.

### Before You Begin

- The ACL exists.
- The ACE exists.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **Eth**.
8. Select the **Vlan Id** tab.
9. Select **Insert**.
10. Specify the operation type.

11. Enter the VLAN ID or select from a list.
12. Select **Insert**.

#### **VLAN ID** field descriptions

Use the data in the following table to use the **Vlan Id** tab.

| Name            | Description                                                                   |
|-----------------|-------------------------------------------------------------------------------|
| <b>AcId</b>     | Specifies the ACL ID.                                                         |
| <b>AcId</b>     | Specifies the ACE ID.                                                         |
| <b>Oper</b>     | The eq parameter specifies an operator for a field match condition: equal to. |
| <b>VlanId</b>   | Specifies the VLAN ID on which to perform a match.                            |
| <b>OperMask</b> | Specifies the mask value for a VLAN attribute.                                |

## Viewing All ACE Ethernet Entries for an ACL

View all of the ACE Ethernet entries associated with an ACL.

#### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **Eth**.

#### **Ethernet** field descriptions

Use the data in the following table to use the **Ethernet** tab.

| Name                   | Description                                                                                                                                                                                       |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>            | Shows the ACL ID.                                                                                                                                                                                 |
| <b>AcId</b>            | Specifies the ACE ID.                                                                                                                                                                             |
| <b>SrcAddrList</b>     | Shows the list of Ethernet source addresses to match.                                                                                                                                             |
| <b>SrcAddrOper</b>     | Shows the operators for the ACE Ethernet source MAC address.                                                                                                                                      |
| <b>SrcAddrOperMask</b> | Shows the source MAC address mask value in hexadecimal format if the <b>SrcAddrOper</b> variable is mask. The value of this field is empty or 000000000000 if the <b>SrcAddrOper</b> field is eq. |
| <b>DstAddrList</b>     | Shows the list of Ethernet destination addresses to match.                                                                                                                                        |
| <b>DstAddrOper</b>     | Shows the operators for the ACE Ethernet destination MAC address.                                                                                                                                 |

| Name                       | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DstAddrOperMask</b>     | Shows the destination MAC address mask value in hexadecimal format if the <b>DstAddrOper</b> variable is mask. The value for this field is empty or 000000000000 if the <b>DstAddrOper</b> field is eq                                                                                                                                                                                              |
| <b>EtherTypeList</b>       | Shows the EtherType value from the Ethernet header. For example, ARP uses 0x0806 and IP uses 0x0800.<br>Platform support determines the behavior for 802.1Q/p tagged packets. The EtherType for 802.1Q tagged frames is 0x8100.<br>The range is 0–65535 and supports lists and ranges of values. An invalid Ether-type of 65536 indicates that you do not want the parameter in the match criteria. |
| <b>EtherTypeOper</b>       | Shows the Ethernet type operators.                                                                                                                                                                                                                                                                                                                                                                  |
| <b>VlanTagPrio</b>         | Shows the priority bits (3-bit field) from the 802.1Q/p tag.                                                                                                                                                                                                                                                                                                                                        |
| <b>VlanTagPrioOper</b>     | Shows the operators for the ACE Ethernet VLAN tag priority.                                                                                                                                                                                                                                                                                                                                         |
| <b>VlanTagPrioOperMask</b> | Shows the VLAN tag priority mask value in hexadecimal format if the <b>VlanTagPrioOper</b> field is mask.                                                                                                                                                                                                                                                                                           |
| <b>Port</b>                | Shows the port number or port list to match.                                                                                                                                                                                                                                                                                                                                                        |
| <b>PortOper</b>            | Shows the operator for the ACE Ethernet port.                                                                                                                                                                                                                                                                                                                                                       |
| <b>VlanId</b>              | Shows the VLAN ID to match.                                                                                                                                                                                                                                                                                                                                                                         |
| <b>VlanIdOper</b>          | Shows the operator for the ACE Ethernet VLAN ID.                                                                                                                                                                                                                                                                                                                                                    |
| <b>VlanIdOperMask</b>      | Shows the VLAN ID mask value in hexadecimal format if the <b>VlanIdOper</b> field is mask.                                                                                                                                                                                                                                                                                                          |

## Configure an ACE IP Source Address

Configure ACE IP source address entries to have the filter look for specific source IP addresses.

### Before You Begin

- The ACL exists.
- The ACE exists.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration** > **Security** > **Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.

6. Select the appropriate ACE.
7. Select **IP**.
8. Select the Source Address tab.
9. Select **Insert**.
10. Specify the operation type.
11. In the **IPAddr** box, enter the source IP address.
12. Select **Insert**.

### **Source Address** field descriptions

Use the data in the following table to use the **Source Address** tab.

| Name            | Description                                                                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>     | Specifies the ACL ID.                                                                                                                              |
| <b>AcId</b>     | Specifies the ACE ID.                                                                                                                              |
| <b>Oper</b>     | The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits. |
| <b>IPAddr</b>   | Specifies the source IP address.                                                                                                                   |
| <b>OperMask</b> | Specifies the mask value for the source IP address.                                                                                                |

## Configure an ACE IP Destination Address

Configure ACE IP destination address entries to have the filter look for specific destination IP addresses.

### **Before You Begin**

- The ACL exists.
- The ACE exists.

### **Procedure**

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **IP**.
8. Select the **Destination Address** tab.
9. Select **Insert**.
10. Specify the operation type.
11. In the **IPAddr** box, enter the destination IP address.
12. Select **Insert**.

**Destination Address** field descriptions

Use the data in the following table to use the **Destination Address** tab.

| Name            | Description                                                                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>     | Specifies the ACL ID.                                                                                                                              |
| <b>AcId</b>     | Specifies the ACE ID.                                                                                                                              |
| <b>Oper</b>     | The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits. |
| <b>IPAddr</b>   | Specifies the destination IP address.                                                                                                              |
| <b>OperMask</b> | Specifies the mask value for the destination IP address.                                                                                           |

## Configure an ACE IP DSCP

Configure ACE IP DSCP entries to have the filter look for packets with specific DSCP markings.

**Before You Begin**

- The ACL exists.
- The ACE exists.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **IP**.
8. Select the **DSCP** tab.
9. Select **Insert**.
10. Specify the operation type.
11. In the **List** box, enter the count for the DSCP values.
12. Select **Insert**.

**DSCP** field descriptions

Use the data in the following table to use the **DSCP** tab.

| Name        | Description           |
|-------------|-----------------------|
| <b>AcId</b> | Specifies the ACL ID. |
| <b>AcId</b> | Specifies the ACE ID. |

| Name            | Description                                                                                                                                                                                                                                                                                             |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Oper</b>     | The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.                                                                                                                                                      |
| <b>List</b>     | Specifies a count for the number of discrete ranges entered for the DSCP values. Entries include 0–256, disable, phbcs0, phbcs1, phbaf11, phbaf12, phbaf13, phbcs2, phbaf21, phbaf22, phbaf23, phbcs3, phbaf31, phbaf32, phbaf33, phbcs4, phbaf41, phbaf42, phbaf43, phbcs5, phbef, phbcs6, and phbcs7. |
| <b>OperMask</b> | Specifies the mask value.                                                                                                                                                                                                                                                                               |

## Configure an ACE IP protocol

Configure ACE IP protocol entries to have the filter look for packets of specific protocols.

### Before You Begin

- The ACL exists.
- The ACE exists.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **IP**.
8. Select the **Protocol** tab.
9. Select **Insert**.
10. Specify the operation type.
11. In the **List** box, enter the IP protocol type.
12. Select **Insert**.

### *Protocol field descriptions*

Use the data in the following table to use the **Protocol** tab.

| Name        | Description           |
|-------------|-----------------------|
| <b>AcId</b> | Specifies the ACL ID. |
| <b>AcId</b> | Specifies the ACE ID. |

| Name        | Description                                                                                                |
|-------------|------------------------------------------------------------------------------------------------------------|
| <b>Oper</b> | The eq parameter specifies an operator for a field match condition: equal to.                              |
| <b>List</b> | Specifies the IP protocol type. Entries include 0–256, undefined, tcp, udp, ipsecesp, vrrp, and undefined. |

## Configure ACE IP options

Configure ACE IP option entries to have the filter look for packets with an IP option specified.

### Before You Begin

- The ACL exists.
- The ACE exists.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **IP**.
8. Select the **Options** tab.
9. Select **Insert**.
10. Specify the logical operator.  
**Any** is the only choice.
11. Select **Insert**.

### **Options** field descriptions

Use the data in the following table to use the **Options** tab.

| Name         | Description                                                                    |
|--------------|--------------------------------------------------------------------------------|
| <b>AcId</b>  | Specifies the ACL ID.                                                          |
| <b>AceId</b> | Specifies the ACE ID.                                                          |
| <b>Oper</b>  | Specifies the logical operator for the ACE IP options. Any is the only option. |

## Configure ACE IP Fragmentation

Configure ACE IP fragmentation entries to have the filter look for packets with the fragmentation flag.

**Before You Begin**

- The ACL exists.
- The ACE exists.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.
4. Select the appropriate ACL.
5. Select **ACE**.
6. Select the appropriate ACE.
7. Select **IP**.
8. Select the **Fragmentation** tab.
9. Select **Insert**.
10. Specify the operator for IP fragmentation.  
**Eq** is the only choice.
11. Specify the fragmentation bits to match from the IP header.
12. Select **Insert**.

**Fragmentation** field descriptions

Use the data in the following table to use the **Fragmentation** tab.

| Name                 | Description                                                                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>          | Specifies the ACL ID.                                                                                                                                                             |
| <b>AcId</b>          | Specifies the ACE ID.                                                                                                                                                             |
| <b>Oper</b>          | Specifies the logical operator for the ACE IP options. Any is the only option.                                                                                                    |
| <b>Fragmentation</b> | Specifies the IP fragmentation bits to match from the IP header: <ul style="list-style-type: none"> <li>• noFragment</li> <li>• anyFragment</li> </ul> The default is noFragment. |

[View all ACE IP Entries for an ACL](#)

View all of the ACE IP entries associated with an ACL.

**Procedure**

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **ACL** tab.

4. Select the appropriate ACL.
5. Select **IP**.

### *IP field descriptions*

Use the data in the following table to use the **IP** tab.

| Name                        | Description                                                                                                                        |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>                 | Shows the ACL IP ID.                                                                                                               |
| <b>AcId</b>                 | Shows the ACE ID.                                                                                                                  |
| <b>SrcAddrOper</b>          | Shows the operators for the ACE IP source address.                                                                                 |
| <b>SrcAddrIpAddr</b>        | Shows the IP source address to match from the IP header.                                                                           |
| <b>SrcAddrOperMaskRange</b> | Shows the IP mask value if <b>SrcAddrOper</b> is set to mask, or the highest IP address if <b>SrcAddrOper</b> is set to range.     |
| <b>DstAddrOper</b>          | Shows the operators for the ACE IP destination address.                                                                            |
| <b>DstAddrIpAddr</b>        | Shows the IP destination address to match from the IP header.                                                                      |
| <b>DstAddrOperMaskRange</b> | Shows the IP mask value if <b>DstAddrIpAddr</b> is set to mask, or the highest IP address if <b>DstAddrIpAddr</b> is set to range. |
| <b>DscpList</b>             | Shows how the 6-bit DSCP parameter from the TOS byte in the IPv4 header encodes PHB information following RFC 2474.                |
| <b>DscpOper</b>             | Shows the operators for the ACE IP DSCP.                                                                                           |
| <b>DscpOperMask</b>         | Shows the mask value in hexadecimal format when the mask option is selected in <b>DscpOper</b> .                                   |
| <b>ProtoList</b>            | Shows the IP protocol type from the IP header to match. The range is 0–255.                                                        |
| <b>ProtoOper</b>            | Shows the operators for the ACE IP protocols.                                                                                      |
| <b>Options</b>              | Shows the IP options to match from the IP header.                                                                                  |
| <b>OptionsOper</b>          | Shows the logical operator. Any is the only option.                                                                                |
| <b>Fragmentation</b>        | Shows the IP fragmentation bits to match from the IP header.                                                                       |
| <b>FragOper</b>             | Shows the operator for IP fragmentation.                                                                                           |

## Configuring an ACE IPv6 source address

Configure ACE IPv6 source address entries to have the filter look for specific source IP addresses.

### Before You Begin

- The ACL exists.

- The ACE exists.

#### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IPv6**.
8. Click the **Source Address** tab.
9. Click **Insert**.
10. In the **Oper** field, select the operation type.
11. In the **List** field, enter the source IP address.
12. In the **OperMask** field, enter the operation mask value.
13. Click **Insert**.

#### *Source Address field descriptions*

Use the data in the following table to use the **Source Address** tab.

| Name            | Description                                                                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>     | Specifies the ACL ID.                                                                                                                              |
| <b>AcId</b>     | Specifies the ACE ID.                                                                                                                              |
| <b>Oper</b>     | The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits. |
| <b>List</b>     | Specifies the source IP address.                                                                                                                   |
| <b>OperMask</b> | Specifies the mask value for the source IP address.                                                                                                |

## Configuring an ACE IPv6 destination address

Configure ACE IPv6 destination address entries to have the filter look for specific destination IP addresses.

#### Before You Begin

- The ACL exists.
- The ACE exists.

#### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.

4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IPv6**.
8. Click the **Destination Address** tab.
9. Click **Insert**.
10. In the **Oper** field, select the operation type.
11. In the **List** field, enter the destination IP address.
12. In the **OperMask** field, enter the operation mask value.
13. Click **Insert**.

### **Destination Address** field descriptions

Use the data in the following table to use the **Destination Address** tab.

| Name            | Description                                                                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>     | Specifies the ACL ID.                                                                                                                              |
| <b>AcId</b>     | Specifies the ACE ID.                                                                                                                              |
| <b>Oper</b>     | The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits. |
| <b>List</b>     | Specifies the destination IP address.                                                                                                              |
| <b>OperMask</b> | Specifies the mask value for the destination IP address.                                                                                           |

## Configuring an ACE IPv6 next header

Configure ACE IPv6 next header entries to have the filter look for specific next headers.

### Before You Begin

- The ACL exists.
- The ACE exists.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IPv6**.
8. Click the **Next Hdr** tab.
9. Click **Insert**.
10. In the **Oper** field, select the operation type.

11. In the **NextHdr** field, select the next header type.
12. Click **Insert**.

#### **Next Header** field descriptions

Use the data in the following table to use the **Next Hdr** tab.

| Name           | Description                                                                                                                                         |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>    | Specifies the ACL ID.                                                                                                                               |
| <b>AcId</b>    | Specifies the ACE ID.                                                                                                                               |
| <b>Oper</b>    | The eq parameter specifies an operator for an “equal to” field match condition.                                                                     |
| <b>NextHdr</b> | Specifies the next header of the IPv6 header. Specifies hop-by-hop, tcp, udp, routing, fragment, ipsecESP, ipsecAH, icmpv6, noNxtHdr, or undefined. |

## Configuring an ACE IPv6 traffic class

Configure ACE IPv6 traffic class.

#### **Before You Begin**

- The ACL exists.
- The ACE exists.

#### **Procedure**

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IPv6**.
8. Click the **Traffic Class** tab.
9. Click **Insert**.
10. In the **Oper** field, select the operation type.
11. In the **TrafficCls** field, enter the traffic class number.
12. Click **Insert**.

#### **Traffic Class** field descriptions

Use the data in the following table to use the **Traffic Class** tab.

| Name        | Description           |
|-------------|-----------------------|
| <b>AcId</b> | Specifies the ACL ID. |
| <b>AcId</b> | Specifies the ACE ID. |

| Name              | Description                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Oper</b>       | The eq parameter specifies an operator for an “equal to” field match condition.                                                                         |
| <b>TrafficCls</b> | Specifies the traffic class attribute of the IPv6 header. Traffic class identifies different classes or priorities of IPv6 packets. The range is 0–255. |

## Viewing all ACE IPv6 entries for an ACL

View all of the ACE IPv6 entries associated with an ACL.

### Before You Begin

- The ACL exists.
- The ACE exists.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **IPv6**.
8. Click the **IPv6** tab.

### IPv6 field descriptions

Use the data in the following table to use the **IPv6** tab.

| Name                  | Description                                             |
|-----------------------|---------------------------------------------------------|
| <b>AcId</b>           | Specifies the ACL ID.                                   |
| <b>AcId</b>           | Specifies the ACE ID.                                   |
| <b>SrcAddrList</b>    | Shows the source IP address.                            |
| <b>SrcAddrOper</b>    | Shows the operators for the ACE IP source address.      |
| <b>DstAddrList</b>    | Shows the destination IP address.                       |
| <b>DstAddrOper</b>    | Shows the operators for the ACE IP destination address. |
| <b>NxtHdrNxtHdr</b>   | Shows the next header of the IPv6 header.               |
| <b>NxtHdrOper</b>     | Shows the operators for the next header.                |
| <b>TrafficClsOper</b> | Shows the operators for the traffic class.              |
| <b>TrafficCls</b>     | Shows the traffic class attribute of the IPv6 header.   |
| <b>SrcAddrMask</b>    | Shows the mask value for the source IP address.         |
| <b>DstAddrMask</b>    | Shows the mask value for the destination IP address.    |

## Configuring an ACE source port

Configure ACE source port entries to have the filter look for packets with a specific source port.

### Before You Begin

- The ACL exists.
- The ACE exists.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Proto**.
8. Click the **Source Port** tab.
9. Click **Insert**.
10. Specify the operator for the source port.
11. Specify the port number or port list to match.
12. Click **Insert**.

### **Source Port** field descriptions

Use the data in the following table to use the **Source Port** tab.

| Name            | Description                                                                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>     | Specifies the ACL ID.                                                                                                                              |
| <b>AcId</b>     | Specifies the ACE ID.                                                                                                                              |
| <b>Port</b>     | Specifies the source port (1–65535).                                                                                                               |
| <b>Oper</b>     | The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits. |
| <b>OperMask</b> | Specifies the mask parameter, {0-0xFFFF}.                                                                                                          |

## Configuring an ACE destination port

Configure ACE destination port entries to have the filter look for packets with a specific destination port.

### Before You Begin

- The ACE exists.
- The ACL exists.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Proto**.
8. Click the **Destination Port** tab.
9. Click **Insert**.
10. Specify the operator for the destination port.
11. Specify the port number or port list to match.
12. Click **Insert**.

### *Destination Port* field descriptions

Use the data in the following table to use the **Destination Port** tab.

| Name            | Description                                                                                                                                                               |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>     | Specifies the ACL ID.                                                                                                                                                     |
| <b>AcId</b>     | Specifies the ACE ID.                                                                                                                                                     |
| <b>Oper</b>     | The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.                        |
| <b>Port</b>     | Specifies the port number. As noted at the bottom of the tab, potential entries include 0–65535, echo, ftpdata, ftpcontrol, ssh, telnet, dns, http, h.323, and undefined. |
| <b>OperMask</b> | Specifies the mask parameter, {0-0xFFFF}.                                                                                                                                 |

## Configuring an ACE ICMP message type

Configure ACE Internet Control Message Protocol (ICMP) message type entries to have the filter look for packets of a specific ICMP message type.

### Before You Begin

- The ACL exists.
- The ACE exists.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.

5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Proto**.
8. Click the **Icmp Msg Type** tab.
9. Click **Insert**.
10. Specify the operator for the ICMP message type.
11. In the **List** box, specify the ICMP messages to match.
12. Click **Insert**.

### *Icmp Msg Type field descriptions*

Use the data in the following table to use the **Icmp Msg Type** tab.

| Name        | Description                                                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b> | Specifies the ACL ID.                                                                                                                                                                                                                                       |
| <b>AcId</b> | Specifies the ACE ID.                                                                                                                                                                                                                                       |
| <b>Oper</b> | Specifies the operator for the ACE protocol ICMP message type. Equal (eq) is the only option.                                                                                                                                                               |
| <b>List</b> | Specifies the ICMP message type (0–255), or echoreply, destunreach, sourcequench, redirect, echo-request, routeradv, routerselect, time-exceeded, param-problem, timestamp-request, timestamp-reply, addressmask-request, addressmask-reply, or traceroute. |

## Configuring an ACE ICMPv6 message type

### About This Task

Configure ACE Internet Control Message Protocol v6 (ICMPv6) message type entries to have the filter look for packets of a specific ICMPv6 message type.

### Before You Begin

- The ACL exists.
- The ACE exists.

### Procedure

1. In the navigation pane, expand the following folders: **Configuration > Security > Data path**
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Proto**.
8. Click the **Icmpv6 Msg Type** tab.
9. Click **Insert**.

10. Specify the operator for the ICMPv6 message type.
11. In the **List** field, specify the ICMPv6 messages to match.
12. In the **Count** field, specify 1 through 100.
13. Click **Insert**.

### **Icmpv6 Msg Type** field descriptions

Use the data in the following table to use the **Icmpv6 Msg Type** tab.

| Name  | Description                                                                                                                                                                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AclId | Specifies the ACL ID.                                                                                                                                                                                                                                         |
| AceId | Specifies the ACE ID.                                                                                                                                                                                                                                         |
| Oper  | Specifies the operator for the ACE protocol ICMPv6 message type. Equal (eq) is the only option.                                                                                                                                                               |
| List  | Specifies the ICMPv6 message type (0–255), or echoreply, destunreach, sourcequench, redirect, echo-request, routeradv, routerselect, time-exceeded, param-problem, timestamp-request, timestamp-reply, addressmask-request, addressmask-reply, or traceroute. |
| Count | Specifies 1–100.<br>Enables the ability to count matching packets. Use this parameter with either a security or QoS ACE. The default is disabled.                                                                                                             |

## Configuring an ACE TCP flag

Configure ACE TCP flag entries to have the filter look for packets with a specific TCP flag.

### Before You Begin

- The ACL exists.
- The ACE exists.

### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **ACE**.
6. Select the appropriate ACE.
7. Click **Proto**.
8. Click the **TCP Flags** tab.
9. Click **Insert**.
10. Specify the operator for the TCP flags entry.
11. In the **List** box, specify the TCP flags to match.

12. Click **Insert**.

### **TCP Flags** field descriptions

Use the data in the following table to use the **TCP Flags** tab.

| Name            | Description                                                                                                                                                     |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>     | Specifies the ACL ID.                                                                                                                                           |
| <b>AcId</b>     | Specifies the ACE ID.                                                                                                                                           |
| <b>Oper</b>     | The eq and mask parameters specify an operator for a field match condition: equal to or mask. The mask operator is an implied eq on the mask bits.              |
| <b>List</b>     | Specifies one or more TCP flags—none, fin (finish connection), syn (synchronize), rst (reset connection), push, ack (acknowledge), urg (urgent), and undefined. |
| <b>OperMask</b> | Specifies the mask value.                                                                                                                                       |

## Configure an ACE to Filter IPv4 Routed Packets

Configure an ACE to filter IPv4 routed packets.

### Note

This procedure does not apply to VSP 8600 Series or XA1400 Series.

### Before You Begin

- The ACL exists.
- The ACE exists.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select **IpRouted** tab.
4. Select **Insert**.
5. In the **AcId** field, type the appropriate ACL ID.
6. In the **AcId** field, type the appropriate ACE ID.
7. **RoutedOnly**
8. Select **Insert**.

### **IpRouted** Field Descriptions

The following table describes values on the **IpRouted** tab.

| Name        | Description                                     |
|-------------|-------------------------------------------------|
| <b>AcId</b> | Specifies the ACL ID. Value range of 1 to 2048. |
| <b>AcId</b> | Specifies the ACE ID. Value range of 1 to 2000. |

## Configure an ACE to Filter IPv6 Routed Packets

Configure an ACE to filter IPv6 routed packets only.

### Note

This procedure does not apply to VSP 8600 Series or XA1400 Series.

### Before You Begin

- The ACL exists.
- The ACE exists.

### Procedure

1. In the navigation pane, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the **Ipv6Routed** tab.
4. Select **Insert**.
5. In the **AcId** field, type the appropriate ACL ID.
6. In the **AcId** field, type the appropriate ACE ID.
7. Select **RoutedOnly**.
8. Select **Insert**.

### *Ipv6Routed* Field Descriptions

The following table describes values on the **Ipv6Routed** tab.

| Name              | Description                                       |
|-------------------|---------------------------------------------------|
| <b>AcId</b>       | Specifies the ACL ID.                             |
| <b>AcId</b>       | Specifies the ACE ID.                             |
| <b>RoutedOnly</b> | Specifies the match for IPv6 routed packets only. |

## Configure Ingress Policer and Port Rate Limiter

### Note

This procedure only applies to VSP 4900 Series and VSP 7400 Series switches.

Perform this procedure to limit the number of packets that can be attached to an ACL ACE. If you want to modify the ingress bandwidth rate limiter values, you must first disable the ACE.

#### Note

You can attach one policer to ACL and ACE. Every policer is independent.

### Before You Begin

Ensure that both the ACL and the ACE exist.

### Procedure

1. In the navigation tree, expand **Configuration > Security > Data Path**.
2. Select **Advanced Filters (ACE/ACLs)**.
3. Select the appropriate ACL.
4. Select the appropriate ACE.
5. Select **Policer**.
6. Select **Insert**.
7. For **SvcRateValue**, type the service rate value.
8. For **PeakRateValue**, type the peak rate value.
9. Select **Insert**.
10. Select **Apply**.

### *Policer Field Descriptions*

| Name                 | Description                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>          | Specifies the ACL identifier numeric value for the filter.                                                                                      |
| <b>AcId</b>          | Specifies the ACE identifier numeric value for the filter.                                                                                      |
| <b>SvcRateValue</b>  | Specifies the service rate in kilobits for the flow of packets from the filter. The range is 8 to 4000000000 and the granularity is 8 kilobits. |
| <b>PeakRateValue</b> | Specifies peak rate in kilobits for the flow of packets from the filter. The range is 8 to 4000000000 and the granularity is 8 kilobits.        |
| <b>Oper</b>          | Specifies the operational status of the policer.                                                                                                |

## Viewing ACE Port Statistics

### About This Task

Use port statistics to ensure that the ACE is operating correctly.

### Procedure

1. In the navigation pane, expand the **Configuration > Security > Data Path** folders.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.

4. Select a field on the **ACL** tab.
5. Click **ACE**.
6. Click the **Statistics** tab.

### Statistics Field Descriptions

Use the data in the following table to use the **Statistics** tab.

| Name                    | Description                                                                                                                       |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>             | Specifies the associated ACL index.                                                                                               |
| <b>AcId</b>             | Specifies the ACE index.                                                                                                          |
| <b>MatchCountPkts</b>   | Specifies a packet count of the matching packets.                                                                                 |
| <b>MatchCountOctets</b> | Specifies the number of octets of the matching packets.                                                                           |
| <b>GreenBytes</b>       | Specifies the number of bytes sent with a rate lower than the committed-rate of the matching ACE.                                 |
| <b>GreenPackets</b>     | Specifies the number of packets sent with a rate lower than the committed-rate of the matching ACE.                               |
| <b>YellowBytes</b>      | Specifies the number of bytes sent with a rate lower than peak-rate and higher than the committed-rate of the matching ACE.       |
| <b>YellowPackets</b>    | Specifies the number of packets sent with a rate lower than the peak-rate and higher than the committed-rate of the matching ACE. |
| <b>RedBytes</b>         | Specifies the number of bytes sent with a rate higher than the peak-rate of the matching ACE.                                     |
| <b>RedPackets</b>       | Specifies the number of packets sent with a rate higher than the peak-rate of the matching ACE.                                   |

### Viewing all ACE protocol entries for an ACL

View all of the ACE protocol entries associated with an ACL.

#### Procedure

1. In the navigation tree, expand the following folders: **Configuration > Security > Data Path**.
2. Click **Advanced Filters (ACE/ACLs)**.
3. Click the **ACL** tab.
4. Select the appropriate ACL.
5. Click **Proto**.

**Protocol** field descriptions

Use the data in the following table to use the **Protocol** tab.

| Name                        | Description                                                                                                                                                                                                                                                                                     |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AcId</b>                 | Specifies the ACL ID.                                                                                                                                                                                                                                                                           |
| <b>AcId</b>                 | Specifies the ACE ID.                                                                                                                                                                                                                                                                           |
| <b>SrcPort</b>              | Specifies the port number or port list to match.                                                                                                                                                                                                                                                |
| <b>SrcPortOper</b>          | Specifies the operator for the ACE protocol source port.                                                                                                                                                                                                                                        |
| <b>SrcPortOperMaskRange</b> | The value is displayed in hexadecimal format when <b>SrcPortOper</b> is set to mask. When <b>SrcPortOper</b> is set to range, this field is used as the high range value. In this case, the value is displayed in decimal format. When <b>SrcPortOper</b> is set to eq, this field is set to 0. |
| <b>DstPort</b>              | Specifies port number or port list to match.                                                                                                                                                                                                                                                    |
| <b>DstPortOper</b>          | Specifies the operator for the ACE protocol destination port.                                                                                                                                                                                                                                   |
| <b>DstPortOperMaskRange</b> | The value is displayed in hexadecimal format when <b>DstPortOper</b> is set to mask. When <b>DstPortOper</b> is set to range, this field is used as the high range value. In this case, the value is displayed in decimal format. When <b>SrcPortOper</b> is set to eq, this field is set to 0. |
| <b>IcmpMsgTypeList</b>      | Specifies one or a list of ICMP messages to match. The valid range is 0–255 (reserved).                                                                                                                                                                                                         |
| <b>IcmpMsgTypeOper</b>      | Specifies the operator for the ACE protocol ICMP message types.                                                                                                                                                                                                                                 |
| <b>TcpFlagsList</b>         | Specifies one or a list of TCP flags to match. The valid range is 0–63.                                                                                                                                                                                                                         |
| <b>TcpFlagsOper</b>         | Specifies the operator for the ACE protocol TCP flags.                                                                                                                                                                                                                                          |
| <b>TcpFlagsOperMask</b>     | Displays the mask value in hexadecimal format when <b>TcpFlagsOper</b> is set to mask. When <b>TcpFlagsOper</b> is set to eq, this field displays 0x0.                                                                                                                                          |

# Troubleshooting

---

- [Data Collection Required for Technical Support Cases](#) on page 3810

The Troubleshooting section describes common problems and error messages with the techniques to resolve them, as well as information about troubleshooting tools.

The topics in this section provide necessary concepts and procedures to troubleshoot issues with the switch and connectivity issues in the network.

## Data Collection Required for Technical Support Cases

---

If you need to call Technical Support for assistance, you might need to provide specific switch information or files, like core files, to help the team analyze the issue.

The topics in this section provide details about how to gather information before you contact Technical Support.

### Important

The following list provides best practices for working with core files:

- Use Secure Copy (SCP) to transfer the files from the switch. If you use FTP, ensure you transfer the files in binary mode. Do not transfer the files in ASCII mode.
- After you download a core file from the switch, extract it to ensure it downloaded correctly and completely. If you receive errors, download the file again.
- Do not delete the core files from the switch until Technical Support confirms that they can read the files.

## Data Collection for an Outage

Perform the following data collection procedures when the switch is in an outage condition and you require Technical Support to perform a root cause analysis.

### Collect Data Before You Restart

Perform this procedure before you restart the chassis.

#### Procedure

1. Capture the current state of the chassis:

```
terminal more disable
```

```
show tech
```

#### Note

`show tech` is an alias for `show fulltech`. Both commands provide the same output.

2. Capture Flight Recorder trace information.

```
flight-recorder all {slot[-slot][, ...]}
```

The **all** command executes three separate commands: `flight-recorder snapshot`, `flight-recorder trace`, and `flight-recorder archive`.

3. Reset the chassis:

- a. Reset the chassis without creating a core file:

```
reset -y
```

- b. Create an ssio core file, a cbc-p-main.x core file, skip the confirmation question, and then reset the chassis:

```
reset -coredump -y
```

- c. Create an ssio core file, a cbc-p-main.x core file, prompt for the confirmation question, and then reset the chassis:

```
reset -coredump
```

#### Note

Create a core file only when there is a need to analyze a problem. If you reset the switch for any other reason the command is `reset -y`.

4. Continue with [Collecting data after you restart](#).

#### Example

The following example shows output of the `flight-recorder all 1` command.

```
Switch:1#flight-recorder all 1
Processing Flight-recorder snapshot for 1 ....

Flight-recorder snapshot for slot 1 complete, filename is /intflash/PMEM/1/pmem.
20111019114431.1.bin.gz.

Processing Flight-recorder trace for 1 ....
```

```
Flight-recorder trace for slot 1 complete, filename is /intflash/flrec/1/trace.20111019114434.1.txt.

Processing Flight-recorder archive for slot 1 ....

Flight-recorder archive for slot 1 complete, filename is /intflash/archive/1/archive.20111019114446.1.tar.
```

### Collecting Data After You Restart

#### About This Task

Perform this procedure after you restart the affected chassis.

#### Procedure

1. Use FTP to transfer the following information:
  - Configuration files from each chassis: Stored on the internal flash at `/intflash/`.
  - Log files from each chassis: Stored on the internal flash at `/intflash/`.
  - Generated archive files for slot: Stored on the internal flash. For example: `/intflash/archive/<slot>`

#### Note

For , if the core file is not on the primary control processor (CP), you can use FTP to connect to the internal flash of the primary CP. For example, `cp mnt/intflash/archive/<slot>/<filename> /intflash/<filename>`

To copy the file to internal flash or usb device in the primary CP, use the following command: `cp mnt/intflash/archive/<slot>/<filename> {/intflash/<filename> | /usb/<filename>}`

2. Show core information:

```
show core-files
```

If the timestamp for an entry in the command output matches the time the outage first occurred, or is later than that time, transfer that core file to an FTP server. Core files are stored on the internal flash at: `/intflash/coreFiles/`

3. Obtain the network diagram of the relevant nodes, down to the port level.

## Data Collection for Non Outage Problems

Use the information in this section to collect data for problems that are less service-impacting than an outage.

### Gathering Critical Information

This section identifies the critical information that you must gather before you contact Technical Support.

You must attempt to resolve the problem using this document. Contact Technical Support as a final step taken only after you are unable to resolve the issue using the information and steps provided in this document.

Gather the following information before you contact Technical Support:

- a detailed description of the problem
- the date and time when the problem started
- the frequency of the problem
- if this is a new installation
- if there is relevant information recorded on the support portal — Were related problem solutions found? Is there currently a work around for this issue? For more information, see support on the Extreme Portal at <https://extremeportal.force.com/ExtrSupportHome>.
- if the system was recently upgraded — Have you recently changed or upgraded the system, the network, or a custom application? (For example, has configuration or code been changed?) When were these changes made? Provide the date and time. Who made these changes? Were the changes made by a partner or customer? Provide the names of the individuals who made the changes.

## Troubleshooting Planning Fundamentals

You can better troubleshoot the problems on the network by planning for these events in advance. To do this, you must know the following:

- that the system is properly installed and routinely maintained
- the configuration of the network
- the normal behavior of the network

### Proper Installation and Routine Maintenance

The following table lists the documents that provide maintenance and installation procedures.

To prevent problems, follow proper maintenance and installation procedures.

**Table 275: Maintenance and installation documentation**

| Subject area                              | Document                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Transceiver installation and requirements | <a href="#">Extreme Optics website</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Network Configuration

To keep track of the network configuration, gather the information described in the following sections. This information, when kept up-to-date, is extremely helpful for locating information if you experience network or device problems.

### *Site network map*

A site network map identifies where each device is physically located on site, which helps locate the users and applications that a problem affects. You can use the map to systematically search each part of the network for problems.

### *Logical connections*

The switch supports virtual LANs (VLAN). With VLANs, you must know how the devices connect logically as well as physically.

### *Device configuration information*

Maintain online and paper copies of the device configuration information. Store all online data with the regular data backup for the site. If the site does not use a backup system, copy the information onto an external storage device, and store the backup at an offsite location.

You can use the File Transfer Protocol (FTP) and Trivial FTP (TFTP) to store configuration files on a remote server.

### *Other important data about the network*

For a complete picture of the network, have the following information available:

- all passwords

Store passwords in a safe place. A good practice is to keep records of previous passwords in case you must restore a device to a previous software version and need to use the old password that was valid for that version.

- device inventory

Maintain a device inventory, which lists all devices and relevant information for the network. The inventory allows you to easily see the device type, IP address, ports, MAC addresses, and attached devices.

- MAC address-to-port number list

If you do not manage the hubs or switches, you must keep a list of the MAC addresses that correlate to the ports on the hubs and switches.

- change control

Maintain a change control system for all critical systems. Permanently store change control records.

- contact details

Store the details of all support contracts, support numbers, engineer details, and telephone and fax numbers.

## Normal Behavior on the Network

If you are familiar with the network when it is fully operational, you can be more effective at troubleshooting problems that arise. To understand the normal behavior of the network, monitor the network over a long period of time. During this time you can see a pattern in the traffic flow, such as which devices users access most or when peak usage times occur.

To identify problems, you can use a baseline analysis, which is an important indicator of overall network health. A baseline serves as a useful reference of network traffic during normal operation, which you can then compare to captured network traffic while you troubleshoot network problems. A baseline analysis speeds the process of isolating network problems. By running tests on a healthy network, you compile normal data for your network. You can compare this normal data against the results that you get when the network experiences trouble.

For example, ping each node to discover how long it typically takes to receive a response from devices on your network. Capture and save each response time and you can use these baseline response times to help you troubleshoot. You can also use the **show tech/show fulltech** and **show khi performance {buffer-pool|cpu|memory|process|pthread|slabinfo}** commands to obtain baseline output for normal system behavior.

### Note

Depending on the hardware platform, the output of **show khi performance memory** command can differ.

In the following example, the **show khi performance memory** command shows the average memory utilization at various time intervals. The **show khi performance memory history** command shows the VMSize utilization values in kilobytes for each process at various time intervals. After 1 hour elapses, the system stores this information in `/intflash/coreFiles/slot/khi_mem_log`.

```
Switch:1#show khi performance memory
Slot:1Slot:1
  Used: 1609636 (KB)
  Free: 2396068 (KB)
  Current utilization: 40 %
  5-minute average utilization: 40 %
  5-minute high water mark: 40 (%)
  10-minute average utilization: 39 %
  10-minute high water mark: 39 (%)
  1-Hour average utilization: 37 %
  1-Day average utilization: 0 %
  1-Month average utilization: 0 %
  1-Year average utilization: 0 %

Switch:1#show khi performance memory history
Slot:1
Values indicate VMSize in KB
```

| Pid  | Pname     | 5-Min | 10-Min | 1-Hour | 1-Day | 1-Month | 1-Year |

## Troubleshooting Fundamentals

This section provides conceptual information and helpful tips for common problems.

### Connectivity Problems

Use the following general tasks to isolate connectivity problems:

- Check physical connectivity. Verify if an alarm for link or port down exists.
- Check the link state by viewing the **show interface {gigabitEthernet|loopback|vlan}** command output.
- Use tools like ping or trace to verify if the connectivity issue is localized to an individual port or VLAN.
- Try to localize the affected range of ports and slot.

If you contact technical support staff to help troubleshoot connectivity problems, always provide source and destination IP pairs to facilitate in troubleshooting. Be sure to provide both working and non-working pairs for comparison.

```

Switch:1#show interface vlan

-----
Vlan Basic

```

```

```

## Routing Table Problems

Routing table problems include but are not limited to:

- inactive routes
- unnecessary routes
- black hole routes

**Note**

Only black hole routes that belong to the static type protocol are supported. An inter-VRF black hole route is not installed in the routing table of the destination VRF on the same switch.

- flapping links (links that go up and come down) that cause the routes to flap
- incorrect route tables
- invalid Address Resolution Protocol (ARP) cache that causes incorrect IP to MAC assignment
- problems with administrative distance or other parameters

**Important**

Do not restart a device to clear a problem. In restarting the device, you also clear the logs. Logs are vital and can help determine many problems.

## Cable Connection Problems

You can usually trace port connection problems to a poor cable connection or to an improper connection of the port cables at either end of the link. To remedy such problems, make sure that the cable connections are secure and that the cables connect to the correct ports at both ends of the link. If you use homemade cables, ensure that the cables are wired correctly.

### *1000BASE-T cables*

1 Gb/s ports operate using Category 5 UTP cabling only. Category 5 UTP cable is a two-pair cable. To minimize crosstalk noise, maintain the twist ratio of the cable up to the point of termination; untwist at termination cannot exceed 0.5 in. (1.27 cm).

### *Pluggable optic cables*

Cables for the optical transceivers vary depending on the specific device type.

For more information about the cable requirements for optical transceivers, see [Extreme Optics](#) website.

## Alarm Database

The switch contains a local alarms mechanism. Local alarms are raised and cleared by applications running on the switch. View active alarms by using the **show alarm database** command in the CLI. Local alarms are an automatic mechanism run by the system that do not require additional configuration.

Check local alarms regularly to ensure no alarms require additional attention. The raising and clearing of local alarms also creates a log entry for each event. For more information about viewing logs, see [Viewing Logs](#) on page 2489.

View the alarm database regularly to monitor alarm conditions, even if you do not observe a performance problem. Review the alarm messages to determine if the system performs as expected.

Not all alarm conditions indicate a problem so you must be familiar with expected behavior.

The alarm database shows the following alarm text:

```
CP1 [01/01/70 00:03:06.796] 0x00010844 00000000 Global Router HW WARNING
USB found in slot 1 has VendorId 05dc ProductId a01a and Manufacturer
Lexar and did not match supported devices
```

This alarm means that you have tried to insert an unsupported USB device into the USB slot. Only the USB device provided with your system can be inserted into the USB slot.

## LED Indications of Problems

For information on LEDs on the chassis, see the hardware installation documentation.

## Connectivity Fault Management

**Table 276: Connectivity Fault Management product support**

| Feature                                                                                                                                                       | Product                          | Release introduced |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|--------------------|
| IEEE 802.1ag Connectivity Fault Management (CFM): <ul style="list-style-type: none"> <li>• Layer 2 Ping</li> <li>• TraceRoute</li> <li>• TraceTree</li> </ul> | 5320 Series                      | Fabric Engine 8.6  |
|                                                                                                                                                               | 5420 Series                      | VOSS 8.4           |
|                                                                                                                                                               | 5520 Series                      | VOSS 8.2.5         |

## CFM Fundamentals

The Shortest Path Bridging MAC (SPBM) network needs a mechanism to debug connectivity issues and to isolate faults. This is performed at Layer 2, not Layer 3. Connectivity Fault Management (CFM) operates at Layer 2 and provides an equivalent of ping and traceroute. To support troubleshooting of the SPBM cloud, the switch supports a subset of CFM functionality. Configure CFM on all SPBM VLANs.

CFM is based on the IEEE 802.1ag standard.

IEEE 802.1ag Connectivity Fault Management (CFM) provides OAM tools for the service layer, which allows you to monitor and troubleshoot an end-to-end Ethernet service instance. CFM is the standard for Layer 2 ping, Layer 2 traceroute, and the end-to-end connectivity check of the Ethernet network.

The 802.1ag feature divides or separates a network into administrative domains called Maintenance Domains (MD). Each MD is further subdivided into logical groupings called Maintenance Associations (MA). A single MD can contain several MAs.

Each MA is defined by a set of Maintenance Points (MP). An MP is a demarcation point on an interface that participates in CFM within an MD. Two types of MP exist:

- Maintenance End Point (MEP)
- Maintenance Intermediate Point (MIP)

CFM supports three kinds of standard CFM messages: Continuity Check Message (CCM), Loopback Message (LBM), and Linktrace Message (LTM). Messages are sent between Maintenance Points (MP) in the system.

On the switch, CFM is implemented using the LBM and LTM features only to debug SPBM. CCM messages are not required or supported.

You can assign maintenance levels for each CFM SPBM MEP and MIP to each SPBM B-VLAN individually or you can assign maintenance levels and global MEPs for all SPBM VLANs.

#### *Autogenerated CFM and Explicitly Configured CFM*

The switch simplifies CFM configuration with autogenerated CFM. With autogenerated CFM, you use the commands **cfm spbm enable** and **cfm cmac enable** and the switch creates default MD, MA, MEPs, and MIPs for SPBM B-VLANs and C-VLANs respectively.

If you choose to configure CFM explicitly, you must configure an MD, MA, MEPs, and MIPs.

- For SPBM B-VLANs, the switch provides two methods to configure CFM, namely, autogenerated and explicitly configured. You cannot use both.
- For C-VLANs, you can only use autogenerated CFM.

#### **Autogenerated CFM**

You can use autogenerated CFM at a global level to create a MEP and a MIP at a specified level for every SPBM B-VLAN and C-VLAN on the chassis. If you use autogenerated CFM commands, you do not have to configure explicit MDs, MAs, MEPs, or MIPs, and associate them with multiple VLANs.

If you do not want to use autogenerated CFM commands, you can choose to configure explicit MDs, MAs, MEPs, and MIPs for SPBM B-VLANs. However, you cannot use both an autogenerated CFM configuration and an explicit CFM configuration together.

#### **Note**

Previous explicit CFM configurations of MDs, MAs, and MEPs on SPBM B-VLANs continue to be supported. However, if you want to enable the autogenerated commands you must first remove the existing MEP and MIP on the SPBM B-VLANs. The switch only supports one type of MEP or MIP for each SPBM B-VLAN.

For information on autogenerated CFM configuration using CLI see:

- [Configuring Autogenerated CFM on SPBM B-VLANs](#) on page 3832
- [Configure Autogenerated CFM on C-VLANs](#) on page 3833

For information on autogenerated CFM configuration using EDM see:

- [Configure Autogenerated CFM on SPBM B-VLANs](#) on page 3858
- [Configure Autogenerated CFM on C-VLANs](#) on page 3859

### Explicitly configured CFM

If you choose to explicitly configure CFM, you must configure an MD, MA, MEPs, and MIPs. You can configure explicit CFM only on SPBM B-VLANs.

For explicit configuration information for CLI see [Configuring Explicit Mode CFM](#) on page 3835.

For explicit configuration information for EDM see [Configuring Explicit CFM](#) on page 3861.

### Using CFM

For SPBM B-VLANs, the autogenerated MEPs and MIPs respond to **12 ping**, **12 traceroute**, and **12 tracertree** in the same manner as the MEPs and MIPs created explicitly. For C-VLANs, the autogenerated MEPs and MIPs respond to **12 ping** and **12 traceroute**, but not to **12 tracertree** because no multicast trees exist on C-VLANs. The CFM show commands that display MD, MA, and MEP information work for both autogenerated and explicitly configured CFM MEPs.

You can use CFM to troubleshoot networks and hosts that support the CFM protocol. After you configure CFM, CFM works in the network whether or not SPBM is in use.

You cannot use CFM to troubleshoot networks and hosts that do not support the CFM protocol, such as a customer domain that does not support CFM. Only devices that support the CFM protocol respond to **12 ping** and **12 traceroute** requests.

### *Maintenance Domain (MD)*

A Maintenance Domain (MD) is the part of a network that is controlled by a single administrator. For example, a customer can engage the services of a service provider, who, in turn, can engage the services of several operators. In this scenario, there can be one MD associated with the customer, one MD associated with the service provider, and one MD associated with each of the operators.

You assign one of the following eight levels to the MD:

- 0–2 (operator levels)
- 3–4 (provider levels)
- 5–7 (customer levels)

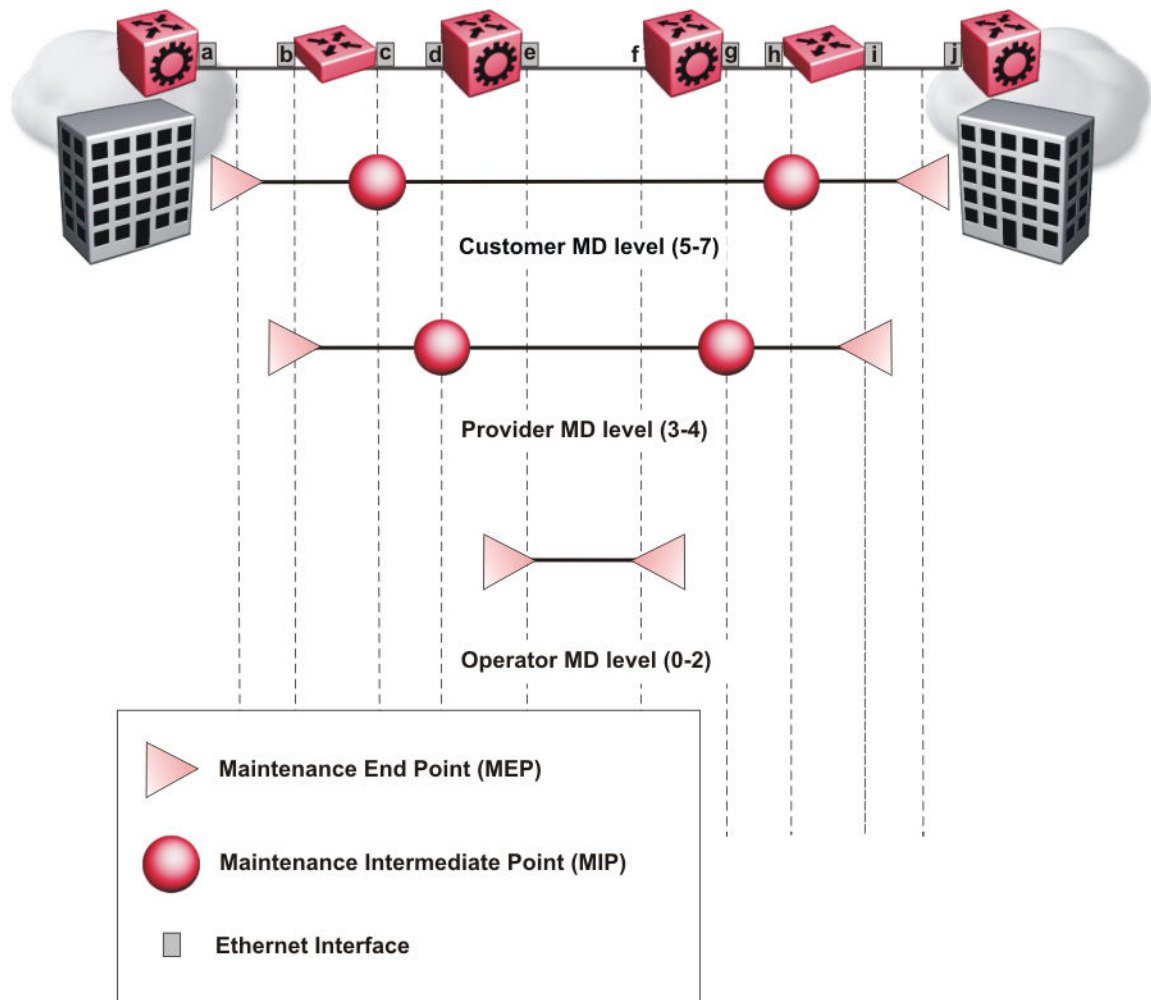

The levels separate MDs from each other and provide different areas of functionality to different devices using the network. An MD is characterized by a level and an MD name (optional).

A single MD can contain several Maintenance Associations (MA).

### *Maintenance Association (MA)*

An MA represents a logical grouping of monitored entities within its Domain. It can therefore represent a set of Maintenance association End Points (MEPs), each configured with the same Maintenance Association ID (MAID) and MD Level, established to verify the integrity of a single service instance.

The following figure shows MD level assignment in accordance with the 802.1ag standard. As shown in the figure, MIPs can be associated with MEPs. However, MIPs can also function independently of MEPs.

**Figure 257: MD level assignment**

*Maintenance Association Endpoint (MEP)*

A Maintenance Endpoint (MEP) represents a managed CFM entity, associated with a specific Domain Service Access Point (DoSAP) of a service instance, which can generate and receive CFM Protocol Data Units (PDU) and track any responses. A MEP is created by MEP ID under the context of an MA. MEP functionality can be divided into the following functions:

- Fault Detection
- Fault Verification

- Fault Isolation
- Fault Notification

Fault detection and notification are achieved through the use of Continuity Check Messages (CCM). CCM messages are not supported.

### *Fault Verification*

Fault verification is achieved through the use of Loopback Messages (LBM). An LBM is a unicast message triggered by the operator issuing an operational command. LBM can be addressed to either a MEP or Maintenance Intermediate Point (MIP) but only a MEP can initiate an LBM. The destination MP can be addressed by its MAC address. The receiving MP responds with a Loopback Response (LBR). LBM can contain an arbitrary amount of data that can be used to diagnose faults as well as performance measurements. The receiving MP copies the data to the LBR.

### *LBM Message*

The LBM packet is often compared to a ping. A MEP transmits the LBM packet. This packet can be addressed to another MEP or to the MAC address of the MP; in the case of SPBM, this is the SPBM system ID or its virtual SMLT MAC. Only the MP for which the packet is addressed responds with an LBR message.

- Provides “ICMP ping like” functionality natively at Layer-2.
- DA is the MAC address of the target.
- Includes a transaction identifier that allows the corresponding LBR to be identified when more than one LBM request is waiting for a response.
- Bridges forward the frame using the normal FDB rules.
- Only the target (MIP or MEP) responds.
- Initiator can choose the size and contents data portion of the LBM frame.
- Can be used to check the ability of the network to forward different sized frames.

### *L2 Ping*

The **12 ping** command is a proprietary command that allows a user to trigger an LBM message.

For B-VLANs, specify either the destination MAC address or node name.

This provides a simpler command syntax than the standard LBM commands, which require the user to specify the MD, MA, and MEP ID information. The **12 ping** command provides a ping equivalent at Layer 2 for use with nodes on the SPBM B-VLAN in the customer domain. SPBM B-VLANs support the SMLT virtual option for the source mode.

#### **Important**

CFM CMAC Layer 2 ping and Layer 2 traceroute traversing over Fabric Extend tunnels are not supported when originating from a VSP 4450 Series.

### *Fault Isolation*

Fault isolation is achieved through the use of Linktrace Messages (LTM). LTM is intercepted by all the MPs on the way to the destination MP. The switch supports two types of LTM.

The first type, the unicast LTM, can be addressed to either MEP or MIP MAC address. Each MP on the way decrements the TTL field in the LTM frame, sends Linktrace Reply (LTR), and forwards the original LTM to the destination. The LTM is forwarded until it reaches its destination or the TTL value is decremented to zero. LTR is a unicast message addressed to the originating MEP.

The second type, the proprietary LTM, is used to map the MAC addresses of the SPBM network; in this case the target MAC is not an MP, but rather a service instance identifier (I-SID).

### *Link Trace Message*

Connectivity Fault Management offers link trace messaging for fast fault detection. Link trace messages allow operators, service providers and customers to verify the connectivity that they provide or use and to debug systems.

#### **Link trace message — unicast**

The link trace message (LTM) is often compared to traceroute. A MEP transmits the LTM packet. This packet specifies the target MAC address of an MP which is the SPBM system id or the virtual SMLT MAC. MPs on the path to the target address respond with an LTR.

- Trace the path to any given MAC address.
- DA is unicast
- LTM contains:
  - Time to live (TTL)
  - Transaction Identifier
  - Originator MAC address
  - Target MAC address
- CFM unaware entities forward the frame as is like any other data frame.
- MIP or MEP that is not on the path to the target discards the LTM and does not reply.
- MIP that is on the path to the target
  - Forwards the LTM after decrementing the TTL and replacing the SA with its own address.
  - Sends a reply (LTR) to the originator.
  - Identifies itself in the forwarded LTM and LTR by modifying TLV information.
- If the MIP or MEP is a target
  - Sends an LTR to the originator.
  - Identifies itself in the forwarded LTM and LTR by modifying TLV information.
- A MEP that is not the target but is on the path to the target
  - Generates a reply as described above.

- It also sets one of the flags fields in the reply to indicate that it is the terminal MEP.

#### Link trace message — multicast

The multicast link trace message (LTM) can be used to trace the multicast tree from any node on any I- SID using the nickname MAC address and the I-SID multicast address.

Specifying a multicast target address for an LTM allows for the tracing of the multicast tree corresponding to that destination address (DA). With a multicast target every node that is in the active topology for that multicast address responds with a Linktrace reply and also forwards the LTM frame along the multicast path. Missing Linktrace replies (LTRs) from the nodes in the path indicate the point of first failure.

This functionality allows you to better troubleshoot I-SID multicast paths in a SPBM network.

### L2 Traceroute

The **12 traceroute** command is a proprietary command that allows you to trigger an LTM message.

Use this command as follows:

- For B-VLANs, specify either the destination MAC address or node name.
- For C-VLANs, specify the destination MAC address.

This command provides a simpler command syntax than the standard LTM commands, which require you to specify the MD, MA, and MEP ID information. The **12 traceroute** command provides a trace equivalent at Layer 2 for use with nodes on the SPBM B-VLAN in the customer domain.

#### Important

Only the VSP 4450 Series switch supports CFM configuration on C-VLANs. CFM C-MAC Layer 2 ping and Layer 2 traceroute traversing over Fabric Extend tunnels are not supported when originating from a VSP 4450 Series.

You can use CFM to troubleshoot networks and hosts that support the CFM protocol. After you configure CFM, CFM works in the network whether or not SPBM is in use.

You cannot use CFM to troubleshoot networks and hosts that do not support the CFM protocol, such as a customer domain that does not support CFM. Only devices that support the CFM protocol respond to **12 ping** and **12 traceroute** requests.

#### 12 traceroute with IP address

You can specify an IP address as the destination address for the **12 traceroute** command. In this case, the IP address can be either a C-VLAN or a B-VLAN in the SPBM cloud.

The **12 traceroute** command converts Layer 3 IP information to an appropriate Layer 2 VLAN and MAC combination. The system can also target IP addresses that are not SPBM derived routes.

If you enable ECMP, **12 traceroute** runs internally for each of the VLAN paths returned, and displays a summary of the results. If you disable ECMP, the results display only one path.

**Note**

If you use the **12 traceroute ip-address** command on a DvR Leaf node, the output only shows DvR Controller IP addresses if the IP address or host route specified is unknown in the DvR domain.

**Destination addresses for C-VLAN I2 traceroute and linktrace messages**

For C-VLANs, CFM uses the following destination MAC addresses for the corresponding maintenance domain (MD) levels for **12 traceroute** and **linktrace** messages.

The switch supports both **12 traceroute** and **linktrace** for C-VLANs, as a best practice, use **12 traceroute**.

**Table 277: MD levels and corresponding destination addresses for CFM for C-VLANs**

| CFM MD Level | Destination MAC address |
|--------------|-------------------------|
| 0            | 01:80:c2:00:00:38       |
| 1            | 01:80:c2:00:00:39       |
| 2            | 01:80:c2:00:00:3a       |
| 3            | 01:80:c2:00:00:3b       |
| 4            | 01:80:c2:00:00:3c       |
| 5            | 01:80:c2:00:00:3d       |
| 6            | 01:80:c2:00:00:3e       |
| 7            | 01:80:c2:00:00:3f       |

*L2 Tracetree*

The **12 tracetree** command is a proprietary command that allows a user to trigger a multicast LTM message by specifying the B-VLAN and I-SID. This command allows the user to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID.

**Note**

The VSP 4450 Series does not support the **12 tracetree** command on C-VLANs because no multicast tree exists on C-VLANs.

### *L2 Tracetree-fan*

The **12 tracetree-fan** command allows a user to trigger an LTM on the internal Fabric Area Network I-SID. This command allows the user to trace the FAN tree.

### *Maintenance Domain Intermediate Point (MIP)*

MIPs do not initialize any CFM messages. MIPs passively receive CFM messages, process the messages received and respond back to the originating MEP. By responding to received CFM messages, MIPs can support discovery of hop-by-hop path among MEPs, allow connection failures to be isolated to smaller segments of the network to help discover location of faults along the paths. MIPs can be created independent of MEPs. MIP functionality can be summarized as:

- Respond to Loopback (ping) messages at the same level as itself and addressed to it.
- Respond to Linktrace (traceroute) messages.
- Forward Linktrace messages after decrementing the TTL.

### *Layer 2 Tracemroute*

The **12tracemroute** command is a proprietary command that allows the user to trace the multicast tree for a certain multicast flow. The user specifies source, group, and service context (either VLAN or VRF) for the multicast flow to trace.

CFM sends a multicast LTM using an internal calculation to map the source, group, and context to the corresponding target address. The LTR comes from all leaves of the multicast tree for that flow, as well as transit nodes. The target MAC used in the LTM is a combination of the data I-SID and the nickname and the packet is sent on the appropriate SPBM B-VLAN. The user can see the generated multicast tree for that flow, which includes the data I-SID and nickname.

### *Nodal MPs*

Nodal MPs provide both MEP and MIP functionality for SPBM deployments. Nodal MPs are associated with a B-VLAN and are VLAN encapsulated packets. The Nodal MEP provides traceability and troubleshooting at the system level for a given B-VLAN. Each node (chassis) has a given MAC address and communicates with other nodes. The SPBM instance MAC address is used as the MAC address of the Nodal MP. The Nodal B-VLAN MPs supports eight levels of CFM and you configure the Nodal B-VLAN MPs on a per B-VLAN basis. Virtual SMLT 10 MAC addresses are also able to respond for LTM and LBM.

#### **Nodal B-VLAN MEPs**

The Nodal B-VLAN MEPs created on the CP and function as if they are connected to the virtual interface of the given B-VLAN. Because of this they are supported for both port and MLT based B-VLANs. To support this behavior a MAC Entry is added to the FDB and a new CFM data-path table containing the B-VLAN and MP level are added to direct CFM frames to the CP as required.

#### **Nodal B-VLAN MIPs**

The Nodal MIP is associated with a B-VLAN. VLAN and level are sufficient to specify the Nodal MIP entity. The Nodal MIP MAC address is the SPBM system ID for the node on

which it resides. If the fastpath sends a message to the CP, the MIP responds if it is not the target and the MEP responds if it is the target.

### Nodal B-VLAN MIPs with SMLT

When Nodal MEPs or MIPs are on SPBM B-VLANs the LTM code uses a unicast MAC DA. The LTM DA is the same as the target MAC address, which is the SPBM MAC address or the SMLT MAC address of the target node.

The switch supports SMLT interaction with SPBM. This is accomplished by using two B-VIDs into the core from each pair of SMLT terminating nodes. Both nodes advertise the Nodal B-MAC into the core on both B-VIDS. In addition each node advertises the SMLT virtual B-MAC on one of the two B-VLANs.

The Nodal MEP and MIP are expanded to respond to both the Nodal MAC address as well as the Virtual SMLT MAC address if both MACs are being advertised on its B-VLAN. In addition a source mode is added to the LTM and LBM command to use either the Nodal MAC or the SMLT virtual MAC address as the source MAC in the packet.

### Configuration Considerations

When you configure CFM, be aware of the following configuration considerations.

#### General CFM

- A single switch has a limit of one MEP and one MIP on a C-VLAN or B-VLAN.
- The maintenance level for MEPs and MIPs on a given B-VID (in a network) must be configured to the same level for them to respond to a given CFM command.
- You can configure global CFM at only one MD level for each switch for each VLAN type.
- All nodal MEPs and MIPs are restricted to SPBM B-VIDs.
- SMLT Virtual MAC for C-VLAN does not exist, so the switch does not support this option for the **12 ping** and **12 traceroute** commands.

#### Autogenerated CFM

- Autogenerated MEPs are not unique across the entire network unless you configure the global MEP ID on each switch to a different value. You must configure a unique MEP ID at a global level, for CFM.
- A single switch can have only one autogenerated MEP or MIP for each B-VLAN or C-VLAN.

#### Explicit CFM

- Previous explicit CFM configurations of MDs, MAs and MEPs on SPBM B-VLANs continue to be supported. However, if you want to enable autogenerated CFM you must first remove the existing MEP and MIP on the SPBM B-VLAN.
- You can assign maintenance levels for each CFM SPBM MEP and MIP to each SPBM B-VLAN individually or you can assign maintenance levels and global MEPs for all SPBM VLANs by following the appropriate procedure:
  - [Assigning a MEP/MIP Level to an SPBM B-VLAN](#) on page 3839

- [Assigning MEP/MIP Levels to SPBM B-VLANs Globally](#) on page 3840
- [Configure CFM Nodal MEP](#) on page 3863

#### C-VLAN versus SPBM B-VLAN considerations

##### Important

Only VSP 4450 Series supports CFM configuration on C-VLANs.

CFM breaks the network into sections, called MEPs, so you can determine exactly where the problem exists.

The MEPs and MIPs configured for SPBM VLANs do not respond to CFM messages sent from C-MAC VLANs because the VLAN and packet encapsulation are different.

To forward customer traffic across the core network backbone, SPBM uses IEEE 802.1ah Provider Backbone Bridging (PBB) MAC-in-MAC encapsulation, which hides the customer MAC (C-MAC) addresses in a backbone MAC (B-MAC) address pair. MAC-in-MAC encapsulation defines a B-MAC destination address (BMAC-DA) and a B-MAC source address (BMAC-SA). In SPBM, each node populates its forwarding database (FDB) with the B-MAC information derived from the IS-IS shortest path tree calculations.

Typically the SPBM Backbone Core Bridges (BCBs) in the SPBM cloud only learn the B-MAC addresses. The Backbone Edge Bridges (BEBs) know the Customer MACs on the appropriate BEBs that terminate the virtual services networks (VSNs). As such, the nodes within the SPBM cloud have no knowledge of the C-MAC addresses in the VSNs.

##### Important

To trace a route to a MAC address, the MAC address must be in the VLAN FDB table.

- For C-VLANs, you have to trigger an **12 ping** to learn the C-MAC address.
- For B-VLANs, you do not have to trigger an **12 ping** to learn the C-MAC address because IS-IS populates the MAC addresses in the FDB table.

In both cases, linktrace traces the path up to the closest device to that MAC address that supports CFM in the SPBM cloud.

#### C-VLAN source addresses

CFM uses either the VLAN MAC or the CFM C-MAC for the BMAC-SA for the C-VLANs. The CFM C-MAC is the value of the management base MAC, which ends in `0x64`. The system creates the VLAN MAC after a user adds an IP address to a VLAN.

If a VLAN has a MAC address, the system uses the VLAN MAC as the BMAC-SA by default. If a VLAN does not have a MAC address, the system uses the CFM C-MAC for the BMAC-SA. You may also configure the system to use the CFM C-MAC, even if a VLAN MAC exists.

## CFM Configuration Using CLI

This section provides procedures to configure and use Connectivity Fault Management (CFM) using Command Line Interface (CLI). The Shortest Path Bridging MAC (SPBM) network needs a mechanism to debug connectivity issues and to isolate faults. This is performed at Layer 2, not Layer 3. To support troubleshooting of the SPBM cloud, the switch supports a subset of CFM functionality.

### Note

When you enable CFM in an SBPM network, as a best practice, enable CFM on the Backbone Edge Bridges (BEB) and on all Backbone Core Bridges (BCB). If you do not enable CFM on a particular node, you cannot obtain CFM debug information from that node.

You can configure CFM using one of two modes: simplified or explicit. Both modes are described in the following sections, but the simplified mode should be used.

### Note

If you enable the **cfm spbm enable** command, you cannot assign a MEP/MIP level to an individual SPBM B-VLAN or configure CFM MD maintenance levels individually.

Regardless of whether you have chosen to configure individually or globally, there is one MEP per SPBM B-VLAN and one MIP level per SPBM B-VLAN.

### *Autogenerated CFM*

CFM provides two methods for configuration; autogenerated and explicit. You cannot use both. You must choose one or the other. Use the procedures in this section to configure autogenerated MEPs that eliminate the need to configure a MD, MA, and MEP ID to create a MEP.

- For SPBM B-VLANs, you can use either autogenerated or explicitly configured CFM MEPs.
- For C-VLANs, you can only use autogenerated CFM MEPs.

The CFM show commands that display MD, MA, and MEP information work for both autogenerated and explicitly configured CFM MEPs.

Previous explicit CFM configurations of MDs, MAs and MEPs on SPBM B-VLANs continue to function. However, if you want to enable the autogenerated commands you must first remove the existing MEP and MIP on the SPBM B-VLAN.

The switch only supports one MEP and one MIP, either autogenerated or explicitly configured, on the SPBM B-VLAN. Similarly, the switch only supports one MEP and one MIP on the C-VLAN. This means that if you want to use these autogenerated MEPs, you cannot use your existing CFM configuration. You must first remove the existing MEP or MIP on the SPBM B-VLAN.

For information on configuring autogenerated CFM using the CLI, see:

- [Configuring Autogenerated CFM on SPBM B-VLANs](#) on page 3832

- [Configure Autogenerated CFM on C-VLANs](#) on page 3833

### Configuring Autogenerated CFM on SPBM B-VLANs

Use this procedure to configure the autogenerated CFM MEP and MIP level for every SPBM B-VLAN on the chassis. This eliminates the need to explicitly configure an MD, MA, and MEP ID, and to associate the MEP and MIP level to the SPBM B-VLAN.

When you enable this feature, the device creates a global MD (named `spbm`) for all the SPBM Nodal MEPs. This MD has a default maintenance level of 4, which you can change with the `level` attribute. All the MEPs that the device creates use the MEP ID configured under the global context, which has a default value of 1.

The nodal MEPs are automatically associated with the SPBM B-VLANs configured. The MIP level maps to the global level. When you enable the feature, the device automatically associates the MIP level with the SPBM B-VLANs configured. The feature is disabled by default.

#### Important

CFM supports one MEP or MIP for each SPBM B-VLAN only. This means that if you want to use these autogenerated MEPs, you cannot use your existing CFM configuration. You must first remove the existing MEP or MIP on the SPBM B-VLAN. If you want to continue configuring MEPs manually, skip this procedure.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the maintenance level for every CFM SPBM MEP and MP level on all the SPBM B-VLANs:

```
cfm spbm level <0-7>
```

You can change this level from the default of 4 either before or after the feature is enabled.

Only configure global CFM at one MD level for each chassis for each VLAN type.

3. Assign a global CFM MEP ID for all CFM SPBM MEPs:

```
cfm spbm mepid <1-8191>
```

4. Enable the autogenerated CFM for SPBM B-VLANs globally:

```
cfm spbm enable
```

5. (Optional) Configure the maintenance level for every CFM SPBM MEP and MP level on all the SPBM B-VLANs to the default:

```
default cfm spbm level
```

6. (Optional) Assign a global CFM MEP ID for all CFM SPBM MEPs to the default:

```
default cfm spbm mepid
```

7. (Optional) Disable the global CFM MEPs and MIPs:

```
no cfm spbm enable
```

8. Display the global CFM MEP configuration:

```
show cfm spbm
```

**Example**

Configure autogenerated CFM MEPs and MIPs:

```
Switch>enable
Switch#configure terminal
Switch(config)#cfm spbm level 6
Switch(config)#cfm spbm mepid 4
Switch(config)#cfm spbm enable
Switch(config)#show cfm spbm

LEVEL ADMIN      MEPID      MAC
-----
6          enable      4          00:15:e8:b8:a3:df
```

Variable Definitions

The following table defines parameters for the **cfm spbm** command.

| Variable              | Value                                                                                                                                                                                        |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>level</i> <0-7>    | Specifies the global SPBM CFM maintenance level for the chassis within the range of 0 to 7. The default is 4. Only configure global CFM at one MD level for each chassis for each VLAN type. |
| <i>mepid</i> <1-8191> | Specifies the global MEP ID within the range of 1-8191. Select a unique ID for each switch to ensure that the MEPs are unique across the network. The default is 1.                          |
| <i>enable</i>         | Enables autogenerated CFM on all SPBM B-VLANs.                                                                                                                                               |

**Configure Autogenerated CFM on C-VLANs**

Use this procedure to configure the autogenerated CFM MEP and MIP level for every C-VLAN on the chassis.

**Note**

For C-VLANs, you can only use autogenerated CFM MEPs.

**Important**

CFM supports one MEP or MIP for each C-VLAN. Only autogenerated CFM provides support for configuring MEP and MIPs on C-VLANs. You cannot explicitly configure C-VLANs.

**About This Task**

When you enable this feature, you create a global MD (named cmac) for all the customer MAC (C-MAC) MEPs. This global MD has a default maintenance level of 4, which you can change with the level attribute. The autogenerated CFM commands also

create an MA for each C-VLAN, a MEP for each C-VLAN, associate the MEP with the corresponding C-VLAN, and a MIP with the C-VLAN.

All the MEPs that the device creates use the MEP ID configured under the global context, which has a default value of 1. The device automatically associates the MEPs with the C-VLANs configured. The MIP level maps to the global level. The device automatically associates the MIP level with the C-VLANs configured when you enable the feature.

The feature is disabled by default.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Configure the maintenance level for every CFM C-MAC MEP and MP level on all the C-VLANs:

```
cfm cmac level <0-7>
```

Only configure global CFM at one MD level for each chassis for each VLAN type.

3. Assign a global CFM MEP ID for all CFM C-MAC MEPs:

```
cfm cmac mepid <1-8191>
```

4. Enable the autogenerated CFM for C-VLANs:

```
cfm cmac enable
```

5. (Optional) Configure the maintenance level for every CFM C-MAC MEPs and MP level on all the C-VLANs to the default:

```
default cfm cmac level
```

6. (Optional) Assign a global CFM MEP ID for all CFM C-MAC MEPs to the default:

```
default cfm cmac mepid
```

7. (Optional) Disable the global CFM MEPs and MIPs:

```
no cfm cmac enable
```

8. Display the global CFM MEP configuration:

```
show cfm cmac
```

### Example

Configure autogenerated CFM MEPs and MIP level:

```
Switch>enable
Switch#configure terminal
Switch(config)#cfm cmac level 0
Switch(config)#cfm cmac mepid 4
Switch(config)#cfm cmac enable
Switch(config)#show cfm cmac

LEVEL ADMIN      MEPID      MAC
-----
0          enable      4          00:15:e8:b8:a3:de
```

### Variable Definitions

The following table defines parameters for the **cfm cmac** command.

| Variable              | Value                                                                                                                                                                                                                                                                                                                           |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>level</i> <0-7>    | Specifies the global C-MAC CFM maintenance level for the chassis within the range of 0 to 7. The default is 4.<br>Only configure global CFM at one MD level for each chassis for each VLAN type.                                                                                                                                |
| <i>mepid</i> <1-8191> | Specifies the global MEP ID within the range of 1-8191. Select a unique ID for each switch to ensure that the MEPs are unique across the network. The default is 1.<br><br><b>Note:</b><br>The MA takes its name from this value for autogenerated CFM. For example, if you specify 500 as the MEP ID, the MA will also be 500. |
| <i>enable</i>         | Enables autogenerated CFM for all C-MAC VLANs.                                                                                                                                                                                                                                                                                  |

### Configuring Explicit Mode CFM

In the explicit mode of configuring CFM, you can manually configure an MD, MA, MEP and then associate the MEP to a B-VLAN and assign a MIP level to a B-VLAN.

**Note**

If you use autogenerated CFM, these steps are unnecessary.

### Configuring CFM MD

Use this procedure to configure the Connectivity Fault Management (CFM) Maintenance Domain (MD). An MD is the part of a network that is controlled by a single administrator. A single MD can contain several Maintenance Associations (MA).

#### Procedure

1. Enter Global Configuration mode:  
`enable`  
  
`configure terminal`
2. Create the CFM MD:  
`cfm maintenance-domain WORD<0-22> [index <1-2147483647>] [maintenance-level <0-7>] [level <0-7>]`
3. Display the CFM MD configuration:  
`show cfm maintenance-domain`
4. Delete the CFM MD:  
`no cfm maintenance-domain WORD<0-22>`

#### Example

```
Switch:1> enable
Switch:1# configure terminal
```

```
Switch:1(config)# cfm maintenance-domain mdl index 99 maintenance-level 3
```

```
Switch:1(config)# show cfm maintenance-domain
```

```
=====
Maintenance Domain
=====
Domain Name      Domain Index    Level Domain Type
-----
mdl              99              3      NODAL
Total number of Maintenance Domain entries: 1.
```

```
Switch:1(config)# no cfm maintenance-domain mdl
```

```
Switch:1(config)# show cfm maintenance-domain

=====
Maintenance Domain
=====
Domain Name      Domain Index    Level Domain Type
-----
Total number of Maintenance Domain entries: 0.
```

## Variable Definitions

The following table defines parameters for the **cfm maintenance-domain** command.

| Variable                       | Value                                                                      |
|--------------------------------|----------------------------------------------------------------------------|
| <i>WORD</i> <0-22>             | Specifies the maintenance domain name.                                     |
| <i>index</i> <1-2147483647>    | Specifies a maintenance domain entry index.                                |
| <i>maintenance-level</i> <0-7> | Specifies the MD maintenance level when creating the MD. The default is 4. |
| <i>level</i> <0-7>             | Modifies the MD maintenance level for an existing MD. The default is 4.    |

## Configuring CFM MA

Use this procedure to configure the CFM Maintenance Association (MA). An MA represents a logical grouping of monitored entities within its domain. It can therefore represent a set of Maintenance Association End Points (MEPs), each configured with the same Maintenance Association ID (MAID) and MD Level, established to verify the integrity of a single service instance.

### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Create the CFM MA:

```
cfm maintenance-association WORD<0-22> WORD<0-22> [index <1-2147483647>]
```

3. Display the CFM MA configuration:  

```
show cfm maintenance-association
```
4. Use the following command, if you want to delete the CFM MA:  

```
no cfm maintenance-association WORD<0-22> WORD<0-22>
```

**Example**

```
Switch:1> enable

Switch:1# configure terminal

Switch:1(config)# cfm maintenance-association mdl mal index 98

Switch:1(config)# show cfm maintenance-association
```

```
=====
                        Maintenance Association Status
=====
Domain Name           Assn Name           Domain Idx  Assn Idx
-----
mdl                   mal                 1           98

Total number of Maintenance Association entries: 1.

=====
                        Maintenance Association config
=====
Domain Name           Assn Name
-----
mdl                   mal

Total number of MA entries: 1.
```

Variable Definitions

The following table defines parameters for the **cfm maintenance-association** command.

| Variable                                 | Value                                                                                                              |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <i>WORD&lt;0-22&gt; WORD&lt;0-22&gt;</i> | Creates the CFM MA. The first parameter, specifies the MD name. The second parameter, specifies the MA short name. |
| <i>index &lt;1-2147483647&gt;</i>        | Specifies a maintenance association entry index.                                                                   |

**Configuring CFM MEP**

Use this procedure to configure the CFM Maintenance Endpoint (MEP). A MEP represents a managed CFM entity, associated with a specific Domain Service Access Point (DoSAP) of a service instance, which can generate and receive CFM Protocol Data Units (PDU) and track any responses. A MEP is created by MEP ID under the context of an MA.

## Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Create the CFM MEP:  

```
cfm maintenance-endpoint WORD<0-22> WORD<0-22> <1-8191> enable [state <enable>]
```
3. Enable an existing CFM MEP:  

```
cfm maintenance-endpoint WORD<0-22> WORD<0-22> <1-8191> enable
```
4. Disable an existing CFM MEP:  

```
no cfm maintenance-endpoint WORD<0-22> WORD<0-22> <1-8191> enable
```
5. Display the CFM MEP configuration:  

```
show cfm maintenance-endpoint
```
6. Delete an existing CFM MEP:  

```
no cfm maintenance-endpoint WORD<0-22> WORD<0-22> <1-8191>
```

## Example

```
Switch:1> enable
```

```
Switch:1# configure terminal
```

```
Switch:1(config)# cfm maintenance-endpoint mdl mal 1 state enable
```

```
Switch:1(config)# show cfm maintenance-endpoint
```

```
=====
Maintenance Endpoint Config

```

## Variable Definitions

The following table defines parameters for the **cfm maintenance-endpoint** command.

| Variable                        | Value                                                                                      |
|---------------------------------|--------------------------------------------------------------------------------------------|
| <i>WORD&lt;0-22&gt;</i>         | The first parameter, specifies the MD name.                                                |
| <i>WORD&lt;0-22&gt;</i>         | The second parameter, specifies the MA short name.                                         |
| <i>&lt;1-8191&gt;</i>           | Specifies the MEP ID.                                                                      |
| <i>enable</i>                   | Enables an existing MEP. Use this parameter with the no option to disable an existing MEP. |
| <i>state {enable   disable}</i> | Enables or disables the MEP when creating the MEP. The default is disabled.                |

### Assigning a MEP/MIP Level to an SPBM B-VLAN

Use this procedure to assign a nodal MEP to an SPBM B-VLAN. The Nodal MEP provides traceability and troubleshooting at the system level for a given B-VLAN. The Nodal B-VLAN MEPs created on the CP and function as if they are connected to the virtual interface of the given B-VLAN. Because of this they are supported for both port and MLT based B-VLANs.

Nodal MPs provide both MEP and MIP functionality for SPBM deployments. Nodal MPs are associated with a B-VLAN and are VLAN encapsulated packets. Each node (chassis) has a given MAC address and communicates with other nodes. The SPBM instance MAC address is used as the MAC address of the Nodal MP.

#### Before You Begin

- You must configure a CFM MD, MA, and MEP.

#### Procedure

1. Add nodal MEPs to the B-VLAN:  

```
vlan nodal-mep <1-4059> WORD<0-22> WORD<0-22> <1-8191>
```
2. Display the nodal MEP configuration:  

```
show vlan nodal-mep <1-4059>
```
3. Remove the nodal MEPs from the B-VLAN:  

```
no vlan nodal-mep <1-4059> WORD<0-22> WORD<0-22> <1-8191>
```
4. Add nodal MIP level to the B-VLAN:  

```
vlan nodal-mip-level <1-4059> WORD<0-15>
```
5. Display the nodal MIP level configuration:  

```
show vlan nodal-mip-level [<1-4059>]
```
6. Remove the nodal MIP level from the B-VLAN:  

```
no vlan nodal-mip-level <1-4059> WORD<0-15>
```

#### Example

```
Switch:1> enable

Switch:1# configure terminal

Switch:1(config)# vlan nodal-mep 100 md1 ma1 2
```

```
Switch:1(config)# show vlan nodal-mep
```

```

## Variable Definitions

The following table defines parameters for the **vlan nodal-mep** command.

| Variable   | Value                                                             |
|------------|-------------------------------------------------------------------|
| <1-4059>   | Specifies the VLAN ID.                                            |
| WORD<0-22> | The first parameter, specifies the Maintenance Domain name.       |
| WORD<0-22> | The second parameter, specifies the Maintenance Association name. |
| <1-8191>   | Specifies the nodal MEPs to add to the VLAN.                      |

The following table defines parameters for the **vlan nodal-mip-level** command.

| Variable   | Value                                                                        |
|------------|------------------------------------------------------------------------------|
| <1-4059>   | Adds the nodal MIP level. Specifies the VLAN ID.                             |
| WORD<0-15> | Adds the nodal MIP level, which has up to eight levels, ranging from 0 to 7. |

## Assigning MEP/MIP Levels to SPBM B-VLANs Globally

### Note

If you enable the **cfm spbm enable** command, you cannot assign a MEP/MIP level to an individual SPBM B-VLAN or configure CFM MD maintenance levels individually.

### About This Task

Enables the global CFM MEP and MIPs for all SPBM B-VLANs.

### Procedure

1. Enter Global Configuration mode:  

```
enable
```

```
configure terminal
```
2. Enable simplified CFM configuration for SPBM VLANs:  

```
cfm spbm enable
```
3. Enter the CFM SPBM level:  

```
cfm spbm level <0-7>
```
4. Enter the CFM SPBM MEPID level:  

```
cfm spbm mepid <1-8191>
```

### Example

```
Switch:1(config)# cfm spbm level 7
Switch:1(config)# cfm spbm mepid 12
Switch:1(config)# cfm spbm enable
```

### Variable Definitions

The following table defines parameters for the **simplified CFM** commands.

| Variable                      | Value                                                                                                        |
|-------------------------------|--------------------------------------------------------------------------------------------------------------|
| <i>spbm level &lt;0-7&gt;</i> | Configures the maintenance level for every CFM SPBM MEP and MIP level on all SPBM B-VLANs. The default is 4. |
| <i>mepid &lt;1-8191&gt;</i>   | Assigns a global MEP ID for all CFM SPBM MEPs. The default is 1.                                             |
| <i>no cfm spbm enable</i>     | Disables global configuration of CFM SPBM MEP and MIP levels on all SPBM B-VLANs.                            |
| <i>default cfm spbm level</i> | Returns maintenance level to default for all CFM SPBM MEP and MIP level on all SPBM B-VLANs.                 |
| <i>default cfm spbm mepid</i> | Returns MEP ID for all CFM SPBM MEPs to default.                                                             |
| <i>show cfm spbm</i>          | Displays the global CFM MEP configuration for SPBM B-VLANs.                                                  |

### Trigger a Loopback Test (LBM)

Use this procedure to trigger a loopback test.

The LBM packet is often compared to ping. An MEP transmits the loopback message to an intermediate or endpoint within a domain for the purpose of fault verification. This can be used to check the ability of the network to forward different sized frames.

### Note

Product Notice: This procedure does not apply to VSP 8600 Series.

### Before You Begin

- You must have a MEP that is associated with a B-VLAN.

### Procedure

Trigger the loopback test:

```
loopback WORD<0-22> WORD<0-22> <1-8191> <0x00:0x00:0x00:0x00:0x00:0x00>
[burst-count <1-200>] [data-tlv-size <0-400>] [frame-size <64-1500>]
[interframe-interval <msecs>] [priority <0-7>] [source-mode {nodal|
noVlanMac|smltVirtual}][testfill-pattern <all-zero|all-zero-crc|pseudo-
random-bit-sequence|pseudo-random-bit-sequence-crc>] [time-out <1-10>]
```

### Example

```
Switch:1# loopback md1 4001 13 00:14:0D:A2:B3:DF burst-count 10 priority
3 time-out 5
```

```
Result of LBM from mep: spbm.bvlan1000.8 to MAC address: 00:66:00:66:00:66 :
Sequence number of the first LBM is 150404162
The total number of LBMs sent out is 1
The number of LBRs received is 1
The number of LBRs lost is 0
The percentage of LBMs lost is 0.00%
The RTT Min is 15071 microsecs, Max is 15071 microsecs, Average is 15071.00 microsecs
The Standard Deviation of RTT is 0.00 microsecs
```

### Variable Definitions

The following table defines parameters for the **loopback** command.

| Variable                        | Value                                                  |
|---------------------------------|--------------------------------------------------------|
| <i>WORD</i> <0-22>              | The first parameter, specifies the MD name.            |
| <i>WORD</i> <0-22>              | The second parameter, specifies the MA name.           |
| <1-8191>                        | Specifies the MEP ID.                                  |
| <0x00:0x00:0x00:0x00:0x00:0x00> | Specifies the remote MAC address to reach the MEP/MIP. |
| <i>burst-count</i> <1-200>      | Specifies the burst-count.                             |
| <i>data-tlv-size</i> <0-400>    | Specifies the data TLV size.                           |
| <i>frame-size</i> <64-1500>     | Specifies the frame-size. The default is 0.            |
| <i>priority</i> <0-7>           | Specifies the priority. The default is 7.              |

| Variable                                                                                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>source-mode {nodal   noVlanMac   smltVirtual}  </code>                                                          | <p>Specifies the source mode:</p> <ul style="list-style-type: none"> <li>• nodal</li> <li>• noVlanMac — Use this value with C-VLAN only. When you select this option, even if a VLAN MAC address exists, the system uses the CFM C-MAC as the B-MAC-SA.</li> <li>• smltVirtual—Use this value with B-VLANs only.</li> </ul> <p>The default is nodal.</p>                                                                                                                                                                                                                   |
| <code>testfill-pattern {all-zero   all-zero-crc   pseudo-random-bit-sequence   pseudo-random-bit-sequence-crc}</code> | <p>Specifies the testfill pattern:</p> <ul style="list-style-type: none"> <li>• all-zero — null signal without cyclic redundancy check</li> <li>• all-zero-crc — null signal with cyclic redundancy check with 32-bit polynomial</li> <li>• pseudo-random-bit-sequence — pseudo-random-bit-sequence without cyclic redundancy check</li> <li>• pseudo-random-bit-sequence-crc — pseudo-random-bit-sequence with cyclic redundancy check with 32-bit polynomial.</li> </ul> <p>A cyclic redundancy check is a code that detects errors.<br/>The default is 1: all-zero.</p> |
| <code>time-out &lt;1-10&gt;</code>                                                                                    | <p>Specifies the time-out interval in seconds. The default is 3.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### Trigger Linktrace (LTM)

Use the following procedure to trigger a linktrace.

The Linktrace Message is often compared to traceroute. An MEP transmits the Linktrace Message packet to a maintenance endpoint with intermediate points responding to indicate the path of the traffic within a domain for the purpose of fault isolation. The packet specifies the target MAC address of an MP, which is the SPBM system ID or the virtual SMLT MAC. MPs on the path to the target address respond with an LTR.

**Note**

Product Notice: This procedure does not apply to VSP 8600 Series.

### Before You Begin

- You must have a MEP that is associated with a VLAN.

### Procedure

Trigger the linktrace:

```
linktrace WORD<0-22> WORD<0-22> <1-8191> <0x00:0x00:0x00:0x00:0x00:0x00>
[detail] [priority <0-7>] [source-mode <nodal|noVlanMac|smltVirtual>]
[ttl-value <1-255>]
```

## Example

```
Switch:1# linktrace mdl 4001 13 00:bb:00:00:14:00 priority 7
```

```
Please wait for LTM to complete or press any key to abort
```

```
Received LTRs:
```

```
SeqNum: 10575 MD: mdl MA:4001 MepId: 13 Priority: 7
```

```
-----
TTL SRC MAC FWDYES TERMMEP RELAY ACTION
-----
63 00:bb:00:00:10:00 true false Fdb
62 00:bb:00:00:14:00 false true Hit
```

## Variable Definitions

The following table defines parameters for the **linktrace** command.

| Variable                                                                     | Value                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>WORD</i> <0-22>                                                           | The first parameter, specifies the MD name.                                                                                                                                                                                                                                                                                                   |
| <i>WORD</i> <0-22>                                                           | The second parameter, specifies the MA name.                                                                                                                                                                                                                                                                                                  |
| <1-8191>                                                                     | Specifies the MEP ID.                                                                                                                                                                                                                                                                                                                         |
| <0x00:0x00:0x00:0x00:0x00:0x00>                                              | Specifies the target MAC address to reach the MEP.                                                                                                                                                                                                                                                                                            |

| <i>priority</i> <0-7>                                                        | Specifies the priority. The default is 7.                                                                                                                                                                                                                                                                                                     |
| <i>source-mode</i> { <i>nodal</i>   <i>noVlanMac</i>   <i>smltVirtual</i> }} | Specifies the source mode: <ul style="list-style-type: none"> <li>1: nodal</li> <li>noVlanMac — Use this value with C-VLAN only. When you select this option, even if a VLAN MAC address exists, the system uses the CFM C-MAC as the B-MAC-SA.</li> <li>2: smltVirtual—Use this value with B-VLANs only.</li> </ul> The default is 1: nodal. |
| <i>tvl-value</i> <1-255>                                                     | Specifies the Time-to-Live value. The default is 64.                                                                                                                                                                                                                                                                                          |

### Trigger a Layer 2 Ping

Use this procedure to trigger a Layer 2 ping, inside an SPBM cloud or network, which acts like native **ping**. This feature enables CFM to debug Layer 2. It can also help you debug IP shortcuts and the record for the shortcuts' ARP.

### Before You Begin

- You must have a MEP that is associated with a VLAN.

### Procedure

Trigger a Layer 2 ping:

```
12 ping {vlan <1-4059> routernodename WORD<0-255> | vlan <1-4059> mac <0x00:0x00:0x00:0x00:0x00:0x00>} [burst-count <1-200>] [data-tlv-size
```

```
<0-400>] [frame-size <64-1500>] [priority <0-7>] [source-mode <nodal|
smltVirtual>] [testfill-pattern <all-zero|all-zero-crc|pseudo-random-
bit-sequence|pseudo-random-bit-sequence-crc>] [time-out <1-10>]
```

OR

```
l2 ping {ip-address WORD<0-255>} [burst-count <1-200>] [data-tlv-size
<0-400>] [frame-size <64-1500>] [priority <0-7>] [source-mode <nodal|
smltVirtual>] [testfill-pattern <all-zero|all-zero-crc|pseudo-random-
bit-sequence|pseudo-random-bit-sequence-crc>] [time-out <1-10>] [vrf
WORD<1-16>]
```

### Example

```
Switch:1# l2 ping vlan 2 mac 00.14.0d.bf.a3.df
```

```
Please wait for l2ping to complete or press any key to abort
----00:14:0d:bf:a3:df L2 PING Statistics---- 0(68) bytes of data
1 packets transmitted, 0 packets received, 100.00% packet loss
```

```
Switch:1# l2 ping vlan 2 routernodename MONTIO
```

```
Please wait for l2ping to complete or press any key to abort
----00:14:0d:a2:b3:df L2 PING Statistics---- 0(68) bytes of data
1 packets transmitted, 1 packets received, 0.00% packet loss
round-trip (us) min/max/ave/stdv = 26895/26895/26895.00/ 0.00
```

```
Switch:1# l2 ping ip-address 192.0.2.10
```

```
Please wait for l2ping to complete or press any key to abort

### Variable Definitions

The following table defines parameters to configure the Layer 2 ping parameters.

| Variable                                                                                                                                                        | Value                                                                                                                                                                                                                                                                                                                               |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>{vlan &lt;1-4059&gt; routernodename WORD&lt;0-255&gt; } {vlan &lt;1-4059&gt; mac &lt;0x00:0x00:0x00:0x00:0x00:0x00&gt; } {ip-address WORD&lt;0-255&gt; }</i> | Specifies the destination for the Layer 2 ping: <ul style="list-style-type: none"> <li>• &lt;1-4059&gt; — Specifies the VLAN ID.</li> <li>• WORD&lt;0-255&gt; — Specifies the Router node name.</li> <li>• &lt;XX:XX:XX:XX:XX:XX&gt; — Specifies the MAC address.</li> <li>• &lt;A.B.C.D&gt; — Specifies the IP address.</li> </ul> |
| <i>burst-count &lt;1-200&gt;</i>                                                                                                                                | Specifies the burst count.                                                                                                                                                                                                                                                                                                          |
| <i>data-tlv-size &lt;0-400&gt;</i>                                                                                                                              | Specifies the data TLV size. The default is 0.                                                                                                                                                                                                                                                                                      |

| Variable                                                                                                              | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

The default is 3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>source-mode{nodal   smltVirtual}]  </code>                                                                      | <p>Specifies the source mode:</p> <ul style="list-style-type: none"> <li>• 1: nodal</li> <li>• 2: smltVirtual—Use this value with B-VLANs only.</li> </ul> <p>The default is 1: nodal.</p>                                                                                                                                                                                                                                                                                                                                                                              |
| <code>vrf WORD&lt;1-16&gt;</code>                                                                                     | Specifies the VRF name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### Trigger a Layer 2 Traceroute

#### Note

This procedure does not apply to XA1400 Series.

Use this procedure to trigger a Layer 2 traceroute, which acts like native **traceroute**. This feature enables CFM to debug Layer 2 in an SPBM cloud or network. It can determine the path used by IS—IS to get from one MEP to another, by showing all the hops between. Therefore, it can show where connectivity is lost. It can also work for IP shortcuts.

#### Important

To trace a route to a MAC address, the MAC address must be in the VLAN FDB table.

- For B-VLANs, you do not have to trigger an **l2ping** to learn the MAC address because IS-IS populates the MAC addresses in the FDB table.

**linktrace** traces the path up to the closest device to that MAC address that supports CFM.

### Before You Begin

- You must have a MEP that is associated with a VLAN.

### Procedure

Trigger a Layer 2 traceroute:

```
12 traceroute {ip-address WORD<0-255>} [ttl <1-255>] [vrf WORD<1-16>]
```

```
12 traceroute {<vlan <1-4059> routernodename WORD<0-255> | <vlan <1-4059> mac <0x00:0x00:0x00:0x00:0x00:0x00>} [priority <0-7>] [source-mode <nodal|smltVirtual>] [ttl <1-255>]
```

### Examples

```
Switch:1#12 traceroute vlan 2 routernodename Switch-MONTIO
Please wait for l2traceroute to complete or press any key to abort

l2traceroute to Switch-MONTIO (00:14:0d:a2:b3:df), vlan 2
0 Switch-PETER4 (00:15:9b:11:33:df)
1 Switch-MONTIO (00:14:0d:a2:b3:df)

Switch:1#12 traceroute ip-address 192.0.2.10
Please wait for l2trace to complete or press any key to abort

L2 Trace Statistics : IP 192.0.2.10, paths found 1
=====
Switch-SHAMIM (00:1a:8f:08:53:df), vlan 2
0 Switch-PETER4 (00:15:9b:11:33:df)
1 Switch-MONTIO (00:14:0d:a2:b3:df)
```

### Variable Definitions

The following table defines parameters for the **12 traceroute** command.

| Variable                                                                                                                                                              | Value                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{vlan &lt;1-4059&gt; routernodename WORD&lt;0-255&gt; } {vlan &lt;1-4059&gt; mac &lt;0x00:0x00:0x00:0x00:0x00:0x00&gt; } {ip-address WORD&lt;0-255&gt; }</code> | Specifies the destination for the Layer 2 traceroute: <ul style="list-style-type: none"> <li>• <code>&lt;1-4059&gt;</code> — Specifies the VLAN ID</li> <li>• <code>WORD&lt;0-255&gt;</code> — Specifies the Router Node Name</li> <li>• <code>&lt;XX:XX:XX:XX:XX:XX&gt;</code> — Specifies the MAC address</li> <li>• <code>WORD&lt;0-255&gt;</code> — Specifies the IP address</li> </ul> |
| <code>ttl-value &lt;1-255&gt;</code>                                                                                                                                  | Specifies the TTL value. The default is 64.                                                                                                                                                                                                                                                                                                                                                 |
| <code>priority &lt;0-7&gt;</code>                                                                                                                                     | Specifies the priority. The default is 7.                                                                                                                                                                                                                                                                                                                                                   |
| <code>source-mode {nodal   smltVirtual} }</code>                                                                                                                      | Specifies the source mode: <ul style="list-style-type: none"> <li>• 1: nodal</li> <li>• 2: smltVirtual—Use this value with B-VLANs only.</li> </ul> The default is 1: nodal.                                                                                                                                                                                                                |
| <code>vrf WORD&lt;1-16&gt;</code>                                                                                                                                     | Specifies the VRF name.                                                                                                                                                                                                                                                                                                                                                                     |

Trigger a Layer 2 Tracetree

**Note**

This procedure does not apply to XA1400 Series.

Use this procedure to trigger a Layer 2 tracetable. Layer 2 tracetable allows a user to trigger a multicast LTM message by specifying the B-VLAN and I-SID. The command allows the user to view a multicast tree on the SPBM B-VLAN from the source node to the destination nodes for a particular I-SID.

### Note

This command is supported on SPBM B-VLANs only, not C-VLANs.

### Before You Begin

- On the source and destination nodes, you must configure a CFM MD, MA, and MEP.
- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

### Procedure

Trigger a Layer 2 tracetable:

```
l2 tracetable {<1-4059> <1-16777215> [routernodename WORD<0-255> |
<1-4059> <1-16777215>] [mac <0x00:0x00:0x00:0x00:0x00:0x00>]} [priority
<0-7>] [source-mode <nodal|noVlanMac|smltVirtual>] [ttl-value <1-255>]
```

### Example

```
Switch:1#l2 tracetable 500 1
Switch:1# l2 tracetable 500 1
```

Please wait for l2tracetable to complete or press any key to abort

```
l2tracetable to 53:55:10:00:00:01, vlan 500 i-sid 1 nickname 5.55.10
hops 64
1  Switch-PETER4          00:15:9b:11:33:df -> Switch-MONTI0      00:14:0d:a2:b3:df
2  Switch-MONTI0         00:14:0d:a2:b3:df -> Switch-LEE2        00:15:e8:b8:a3:df
```

### Variable Definitions

The following table defines parameters for the **l2 tracetable** command.

| Variable                                                                                                                                                       | Value                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>{ &lt;1-4059&gt;&lt;1-16777215&gt; routernodename WORD&lt;0-255&gt;   &lt;1-4059&gt;&lt;1-16777215&gt; mac &lt;0x00:0x00:0x00:0x00:0x00:0x00&gt;}</code> | <ul style="list-style-type: none"> <li>• <code>&lt;1-4059&gt;</code> — Specifies the VLAN ID.</li> <li>• <code>&lt;1-16777215&gt;</code> — Specifies the I-SID.</li> <li>• <code>WORD&lt;0-255&gt;</code> — Specifies the Router Node Name.</li> <li>• <code>&lt;0x00:0x00:0x00:0x00:0x00:0x00&gt;</code> — Specifies the MAC address.</li> </ul> |
| <code>ttl-value &lt;1-255&gt;</code>                                                                                                                           | Specifies the TTL value. The default is 64.                                                                                                                                                                                                                                                                                                       |
| <code>priority &lt;0-7&gt;</code>                                                                                                                              | Specifies the priority value. The default is 7.                                                                                                                                                                                                                                                                                                   |
| <code>source-mode&lt;nodal noVlanMac smltVirtual&gt;</code>                                                                                                    | Specifies the source mode. The default is nodal.                                                                                                                                                                                                                                                                                                  |

*Triggering a Layer 2 Tracetree-fan***About This Task**

Use this procedure to trigger a Layer 2 tracetree-fan from the nickname server to make sure that all the nodes towards the nickname client support the FAN protocol. Layer 2 tracetree-fan allows a user to trigger an LTM on the internal Fabric Area Network (FAN) I-SID. This command allows the user to trace the FAN tree.

**Procedure**

Trigger a Layer 2 tracetree-fan:

```
l2 tracetree-fan [mac <0x00:0x00:0x00:0x00:0x00:0x00>] [priority <0-7>]
[routernodename WORD<0-255>] [ttl-value <1-255>]
```

**Example**

```
Switch:1# l2 tracetree-fan
```

```
Switch:1# l2 tracetree-fan
```

```
Please wait for l2tracetree to complete or press any key to abort
```

```
l2tracetree to b1:ad:aa:41:b0:84, vlan 4051 i-sid 16777001 nickname 0.00.00 hops 64
```

```
1  Switch-PETER4          b0:ad:aa:41:b0:84 -> Switch-MONTI0      b0:ad:aa:41:48:84

```

*Trigger a Layer 2 Tracemroute***Note**

This procedure does not apply to XA1400 Series.

Use this procedure to debug the IP Multicast over Fabric Connect stream path using **12 tracemroute** on the VLAN (Layer 2) or the VRF (Layer 3). This procedure queries the SPBM multicast module to determine the B-VLAN, I-SID and nickname for the S and G streams. The nickname and I-SID are used to create a multicast MAC address.

**Note**

The VLAN option is only valid for a VLAN that has an I-SID configured and IGMP snooping enabled.

**Before You Begin**

- On the source and destination nodes, you must configure an autogenerated or an explicit CFM MD, MA, and MEP.
- Enable the MEP.
- Assign a nodal MEP to the B-VLAN.

**Procedure**

1. To enter User EXEC mode, log on to the switch.

## 2. Trigger a Layer 2 tracemroute on the VLAN:

```
l2 tracemroute source <A.B.C.D> group <A.B.C.D> vlan <1-4059>[priority
<0-7>] [ttl-value <1-255>]
```

**Note**

For the preceding command, if you do not specify a VLAN, **l2 tracemroute** uses the global default VRF.

Wait for the l2 tracemroute to complete or press any key to abort.

## 3. Trigger a Layer 2 tracemroute on the VRF:

```
l2 tracemroute source <A.B.C.D> group <A.B.C.D> vrf WORD<1-16>
[priority <0-7>] [ttl-value <1-255>]
```

**Note**

For the preceding command, if you do not specify a VRF, **l2 tracemroute** uses the global default VRF.

Wait for the l2 tracemroute to complete or press any key to abort.

**Examples**

The following is a sample output for a Layer 2 tracemroute on a VLAN:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#l2 tracemroute source 192.0.2.81 233.252.0.1 vlan 201

Please wait for l2 tracemroute to complete or press any key to abort.

Source 192.0.2.81

Group: 233.252.0.1

VLAN:201

BMAC: 03:00:03:f4:24:01

B-VLAN: 10

I-SID: 16000001

=====
1 PETER4 00:03:00:00:00:00 -> LEE1 00:14:0d:bf:a3:df
2 LEE1 00:14:0d:bf:a3:df -> LEE2 00:15:e8:b8:a3:df
```

The following is a sample output for a Layer 2 tracemroute on a VRF:

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)#l2 tracemroute source 192.0.2.10 group 233.252.0.1 vrf red

Please wait for l2 tracemroute to complete or press any key to abort.

Source 192.0.2.10

Group: 233.252.0.1

VRF: redID 1
```

```

BMAC: 03:00:04:f4:24:01

B-VLAN: 20

I-SID: 16000001

1 PETER4 00:03:00:00:00:00 -> LEE1 00:14:0d:bf:a3:df
2 LEE1 00:14:0d:bf:a3:df -> LEE2 00:15:e8:b8:a3:df
    
```

**Variable Definitions**

The following table defines parameters for the **12 tracemroute** command.

| Variable                | Value                                                                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <i>source</i> <A.B.C.D> | Specifies the source IP address.                                                                                                          |
| <i>group</i> <A.B.C.D>  | Specifies the IP address of the multicast group.                                                                                          |
| <i>vlan</i> <1-4084>    | Specifies the VLAN value.                                                                                                                 |
| <i>vrf</i> WORD<1-16>   | Specifies the VRF name. If you do not specify a VRF name, then the results are shown for the flow in the Global Router (default) context. |
| <i>priority</i> <0-7>   | Specifies the priority value.                                                                                                             |
| <i>ttl</i> <1-255>      | Specifies the time-to-live (TTL) for the trace packet, which is how many hops the trace packet takes before it is dropped.                |

*Use Trace CFM to Diagnose Problems*

Use the following procedure to display trace information for CFM.

**About This Task**

Use trace to observe the status of a software module at a certain time.

For example, if you notice a CPU utilization issue (generally a sustained spike above 90%) perform a trace of the control plane activity.

Use the **trace level 120 <0-4>** command to trace CFM module information, including CLI, instrumentation, show config, and platform dependent code. The CFM module ID is 120.

Use the **trace cfm level <0-4>** command to trace platform independent code and CFM protocol code.

**Caution**  
**Risk of traffic loss**

Using the trace tool inappropriately can cause CPU lockup conditions, loss of access to the device, loss of protocols, and service degradation.

## Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Clear the trace:

```
clear trace
```

3. Begin the trace operation:

```
trace cfm level <0-4>
```

Wait approximately 30 seconds, and then stop trace.

4. Stop tracing:

```
trace shutdown
```

5. View the trace results:

```
show trace cfm
```

6. Begin the trace operation for the CFM module:

```
trace level 120 <0-4>
```

Wait approximately 30 seconds, and then stop trace.

7. View trace results:

```
trace screen enable
```

### Important

If you use trace level 3 (verbose) or trace level 4 (very verbose), do not use the screen to view commands due to the volume of information the system generates and the effect on the system.

8. Save the trace file to the Compact Flash card for retrieval.

```
save trace [file WORD<1-99>]
```

If you do not specify a file name, the file name is systrace.txt. By default, the system saves the file to the external flash.

9. Search trace results for a specific string value, for example, the word error:

```
trace grep [WORD<0-128>]
```

If you use this command and do not specify a string value, you clear the results of a previous search.

## Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)# clear trace
Switch:1(config)# trace cfm level 3
Switch:1(config)# trace shutdown
Switch:1(config)# show trace cfm
```

```
=====
                          CFM Tracing Info
=====
```

```
Status      : Enabled
```

```

Level      : VERBOSE
Switch:1(config)#trace level 120 3
Switch:1(config)# save trace
Switch:1(config)# trace grep error
Switch:1(config)#trace grep 00-1A-4B-8A-FB-6B
    
```

### Variable Definitions

The following table defines parameters for the **trace** command.

| Variable                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>cfm level</i> [<0-4>]           | Starts the trace by specifying the level. <ul style="list-style-type: none"> <li>• &lt;0-4&gt; specifies the trace level from 0–4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.</li> </ul>                                                                                                                                                                                                                                                                                                                   |
| <i>filter</i>                      | Configures a filter trace for a file or module.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>flags</i>                       | Configures trace flags for IS-IS or OSPF.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>grep</i> [WORD<0-128>]          | Searches trace results for a specific string value, for example, the word error. Performs a comparison of trace messages.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>level</i> [<Module_ID>] [<0-4>] | Starts the trace by specifying the module ID and level. <ul style="list-style-type: none"> <li>• &lt;Module_ID&gt; specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the <b>show trace modid-list</b> command or CLI command completion Help.</li> <li>• &lt;0-4&gt; specifies the trace level from 0–4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.</li> </ul> |
| <i>route-map</i>                   | Enables or disables the trace route-map. The values are on and off.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>screen</i> {disable enable}     | Enables the display of trace output to the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>shutdown</i>                    | Stops the trace operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>spbm isis level</i> [<0-4>]     | Starts the trace by specifying the level. <ul style="list-style-type: none"> <li>• &lt;0-4&gt; specifies the trace level from 0–4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.</li> </ul> The default is 1, very terse.                                                                                                                                                                                                                                                                                     |

The following table defines parameters for the **save trace** command.

| Variable                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Use Trace SPBM to Diagnose Problems

Use the following procedure to display trace information for SPBM IS-IS. In the case of IS-IS, this procedure also provides information related to the flags set.

#### About This Task

Use the **trace level 119 <0-4>** command to trace IS-IS module information, including CLI, instrumentation, show config and platform dependent code. The IS-IS module ID is 119.

Use the **trace level 125 <0-4>** command to trace SPBM module information, including CLI, instrumentation, show config and platform dependent code. The SPBM module ID is 125.

Use the **trace spbm isis level** command to trace platform independent code, IS-IS protocol, IS-IS hello, IS-IS adjacency, LSP processing, and IS-IS computation.

#### Caution Risk of traffic loss

Using the trace tool inappropriately can cause CPU lockup conditions, loss of access to the device, loss of protocols, and service degradation.

#### Procedure

1. Enter Global Configuration mode:

```
enable
```

```
configure terminal
```

2. Clear the trace:

```
clear trace
```

3. Begin the trace operation:

```
trace spbm isis level <0-4>
```

Wait approximately 30 seconds, and then stop trace.

4. Stop tracing:

```
trace shutdown
```

5. Display the trace information for SPBM IS-IS:

```
show trace spbm isis
```

6. Begin the trace operation for the SPBM module:

```
trace level 125 <0-4>
```

Wait approximately 30 seconds, and then stop trace.

7. Begin the trace operation for the IS-IS module:

```
trace level 119 <0-4>
```

Wait approximately 30 seconds, and then stop trace.

8. View trace results:

```
trace screen enable
```

### Important

If you use trace level 3 (verbose) or trace level 4 (very verbose), do not use the screen to view commands due to the volume of information the system generates and the effect on the system.

9. Save the trace file to the Compact Flash card for retrieval.

```
save trace [file WORD<1-99>]
```

If you do not specify a file name, the file name is systrace.txt. By default, the system saves the file to the external flash.

10. Search trace results for a specific string value, for example, the word error:

```
trace grep [WORD<0-128>]
```

If you use this command and do not specify a string value, you clear the results of a previous search.

### Example

```
Switch:1>enable
Switch:1#configure terminal
Switch:1(config)# clear trace
Switch:1(config)# trace spbm isis level 3
Switch:1(config)# trace shutdown
Switch:1(config)# show trace spbm isis
=====
                        SPBM ISIS Tracing Info
=====
Status      : Enabled
Level       : VERY_TERSE
Flag Info   :
Switch:1(config)#trace level 125 3
Switch:1(config)#trace level 119 3
Switch:1(config)# save trace
```

```
Switch:1(config)# trace grep error
Switch:1(config)#trace grep 00-1A-4B-8A-FB-6B
```

## Variable Definitions

The following table defines parameters for the **trace** command.

| Variable                           | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>cfm level</i> [<0-4>]           | Starts the trace by specifying the level. <ul style="list-style-type: none"> <li>&lt;0-4&gt; specifies the trace level from 0–4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.</li> </ul>                                                                                                                                                                                                                                                                                                                 |
| <i>filter</i>                      | Configure a filter trace for a file or module.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>flags</i>                       | Configure trace flags for IS-IS or OSPF.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>grep</i> [WORD<0-128>]          | Searches trace results for a specific string value, for example, the word error. Performs a comparison of trace messages.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>level</i> [<Module_ID>] [<0-4>] | Starts the trace by specifying the module ID and level. <ul style="list-style-type: none"> <li>&lt;Module_ID&gt; specifies the module for the trace. Different hardware platforms support different ID ranges because of feature support differences. To see which module IDs are available on the switch, use the <b>show trace modid-list</b> command or CLI command completion Help.</li> <li>&lt;0-4&gt; specifies the trace level from 0–4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.</li> </ul> |
| <i>route-map</i>                   | Enables or disables the trace route-map. The values are on and off.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>screen</i> {disable enable}     | Enables the display of trace output to the screen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>shutdown</i>                    | Stops the trace operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>spbm isis level</i> [<0-4>]     | Starts the trace by specifying the level. <ul style="list-style-type: none"> <li>&lt;0-4&gt; specifies the trace level from 0–4, where 0 is disabled; 1 is very terse; 2 is terse; 3 is verbose, 4 is very verbose.</li> </ul> <p>The default is 1, very terse.</p>                                                                                                                                                                                                                                                                            |

The following table defines parameters for the **save trace** command.

| Variable               | Value                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>file</i> WORD<1-99> | Specifies the file name in one of the following formats: <ul style="list-style-type: none"> <li>• a.b.c.d:&lt;file&gt;</li> <li>• x:x:x:x:x:x &lt;file&gt;</li> <li>• /intflash/&lt;file&gt;</li> <li>• /extflash/&lt;file&gt;</li> <li>• /usb/&lt;file&gt;</li> <li>• /mnt/intflash/ &lt;file&gt;</li> <li>• /mnt/extflash/ &lt;file&gt;</li> </ul> /mnt/intflash is the internal flash of the CPU.<br>/mnt/extflash is the external flash of the CPU. |

## CFM Configuration Using EDM

This section provides procedures to configure Connectivity Fault Management (CFM) using Enterprise Device Manager (EDM).

**Note**

When you enable CFM in an SPBM network, as a best practice, enable CFM on the Backbone Edge Bridges (BEB) and on all Backbone Core Bridges (BCB). If you do not enable CFM on a particular node, you cannot obtain CFM debug information from that node.

### Autogenerated CFM

CFM provides two methods for creating MEPs: autogenerated and explicit. You cannot use both. You must choose one or the other. Use the procedures in this section to configure autogenerated MEPs that eliminate the need to configure an MD, MA, and MEP ID to create a MEP.

- For SPBM B-VLANs, you can use either autogenerated or explicitly configured CFM MEPs.
- For C-VLANs, you can only use autogenerated CFM MEPs.

Previous explicit CFM configurations of MDs, MAs and MEPs on SPBM B-VLANs continue to function. However, if you want to enable the autogenerated commands, you must first remove the existing MEP and MIP on the SPBM B-VLAN. The switch only supports one MEP or MIP on the SPBM B-VLAN, either explicitly configured or autogenerated.

For autogenerated CFM configuration information for EDM, see the following tasks:

- [Configure Autogenerated CFM on SPBM B-VLANs](#) on page 3858
- [Configure Autogenerated CFM on C-VLANs](#) on page 3859

## Configure Autogenerated CFM on SPBM B-VLANs

Use this procedure to configure the autogenerated CFM MEP and MIP level for every SPBM B-VLAN on the chassis. This configuration eliminates the need to explicitly configure an MD, MA, and MEP ID and to associate the MEP and MIP level to the SPBM B-VLAN.

To configure autogenerated CFM on C-VLANs, see [Configure Autogenerated CFM on C-VLANs](#) on page 3859.

### About This Task

When you enable this feature, the device creates a global MD (named `spbm`) for all the SPBM Nodal MEPs. This MD has a default maintenance level of 4, which you can change with the `level` attribute. All the MEPs that the device creates use the MEP ID configured under the global context, which has a default value of 1. The nodal MEPs are automatically associated with the SPBM B-VLANs configured. The MIP level maps to the global level. When you enable the feature, the device automatically associates the MIP level with the SPBM B-VLANs configured. The feature is disabled by default.

#### Important

CFM supports one MEP or MIP for each SPBM B-VLAN only. This means that if you want to use these autogenerated MEPs, you cannot use your existing CFM configuration. You must first remove the existing MEP or MIP on the SPBM B-VLAN. If you want to continue configuring MEPs manually, skip this procedure.

### Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **CFM**.
3. Select the **Global** tab.
4. Select **enable** next to **SpbmAdminState**.
5. Select **Apply**.

### Global Field Descriptions

Use the data in the following table to configure the global MEP and MIP parameters.

| Name                  | Description                                                                                                                                                                                  |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SpbmAdminState</b> | Enables or disables autogenerated CFM for B-VLANs. The default is disable.                                                                                                                   |
| <b>SpbmLevel</b>      | Specifies the global SPBM CFM maintenance level for the chassis within the range of 0 to 7. The default is 4. Only configure global CFM at one MD level for each chassis for each VLAN type. |
| <b>SpbmMepId</b>      | Specifies the global MEP ID within the range of 1 to 8191. Select a unique ID for each switch to ensure that the MEPs are unique across the network. The default is 1.                       |

| Name                  | Description                                                                                                                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CmacAdminState</b> | Enables or disables autogenerated CFM for C-VLANs. The default is disable. This field does not apply for all hardware platforms.                                                                                                                    |
| <b>CmacLevel</b>      | Specifies the global C-MAC CFM maintenance level for the chassis within the range of 0 to 7. The default is 4. Only configure global CFM at one MD level for each chassis for each VLAN type. This field does not apply for all hardware platforms. |
| <b>CmacMepId</b>      | Specifies the global MEP ID within the range of 1 to 8191. Select a unique ID for each switch to ensure that the MEPs are unique across the network. The default is 1. This field does not apply for all hardware platforms.                        |
| <b>Bmac</b>           | Displays the B-MAC address of the node. This field does not apply for all hardware platforms.                                                                                                                                                       |
| <b>Cmac</b>           | Displays the C-MAC address of the node. This field does not apply for all hardware platforms.                                                                                                                                                       |

### Configure Autogenerated CFM on C-VLANs

Use this procedure to configure the autogenerated CFM MEP and MIP level for every C-VLAN on the chassis.

To configure autogenerated CFM on SPBM B-VLANs, see [Configure Autogenerated CFM on SPBM B-VLANs](#) on page 3858.

#### Note

For C-VLANs, you can only use autogenerated CFM MEPs.

#### Important

CFM supports one MEP or MIP on each C-VLAN. Only autogenerated CFM provides support for configuring MEP and MIPs on C-VLANs. You cannot explicitly configure C-VLANs.

### About This Task

When you enable this feature, you create a global MD (named `cmac`) for all the customer MAC (C-MAC) MEPs. This MD has a default maintenance level of 4, which you can change with the `level` attribute. The autogenerated CFM commands also create an MA for each C-VLAN, a MEP for each C-VLAN, and associate the MEP with the corresponding C-VLAN and a MIP with the C-VLAN.

All the MEPs that the device creates use the MEP ID configured under the global context, which has a default value of 1. The device automatically associates the MEPs with the C-VLANs configured. The MIP level maps to the global level. The device automatically associates the MIP level with the C-VLANs configured when you enable the feature.

The feature is disabled by default.

### Procedure

1. In the navigation pane, expand **Configuration > Serviceability > Diagnostics**.
2. Select **CFM**.
3. Select the **Global** tab.
4. Select **enable** next to **CmacAdminState**.
5. In the fields provided, specify a maintenance level and a MEP ID.
6. Select **Apply**.

### Global Field Descriptions

Use the data in the following table to configure the global MEP and MIP parameters.

| Name                  | Description                                                                                                                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SpbmAdminState</b> | Enables or disables autogenerated CFM for B-VLANs. The default is disable.                                                                                                                                                                          |
| <b>SpbmLevel</b>      | Specifies the global SPBM CFM maintenance level for the chassis within the range of 0 to 7. The default is 4. Only configure global CFM at one MD level for each chassis for each VLAN type.                                                        |
| <b>SpbmMepId</b>      | Specifies the global MEP ID within the range of 1 to 8191. Select a unique ID for each switch to ensure that the MEPs are unique across the network. The default is 1.                                                                              |
| <b>CmacAdminState</b> | Enables or disables autogenerated CFM for C-VLANs. The default is disable. This field does not apply for all hardware platforms.                                                                                                                    |
| <b>CmacLevel</b>      | Specifies the global C-MAC CFM maintenance level for the chassis within the range of 0 to 7. The default is 4. Only configure global CFM at one MD level for each chassis for each VLAN type. This field does not apply for all hardware platforms. |
